## **Abstract**

**This paper presents the state-of-art of Internet of Things (IoT), an enabler of new forms of communication between people and things, and between things. The main strength of IoT concept is the high influence it has to everyday life by creating new dimension to the world, resembling to what the Internet once did. This paper describes the definitions of IoT, summarizes its main enabling technologies. The content includes strengths and limitations of applications based IoT in logistic, transportation, healthcare, and environment and disaster. Finally, the open challenges of IoT are debated to encourage more investigations into the domains.**

23

24 **Keywords : Internet of Things, IoT, limitations, strengths**

25

## 26 **Introduction**

27 The term “Internet of Things (IoT)” (Huang & Li, 2010; Uckelmann, Harrison, &  
28 Michahelles, 2011) has been around since the past few years and gaining  
29 recognition with the breakthrough of advanced wireless technology. Even though  
30 there are heterogeneous definitions on the interpretation of “Internet of Things”  
31 but it has a corresponding boundary related to the integration of the physical  
32 world with the virtual world of the Internet. IoT can broadly be defined as a global  
33 network infrastructure, linking uniquely identified physical and virtual objects,  
34 things and devices through the intelligent objects, communication and actuation  
35 capabilities. In other words, the paradigm of IoT is described as “any-time, any-  
36 place and any-one connected” (Ryu, Kim, Lee, & Song, 2012). Its implication is  
37 based on the technology that makes things and people getting closer than the old  
38 days.

39 In the perspective of “things”, numerous devices and objects will be  
40 connected to the Internet. Each individually provides data, information or even  
41 services. The devices providing things can be personal objects we carry around  
42 such as smart phones, tablets and digital cameras. Our daily environment, home,  
43 vehicle or office connected through a gateway device can also provide “things”  
44 (Coetzee & Eksteen, 2011). Although Radio-Frequency IDentification (RFID) is  
45 precisely the first idea popped up, but indeed many more technologies such as

46 sensor technologies, smart things and actuators are also contributed. Whereas the  
47 Machine-to-Machine Communication (M2M) and Vehicular-to-Vehicular  
48 communication (V2V) are the real applications in the markets revealing the most  
49 benefits of IoT (Atzori, Iera, & Morabito, 2010; Uckelmann et al., 2011).

50 The aim of this paper is to explore the development and the deployment of  
51 IoT in significant application domains. The organization of paper is as follows,  
52 Section 2 describes the structure of IoT. Section 3 presents a review of the  
53 existing application of IoT categorized into the areas of logistics, transportation,  
54 healthcare, and environment and disaster. Section 4 is the discussion of IoT  
55 applications based on its benefits and limitations. Section 5 is the challenge of IoT  
56 in those application domains.

57

## 58 **The Structure of Internet of Things**

59 The Internet of Things can be viewed as a gigantic network consisting of  
60 networks of devices and computers connected through a series of intermediate  
61 technologies where numerous technologies such as RFIDs, barcodes, wired and  
62 wireless connections may act as enablers of this connectivity. By International  
63 Telecommunications Union (ITU), the perception of IoT was structured as four  
64 dimensions of things as illustrated (Figure 1) (Atzori et al., 2010; Coetzee &  
65 Eksteen, 2011).

### 66 ***Tagging Things***

67 Real-time item traceability and addressability of RFIDs is what make them  
68 stand at the forefront in terms of the IoT vision. RFIDs are gaining strong support

69 from the business community due to their maturity, low cost, and low power.  
70 RFIDs act as an electronic barcode to help in the automatic identification of  
71 anything attached. For RFID tags, they are available in 2 types: active and  
72 passive. The active tags embedded with battery on-board, are widely used in  
73 retail, healthcare, and facilities management. The passive tags, containing no  
74 batteries, are powered by the reader and are more likely to be used in bank cards  
75 and road toll tags (Aggarwal, 2012).

### 76 *Feeling Things*

77 Sensors act as primary devices to collect data from the environment.  
78 Necessary data is provided via communications established between the physical  
79 and the information worlds (Vermesan & Friess, 2013). Recent advances in  
80 technologies make them consume less power with low cost and high efficiency.

### 81 *Shrinking Things*

82 Miniaturization and nanotechnology has provoked the ability of smaller  
83 things to interact and connect within the “things” or “smart devices”. A clear  
84 advantage is the improvement in quality of life. For example, the application of  
85 nano-sensors for monitoring water quality at reduced cost, and nano-membranes  
86 for assisting in the treatment of waste water (Vermesan & Friess, 2013). In  
87 healthcare, its application can be seen in the diagnosis and treatment of disease,  
88 including the diagnosis of HIV and AIDS and nano-drugs for other diseases  
89 (Gubbia, Buyyab, Marusic, & Palaniswami, 2013).

### 90 *Thinking Things*

91 Embedded intelligence in devices through sensors has formed the network  
92 connection to the Internet. It can make the domestic electric appliances realizing  
93 the intelligent control, for example refrigerators that can detect the quantities of  
94 various items and the freshness of perishable items. Embedded smart sensors may  
95 provide the means to communicate with users by sending alert via the Internet  
96 connectivity. The connection can primarily be wireless or other available  
97 communications such as DSL, GPRS, WiFi, LAN and 3G (Uckelmann et al.,  
98 2011). Not only to communicate, smart things must also be able to “...process  
99 information, self-configure, self-maintain, self-repair, make independent  
100 decisions, or even play an active role in their own disposal...” (Vermesan &  
101 Friess, 2013) which will change the way information communicates from human-  
102 human to human-thing and to thing-thing.

103

#### 104 **Applications based IoT**

105 One of the most important engines of the innovation and development of  
106 IoT is its applications, otherwise public acceptance of IoT will never happen  
107 (Coetzee & Eksteen, 2011). Based on the concept of IoT, information generated  
108 from daily enabling objects in our environment can possibly communicate with  
109 each other. This information can drive many applications possible. Applications  
110 directly applicable or closer to our current living habitudes, can possibly be  
111 categorized into four following domains (Q. Yang, Wang, & Yue, 2012).

112

### 113 *Logistics and Supply Chain Management*

114 Traditionally, most of the logistic enterprises require manifold reports  
115 tracking, along with specific time and location to control the movement of goods.  
116 However, in the IoT society, the logistic commodity has tremendously changed to  
117 an autonomous society by variety of applications available to support the needs.  
118 The systems in (Li & Luo, 2010), (Wei, 2011), and (El-Baz, Bourgeois, Saadi, &  
119 Bassi, 2013) are logistic applications implemented to track the movement of  
120 goods in real-time. The data scanned from tags of barcode or RFID was  
121 transmitted to the logistic center or RFID receivers. Data was then transmitted  
122 through Wireless Sensor Networks (WSNs) (Li & Luo, 2010), GSM network  
123 (Wei, 2011), 3G network or a new High Performance Computing (HPC)  
124 infrastructure through broker (El-Baz et al., 2013) to be processed at the data  
125 center. The solutions in this domain are very promising since they have adopted  
126 comprehensive and diversified transmission protocols. Several devices such as  
127 RFID, Near Field Communication (NFC), and mobile phone can also act as data  
128 collectors. But they do have substantial limitations.

129 For example, the supermarket chain management (Li & Luo, 2010) was  
130 developed based on standard relational database, which can lead to worrisome  
131 situation when dealing with large volume of “things”. The occurrence of  
132 incomplete information or missing information procreated from the  
133 communication distance of the mobile logistic information reader (Wei, 2011) and  
134 the data collision during transmission may as well jeopardize the results.

135 Not only the applications to support the front-end and back-end operation  
136 are essential, the abilities to control and identify the next destination of goods/raw  
137 material are also indispensable. The real time tracking of logistic entities using the  
138 combination capabilities of RFIDs, mobile devices and the integrated browser  
139 interface was conducted (Lin, 2011). The position of objects was derived from  
140 GPS, WIFI, GSM, and GPRS. Even overall detection accuracy of geographical  
141 location was over 97% for moving entities and roughly 100% for the action-less  
142 entities. However its hindrances are i) the detection of geographical position  
143 function needed to support variety of browsers since different logistic users may  
144 use different mobile devices and ii) the browsers themselves should have the  
145 ability to automatically detect and confirm on what positioning devices to be  
146 launched.

147 To increase the accuracy of the logistic process, not only the ability to  
148 detect location of goods is desired, the reliability of RFIDs signals is also  
149 essential. Particularly in the environment where there is limited accessibility to the  
150 IoT infrastructure. A launch of AspireRFID (Soldatos et al., 2010) , a RFID  
151 middleware with a range of tools to facilitate RFID deployment ("RFID Journal,"  
152 2009) was a breakthrough. The integration of the EPC (Electronic Product  
153 Code)global based RFID architecture with "Session Initiation Protocol (SIP)"  
154 (Anggorojati, Mahalle, Prasad, & Prasad, 2013) to simultaneously detect locations  
155 and mobility management of RFID tags revealed outstanding performance in cost  
156 consumption of tags registration and tracking.

157 In large logistic enterprises, the efficacy to automatically locate and move  
158 assembly parts has incurred the adoption of robots. The infrared motion capture  
159 system or computer vision system with complex machine learning algorithms was  
160 basically used to control the navigation and object manipulation of robots.  
161 However, that feature of the proposed robot was handled by RF-Compass and  
162 RFID (Wang, Adib, Knepper, Katabi, & Rus, 2013). Both the robots and the  
163 objects the robot will work on, are embedded with an ultra low-power RF-  
164 compass and a low cost RFIDs as a replacement of WiFi-nodes. The RF-Compass  
165 could pinpoint the center position and the orientation of objects with 80-90%  
166 accuracy when robots were grasping objects. Even though this study demonstrates  
167 low computation time when compared with machine-learning architecture, it has a  
168 limited line-of-sight detection and no proven evidence on handling small objects.

169 The review of IoT applications in logistics (Table 1) indicates that in order  
170 to maintain the effectiveness of IoT, the system should at least comprise the basic  
171 following capabilities:

172 *Autonomous control:* Mechanisms to overcome limitations in the  
173 management and exploitation of millions of unreliable, non-autonomous things  
174 and of the corresponding data and information flows should be implemented.  
175 Instead of having a central control unit for decision making responsibilities,  
176 decentralized control of multiplicity of smaller self-organizing units will be more  
177 efficient. The capability and possibility to render decisions independently will as  
178 well improve the robustness and increase the scalability of process control.

179            *Smart logistic entities:* Each commodity in logistic networks is embedded  
180 with sensors to record information of items for fast updating of transactions of  
181 specific goods. The protection of thieves, and fast tracking and tracing of goods  
182 states can as well be autonomously triggered as alarm mechanisms by these  
183 sensors.

184            *Unique addressability:* Right product, right quantity, right time, right  
185 place, right condition and right price are what expected in logistics. Right product  
186 relates to accurate and appropriate information on product which can be deduced  
187 from auto-ID, sensor information or any other kinds of linked information. Right  
188 time means product can be acquired anytime when needed. Right place refers to  
189 goods located independently of unreliable network connectivity. Effective data  
190 synchronization protocols and caching techniques are necessary to ensure  
191 availability of information at the right place. The right price means the product  
192 price lies between the costs for information provisioning and the achievable  
193 market price.

194            *ERP interface:* Real-time access to the ERP solution helps the shop  
195 administrators to better inform customers about availability of products and give  
196 them more product information in general.

197

### 198 ***Transportation***

199            The development in transportation is presumed to be one of the factors to  
200 indicate the well-being of the country. That is why transportation problems are  
201 very challenging in the field of IoT. A proposal on a road condition monitoring

202 and alert application was initiated (Ghose et al., 2012). Its main idea was to apply  
203 the principles of crowd sourcing and participatory sensing. The process began  
204 with user identified the route he wishes and marked some points as pothole in the  
205 smart phone's application. When the vehicle ran over the defined route,  
206 accelerometer which continuously captured data would send raw data via mobile  
207 network. Related features were then extracted to generate a confidence score to  
208 indicate the abnormalities of the routes by showing the plot of pothole  
209 information. Distinct advantage has expressed from the adoption of user's smart  
210 phone as a connector device with no additional cost applying on the existing  
211 hardware. Albeit, remain issues are the upload and download process of route-  
212 map which involve considerable network traffic may induce vulnerability to the  
213 system. Moreover, the road condition classification is performed at the phone  
214 itself is very time-consuming and it may drain out the battery of the mobile phone.

215 For large cities, problems such as finding parking spaces, waiting in line for  
216 toll-way payment can be cumbersome which had urged the idea of applying the  
217 license plate as a unique identity of driver (Ren, Jiang, Wu, Yang, & Liu, 2012).  
218 The license plate was captured by the recognition equipment whereas sensors  
219 embedded in license plate would collect the information of road surface. The data  
220 was then forwarded to calculate the optimal path and guiding passage of vehicles.  
221 The system are not only able to invoke the traffic scheduling, vehicle positioning  
222 and vehicle query for passenger, it also can locate the parking spaces in nearby  
223 location. This design provides variety of benefits to driver in terms of managing  
224 highway automatic toll collection, avoiding busy traffic induction, locating

225 parking space and adding more security to the vehicle. A clear drawback, however  
226 is this design struggles to support too many functions which invoke high cost and  
227 difficulties for implementation.

228         Electric vehicles, an important means to reduce both the fuel cost and the  
229 impact of global warming have also gained considerable attention from drivers.  
230 Government in many countries has supported researches on systems to monitor  
231 performance of Lithium-ion (Li-on) battery for electric vehicle as explored  
232 (Haiying et al., 2012). The system presented was designed to detect the functions  
233 of Li-on power battery by deriving the driving situation from the realistic working  
234 conditions for driver so that the driver was able to get the idea of the route status.  
235 This solution was embedded with many essential functions such as dynamic  
236 performance test of the Li-on battery, remote monitoring with on-line debugging  
237 and error correction that could significantly reduce the maintenance cost. For as  
238 much as the underlying issue of such design is the battery life, the extensible  
239 function of age-tracking and end-of-life predictions of battery should be bundled  
240 so that the fading battery can be tracked to assure of the readiness, reliability, and  
241 security of the electric buses.

242         The safety supervision in the distribution of hazardous or valuable goods is  
243 imperative for shipping companies. A study to master the operation of the entire  
244 fleet from the command center in real time was conducted (Shengguang, Lin,  
245 Yuanshuo, & Rucai, 2013). Each vehicle was embedded with GPS to form a  
246 multi-hop network for the command center to share the perception of drivers. A  
247 combination of RFID reader and 3G video surveillance was used to monitor status

248 of goods whereas temperature and humidity sensors in the vehicle were used to  
249 detect a quality of transport goods. If indicators exceeded the limit, the alarm  
250 would be raised. Other unpredicted events such as driver fatigue or unauthorized  
251 access were also detected and forwarded to command center. This design has  
252 achieved the effectiveness in road traffic safety and travel reliability. The  
253 limitations disengaged are the adoption of several technologies in this design will  
254 increase the cost of both deployment and support. Moreover, the location of  
255 vehicles can be inaccurate when vehicles are moving in high speed or approaching  
256 blind spots for GPS.

257       The IoT applications in transportation reviewed are summarized (Table 2).  
258 From those, it can be concluded that the underlie system should at least include  
259 the following system units:

260       *Vehicle System:* main components of vehicle system are

- 261       i) GPS system: This system is mainly responsible for receiving  
262       comprehensive information such as location, time and weather  
263       from satellites. It is not only a map embedded with resources about  
264       major cities and road information, but it also gives a fast and  
265       accurate GPS positioning, even if the satellite signal is poor.
- 266       ii) Wireless communication system: GPS and RFID data are  
267       forwarded to a control center through the Internet. Data will then  
268       be displayed on electronic maps of monitoring center to facilitate  
269       the management of real-time scheduling.

270            *Station System:* The station subsystem generally consists of  
271 communication module and control module. The former includes the GPRS  
272 receiver, which is responsible for receiving and decoding the transmitted data  
273 packets from the monitoring center. The latter is a communication interface  
274 module to receive data and display real-time transit vehicle information.

275            *Monitor Center:* The collected information is transmitted to the  
276 communication equipment through the Internet. Then communication equipment  
277 will send the received information to the real-time database system to compare  
278 with the data of events. The collaboration of real-time data in the database and  
279 GIS technology, the visualization the road traffic information can be integrated for  
280 visualization.

281

## 282 ***Healthcare***

283            Improvement in human health and well-being is the ultimate goal of any  
284 economic, technological and social development. The rapid rising and aging of  
285 population is one of the macro powers causing great pressure to healthcare  
286 systems. A solution to solve the difficulties in accessing to healthcare of people in  
287 rural area of developing countries (Rohokale, Prasad, & Prasad, 2011) was  
288 implemented. A person registered with the rural healthcare center (RHC) was  
289 requested to wear an active RFID sensor to detect any change on the normal  
290 parameters. If those parameters exceeded certain values, information would be  
291 cooperatively routed to the RHC doctor. In an environment without the Internet,  
292 the mobile network facility could be utilized to convey the information. This

293 approach is proven to be a reliable critical healthcare application that continuously  
294 monitors and controls health parameters of human.

295         The other approach was the integration of clinical devices in the patient's  
296 environment (Jara, Zamora, & Skarmeta, 2012) which allowed user to use a  
297 mobile phone to transmit health data to medical centers. A home gateway was  
298 located at the patient's house to connect to the Internet while the mobile personal  
299 health device acted as an integration of medical devices from different vendors.  
300 The system continuously analyzed the vital signs from the patient to detect  
301 anomalies. The noticeable flaw of the system is the security threats and attacks in  
302 the mobile network, although GSM has adopted an encryption as protection  
303 mechanism but as it is wide-spread in nature, interception of information  
304 transmitted is possible.

305         A "non-contact health monitoring system (NCHMS)" (N. Yang, Zhao, &  
306 Zhang, 2012) was another choice of IoT healthcare service which is more  
307 convenient to users. The system monitored the user's facial expressions, postures,  
308 and sounds. The monitoring system collected users' data through digital cameras,  
309 microphones, and other equipment. The feature extraction, expression recognition,  
310 and classification were performed at the server. The variations in user's facial  
311 expressions, postures, and sounds were used as identifications to classify if users  
312 were in danger or having diseases. If any of these parameters changed, the system  
313 determines the necessary treatment, reminds the user and notifies the hospital and  
314 related persons. The system demonstrated promising strength in term of ease-of-  
315 use. But the adoption of camera as collector device can cause difficulties in

316 actively synthesizing images for transmission as well as the angle of images  
317 captured. As for microphone, the recognition of voice could also be suffered from  
318 the clamor in the environment. Another serious drawback is the machine learning  
319 technique, normally involved with time-complexity in the analysis of the large  
320 volume of learning data set.

321         The IoT applications in healthcare reviewed are summarized (Table 3). In  
322 a nutshell, solutions for Healthcare should at least underlie the following  
323 capabilities:

324         *Tracking and monitoring:* All patients shall be tracked and monitored with  
325 any wearable WSN devices at all time regarding that sensors can effectively  
326 generate health signal in an enhancement with the communication capacity.

327         *Remote service:* Telemedicine and remote diagnosis are necessary to  
328 provide emergency detection and first aids for patients with congenital disease.

329         *Information management:* Information regarding health such as  
330 medication, therapy, and advices for patients should be distributed through the  
331 value chain.

332         *Cross-organization integration:* The integration of hospital information  
333 systems (HISs) shall be extended to patient homes and other hospital chains.

334

### 335 ***Environment and Disaster***

336         At present, natural and accidental disasters are taking place more frequent.  
337 To lessen the effects of natural disasters, technologies in IoT could play a crucial  
338 role in alerting before disasters happen, and in disaster recovery after they end.

339 A heritage site monitoring system, namely “Health Monitoring and Risk  
340 Evaluation of Earthen Sites (HMRE2S)” model (Xiao et al., 2013) was conducted  
341 to monitor the environmental information of cultural sites. The environment  
342 information such as temperature, humidity, and light were collected via intelligent  
343 monitoring system. This experiment was claimed to provide accurate results but  
344 generalization for other sites may not be applicable since it was explored on a  
345 small heritage land. For larger cultural sites, the accuracy remains questionable.

346 Another contribution to global warming is the smart environment which  
347 increasingly attracted interest from the society. A smart heat and electricity  
348 management system (Kyriazis, Varvarigou, Rossi, White, & Cooper, 2013) was  
349 presented to monitor real-time electricity usage of the buildings and individual  
350 appliances where smart meters were used as data recorders. When the power  
351 consumption of those objects was above the limit, users would be promptly  
352 informed of such deformed situation.

353 Considering disaster, a waste from oil depot can cause terrible disaster to  
354 the environment because it is easy to get ablaze and burst. A surveillance system  
355 for safety management of oil depot was introduced in China (Du, Mao, & Lu,  
356 2012 ). The sensing layer of the system consisted of RFID tags and non-explosive  
357 PDAs to identify and interact with the key facilities in the oil depot. 3G was used  
358 as the communication layer to forward the data from the worksite to the Internet,  
359 where users accessed the safety management information via enterprise intranet.  
360 This IoT based safety management information system was proven to be stable  
361 since it was actually deployed in 2 oil depots with 24 PDAs and 100 RFID tags.

362

363           The IoT applications in environment/disaster reviewed are summarized  
364 (Table 4). The conclusion can be drawn that the prime features of solutions should  
365 meagerly be equipped with following features:

366           *Environment sensors:* Intelligent sensors for the humidity, temperature and  
367 pressure in the air, and other natural calamities will serve as front-end devices to  
368 gather as well as process contextual information from environment. The built-in  
369 fault detection and diagnostic capability is also actuated through the convergence  
370 of global industrial system.

371           *WSN and mobile communication:* The sensor nodes will be utilized for  
372 providing senses without users' intervention. The wireless network of sensor  
373 nodes would help sense the environment and objects around and communicate to  
374 the other things. Essential pillars are WSN and advanced mobile communication  
375 technology (3G and 4G) which can provide uninterruptable high-speed  
376 communication.

377           *Participatory sensing applications:* The utilization of each person mobile  
378 phone, vehicle and associated sensors as automatic sensory stations can help  
379 capturing a multi-sensor snapshot of the immediate environment. By combining  
380 these individual snapshots in an intelligent manner, it is possible to create a clear  
381 picture of the physical world that can be shared and, for example; used as an input  
382 to the smart environment services decision processes.

383

## 384 **Discussion on IoT in Applications**

385 Under the vision of IoT, applications can be fully automated by  
386 configuring themselves when exposed to a new environment. The intelligence  
387 behavior driven by the system can autonomously be triggered to seamlessly cope  
388 with unforeseen situations. However the applications in the above domains can  
389 deliver more analytical results if the following hindrances are properly taken care  
390 of.

391 Apparently, the major players of collector in the above application  
392 domains are RFIDs and GPS. RFID is one of the most convenient devices to  
393 transmit and receive data via radio frequency without wires at the lowest cost.  
394 Some RFID devices can only be used within the industry due to the range of  
395 electromagnetic spectrum (Coetzee & Eksteen, 2011). A clear disadvantage of its  
396 technology is the reader collision which may occur when the signals from two or  
397 more readers overlap or many tags are present in a small area. Although many  
398 systems use an anti-collision protocol to enable the tags to take turns in  
399 transmitting to a reader, this problem remains. Another strong barricade is the  
400 global standards of RFIDs are not yet established (Haiying et al., 2012).

401 As for GPS, it is recognized as an excellent tool for data collection in  
402 many environments where users can generally see the sky and are able to get close  
403 to the objects to be mapped. GPS requires a clear line-of-sight between the  
404 receiver's antenna and several orbiting satellites. Anything hedging the antenna  
405 from a satellite can potentially weaken the signal to such a degree that it becomes  
406 too difficult to achieve reliable positioning. An obstruction like buildings, trees,

407 crossways, and other obstructions that block sunlight can effectively block GPS  
408 signals where its potentiality could be seriously reduced (Guo, Poling, & Poppe;  
409 Vermesan & Friess, 2013).

410         Since the communication infrastructure of IoT can be any network  
411 available within the range. Hence mobile ad-hoc network, which allows people  
412 and devices to seamlessly form network in areas without pre-existing  
413 communication infrastructure seems to be a better choice (Bakht). The more  
414 convenience, the more applications and the more network services it supports, the  
415 more opportunities for active attackers as well as malicious or misbehaving nodes  
416 to create hostile attacks. These types of attack can seriously damage basic  
417 functions of security, such as integrity, confidentiality and privacy of the node.  
418 Currently, the security goal in mobile ad-hoc networks can only be achieved  
419 through cryptographic mechanisms. These mechanisms are generally more fragile  
420 to physical security threats than fixed wired networks. Besides, standardized  
421 communication interfaces and distributed control intelligence within an industry  
422 network remain disorganized (Lo'pez, Ranasinghe, Harrison, & McFarlane,  
423 2012).

424         As far as IoT dealing with more objects, the volume of the data generated  
425 and the processes involved in the handling of those data become critical. The  
426 ability to extract content from the data becomes even more crucial and complex,  
427 especially when dealing with big data. Variety of technologies and factors  
428 involved in the data management of IoT such as data collection and analysis, data

429 migration and integrity, sensor networks, and complex event processing are not  
430 yet convinced (Vermesan & Friess, 2013).

431

### 432 **Advancement and Hindrances in IoT**

433 The realization of the advancement in IoT indicates sustainable  
434 applications forming a smart environment for humans where plurality of  
435 challenges can be raised.

436 *The first challenge* was driven by embedding intelligence into things. To  
437 enable things and devices to learn and become smarter, more autonomous things  
438 are required to share and exchange experiences with other things.

439 *The second challenge* refers to the management of heterogeneous device  
440 platforms in a decentralized way. To make relationship with other devices, those  
441 platforms shall arrange the device coordinators via their social-behavior.  
442 Furthermore, pertinent issues with respect to end-to-end security, privacy and trust  
443 are also need to be addressed.

444 Moreover, a lot of techniques are required within and across different  
445 levels of IoT-based systems, for example; hardware-coded security at the device  
446 level, security and privacy in storage at the data level. Reputation, trust and  
447 privacy profiling of things and providers are also techniques to prevent  
448 information inference.

449 *The third challenge* refers to the support for scalable data and information  
450 management through rich metadata structures that capture the social aspects of

451 things. Real-time analysis of data will generate the potentially valuable  
452 knowledge from the information flows of exponential amount of data.

453 However, there are other significant challenges which introduce a wide  
454 gap between technology and applications in business in IoT which cannot be  
455 neglect such as:

456 *Unappealing initial investment:* This is a primary hindrance of mass  
457 volume adoption. For example, when suppliers want to adopt RFIDs for tracking  
458 of goods, the initial investment cost is unacceptable for business. Besides, users  
459 do not yet trust for the services provided by the IoT application vendors as  
460 experienced from a huge failure initiated from the deployment of IoT Google  
461 Heath System (Wamba & Chatfield, 2010).

462 *Unavailable devices and service integration:* Even though there are a lot  
463 of promising technology available for IoT applications but there are very few  
464 services which can be integrated. Users need to contact several vendors if they  
465 want to deploy a complete system. Therefore, an assimilated system design  
466 framework is crucial to integrate scatter subsystems and devices for more valuable  
467 services (Lee et al., 2010).

468

## 469 **Forwarding IoT**

470 For the sake of IoT to achieve its vision, a number of challenges needed to  
471 overcome. These challenges range from standardization, communication, and  
472 security to data volume (Coetzee & Eksteen, 2011; Vermesan & Friess, 2013).

473 ***Standardization:***

474 There are numerous efforts towards the standardization in several principal  
475 areas such as RFIDs, EPCglobal, M2M as well as applications. Since standards  
476 are required to allow global interoperability to change this “Intranet of Things”  
477 into the more complete “Internet of Things” (Vermesan & Friess, 2013).

478 The integrated environment is the origin of the success to run multiplicity of  
479 user driven applications and connect various sensors and objects. Complex and  
480 interconnected IoT applications can immensely be supported by open APIs at  
481 various system levels (Agrawal & Vieira, 2013). On one side, the vertical  
482 solutions of vendors based on their own technologies are not ready. On the other  
483 side, a dynamic global network infrastructure requires self configuring  
484 capabilities. Appropriate channels shall be provided for developers to deliver new  
485 applications and combine information generated by several IoT devices to  
486 produce new added value. Interoperable protocol is also a powerful  
487 communication tool in providing access to information, media and services to  
488 synergize the open, global network connecting people, data, and things.

489 ***Communication Infrastructure***

490 Things generated by devices can join networks and facilitate peer-to-peer  
491 communication for specialized purposes. They can increase robustness of  
492 communications channels and networks by forming ad-hoc peer-to-peer networks  
493 in disaster situations to keep the flow of imperative information going in case of  
494 telecommunication infrastructure failures. Therefore, the integrity and stability of  
495 the infrastructure is crucial to provide reliable services.

496 The overall cyber-physical infrastructure (e.g., hardware, connectivity,  
497 software development, communications, and specialized processes at the  
498 intersection of control and sensing) are considered as the compositionality of  
499 cyber-physical systems. The network aspects may consist of Wi-Fi, IP networks  
500 and mobile computing. Those can bring stream of technologies such as cloud,  
501 things, and mobiles. The convergent of main driven platforms with wired and  
502 wireless broadband connections shall strengthen the cloud to connect intelligent  
503 things that can sense and transmit huge data to create services. Cloud stimulates a  
504 global infrastructure for everyone to create content and applications for global  
505 users. Besides, networks of things are globally connected and maintain their  
506 identity online. This global infrastructure allows mobile connection to be  
507 available for services and businesses at anytime and anywhere leading to a  
508 globally accessible network of things, users, and consumers (Agrawal & Vieira,  
509 2013).

510 ***Security, Privacy & Trusts:***

511 As technologies and systems are incorporated, security remains a  
512 preponderant concern to lower system vulnerability and protect essential data.  
513 Regarding that the communication channel in IoT is not only from human to  
514 machine but also from machine to machine where the guarantee on the access  
515 control, authorization, privacy, and protection from malicious is a prime  
516 requirement for IoT acknowledgement.

517 In regard to its wireless and ubiquitous infrastructure, IoT is vulnerable to  
518 lashing malicious attacks. The attacks generally aim to control the physical

519 environments or obtain private data. Thereby, IoT should autonomously tune itself  
520 to different levels of security and privacy, while not affecting the quality of  
521 service and quality of experience. The security should not only ensure the data  
522 stored in the platform but should also cover the transmission of messages from  
523 devices (sensors, actuators, etc.). Specific mechanisms to ensure the availability of  
524 infrastructure should vindicate the Internet attacks such as Denial of Services and  
525 compromised nodes. The most eligible protective action during attacks on IoT-  
526 based infrastructure should be more focusing on assisting operators than coping  
527 with automatic protection (Uckelmann et al., 2011).

528 Although most IoT has achieved a security trust through Public Key  
529 Infrastructures (PKI), decentralized and self-configuring systems can be  
530 considered as alternatives. Not only cryptographic mechanisms are required but  
531 technologies such as homomorphic and searchable encryption are also potential  
532 candidates for developing such approaches. Besides, more self-managed IoT is  
533 wished to serve the heterogeneity and diversity of the devices/gateways. Self-  
534 managed IoT may employ machine learning to process and share data without the  
535 information content being accessible to others. Technologies of decentralized  
536 computing and key management as well as soft identities designed for specific  
537 contexts or applications will be more essential to IoT's privacy (Vermesan &  
538 Friess, 2013).

539 ***Data collection and acquisition:***

540 Data collection from sensors, identification and tracking systems are very  
541 crucial for real time processing. There remain several complexities of process  
542 involving as well as doubts in standards and filtering techniques.

543 Data generated by IoT devices from different vendors and different domains  
544 usually have different features. In most cases, not all data is significant, thus the  
545 identification of smart objects is imperative. In the backend, many more  
546 techniques such as new intelligent methods based on semantic technologies and  
547 tools for processing and analyzing historical and on-site data with the different  
548 qualities are gaining high attraction.

549 The first level of IoT data manipulation is mainly dealing with decoding data  
550 noise where specific filter mechanisms are welcome. Even though automatic  
551 identification helps to avoid mistakes from manual data entry, the corresponding  
552 data needs to provide a high level of accuracy upon the data quality standards  
553 agreed. While the new mechanisms of data aggregation aims to reduce the amount  
554 of transmission data and to taper the utilization of energy sensor nodes such as  
555 fuzzy-based and evaluation on quality of aggregation remain doubtful (Gubbia et  
556 al., 2013).

557 ***Big data:***

558 One significant aspect in IoT is the large number of things being connected to  
559 the Internet, each one providing data. Mechanisms to store and assure the validity  
560 through scalable applications remain a major technological challenge.

561 Each record of raw RFID data generally contains EPC, location and time is at  
562 least 18 bytes long. To extract valuable data from such big data, data mining

563 approach based data management and event processing are indispensable. Not  
564 only the data is always massive, distributed, time-related and position-related, it is  
565 also heterogeneous, and is distributed on resources with limited capabilities. The  
566 fundamental centralized data mining and preprocessing architecture may not be  
567 comprehensible to support data stored in different sites. Yet, a multi-layer mining  
568 model, distributed data mining model, grid based mining model as well as data  
569 mining model from multi-technology integration should be considered as  
570 alternatives (Bin, Yuan, & Xiaoyi, 2010).

571

572 Although IoT has to overcome huge barriers to gain trust from the  
573 societies, it has illustrated the distinguished potential to add a new dimension to  
574 the application in logistics, transportation, healthcare, and environment and  
575 disaster by enabling communication between smart objects. Therefore, IoT should  
576 be considered as a part of future internet that everything can connect in a network  
577 where objects can interact with each others. The development towards several  
578 issues will make IoT a complete solution. Hence more researches in the  
579 application of IoT are imperative. Once successfully implemented, the reduction  
580 of human efforts shall benefit the quality of life as well as business.

744 **Table 2 Summary of IOT in Transportation**

745

| Application  | Technology/Technique  | Strengths/Weaknesses  |
|--|---|---|
| Road Condition Monitoring and Alert system (Ghose et al., 2012)                    | <ul style="list-style-type: none"> <li>• Crowd Sourcing and participatory sensing based application.</li> <li>• Technology: accelerometer, smart phone, GPS(future).</li> <li>• Classifier based algorithm.</li> <li>• When a route is chosen, a confidence score for the area marked and the pothole information will be plotted on mobile.</li> </ul>   | <p>Strengths</p> <ul style="list-style-type: none"> <li>• Reduce cost by using smart phone as a connector device.</li> </ul> <p>Weaknesses</p> <ul style="list-style-type: none"> <li>• Many upload and download of GIS data can induce network traffic</li> <li>• Ease of security attack.</li> <li>• Time consuming of classification.</li> </ul> |
| License plate Identification(Ren et al., 2012)                                     | <ul style="list-style-type: none"> <li>• Use license plate as unique identifier.</li> <li>• Locate optimal path and guiding passage for vehicles.</li> <li>• Automatically Invoke traffic scheduling, vehicle positioning, and vehicle query.</li> <li>• Technology: RFID, recognition equipment.</li> </ul>  | <p>Strengths</p> <ul style="list-style-type: none"> <li>• Automatically suggest optimal path, locating of parking space and adding security for vehicles.</li> </ul> <p>Weaknesses</p> <ul style="list-style-type: none"> <li>• High cost and difficulties in implementation.</li> </ul>  |
| Remote performance monitoring system and simulation testing (Haiying et al., 2012) | <ul style="list-style-type: none"> <li>• Monitor the status of Lithium-ion power battery of electric vehicle.</li> <li>• A simulation of identified route for bus drivers.</li> <li>• A performance testing of battery pack, battery modules and battery systems.</li> <li>• Technology: GPS, RFID.</li> </ul>  | <p>Strengths</p> <ul style="list-style-type: none"> <li>• Online debugging and error correction can significantly reduce the maintenance cost.</li> </ul> <p>Weaknesses</p> <ul style="list-style-type: none"> <li>• no support for age tracking and end-of-life predictions of battery</li> </ul>  |
| transport vehicle monitoring system based on IoT (Shengguang et al., 2013)         | <ul style="list-style-type: none"> <li>• Real-time administration of the entire fleet from the command center.</li> <li>• Technology: GPS, RFID, 3G.</li> <li>• Monitor status of goods through RFID tags attached to goods.</li> <li>• Combine various capabilities of technologies: vehicle electronic sensors, mobile communication technology, navigation systems, smart terminal equipment and the information network.</li> </ul> | <p>Strengths</p> <ul style="list-style-type: none"> <li>• Effective road traffic both safety and reliability.</li> </ul> <p>Weaknesses</p> <ul style="list-style-type: none"> <li>• High cost implementation</li> <li>• Weak signal when vehicles are moving in high speed or approaching blind spots for GPS</li> </ul>                            |
