### Abstract

The present study includes a review of the geographic and stratigraphic distribution of short-faced bears (Ursidae, Tremarctinae) in South America. In addition, the authors discuss biogeographic hypotheses regarding the origin of South American tremarctines. The Tremarctinae subfamily is distributed exclusively in America, from Alaska to southern Patagonia. Its biochron comprises the temporal lapse between Late Miocene and recent times; the first record of Tremarctinae in North America corresponds to the Hemphillian and the last to the Rancholabrean. In South America, the first record corresponds to the Ensenadan. In the present day, it corresponds to the only living tremarctine, the ‘Andean Bear,’ but short-faced bears became extinct during the early Holocene. The extinction of short-faced bears in North and South America appears to have been approximately synchronous. Finally, the fossil record in South America indicates species turnover between the Ensenadan and Bonaerian, during which time the giant species *Arctotherium angustidens* was replaced by *Arctotherium tarjense*, *Arctotherium bonaerense*, and *Arctotherium vetustum* (and probably *Arctotherium wingei*).

### 1. Introduction

The bear genera that constitute the subfamily Tremarctinae (Carnivora: Ursidae) are distributed exclusively in America. Of these, (1) *Plionarctos* Frick is recorded from the Late Miocene to the Early Pliocene of North America with two species, *P. edensis* Frick and *P. harroldorum* Tedford and Martin; (2) *Arctodus* Leidy contains two North American Late Pliocene and Pleistocene species, *A. pristinus* Leidy and *A. simus* (Cope); (3) *Arctotherium* Burmeister comprises five South American species: *A. angustidens* Gervais and Ameghino, which is restricted to the Ensenadan (Early–Middle Pleistocene), *A. vetustum* Ameghino, registered only in the Bonaerian (Middle Pleistocene), and three Bonaerian and Lujanian (Middle Pleistocene–Early Holocene) species, *A. wingei* Ameghino, *A. bonariense* (Gervais), and *A. tarjense* Ameghino (Soibelzon, 2004); and (4) *Tremarctos* Gervais includes

two species, *T. floridanus* (Gildey) from the Late Pliocene and Pleistocene of North America and the only living Tremarctinae, *T. ornatus* (Cuvier) of South America, which has not been recorded as a fossil. The Tremarctinae are a monophyletic group; Ursinae is their sister group (Trajano and Ferrarezzi, 1994; Talbot and Shields, 1996). *Plionarctos* and *Tremarctos* constitute the ‘spectacled bears’ clade, a basal group of the Tremarctinae, and *Arctodus* and *Arctotherium* conform to the ‘short-faced bears’ clade. Within the clade formed by the *Arctotherium* species, *A. vetustum* and *A. wingei* are more primitive than *A. angustidens*. Finally, *A. bonariense* and *A. tarjense* are the most derived species (Soibelzon, 2002).

This study includes a review of the geographic and stratigraphic distribution of short-faced bears in South America. In addition, we discuss the biogeographical hypotheses of Ameghino (1885, 1906), Kraglievich (1926), Trajano and Ferrarezzi (1994), and Cartelle (1998) regarding the origin of South American tremarctines.

## 2. Material and methods

For a detailed list of the stratigraphic and geographic provenances of each sample of material, see Soibelzon (2002; 2004).

*A. vetustum*. MACN A1277, type of *A. vetustum*, Villa Urquiza, Entre Ríos province, Middle–Late Pleistocene. Referred material: Argentina, Buenos Aires province, Mercedes: MACN 1201 (Bonaerian, Middle Pleistocene). Coronel Pringles: MMMP 1233M (Bonaerian [Berman, 1994]). Río Arrecifes: MLP 10-7 (Bonaerian; see Soibelzon et al., 1999). Entre Ríos province, Arroyo Alcaraz: MACN 17486 (Middle–Late Pleistocene).

*A. vetustum?* Brazil, Bahia state, Minas Gerais: MHN s/n (see the skull in Cartelle, 1994).

*A. wingei*. MACN 1453, type of *A. wingei* from Tarija Valley, Bolivia, Pleistocene. UZM 5249, 5715, 5717, 5721–22, and 5723; types of ‘*Ursus brasiliense*’ from several caves in Lagoa Santa region, Brasil (see Winge, 1895–1896). Referred material: Brazil, Minas Gerais state, Lapa da Escrivanía N°5: MACN 6273. Ceará state, Ubajara: GP/2-T4 (out of stratigraphic context; see Trajano and Ferrarezi, 1994). Bahía state, Campo Formoso: IGC 10 (out of stratigraphic context, see Cartelle, 1998). Bolivia, Tarija County, Tarija Valley: MACN 1454 (Pleistocene). Venezuela, Falcon state, ‘El Muaco’ local fauna: #1 (Late Pleistocene; Linares, pers. comm.). Monagas state, ‘Cueva

del Guácharo’ local fauna: #2 (Early Holocene, Linares, pers. comm.).

*A. angustidens*. BMNH 32915–16, 32971–72, 32969, and 32974–91, type of *A. angustidens* from ‘Toscas del Río de La Plata,’ Buenos Aires province; Ensenada. MACN 43, type of ‘*A. latidens*’ from ‘Callejón de Ibáñez’ Buenos Aires; Ensenada (Early–Middle Pleistocene). MACN 5132, type of ‘*A. candioti*’ from an excavation in Buenos Aires City; Ensenada. Referred material: All the material listed next are from the Ensenada, Argentina, Buenos Aires province, Toscas del Río de La Plata: MACN 851, 972, 974, 1202, 1892, 13265, 16260, 1926, 1994, 1997, 2011, 2020, 2024, 2158, 2178, 2179, 2536, 2547, 2548, 3158, 5702, 5705, 6222, 6223, 8262, 8791, 8792, 8794, 9609, 10094, 10459, 2275, 2297, 5690, 5696, 8691, 8700, 10458, and 18008; MLP 99-X-5-1, 82-X-22-1, and 99-X-3-1. La Plata: MLP 35-IX-26-3/6, 39-IV-21-1, and 58-X-4-1. Moreno: MACN 17719. Buenos Aires City: MACN 12529, MNHN PAM 179, Paleontological Collection of Museo Miguel Lillo, Tucumán s/n. Mar del Plata City: MMMP 1232. Mar del Plata marine cliff: MMMP 26S and 162S; MMMP 48S; MACN 17986. Gorina: MLP 68-V-26-1 and 97-I-5-1. Ezeiza: MLP 00-VII-10-1. Ezpeleta: MLP 00-VII-15-1. Vivoratá: MMMP 3980, 3981, and 3982. San Pedro: MLP 97-II-2-1, MST P2 99-IX-15. Campana: MPV 613 and 614. Miramar: MLP 01-IV-1-1 and 87-V-5-1. Mar del Sur: MMMP 018. Río Pergamino: PMUZ 45. Bolivia, Tarija, Tarija Valley: AMNH 117433.

*A. bonariense*. MNHN PAM 264, type of *Ursus bonariensis* from an undetermined site around Luján City (see Gervais, 1855; Soibelzon, 2002; 2004), Buenos Aires province, Middle–Late Pleistocene (Lujanian?). MACN 2668, type of ‘*Pararctotherium enectum*’ from an excavation at the corner of Cangallo and Cerro streets in Buenos Aires City; Early Bonaerian. MACN 9646, type of ‘*Pararctotherium pamparum crassidens*’ from Río Quequén Salado; Lujanian. Referred material: Argentina, Buenos Aires province, Río Quequén Salado: MACN 9645 and 9647, MMCN 69-6-1 (Lujanian). Necochea: MACN 13971 (Pleistocene). Roque Pérez: MACN 14614 (Bonaerian). Mar del Plata marine cliff: MLP 99-X-10-1 (Early Bonaerian).

*A. tarijense*. MACN 1458, type of *A. tarijense* from Tarija Valley, Bolivia; Pleistocene. MACN 2667, type of ‘*Pararctotherium enectum*’ from an excavation in Buenos Aires City; Early Bonaerian (see Ameghino, 1904). MACN 971, type of ‘*Pararctotherium pamparum*’ from Mercedes, Buenos Aires province; Late Bonaerian (see Ameghino, 1904). Referred material: Argentina, Buenos Aires province, Dolores: MACN 8581 and 8582 (Lujanian). Luján: MACN 2180 (Late Lujanian). Río Salto: MCA 1087 (Bonaerian). Río Arrecifes: MLP 10-71 (Bonaerian). Mar Chiquita: MLP 92-XI-28-1. Centinela del Mar: MLP 92-XI-27-1 (Early Lujanian). Junín: MHJ 544 (Late Lujanian). Mar del Plata City: MMMP 1441 (Late Lujanian). Santa Fé Province, Grütly: MLP 34-VIII-1-1 (Bonaerian). Uruguay,

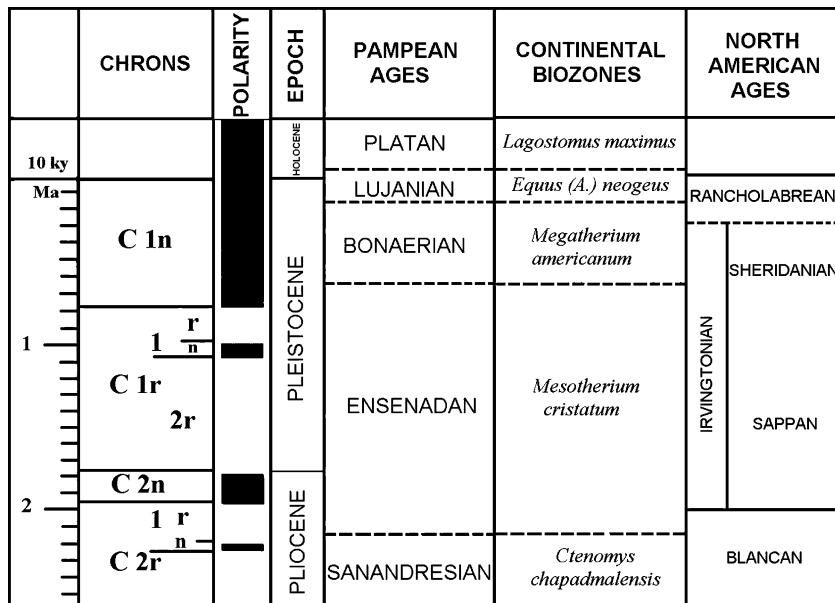

Fig. 1. Chronological chart of the late Cenozoic in South America (modified from Cione and Tonni, 1999).

Río Negro County: GALY s/n (Late Lujanian). Chile, Magallanes County, Pali Aike National Park: UMAG 53643 (Late Lujanian).

*Arctoatherium* sp. Argentina, Buenos Aires province: MACN 12654. Tapalqué: MLP 10-70 (Bonaerian). Santa Fe Province, Río Carcarañá: MACN 11443 (Pleistocene). San Luis Province, Las Lagunitas: MACN 12558 (Pleistocene).

In discussing this record, we rely greatly on the biostratigraphic record of the Pampean area of central Argentina, the best known in South America (see Tonni and Cione, 1999; Cione and Tonni, 1999; 2001; Fig. 1). Cione and Tonni (1999, 2001) consider the *Tolypteutes pampaeus* biozone the biostratigraphical base of the Ensenadan; however, *Tolypteutes pampaeus* could be a poorly defined species, and its temporal range could be wider than the Ensenadan (Carlini and Scillato-Yané, pers. comm.). Therefore, we propose a new taxon to define this biozone: *Mesotherium cristatum*, a well-defined, frequent, geographically widely distributed notungulate restricted to the Ensenadan (Bond, 1999).

### 3. Introduction to the fossil record of Tremarctinae

#### 3.1. Geographic and stratigraphic distribution

The Tremarctinae biochron comprises the temporal lapse between the Middle Hemphillian (earliest Late Miocene) and the present (Fig. 2).

In North America, they are recorded from the earliest Late Miocene to the Early Holocene; the oldest record of a Tremarctinae bear (*Plionarctos* sp.) comes from the Middle Hemphillian (Tedford and Martin, 2001). *P. edenensis* is recorded in the Late Hemphillian and *P. harroldorum* in

the Blancan I (Early Pliocene; Tedford and Martin, 2001). *Plionarctos* has not been recorded in sediments younger than Early Pliocene; *Tremarctos* is recorded from the Blancan III (Late Pliocene) to the present; *T. floridanus* appears from the Blancan III to the Rancholabrean (Middle-Late Pleistocene); and *T. ornatus* only occurs in present times (Kurtén, 1966). The oldest record for *Arctodus* is Blancan IV (Latest Pliocene), and the youngest is Rancholabrean. The biochron of *A. pristinus* comprises the temporal lapse between the Blancan IV and Irvingtonian (Early–Middle Pleistocene); that of *A. simus* comprises the temporal lapse between the Irvingtonian and Rancholabrean (Kurtén, 1967). In North America, the youngest records emerge for *A. simus* ( $9630 \pm 60$   $^{14}\text{C}$  yr BP, Gobetz and Martin, 2001;  $10,800$   $^{14}\text{C}$  yr BP, Gillette, 1996) and *T. floridanus* ( $10,500$   $^{14}\text{C}$  yr BP, Anonymous, 1998;  $7432 \pm 300$   $^{14}\text{C}$  yr BP [C-823]).

In South America, the oldest records of fossil bears are Ensenadan, the ‘Puelchan’ record could be Ensenadan in age (Cione and Tonni, 1995), and the youngest are latest Lujanian (Early Holocene). According to  $^{14}\text{C}$  dates, the two youngest records in South America are *A. tarijense* (UMAG 53643,  $11,210 \pm 50$   $^{14}\text{C}$  yr BP, San Roman et al., 2000; GALY s/n,  $11,600 \pm 130$   $^{14}\text{C}$  yr BP, Ubilla and Perea, 1999). In addition, the only existing extant Tremarctinae (*Tremarctos ornatus*) lives in South America.

#### 3.2. Geographic distribution

The subfamily Tremarctinae is distributed exclusively in America, from Alaska to southern Patagonia. The UMAG 53643 at ‘Cueva de los Chingues,’ Chile (Prevosti et al., 2003) is the southernmost record of Ursidae in the world.

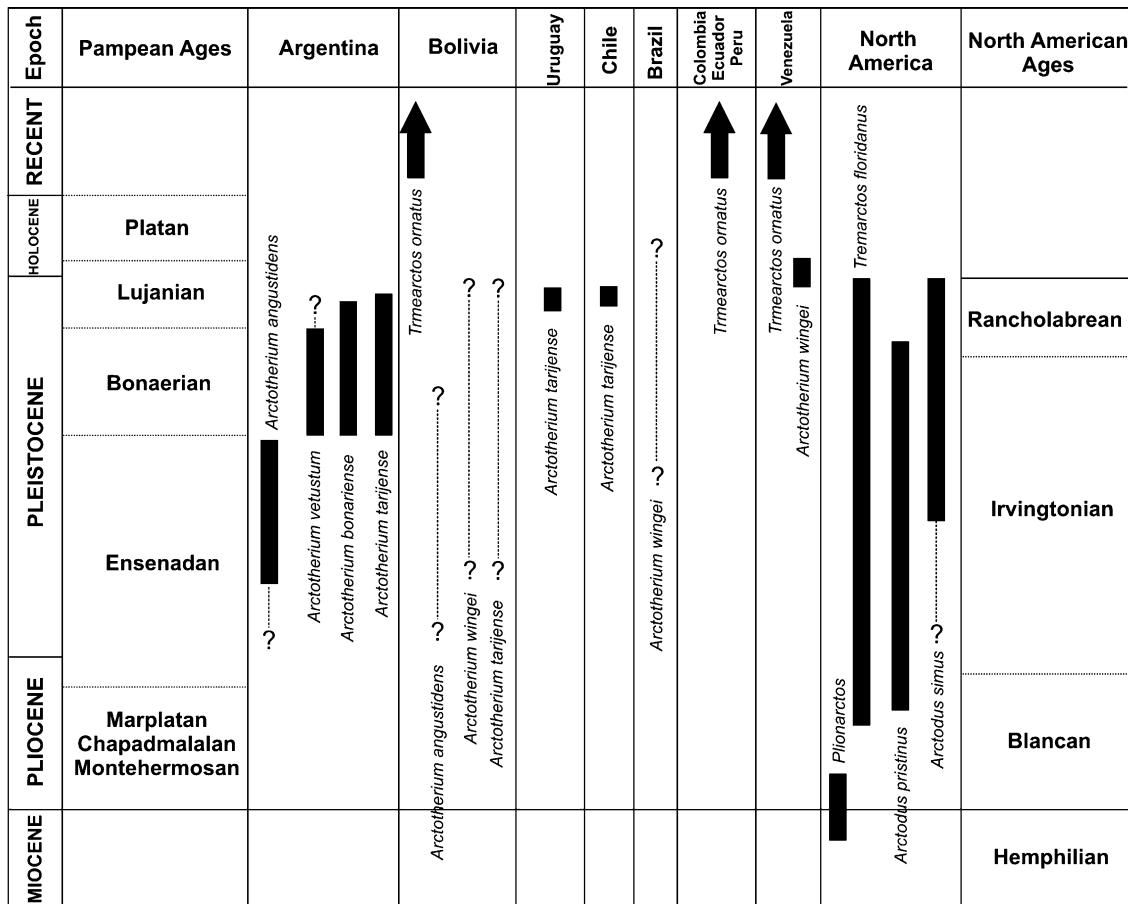

Fig. 2. Chronological chart of the late Cenozoic in North and South America showing the Tremarctinae biochrons (modified from Soibizon, 2002).

In North America, *Plionarctos* is recorded in the central western area, and *Tremarctos floridanus* appears in the southern area. *Arctodus* presents the widest distribution of the North American taxa (Kurtén, 1966, 1967; Kurtén and Anderson, 1980; Soibelzon, 2002).

In South America, *Arctotherium* is recorded mainly on the east side of the continent from Venezuela to southern Patagonia (Venezuela, Brazil, Uruguay, Argentina, Bolivia, and Chile), whereas *Tremarctos ornatus* is distributed on the west (Venezuela, Colombia, Ecuador, Peru, and Bolivia).

## **4. The fossil record of short-faced bears in South America**

#### 4.1. Temporal distribution

The fossil record in South America usually presents serious problems because it often lacks sufficient documentation of the stratigraphic and/or geographic provenance of materials from old collections, such as those from Middle-Late Pleistocene sediments (late Pampean sediments). In some localities, one of the authors (EPT) was able to use the well-known stratigraphy as documentation. Although for some remains, the stratigraphic reassessment provided

additional information, for in another 10–15 records, it was impossible to assess the stratigraphic position.

#### *4.1.1. Ensenadan*

The *M. cristatum* biozone represents the Ensenadan in the Pampean region (Tonni and Cione, 1999; Fig. 1). During the Ensenadan, only one bear species, the gigantic *A. angustidens*, is recorded. For a detailed discussion of the Ensenadan record of short-faced bears, see Soibelzon et al. (2001); Soibelzon (2002; 2004).

The primary, and oldest, record of *A. angustidens* comes from the Toscas del Río de La Plata. This level corresponds to chron C1r2r (Tonni et al., 1999). According to the available magnetostratigraphic information, the age of the Toscas del Río de La Plata is older than 0.98 Ma and younger than 1.76 Ma (Bidegain, 1991; Tonni et al., 1999).

Some specimens of *A. angustidens* were found in the marine cliff from southeastern Buenos Aires province. Three specimens (MMMP 162S, 26S, 48S) came from these marine cliffs north of Mar del Plata City. In this area, sediments have been referred to the Ensenadan, Bonaerian, Lujanian, and Platan (Tonni et al., 1992; Cione and Tonni, 1995; 1999). Recent magnetostratigraphic studies by Bidegain et al. (1998) show that a change from chron C1r to C1n can be identified 7 m above the top of the cliff (3 m

from the base). This finding implies that the age of the sediments where MMMP 26S and 48S were found is 0.98–0.78 Ma. Unfortunately, the stratigraphic procedure used for MMMP 162S is not precise ('middle part of the cliff'); therefore, the sediments to which it has been referred could pertain to chron C1r or the base of chron C1n. If so, the age of the sediments could be younger than 0.78 Ma.

Approximately 50 km south of Mar del Plata City, at the D level of the marine cliff 'Punta Hermengo' (Tonni and Fidalgo, 1982), two specimens (MLP 87-V-5-1 and MLP 01-IV-1-1) were found. No magnetoestratigraphic information exists for this sector of the marine cliff, though Tonni et al. (1998) correlated the D level with the lower to middle section of the northern marine cliff at Mar del Plata City on the basis of the faunistic record. In the B level (Soibelzon and Soibelzon, 1999), at the base of the marine cliff 5 km south of Mar del Sur, MMPH 18 was found. Soibelzon et al. (2001) correlated this level with the lower to middle section of the northern marine cliff at Mar del Plata City.

Several records of *A. angustidens* were found in Tarija Valley (e.g. AMNH 117433 and others housed in museums in La Paz and Tarija, Bolivia), but none contains indicators about the stratigraphic provenance. The Tolomosa (formerly Tarija) Formation is composed of two units: The lower one consists of poorly fossiliferous clays, and the highly fossiliferous upper one is composed of conglomerates. The age of the base of the lower unit is approximately 1 Ma (MacFadden, 2000). Thus, the lower unit could be regarded as Ensenadan in age, though not by its biostratigraphical context. It is noteworthy that the highly fossiliferous upper unit is younger than 0.78 Ma. Thus, the specimens of *A. angustidens* found in Tarija may be Ensenadan in age, according to the record of this species in the Pampean region of Argentina.

In summary, *A. angustidens* is not very frequently recorded (similar to other members of Carnivora) but represents a conspicuous element of the *M. cristatum* biozone. Furthermore, *A. angustidens* is a characteristic species of the Ensenadan, and its biochron comprises the temporal lapse between 1.76 Ma (chron C1r2r) and 0.78 Ma (base of chron C1n) (Soibelzon et al., 2001).

#### 4.1.2. Bonaerian

The *Megatherium americanum* biozone corresponds to chron C1n and represents the Bonaerian in the Pampean region (Tonni and Cione, 1999; Fig. 1). The records of *A. vetustum*, *A. bonariense*, and *A. tarijense* start in the Bonaerian (Soibelzon, 2002), as do many other clades of holartic origin that demonstrate a great increase in diversity (Cione and Tonni, 2001).

In sediments assigned to the Early Bonaerian at Buenos Aires City (Ameghino, 1904), *A. tarijense* (MACN 2667) and *A. bonariense* (MACN 2668) have been recorded. In sediments of the marine cliff outcropping 500 m south of 'Parque Camet' (north of Mar del Plata City), *A. bonariense*

(MLP 99-X-10-1) was found and assigned to the Early Bonaerian (Soibelzon et al., 2001). *A. tarijense* (MACN 971) and *A. vetustum* (MACN 1201) were recorded in the Late Bonaerian of Mercedes (Buenos Aires province; Ameghino, 1904).

In the Bonaerian s.l., both *A. vetustum* (MMMP 1233, Galileo Scaglia in Berman, 1994; MLP 10-7, Soibelzon et al., 1999) and *A. tarijense* (MLP 10-71, Soibelzon et al., 1999; MCA 1087, MLP 34-VIII-1-1) were recorded. Two other specimens of *A. vetustum* are recorded in Entre Ríos province (MACN A1277 from Villa Urquiza and MACN 17486 from Arroyo Alcaraz); because they lack stratigraphic information however, they can be confidently assigned only to the Middle-Late Pleistocene.

In summary, evidence indicates that *A. vetustum* is recorded exclusively in the Bonaerian, at least in the Pampean area. The likely record of *A. vetustum* in Brazil remains to be confirmed from a taxonomic point of view. Also, the fossil records of *A. tarijense* and *A. bonariense* start in the Bonaerian, at least in the Pampean area of Argentina.

#### 4.1.3. Lujanian

The *Equus (Amerhippus) neogeus* biozone represents the Lujanian in the Pampean region (Tonni and Cione, 1999; Fig. 1). This biozone corresponds to chron C1n, as well as the Bonaerian. From the Lujanian, three species have been recorded: *A. wingei*, *A. bonariense*, and *A. tarijense*.

The only species recorded in sediments that represent the Early Lujanian (~130 ka, Isla et al., 2000) is *A. tarijense* (MLP 92-XI-27-1), from the marine cliff at Centinela del Mar, Buenos Aires province.

At Río Quequén Salado (Buenos Aires province), both *A. bonariense* (MACN 9645-47 and MMCN 69-6-1) and *Arctotherium* sp. (MLP 42-VI-24-29) were recorded. On the flow plain of Río Quequén Salado, sediments represent the temporal lapse between approximately 130 ky and 12–10 ky BP (Pardiñas et al., 1996).

From the Late Lujanian (~20 ky, Tonni et al., 1998) of southern South America, only one species, *A. tarijense*, is recorded. Specimen MLP 92-XI-28-1 comes from the marine cliff at Camet Norte, where sediments have been dated  $24,450 \pm 150$   $^{14}\text{C}$  yr BP (Pardiñas et al., 1998). Specimen MMMP 1441 comes from an excavation in Mar del Plata City whose sediments have been assigned to the Late Lujanian (G. Scaglia in Berman, 1994). From an auxiliary channel of Río Salado, 6 km southwest of Junín (Late Lujanian, De Salvo et al., 1969) comes specimen MHJ 544. Finally, also from the Late Lujanian and near Luján City, specimen MACN 2180 was recovered.

The two youngest records of fossil bears in southern South America correspond to *A. tarijense*. The youngest (UMAG 53643; Prevosti et al., 2003) comes from 'Cueva de los Chingues' (Pali Aike National Park;  $52^{\circ}05'37''\text{S}$ ,  $69^{\circ}44'31''\text{W}$ , Magallanes County, Chile) and has been dated as  $11,210 \pm 50$   $^{14}\text{C}$  yr BP (San Roman et al., 2000).

The other young specimen (GALY s/n; cited as '*Paractotherium pamparum*' by Perea and Ubilla, 1983; see Soibelzon, 2002) is from Río Gutiérrez, Río Negro County, Uruguay, and has been dated as  $11,600 \pm 130$   $^{14}\text{C}$  yr BP (Ubilla and Perea, 1999).

Also during the Late Lujanian but in northern South America, *A. wingei* has been recorded (#1 from 'El Muaco' local fauna, Falcón state, Venezuela; #2 from 'El Guácharo' cave local fauna, Monagas state, Venezuela; Linares, pers. comm.). These two are the only records for *A. wingei* that contain a stratigraphic provenance, but there are no  $^{14}\text{C}$  data for them. As we emphasized previously, it is impossible to determine the biochron of *A. wingei* because only these two individuals have stratigraphic information. Other samples of the species lack precise indicators (e.g. MACN 1453 and 1454 from Tarija Valley, Bolivia) or were found out of their stratigraphic context in caves such as Lagoa Santa (e.g. UZM 5249, 5715, 5717, 5721-22, 5723) or others in Brazil (e.g. GP/2-T4; IGC 10). Thus, it is not possible to establish the biochron of *A. wingei* with precision, though Trajano and Ferrarezzi (1994); Cartelle (1998) believe the specimens came from the Late Pleistocene ( $\sim 12$  ka.)

In summary, *A. wingei* is recorded exclusively in the Lujanian, but more records are needed to confirm this preliminary conclusion. At the end of the Lujanian, short-faced bears seem to have become extinct in South America, approximately 2 ka before they became extinct in North America.

#### 4.2. Geographic distribution

##### 4.2.1. Venezuela

The fossil record of *A. wingei* in Venezuela is extremely significant because it is the only one in the northern part of South America (Fig. 3). In the future, the short-faced bears' entrance to South America may be documented in the Late Pliocene or Early Pleistocene of this part of the continent.

##### 4.2.2. Brazil

Trajano and Ferrarezzi (1994) and Cartelle (1998) suggested that all bears recorded in Brazil correspond to *A. wingei*, but at least one (skull MHN s/n from Minas Gerais, Cartelle, 1994) probably corresponds to *A. vetustum* (Soibelzon, 2002).

##### 4.2.3. Uruguay

Few fossil bear remains occur in Uruguay. Of these few, one (Galy s/n) was assigned to *A. tarjense* by Soibelzon (2002). Another was assigned to '*Arctodus bonariensis*' by Perea and Ubilla (2001), but according to a systematic revision of the Tremarctinae subfamily (Soibelzon, 2002; 2004), the fragmentary nature of its record, and the lack of a precise stratigraphic context, it should be considered *Arctotherium* sp., pending further studies.

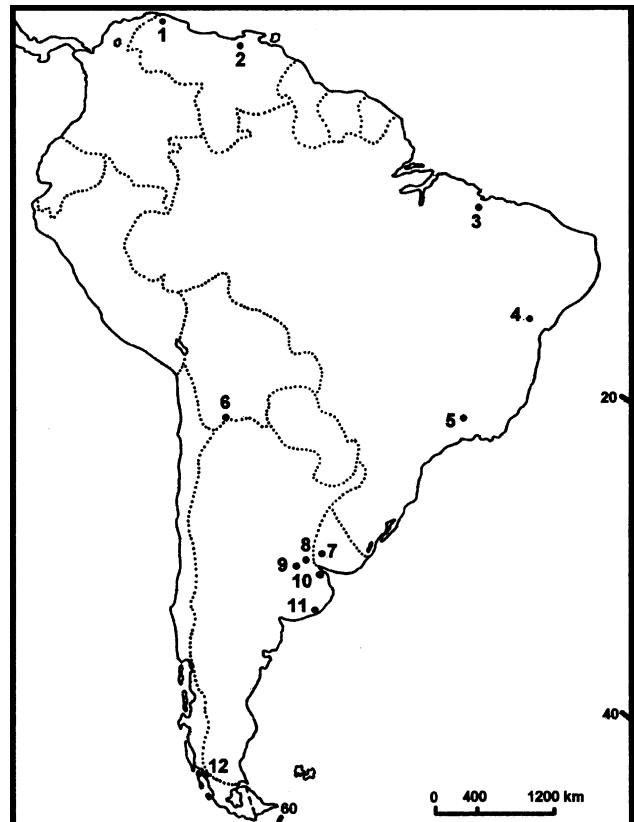

Fig. 3. Map depicting sites with fossil tremarctinae (modified from Soibelzon, 2002). (1), Falcon state and (2), Monagas state, Venezuela; (3), Ceará state; (4) Bahía state, and (5) Minas Gerais state, Brazil; (6), Tarija Valley, Bolivia; (7), Río Negro County, Uruguay; (8), Entre Ríos province; (9), Santa Fe province; (10), 'Toscas del Río de La Plata,' Buenos Aires and La Plata, Buenos Aires province, Argentina; (11), Marine cliff southeast of Buenos Aires province; (12), Pali Aike National Park and 'Cueva del Milodón,' Chile.

##### 4.2.4. Bolivia

All known Bolivian fossil bears come from Tarija Valley. Soibelzon (2002) recognized three species from Bolivia: *A. tarjense*, *A. wingei*, and *A. angustidens*.

##### 4.2.5. Chile

In 1900, a portion of femur found in the 'Cueva del Milodón' (Última Esperanza,  $52^{\circ}05'37''\text{S}$ ,  $69^{\circ}44'31''\text{W}$ ) was referred to *Arctotherium* sp. (Smith Woodward, 1900). Although the specimen is now lost, the size and morphology reflect those of the femur of *Arctotherium*, but it cannot be assigned to any particular species. Curiously, this record was ignored in revisions of the South American fossil Tremarctinae (e.g. Kraglievich, 1926; 1934; Kraglievich and Ameghino, 1940; Kurtén, 1967; Berman, 1994; Trajano and Ferrarezzi, 1994). The discovery of an I2 of *A. tarjense* at 'Cueva de los Chingues' confirms the presence of *Arctotherium* in southern Patagonia (Prevosti et al., 2003).

#### 4.2.6. Argentina

In the Pampean region of Argentina, all *Arctotherium* species (except for *A. wingei*) have been recorded. The most complete record comes from Buenos Aires province, with *A. angustidens*, *A. vetustum*, *A. bonariense*, *A. tarijense*, and *Arctotherium* sp.; some records also appear in Santa Fe, San Luis, and Entre Ríos provinces, but the fossil record in other Argentinean provinces is poor compared with that of Buenos Aires. In Entre Ríos province, only one species, *A. vetustum*, was recorded. *Arctotherium* sp. was recorded in San Luis province, and *A. tarijense* and *Arctotherium* sp. were recorded in Santa Fe province.

#### 4.3. Biogeographical background

Florentino Ameghino (1885) suggested a South American origin for the Tremarctinae subfamily on the basis of the erroneous stratigraphic provenance of specimen MACN 1277 (*A. vetustum*), which he believed to be ‘Mesopotamian’ in age (Late Miocene). This hypothesis was accepted by Carlos Ameghino (1916), but Merriam et al. (1916), Merriam and Stock (1925), and Kraglievich (1926) placed the stratigraphic provenance of MACN 1277 in doubt and, in turn, questioned Ameghino’s (1885, 1906) hypothesis.

The Great American Biotic Interchange (GABI; Stehli and Webb, 1985) was considered a dispersion event, though it is difficult to verify a dispersion or vicariance event for the origin of South American short-faced bears. Only one record for *Arctotherium* occurs in northern South America (*A. wingei* from the Late Pleistocene and Early Holocene of Venezuela; Linares, pers. comm.), which implies that one of the most plesiomorphic taxa of *Arctotherium* (Kurtén, 1967; Soibelzon, 2002) was distributed south of the Panamanian Isthmus.

The first record of *Arctodus* in North America is from the Late Pliocene; thus, the cladogenetic event that resulted in *Arctodus* and *Arctotherium* should be earlier, perhaps in the Early Pliocene. Since as early as the Late Pliocene, the Panamanian Isthmus had emerged, and if we accept the vicariance hypothesis, tremarctine bears must have been recorded in South America at least from that epoch. However, there is no fossil record for bears prior to the Early Pleistocene (Ensenadan) south of the Panamanian Isthmus. According to Webb (1991), the most successful holartic families involved in the GABI diversified north of the Panamanian Isthmus before the interchange, which suggests that the origin of *Arctotherium* must be related to a dispersion event rather than a vicariance event.

According to Trajano and Ferrarezzi (1994), a subsequent second event is needed to explain the occurrence of *T. ornatus* in South America. The absence of *T. ornatus* in the fossil record of either North or South America indicates that this species differentiated during the Holocene from its sister group (*T. floridanus*).

The fossil record of *Arctotherium* in South America also indicates that cladogenetic events occurred in intertropical

areas. For example, *A. wingei* (exclusively), *A. vetustum*, *A. angustidens*, and *A. tarijense* have been recorded in those areas.

#### 5. Conclusions

First, the Tremarctinae subfamily is distributed exclusively in America, from Alaska to southern Patagonia. The fossil record indicates that the geographic origin of the group was central eastern North America and that the group arrived in South America during the GABI. Second, the Tremarctinae biochron comprises the temporal lapse between Late Miocene (~7 Ma) and recent times. The first record of Ursinae in North America (Blancan I) is younger than the first record of Tremarctinae, in support of Kurtén’s (1966) hypothesis with respect to the origin of both subfamilies from Agriotheriinae. The subfamily’s first record is in North America during the Hemingfordian (Early Miocene).

Third, the first records of Tremarctinae in North America correspond to the Hemphillian (*Plionarctos* sp.) and the last to the Rancholabrean (*T. floridanus* and *Arctodus simus*). In South America, the first record corresponds to the Ensenadan (*A. angustidens*) and continues to the present (*Tremarctos ornatus*), though short-faced bears became extinct during the early Holocene. Thus, the extinction of short-faced bears in both North and South America appears to have been approximately synchronous. Fourth and finally, though Berman (1994) suggested that all short-faced bear species in South America were recorded during the Ensenadan-Lujanian, the fossil record indicates a species turnover between the Ensenadan and the Bonaerian. During this time, *A. angustidens* was replaced by *A. tarijense*, *A. bonaeriense*, and *A. vetustum* (and probably *A. wingei*), as was suggested by Kraglievich (1934); Kraglievich and Ameghino (1940).

#### Acknowledgements

The authors thank Dr. Alejandro Kramartz (MACN), Dr. José F. Bonaparte (MACN), Dr. Webb (FMNH); Dr. Tedford (AMNH), Dr. Andy Currant (NHM, Lenders), Drs. Christian De Muizon and Francois Pujos (MNHN), Mr. Daniel Bo (MMPH), Mr. Jorge Petrocelli (MCA), Mr. Jorge Cabañez (Liceo Young), and Drs. Diego Verzi and Mariano Merino (MLP zool) for allowing us to study the material. Dr. Daniel Perea, Dr. Tyson Sacco, and an anonymous reviewer provided valuable suggestions on the manuscript. The authors also thank CONICET; Fundación Antorchas; AMNH Office of Grants and Fellowships; ANPCyT PICT 07-8395; and Secretaría de Ciencia y Técnica de la UNLP for financial support.
