†All odds ratio (OR) and 95% confidence intervals (95% CI) were calculated by comparing each group with reference [individuals without HLA-DRB1 risk alleles (*0101, *0401, *0404, *0405, *0410, *0901, *1001)] and were adjusted for age and sex. The attributable proportions (AP) was 0.45 (0.19–0.72) for smoking and SE alleles, and 0.17 (−0.44–0.79) for smoking and *0901 allele.

Conclusions: Gene-environment interaction of HLA-DRB1 *0901 allele is differ from SE alleles. The DRB1*0405/*0901 heterozygote enhances the susceptibility to both anti-CCP-positive and anti-CCP-negative RA.

The Smoking-Induced Heat Shock Protein DNAjC6 Is Downregulated in Rheumatoid Arthritis. Caroline Ospelt[1], Joanna Stanczyk[2], Christoph Kolling[3], Renate E. Gay[1] and Steffen Gay[4]. [1]Center of Experimental Rheumatology and Center of Integrative Human Physiology, Zurich, Switzerland, [2]Center of Experimental Rheumatology and Center of Integrative Human Physiology, Zurich, Switzerland, [3]Schulthess Clinic Zurich, Switzerland, [4]University Hospital Zurich, Zurich, Switzerland

Background: Previously we had found that the heat shock protein DNAjC6 is upregulated in joints of mice after exposure to cigarette smoke as well as in the synovium of human smokers compared to non-smokers. Smoking has repeatedly been shown to be a risk factor for the development of rheumatoid arthritis (RA) in susceptible individuals. On the other hand nicotine has also been found to have anti-inflammatory properties and smoke exposure delays the onset of collagen-induced arthritis in mice. Also heat shock proteins have been described to protect cells from environmental damage and act as tumor suppressors, as well as to elicit aberrant immune responses. In the current work we aimed at elucidating the effect of increased levels DNAjC6 in joints of smokers and its possible role in pathogenesis of RA.

Material and Methods: Expression of DNAjs, MMPs, IL-6, IL-8 and microRNAs (miRs) in synovial fibroblasts (SFs) and tissues was measured by Real-time PCR. Relative quantification with 18S or let7a as reference genes was used to quantify levels of gene expression. Synovial fibroblasts were transfected with siRNA targeting DNAjC6 or siRNA control by nucleoporation.

Results: Basal mRNA expression levels of 6 DNAj family members representing different subtypes of DNAjs namely DNAjA3, B4, B9, C6, C9 and C15 were measured in RA (n=6) and osteoarthritis (OA; n=8) SFs. Except for DNAjB9, SFs expressed all of the measured DNAjs, but only DNAjC6 was differentially expressed between RA and OA. Thereby, transcript levels of DNAjC6 were 2.3 fold downregulated in RASFs compared to OASFs (dCT 13.6 ±0.4 vs 12.4 ±0.2; p=0.04). Decreased expression of DNAjC6 in RA was also measured in synovial tissues, where it was 3.3 fold lower in RA (n=16) than in OA patients (n=6) (dCT 13.7 ±0.2 vs 12.0 ±0.6; p=0.01). To see the effect of lowered DNAjC6 levels in SFs we silenced its expression in OASFs (n=4) and measured expression levels of MMPs, IL-6 and IL-8. Whereas the expression of the interleukins, MMP-9 and MMP-13 was not altered, expression of MMP-1 and MMP-3 significantly increased by silencing of DNAjC6 (1.9 ±0.2 and 1.7 ±0.2 respectively; p=0.03). In search of mechanisms leading to lowered expression of DNAjC6 in RA, we used computational miR target prediction programs and found that miR-323 potentially targets DNAjC6, but no other members of the DNAj family. In accordance, expression of miR-323 was significantly higher in RASFs (n=6) than in OASFs (n=4) (dCT 8.6 ±0.3 vs 9.4 ±0.1; p=0.04) and basal expression levels of miR-323 in SFs (n=10) negatively correlated with expression of DNAjC6 (Spearman r: −0.8; p=0.006).

Conclusion: In the current work, we identified a novel pathway contributing to the imprinted activated phenotype of SFs in RA. Elevated expression of miR-323 in RASFs causes downregulation of DNAjC6 mRNA which leads to higher expression of MMPs promoting joint destruction. Therefore, increased expression of DNAjC6 in joints of smokers might be a protective mechanism against environmental damage.

Variability of Anti-CCP Kit Testing in Cohorts with and without RA.

Kevin D. Deane[7], Kristen Demoruelle[10], Mark Parish[4], Whitney Hilton[4], Lauren Harrington[4], Lezlie Derber[4], Jason R. Kolfenbach[6], Jan M. Hughes-Austin[4], Michael H. Weisman[3], Ted R. Mikuls[14], James R. O'Dell[8], Richard M. Keating[1], Peter K. Gregersen[5], Jane Buckner[2], Irene Smolik[13], Donna Hart[13], Charles N. Bernstein[13], David B. Robinson[12], Jill Norris[9], V. Michael Holers[7] and Hani S. El-Gabalawy[11]. [1]Oak Park, IL, [2]Benaroya Research Institute at Virginia Mason, Seattle, WA, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]Division of Rheumatology, University of Colorado School of Medicine, Aurora, CO, [5]N Shore Univ Hosp Rsch Ctr, Manhasset, NY, [6]Univ of CO Schl of Med, Aurora, CO, [7]Univ of Colorado School of Med, Aurora, CO, [8]University of Nebraska Medical Center, Omaha, NE, [9]University of Colorado Denver, Aurora, CO, [10]University of Colorado School of Medicine, [11]University of Manitoba, Winnipeg, MB, Canada, [12]University of Manitoba, Winnipeg, MB, Canada, [13]University of Manitoba, [14]University of Nebraska Medical Center, Omaha, NE

Purpose: Anti-CCP positive (CCP+) subjects without current symptoms of RA are important to identify in order to investigate the biology and evolution of RA development. However, it is unknown how clinically-available CCP tests identify CCP+ in individuals who do not currently have RA. Here we examine the sensitivity (SENS) and specificity (SPEC), prevalence and test agreement of 3 CCP kits in RA cases and currently healthy first-degree relatives (FDRs) of probands with RA.

Methods: CCP testing was performed in a single laboratory using standard protocols for 3 ELISA kits: CCP2 (IgG) (Axis-Shield), CCP3 (IgG) and CCP3.1 (IgG, IgA) (INOVA). Sera from 2 established RA cohorts were tested with each kit: a Cree/Ojibway North American Native (NAN) population from Central Canada, and the RA population from the U.S.-based Studies of the Etiologies of RA [SERA] (Caucasian 85%). The SENS/SPEC of kits for RA were calculated compared to non-RA controls (NAN, N=100; SERA random blood donor controls, N=200). Sera from 2 FDR cohorts (NAN and SERA) were also tested with each kit. The NAN FDRs were selected on the basis of CCP2+ at least once during the course of their longitudinal follow-up in the study. SERA FDRs were randomly selected regardless of CCP+ from a cohort of ~1600 subjects. Kappa testing was performed to assess agreement of CCP tests.

Results: See Table 1: The SENS of CCP for RA by any kit was higher in NAN RA cases compared to SERA cases, and the SENS of CCP+ in RA cases was highest using combined kit testing, although SPEC was lower. In NAN and SERA FDRs, CCP3 and 3.1 kits had higher prevalence of positivity compared to CCP2, with differences most pronounced in SERA FDRS: CCP2+(2%), CCP3+(4%) CCP3.1+(9%). Median levels of CCP were lowest in SERA FDRs.

Table 1. Anti-CCP Kit Test Results (Sensitivity/Specificity, Prevalence, and Titers) in Established RA and Healthy First-Degree Relative (FDR) Cohorts

Cohort	CCP2	CCP3	CCP3.1	≥1 of 3 Kits Positive
NANRA (N = 112) vs Non-RA Controls (N = 100)				
SENS	71%	67%	69%	75%
SPEC	97%	98%	96%	95%
SERA RA (N = 230) vs Non-RA Controls (N = 200)				
SENS	54%	63%	65%	67%
SPEC	99%	95%	94%	91%
NAN FDR (N = 31)				
Prevalence of CCP positivity	13/31 (42%)	15/31 (48%)	14/31 (45%)	16/31 (52%)
SERA FDR (N = 299)				
Prevalence of CCP positivity	7/299 (2%)	12/299 (4%)	26/299 (9%)	31/299 (10%)
Median level (range) [levels calculated only in those positive]				
NAN RA	104 (>5–134)	315 (38–401)	366 (39–401)	N/A
NAN FDR	107 (47–127)	280 (25–401)	327 (30–401)	
SERA RA	78 (>5–201)	296 (21–420)	286 (23–406)	
SERA FDR	22 (>5–113)	43 (21–401)	28 (21–401)	

Abbreviations: NAN = North American Native cohorts; SERA = Studies of the Etiologies of Rheumatoid Arthritis cohorts; SENS = sensitivity; SPEC = specificity

See Table 2: Test agreement (kappa) was lowest in SERA FDRs, although kappa improved when anti-CCP cutoffs for positivity were set at 3-times established kit cut-offs.

Table 2. Anti-CCP Kit Agreement, By Cohort

Cohort	CCP2 and 3 (kappa*)	CCP2 and 3.1 (kappa*)	CCP3 and 3.1 (kappa*)
NAN RA	0.81	0.77	0.96
SERARA	0.72	0.71	0.93
NANFDRs			
Standard kit cut-off**	0.74	0.80	0.94
Cut-off >3× normal**	0.87	0.87	1.0
SERAFDRs			
Standard kit cut-off**	0.19	0.15	0.55
Cut-off >3× normal**	0.44	0.44	0.39

*Cohen's kappa
**For CCP2 standard kit cut-off >5 units, ×3 = >15 units, for CCP3, 3.1 standard cut-off >20 units, ×3 = >60 units
Abbreviations: NAN = North American Native cohorts; SERA = Studies of the Etiologies of Rheumatoid Arthritis Cohorts

Conclusion: In this study CCP kits differ in SENS/SPEC for RA, prevalence in FDRs and cohort-related kit agreement. In particular, in SERA FDRs the differential prevalence of CCP+ by kit and decreased kit agreement may indicate that CCP reactivity in these currently healthy individuals, who have perhaps early RA-specific autoimmunity, is fundamentally different than in established disease, possibly due to differences in autoantigen specificity or autoantibody isotypes. Further study is needed to understand the biologic factors behind these CCP results and the role of these CCP tests for identification of pre-clinical RA-specific autoimmunity.

ACR Poster Session B
Rheumatoid Arthritis Treatment - Small Molecules, Biologics and Gene Therapy: Predicting and Measuring Outcomes, Novel Compounds II

Tuesday, November 9, 2010, 9:00 AM–6:00 PM

1095

A Phase IIa, Randomized, Double-Blind, Placebo-Controlled Clinical Study of Apilimod Mesylate, an Oral IL-12/IL-23 Inhibitor, in Patients with Active Rheumatoid Arthritis. Sarah Krausz[3], Maartje J. H. Boumans[3], Daniëlle M. Gerlag[3], Joelle Lufkin[4], Arno W. R. van Kuijk[2], Alian A. B. Bakker[3], Maarten de Boer[3], Beatrijs M. Lodde[3], Kris A. Reedquist[3], Eric W. Jacobson[4], Michael O'Meara[4] and Paul P. Tak[1]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Academic Medical Center/University of Amsterdam, [3]Academic Medical Center-University of Amsterdam, [4]Synta Pharmaceuticals Corp

Objective: Apilimod mesylate (STA-5326) is an oral small-molecule compound. It selectively inhibits production of interleukin (IL)-12 and IL-23, which play an important role in regulating the immune response, and has demonstrated safety and efficacy in a phase I/IIa trial for Crohn's disease. We investigated the efficacy, safety and tolerability of STA-5326 in patients with active rheumatoid arthritis (RA).

Methods: We performed a phase IIa, single-center, randomized, double-blind, placebo-controlled, proof-of-principle study of STA-5326 in combination with methotrexate (MTX) in 29 patients with active RA (3:1, STA-5326 to placebo). In stage I, 9 patients were treated with STA-5326 100 mg QD and 2 with placebo for 4 weeks. In stage II, 8 patients received STA-5326 100mg QD and 3 placebo for 8 weeks. In stage III, 5 patients received STA-5326 100 mg BID and 2 placebo for 8 weeks, with an optional extension of 4 weeks. Clinical response was assessed according to DAS28 and ACR response criteria. Synovial tissue samples were obtained at baseline and day 29 (stage I/II) or day 57 (stage III), and stained for CD3, CD22, CD55, CD68 and IL-1β by immunohistochemistry, and evaluated by digital image analysis.

Results: STA-5326-treated patients (100mg QD) showed a modest, but statistically significant reduction in DAS28 compared to baseline at day 29 and day 57, but an ACR20 response was reached in only 6% of patients at day 29 and 25% at day 57 (Table). This was similar to the response in placebo treated patients. The increased dosage (100mg BID) did not improve clinical efficacy. Consistent with the clinical results, there were no clear cut changes in expression of synovial biomarkers between baseline and day 29 in stages I/II or day 57 in stage III. While only mild adverse events (mainly gastro-intestinal and dizziness) were observed in stages I/II, in stage III all patients experienced debilitating side-effects (nausea and headache) causing 2 of 5 STA-5326-treated patients to withdraw prior to day 57 and only 1 patient to extend the study until day 85.

Table. Changes in DAS28 and ACR responses in RA patients treated with STA-5326 100mg QD, 100mg BID or placebo

Stage I/II, 100mg QD	**Day 29 (n = 17)**	**Day 57 (n = 8, stage II only)**	
ΔDAS28	−0.41 (*p = 0.03*)	−0.61 (*p = 0.004*)	
ACR20	1 (6%)	2 (25%)	
ACR50	0	0	
ACR70	0	0	
Stage III, 100 mg BID	**Day 29 (n = 4)**	**Day 57 (n = 3)**	**Day 85 (n = 1)**
ΔDAS28	−0.67 (*ns*)	−0.47 (*ns*)	−0.50
ACR20	0	1 (33%)	1 (100%)
ACR50	1 (25%)	0	0
ACR70	0	0	0
Placebo (n = 7, pooled)	**Day 29 (n = 7)**	**Day 57 (n = 4)**	**Day 85 (n = 2)**
ΔDAS28	−0.21 (*ns*)	−0.92 (*ns*)	−0.90
ACR20	0	1 (25%)	0
ACR50	0	0	0
ACR70	0	0	0

In stage III, 1 patient withdrew prior to day 29 and 1 patient prior to day 57 due to side effects. Only 1 out of 5 decided to extend the study until day 85. Changes in DAS28 (*p*-value) are compared to baseline, *ns* = not significant

Conclusion: The results presented here do not support the notion that STA-5326 treatment is able to induce robust clinical improvement of RA.

ALD518 (BMS945429), a High-Affinity Anti-Interleukin-6 Monoclonal Antibody, Provides Improvements in Health-Related Quality of Life (HRQoL) in Patients with Rheumatoid Arthritis (RA) and an Inadequate Response to Methotrexate. Vibeke Strand[3], Levan Shalamberidze[6], Aleksandar Dimic[4], Jeffrey Smith[1], Robin Mukherjee[2] and Philip Mease[5]. [1]Alder Biopharmaceuticals Inc., Bothell, WA, [2]Bristol-Myers Squibb, Princeton, NJ, [3]Division of Immunology/Rheumatology, Stanford University, Palo Alto, CA, [4]Institute of Rehabilitation and Treatment, Niska Banja, Serbia, [5]Swedish Medical Center and University of Washington, Seattle, WA, [6]V. Tsitlanadze Scientific Practical Centre of Rheumatology, Tbilisi, Georgia

Background: ALD518 (BMS945429) is a monoclonal antibody directed against IL-6. Rapid and significant ACR responses have previously been demonstrated with ALD518 in patients with RA through 16 weeks[1]. Here, the authors report HRQoL outcomes from a Phase II randomized controlled trial of intravenous ALD518 in patients with active RA and inadequate responses to methotrexate (MTX).

Methods: This was a 16-week, double-blind, placebo (PL)-controlled study in which patients with active RA were randomized 1:1:1:1 to ALD518 80, 160 or 320 mg or PL. Two infusions were given (at Day 1 and Week 8), and patients were maintained on stable doses of MTX (≥10 mg/week) throughout. HRQoL was evaluated by the Medical Outcomes Survey Short Form-36 (SF-36). Analyses were performed on the modified intent-to-treat population for patients with data available at the visit of interest (as observed). Minimum clinically important differences (MCID) were 2.5–5.0 for physical and mental component summary scores (PCS and MCS, respectively); 5.0–10.0 for domain scores and MID for SF-6D=0.041[2,3].

Results: 127 patients were randomized and treated, and 116 completed the trial (80 mg, 29/32; 160 mg, 33/34; 320 mg, 25/28; PL, 29/33); mean age was 52.3 years; mean RA duration was 6.8 years; and mean tender and swollen joint counts were 26.1 and 16.7, respectively. Mean baseline PCS and MCS were 31.0 and 35.0, 2 and 1.5 standard deviations less than normative values of 50, respectively. At Week 12, improvements in PCS and MCS were 7.1 and 12.3 in the 80 mg group, 6.1 and 7.6 in the 160 mg group and 8.5 and 13.5 in the 320 mg group versus 4.2 and 1.8 in the PL group. At Week 16, in the ALD518 80, 160 and 320 mg groups, respectively, improvements in PCS were 6.7, 6.6 and 8.3 versus 4.7 with PL; improvements in MCS were 10.8, 9.4 and 11.0, respectively, versus 3.8 for PL. Improvements at Week 16 in MCS scores were observed to be greater in the ALD518 80 and 320 mg groups (p=0.05 each) when compared with PL, and ≥MCID. Observed mean changes from BL in bodily pain, general health and social functioning in the ALD518 80,160 and 320 mg groups exceeded those with PL; and in vitality in the 160 and 360 mg groups and mental health in 360 mg group. Changes ≥MCID were observed in all domains, including SF-6D (Table).

Domain* (+ age/ gender norm)	**Time point**	**ALD518 80 mg (n = 32)**	**ALD518 160 mg (n = 33)**	**ALD518 320 mg (n = 29)**	**Placebo - (n = 32)**
Physical functioning (79.6)	Baseline score	41.6	49.7	43.8	42.4
	Mean change to Wk 16	15.2	14.8	20.0	13.9
Role physical (80.1)	Baseline score	29.9	30.7	32.5	33.5
	Mean change to Wk 16	18.8	22.0	24.6	14.8
Bodily pain (68.3)	Baseline score	25.3	28.6	29.1	29.2
	Mean change to Wk 16	22.3†	23.0	26.3†	10.0
General health (69.5)	Baseline score	35.6	37.2	38.0	37.6
	Mean change to Wk 16	9.5†	10.1	10.1†	3.0
Vitality (58.2)	Baseline score	32.2	32.8	36.6	40.2
	Mean change to Wk 16	14.5	20.1†	19.8	6.4
Social functioning (83.6)	Baseline score	39.1	40.2	44.8	45.5
	Mean change to Wk 16	24.6†	26.5†	23.7†	7.2
Role emotional (86.8)	Baseline score	39.1	46.2	38.8	42.9
	Mean change to Wk 16	20.1	15.2	21.0	11.6
Mental health (74.9)	Baseline score	44.1	49.1	42.9	51.1
	Mean change to Wk 16	12.6	15.5	20.9†	5.2
SF-6D (0.831)	Baseline score	0.556	0.584	0.579	0.592
	Mean change to Wk 16	0.140	0.150	0.170	0.070

*0–100 scores are presented for each domain to enable interpretation within the context of the MCIDs; shading indicates changes ≥MCID in domain scores and ≥MID in SF-6D; †p < 0.05

Conclusions: Treatment over 16 weeks with the IL-6 inhibitor ALD518 resulted in improvements in physical, mental and emotional aspects of HRQoL that were clinically meaningful. These improvements were statistically significant in some but not all SF-36 domains, which may be due to large changes in the placebo group. These data support continued evaluation of ALD518 for treatment of patients with active RA and inadequate responses to MTX.

Assessment of Inflammation and Damage by MRI in Established RA Patients with Methotrexate Inadequate Response Receiving Golimumab: Results of the GO-FORWARD Trial.

Philip G. Conaghan[3], Paul Emery[4], Mikkel Østergaard[5], Ed C. Keystone[8], Mark C. Genovese[7], Lars Klareskog[6], Weichun Xu[1], Elizabeth C. Hsia[2] and Mahboob U. Rahman[2]. [1]Centocor Research and Development, Inc., [2]Centocor Research and Development, Inc./Univ. of Pennsylvania School of Medicine, Malvern, PA, [3]Chapel Allerton Hospital, Leeds, United Kingdom, [4]Chapel Allerton Hospital, Leeds, United Kingdom, [5]Copenhagen University Hospital at Glostrup and Hvidovre, [6]Karolinska University Hospital, Stockholm, Sweden, [7]Stanford University, Sunnyvale, CA, [8]University of Toronto, Toronto, ON, Canada

Background: Previously reported results of the GO-FORWARD trial have shown the beneficial effects of adding the human monoclonal antibody golimumab (GLM) on signs and symptoms and physical function in an established RA cohort with methotrexate (MTX) inadequate response. Magnetic resonance imaging (MRI) provides a sensitive tool for the objective assessment of both inflammation and damage.

Objective: To evaluate the effect of GLM on the inflammation and structural damage detected by MRI in pts with active RA despite MTX.

Methods: Patients (n=444) were randomly assigned to receive placebo (PBO) + MTX, GLM 100mg + PBO, GLM 50mg + MTX, or GLM 100mg + MTX. A subset of study sites capable and willing participated in the MRI substudy. All pts from each substudy site were eligible for the substudy (n=240). GLM and PBO were administered via subcutaneous injection q4 wks. At wk16, pts in the PBO + MTX, GLM 100mg + PBO, and GLM 50mg + MTX groups with <20% improvement in both tender and swollen joint counts entered early escape to receive GLM 50mg + MTX, GLM 100mg + MTX, and GLM 100mg + MTX, respectively. The main comparison was between the combined GLM + MTX and PBO + MTX groups. MRIs of the pt's dominant wrist and metacarpophalangeal joints were obtained at baseline and wks12, 24, 52 and 104 using 1.5T MRI with contrast enhancement. Results through wk24 are presented here. Images were scored by 2 independent expert readers who were blinded to image time point or sequence, pt identity, or treatment group. Readers scored synovitis (0–21), bone erosions (0–230), and bone edema (osteitis; 0–69) using the Rheumatoid Arthritis MRI Scoring (RAMRIS) system; the average of each RAMRIS score provided by the readers was used in the analysis. Pts who entered early escape at wk16 had their last observation carried forward in the MRI analysis at wk24.

Results: Significant improvements in synovitis and bone edema (osteitis), which are known prognosticators of future structural damage, were observed in the combined GLM + MTX groups versus the PBO + MTX group. The minimal changes in bone erosions observed in all treatment groups (Table), precluded the adequate evaluation of GLM's effect on bone erosions, which is consistent with previously published radiographic data. This could be because the overall GO-FORWARD study population had less active inflammation at baseline (median CRP concentrations ranging from 0.60 to 0.95mg/dL), indicating this population would have minimal changes in bone erosion.

Conclusion: Results of MRI assessments showed that GLM + MTX significantly improved synovitis and bone edema (osteitis) relative to PBO plus MTX as early as wk12 and also at wk24. The effect of GLM on bone erosions could not be determined by semi-quantitative scoring in this population of RA pts who had minimal changes in bone erosion during this study.

Table. RAMRIS scores including at baseline and changes from baseline to weeks 12 and 24

RAMRIS scores: values are mean÷dian (interquartile range)	Placebo + MTX (n = 72)	GLM 100mg + PBO (n = 72)	GLM 50mg + MTX (n = 47)	GLM 100mg + MTX (n = 49)	Combined GLM + MTX (n = 96)

Biomarkers Predictors of Good EULAR Response to B Cell Depletion Therapy (BCDT) in Seropositive Rheumatoid Arthritis Patients.

Gianfranco Ferraccioli[3], Barbara Tolusso[3], Francesca Bobbio Pallavicini[4], Elisa Gremese[3], Viviana Ravagnani[1], Maurizio Benucci[5], Edoardo Podesta'[2], Fabiola Atzeni[6], Giusy Peluso[3], G. Biasi[1], Mariangela Manfredi[5], Piercarlo Sarzi Puttini[6], Bruno Lagana'[2] and Carlomaurizio Montecucco[4]. [1]Department of Clinical and Experimental Medicine, Section of Rheumatology & Internal Medicine, University of Verona, Verona, Italy, [2]Division of Clinical Immunology and Rheumatology, S. Andrea University Hospital, "Sapienza" University of Rome, II School of Medicine, Rome, Italy, [3]Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy, [4]Division of Rheumatology, University of Pavia, IRCCS S. Matteo Foundation, Pavia, Italy, [5]Rheumatology Unit, Department of Internal Medicine, Ospedale di S. Giovanni di Dio, Florence, Italy, [6]Rheumatology Unit, University Hospital L. Sacco, Milan, Italy

Background: The best predictor of a good response to BCDT in Rheumatoid Arthritis (RA) is IgM rheumatoid factor (RF) positivity. No data are available on which biomarkers can identify the best profile of a good responder to BCDT in strictly seropositive RA patients.

Objective: To define possible biomarkers of a 6th months good EULAR response in RA patients strictly seropositive for one or more autoantibodies.

Methods: One hundred and forty eight RA patients (122 female; disease duration: 13.0±10.6 years) who did not respond to previous DMARDs and/or TNF-α blockers were enrolled in a multicentric Italian study to evaluate the efficacy of BCDT. All the RA patients were seropositive to at least one of the Autoantibodies (AAB) tested: RF IgG, RF IgM, RFIgA, anti-CCP2 and anti-MCV (Axis-Shield and Orgentec Diagnostika GmbH). At baseline and every 3 months, demographic, clinical, previous TNF blocker therapies and current therapy with glucocorticoids (GC), immunological and laboratory data, HAQ, DAS score were recorded. Plasma levels of IL6 and BAFF were determined at baseline with ELISA methods. A logistic regression models

was evaluated to determine the influence of the independent variables that reached the value of $p<0.25$ at the univariate analysis, considering the optimal cut-off value resulted by the analysis with receiver operating characteristic (ROC) curves on the dependent variable "good EULAR response at 6th month". A p value at the 0.05 level was accepted as statistically significant.

Results: 74.7% of RA patients were positive for anti-CCP2 antibodies, 79.5% for RF IgG, 63.0% for RF IgM, 53.7% for RF IgA, 88.4% for anti-MCV; 10.1%, 12.2%, 18.2%, 23.0% and 36.5% of RA patients were positive for 1, 2, 3, 4, 5 AAB, respectively. 73.7 % of the patients had been treated with one or more TNFa-blockers and 78.9% were on steroid therapy. A EULAR good response was obtained in 23.9% of subjects at the 6th month FU visit.

On multivariate analysis, "EULAR good response to BCDT after 6th months FU" was closely correlated with baseline lymphocytes count <1875/uL (OR (95% CI): 5.78 (1.56–21.45)), RF IgG levels > 52.1 IU/ml (OR (95% CI): 4.48 (1.05–19.24)), plasma BAFF levels < 1011 pg/ml (OR (95% CI): 6.27 (1.13–34.79)) and no current steroid therapy (OR (95% CI): 0.12 (0.03– 0.51)).

Discussion: Two easy markers (no current steroids and a low lymphocyte count) and two immunological parameters (high RF IgG and low plasma BAFF levels) identify the best responder to BCDT. Data support the original theory that IgG RF could be the main driver of the AAB mediated rheumatoid inflammation.

Candidate Gene Analysis in US Veteran Rheumatoid Arthritis Patients with Clinical Improvement during Treatment with Anti-Tumor Necrosis Factor Agents in the Veterans Affairs Rheumatoid Arthritis (VARA) Registry. Grant W. Cannon[5], Roger K. Wolff[5], Jian Ying[8], Candace L. Hayden[6], Brian C. Sauer[6], Jeffrey R. Curtis[7], Dannette S. Johnson[3], Gail S. Kerr[9], J. Steuart Richards[10], Liron Caplan[2], Andreas Reimold[1] and Ted R. Mikuls[4]. [1]Dallas VA and University of Texas Southwestern, [2]Denver VA and University of Colorado, [3]Jackson VA and University of Mississippi, [4]Omaha VA and University of Nebraska, [5]Salt Lake City VA and University of Utah, Salt Lake City, UT, [6]Salt Lake City VA and University of Utah, [7]University of Alabama, [8]University of Utah, [9]Washington DC VA and Georgetown and Howard Universities, [10]Washington DC VA and Georgetown University

Purpose: While anti-tumor necrosis factor (anti-TNF) agents are effective in rheumatoid arthritis (RA) patients, these benefits are not universal. Several genes are associated with either RA susceptibility or severity. In RA patients being treated with adalimumab, etanercept, or infliximab, multiple SNPs of known RA susceptibility genes were measured and correlated with 28 joint count disease activity scores (DAS28).

Methods: Effectiveness of anti-TNF therapy in RA patients enrolled in the Veterans Affairs RA (VARA) registry was defined by two methods. In method #1, patients receiving ≥90 days of anti-TNF in the VA pharmacy benefits management database were compared. Clinical effectiveness required an average DAS28 ≤3.2 during the observation period from 90 days after initiation of anti-TNF treatment until the end of the anti-TNF course. In method #2, VARA patients initiating an anti-TNF and sustaining a DAS28 ≤3.2 after one year (±2 months) while on continued treatment with the same anti-TNF were defined as having clinical effectiveness. In addition, these patients evaluated by method #2 could not have initiated or escalated corticosteroid therapy, initiated a traditional disease modifying antirheumatic drug, or had more than one joint injection to be classified as having clinical effectiveness.

Caucasian men VARA patients were genotyped for polymorphisms within CTLA4 (5 SNPs), PADI1 (15 SNPs), PTPN22 (5 SNPs), STAT4 (26 SNPs), TRAF1-C5 (17 SNPs), IL10 (4 SNPs), TNF-alpha (3 SNPs) and shared epitope (SE). Using SAS, logistic regression was performed to test the effects of genotypes on the response to the treatment. We assessed significance with a Bonferroni correction ($P_{cutoff}=0.0005$)

Results: Method #1 classified 106 (34%) of 307 eligible patients and method #2 classified 73 (36%) of 201 as having an effective clinical response. With method #1, the increase of each copy of SE was associated with an increase of 67.8% (15.8%, 143.1%) in odds of response to anti-TNF. Comparing to null, compound heterozygous SE is significantly ($p=0.005$) associated with a higher odds of response ((OR 3.1, 95% CI (1.4, 6.7)). The odds of response for homozygous and heterozygous SE were 51.1% and 42.5% higher respectively, but did not reach statistical significance. No association of SE with clinical response was seen with SE by method #2. Neither method demonstrated a significant association with clinical response for the other candidate gene SNPs. Given the small sample size, the power to detect genetic effect is not high, we only have a power of 35% to detect of a 2-fold effect a SNP given the minor allele frequency (MAF) of the SNP is as high as 0.2, and the power would be even lower when either the genetic effect or the MAF is smaller.

Conclusion: This analysis suggests that SE genotype may be associated with anti-TNF effectiveness but failed to demonstrate any statically significant difference in other RA susceptibility gene polymorphism in US veterans with and without clinical effectiveness during anti-TNF therapy. The different results with these two methods emphasize the importance of phenotype definition in these genetic analyses.

CCR1 Antagonist CCX354-C in Phase 2 Clinical Development for Rheumatoid Arthritis. Daniel J. Dairaghi, Vittorio Marchesin, Daniel A. Johnson, Shichang Miao, Lisa C. Seitz, Yu Wang, Penglie Zhang, Jay P. Powers, Bert Ho, Pirow J. Bekker, Juan C. Jaen and Thomas J. Schall. ChemoCentryx

Purpose: CCX354-C is an oral drug targeting the chemokine receptor CCR1, which is instrumental in monocyte/macrophage infiltration into the joints of RA patients. The purpose of the preclinical and clinical studies conducted to date was to determine the safety, pharmacokinetic (PK) and pharmacodynamic (PD) properties of CCX354-C. This paved the way for a Phase 2 clinical trial in patients with RA.

Methods: PK/PD requirements for complete inhibition of CCR1-mediated leukocyte infiltration were defined in rabbits (LPS injection into the knee joint) and rats (thioglycollate-induced sterile peritonitis), following oral dosing of CCX354-C. In the Phase 1 program, 84 male or female healthy volunteers (HVs) received either placebo or CCX354-C orally at doses ranging from 1 to 300 mg in the single-dose study and from 3 to 300 mg/day in the multiple-dose study. In total, 70 HVs received CCX354-C. Blood was collected at pre-specified time points for PK and PD analyses. In the 10, 30, and 100 mg dose cohorts, blood was collected for *ex vivo* analysis of CCR1 receptor coverage on blood monocytes using a flow-cytometric assay with Alexa647-CCL3. Based on this information, 24 patients with stable RA were randomized to receive either placebo or daily doses of 100 to 200 mg CCX354-C for 14 days. In total, 18 RA patients received CCX354-C. Safety, PK and potential effects on concomitant methotrexate administration were assessed in this study.

Results: CCX354-C blocked chemotaxis of human monocytic cells towards 17 separate RA synovial fluids. In the preclinical models, leukocyte infiltration into inflamed rabbit knee or rat peritoneum was effectively blocked if plasma levels of CCX354 were maintained sufficiently high to produce 90% CCR1 blockade on circulating leukocytes.

CCX354-C was well tolerated, displayed excellent oral bioavailability and dose-proportional increases in exposure in all 3 clinical trials conducted in HVs and RA subjects. No serious adverse events or withdrawals due to adverse events have been observed. Plasma levels as high as 5,000 ng/mL and 3,700 ng/mL were reached in the single and multiple-dose studies, respectively. These levels of CCX354 far exceed those required for CCR1 blockade (e.g., 90% inhibition (IC_{90}) of CCR1-mediated chemotaxis of human monocytes in 100% human plasma required 110 ng/mL). The plasma half-life of the drug approached 7 hours at the 300 mg dose. In the RA study, co-administration of CCX354-C with methotrexate had no influence on the plasma levels of either drug. In the clinical *ex vivo* PD assay, high levels of receptor coverage (> 90%) at the 12-hour time point were achieved in blood after a single dose of 100 mg CCX354-C.

Conclusions: The oral CCR1-specific antagonist CCX354-C showed an excellent safety and tolerability profile in Phase 1 studies in 70 HVs and 18 RA patients. PK and PD data indicate that daily doses of 200 mg CCX354-C produce greater than 90% receptor coverage in blood at all times. No drug-drug interactions were noted between CCX354-C and methotrexate. Based on results from these clinical trials and supportive preclinical studies,

a Phase 2 clinical trial has been initiated in 150 patients with active RA with an inadequate response to methotrexate.

Change in CRP at 12 Weeks Predicts the Risk of Rapid Radiographic Progression at 2 Years in Methotrexate-Treated Patients with Early Rheumatoid Arthritis. Boulos Haraoui[4], Paul Emery[3], Neelufar Mozaffarian[1], Benoit Guerette[2], Hartmut Kupper[2], Kaushik Patra[2] and Ed C. Keystone[5]. [1]Abbott Laboratories, Abbott Park, IL, [2]Abbott Laboratories, [3]Chapel Allerton Hospital, Leeds, United Kingdom, [4]Institut de Rhumatologie, Montreal, QC, Canada, [5]University of Toronto, Toronto, ON, Canada

Background: In patients with rheumatoid arthritis (RA), radiographic progression is an important contributor to long-term disability. Hence, identifying patients at risk of rapid radiographic progression (RRP) early in the course of disease is an important goal of medical management, as it affects therapeutic decision-making.

Objective: To determine whether change in CRP after 12 weeks of treatment can indicate risk of RRP in patients with early RA.

Methods: We examined data from methotrexate (MTX)-naïve patients with early RA in the PREMIER study, a 104-week, phase III, placebo-controlled trial in which patients were randomized 1:1:1 to: weekly MTX, adalimumab (ADA) 40 mg every other week, or ADA + MTX. This post hoc analysis evaluated patients from the intention to treat population who had CRP measures at baseline and at week 12, as well as radiographs at baseline and week 104. RRP was defined as an increase of >3 units/year in the modified Total Sharp Score (mTSS). Using week 12 data, quartiles (Qs) of CRP absolute values and percent change from baseline (%ΔCRP) were used to assess relationships with RRP following 2 years of treatment.

Results: Overall, RRP was significantly more likely to occur among patients treated with MTX monotherapy (33.5%) than among patients treated with ADA + MTX (6.7%). In the MTX-treated population, there was an association between increasing Qs of %ΔCRP (less improvement) and RRP prevalence (Table); however, this association was absent in the ADA + MTX population, where the risk of RRP was universally low. Specifically, MTX-treated patients who fell into the top Q (least improvement) of %ΔCRP at week 12 demonstrated 48.5% RRP; ADA + MTX-treated patients in the same Q of %ΔCRP displayed only 6.9% RRP. In both treatment groups, lower CRP improvement at week 12 was observed in the majority of patients ultimately identified with RRP at year 2; 84% of the MTX-treated RRP patients and 54% of the ADA + MTX-treated RRP patients exhibited CRP improvement ≤80% after 12 weeks of treatment. Interestingly, increasing Qs of CRP at 12 weeks produced comparable results to those from the %ΔCRP.

Table. Association of Quartiles (Qs) of %ΔCRP From Baseline to 12 Weeks With % Rapid Radiographic Progression (RRP) From Baseline to 2 Years

%ΔCRP, Qs	MTX (N = 169) n/N (%) of RRP	ADA + MTX (N = 201) n/N (%) of RRP
Min-Q1: −98.61-<−80.34	9/34 (26.5)	6/89 (6.7)
Q1-Q2: −80.34-<−61.28	12/43 (27.9)	3/58 (5.2)
Q2-Q3: −61.28-<−16.67	19/59 (32.2)	2/25 (8.0)
Q3-Max: −16.67-661.36	16/33 (48.5)	2/29 (6.9)

Conclusions: CRP changes from baseline to 12 weeks or absolute CRP levels at 12 weeks were associated with the prevalence of RRP. Of note, association of CRP with poor radiographic prognosis applied mainly to patients treated with MTX monotherapy, as RRP rates were low in patients treated with ADA + MTX and CRP changes were not correlative with frequency of RRP during combination therapy. Based on these data, changes in CRP or CRP levels at 12 weeks appear to be useful tools for early identification of MTX-treated patients who will fail to achieve long-term disease control, as evidenced by significant radiographic damage.

1102

Clinical and Radiographic Implications of Time to Treatment Response in Patients with Early Rheumatoid Arthritis. Ed C. Keystone[7], Michael E. Weinblatt[4], Boulos Haraoui[5], Benoit Guerette[2], Neelufar Mozaffarian[1], Kaushik Patra[3] and Arthur Kavanaugh[6]. [1]Abbott Laboratories, Abbott Park, IL, [2]Abbott Laboratories, France, [3]Abbott Laboratories, [4]Brigham & Womens Hospital, Boston, MA, [5]Institut de Rhumatologie, Montreal, QC, Canada, [6]University of California-San Diego, La Jolla, CA, [7]University of Toronto, Toronto, ON, Canada

Background: For patients with rheumatoid arthritis (RA), there has been increased interest in treating to target early and quickly. While some advocate treatment adjustment at 12 weeks (wks), data support the possibility of later responses to therapy. The longer-term radiographic implications of such a delay in response have not been examined previously.

Objective: To evaluate the association of early (12 wks) and delayed (24 wks) clinical responses with rates of clinical remission, low-disease activity (LDAS), and rapid radiographic progression (RRP) at 52 wks in patients with early RA treated with methotrexate (MTX) monotherapy or adalimumab (ADA) + MTX combination therapy in the PREMIER trial.

Methods: PREMIER was a 104-wk, phase III, randomized, placebo-controlled trial in MTX-naïve patients with early RA, who were randomized 1:1:1 to one of three treatment groups: MTX, ADA 40 mg every other wk (eow), or ADA 40 mg eow + MTX. In this post hoc analysis, observed data comparing MTX with ADA + MTX therapy are presented. Clinical outcome measures included the 28-joint Disease Activity Score (DAS28) and mean change from baseline in modified Total Sharp Score (ΔmTSS) at 52 wks. Patients were categorized on the basis of clinical response (DAS28 improvement ≥1.2 or 20/50/70% improvement in ACR score) at 12 and 24 wks as responders or non-responders: "early responders" achieved the clinical target at wk 12 and maintained the response at wk 24; "delayed responders" did not meet the clinical target until wk 24. The percentages of patients at 52 wks with LDAS (DAS28 <3.2), clinical remission (DAS28 <2.6), and RRP (ΔmTSS >3 units/year) in each group were determined.

Results: In both treatment groups, early clinical responses were associated with better long-term outcomes than delayed responses (Table). Achieving early or delayed ACR70 responses did not result in treatment group differences in the proportion of patients achieving LDAS or clinical remission at wk 52. Importantly, delayed responses to MTX resulted in a high proportion of patients with RRP. Indeed, delayed ACR70 responses were associated with an RRP prevalence of 40%. In addition, an early improvement in DAS28 ≥1.2 with MTX was insufficient to slow radiographic progression (41% RRP). In contrast, early or delayed clinical responses to ADA + MTX resulted in low proportions of RRP at 52 wks, even for patients with a delayed ACR20 response (11% RRP). Of note, ADA + MTX-treated delayed responders had less RRP than MTX-treated early responders.

Table. Association of Treatment and Time to Clinical Reponse With Long-term Outcome

Treatment	Responder Type	Response at Week 12st	Response at Week 24st	% DAS28 <3.2 (LDAS)	% DAS28 <2.6 (Remission)	% ΔmTSS < Uiyr (RRP)
MTX	Early	ACR70R	ACR70R	94	89	18
MTX	Delayed	ACR70NR	ACR70R	70	47	40
ADA-MTX	Early	ACR70R	ACR70R	98	85	5
ADA-MTX	Delayed	ACR70NR	ACR70R	82	41	13**
MTX	Early	ΔDAS28≥1.2	ΔDAS28≥	51	32	41
MTX	Delayed	ΔDAS28≤1.2	ΔDAS28≥	24	10	53
ADA-MTX	Early	ΔDAS28≥1.2	ΔDAS28≥	67**	46*	11*
ADA-MTX	Delayed	ΔDAS28≤1.2	ΔDAS28≥	45	25	5**

*P <0.05; **P <0.01; ***P <0.001 for between treatment group companies of MTX and ADA + MTX
#ΔDAS28 are improvements, values are considered less than prior assessment; R = Responder; NR = Non-responder

Conclusions: MTX-treated patients with early RA who fail to achieve high-level response (*e.g.* ACR70) within 12 wks are at risk for RRP and should be considered for treatment adjustment. ADA + MTX treatment is associated with better clinical outcomes and less severe radiographic progression at 52 wks, even among patients with a delayed clinical response.

Composite Remission Using Clinical, Structural, and Functional Criteria in Patients with Rheumatoid Arthritis (RA) Treated with Etanercept. Mark C. Genovese[4], Andrew S. Koenig[3], Grace S. Park[1] and Scott W. Baumgartner[2]. [1]Amgen Inc., Thousand Oaks, CA, [2]Amgen, Inc., Thousand Oaks, CA, [3]Pfizer Inc., Blue Bell, PA, [4]Stanford University, Sunnyvale, CA

Background: Remission, a goal of treatments for patients with RA, can be defined in terms of signs and symptoms (clinical remission), radiographic progression (structural remission), and function (functional remission). The purpose of this analysis was to examine the incidence of "composite remission" using clinical, structural, and functional criteria in patients receiving etanercept (ETN).

Methods: Data from a clinical trial of patients with early RA (ERA) and established RA (TEMPO) were retrospectively analyzed for 2-year outcomes. Patients in ERA received ETN 10 mg or 25 mg twice weekly (BIW) or methotrexate (MTX). Patients in TEMPO received ETN 25 mg BIW, MTX, or both. Composite remission was defined as: Disease Activity Score based on 28 or 44 joints with erythrocyte sedimentation rate as the indicator of inflammation (DAS28ESR) < 2.6 or DAS44ESR < 1.6 (clinical remission), Total modified Sharp Score annualized progression rate (TSSRATE) ≤ 0 (structural remission), and Health Assessment Questionnaire Disability Index (HAQ-DI) score ≤ 0.5 (functional remission).

Results: Patients had similar baseline clinical characteristics across treatment groups within each study. In the ERA study, mean baseline DAS28ESR scores were 6.3 and mean DAS44ESR scores ranged from 5.2 to 5.3; mean baseline HAQ-DI scores ranged from 1.4 to 1.5. In TEMPO, mean baseline DAS28ESR scores ranged from 6.7 to 6.9, and mean DAS44ESR scores ranged from 5.5 to 5.7; mean baseline HAQ-DI scores ranged from 1.7 to 1.8. Patients achieving composite remission are shown in the table.

Rates of Clinical, Structural, and Functional Composite Remission

	ERA			TEMPO

[a]Radiographic assessments were performed at 24 weeks in TEMPO
[b]HAQ-DI and DAS28ESR were assessed at Week 100 in TEMPO
ERA, Early rheumatoid arthritis; TEMPO, Trial of Etanercept and methotrexate with Radiographic Patient Outcomes; ETN, etanercept; MTX, methotrexate; ND, not done; n, number of patients with composite remission; N, number of patients in cohort; N1, number of patients who had assessment

Conclusions: In both trials the rates of composite remission were similar whether using DAS28ESR or DAS44ESR. Similar remission rates were observed in monotherapy arms across all trials, including ETN 10 mg BIW. These data reinforce the value of monotherapy with ETN or combination therapy with ETN and MTX in early and established RA, and demonstrate that up to a third of patients receiving combination therapy with ETN and MTX are able to attain a composite remission using stringent criteria.

DAS-Driven Therapy Versus Routine Care in Patients with Recent-Onset Active Rheumatoid Arthritis: Data from the GUEPAR Trial and ESPOIR Cohort. Martin Soubrier[1], Cédric Lukas[2], Jean Sibilia[3], Bruno Fautrel[5], Laure Gossec[4], Simon Patternotte[4] and Maxime Dougados[4]. [1]CHU Clermont-Ferrand, Sevice de Rhumatologie, F-63003, Clermont-Ferrand, Puy-de-dôme, France, [2]CHU Montpellier, Service de Rhumatologie, F-34295 Montpellier, France, [3]CHU Strasbourg, Service de Rhumatologie, Strasbourg, France, [4]Hôpital Cochin, Service de Rhumatologie, F-75014, Paris, France, [5]Hôpital Pitié-Salpétrière, Service de Rhumatologie, F-75013, Paris, France

Objectives: To compare the efficacy of disease activity score (DAS28ESR)-driven therapy and routine care in patients with recent-onset rheumatoid arthritis.

Methods: Patients with recent-onset RA from either the GUEPARD study (tight control) or ESPOIR cohort (routine practice group). GUEPARD is a prospective unblinded randomized multicenter controlled one-year trial comparing two initial treatment strategies (initial methotrexate monotherapy versus its combination with adalimumab) in patients with early and active RA (<6 months, DAS28 $>5,1$). In both groups, treatment was adjusted every 3 months with the aim of achieving a low DAS (DAS <3.2) with the use of TNF blockers. ESPOIR is a French, multi-centric early arthritis cohort in which treatment was left to the discretion of the treating physician. The propensity score was used to match the patients (one patient from the GUEPARD trial for two patients from the ESPOIR cohort).

Results: At baseline, all patients in the tight control group (n=65) and routine practrice group (n=130) fulfilled the ACR1987 criteria. They had comparable demographic characteristics (female 77%, age 48.0 $\pm$13.0 years), RF and anti-CCP positivity (67.2% and 63.6%), swollen and tender joint counts (10.5 $\pm$5.5 and 14.0 $\pm$6.8), patient's and doctor's assessment of global disease activity (68.0 $\pm$20.8 mm and 66.5 $\pm$17.8 mm respectively), pain (57.0 $\pm$21.2 mm), fatigue (54.7 $\pm$26.3 mm), on a 0–100 mm VAS, ESR (38.7 $\pm$24.6 mm first hour), CRP (29.4 $\pm$ 32.6 mg/l), typical erosive disease (17.9%), modified total Sharp/VDH score (SHS) (6.5 $\pm$ 10.1), erosion score (2.4 $\pm$ 4.2), narrowing score (4.1 $\pm$7.1), HAQ (1.3 $\pm$0.6). All patients had a DAS score above >5.1 (mean 6.26 $\pm$ 0.87). The tight control group had a longer mean disease duration than the routine practice group (5.6 $\pm$4.6 vs 3.5 $\pm$2.0 months, $p<0.001$)

After one year, the percentage of patients in remission with an HAQ (<0.5) and an absence of radiologic progression was higher in the tight control group (32.3% vs 10.2%, p = 0.011). However, there was no difference in the decrease in DAS (tight control: -3.12 $\pm$1.82, routine practice: -2.65 $\pm$1.66, p=0.12), nor in the percentage of patients in low DAS (tight control: 63.1%, routine practice: 43.8%, p=0.64) and in remission (tight control: 47.7%, routine practice: 29.2%, p=0.35). There was no statistically significant difference in EULAR, ACR20, ACR50, and ACR70 responses. The improvement in HAQ was similar but more patients in the tight control group had an HAQ below 0.5 (70.2% vs 45.2%, p=0.005). Overall, pain, patient and physician assessment, and fatigue decreased more in the tight control group than in the routine practice group. The mean SHS progression was similar in the two groups (tight control: 0.95 $\pm$ 4.6; routine practice: 1.5 $\pm$ 4.1, p=0.46) as was the percentage of patients without progression (71.19% vs 69.23%, p=0.37).

Conclusion: In patients with recent onset active rheumatoid arthritis, a tight control of disease activity with TNF blockers allows more patients to achieve remission without disability and radiographic progression.

Differential Serum Glycosylation Changes in Rheumatoid and Psoriatic Arthritis—In Response to Anti-TNF Therapy. Azita Alavi[1], Oliver M. FitzGerald[3], Emily S. Collins[4], Owen Fraser[2], Edward Tarelli[1], Chin Teck Ng[4], Barry Bresnihan[5], Douglas J. Veale[4] and John S. Axford[1]. [1]St. Georges University of London, United Kingdom, [2]St. Georges University of London, United Kingdom, [3]St. Vincent's University Hospital, Dublin, Ranelagh Dublin, Ireland, [4]St. Vincent's University Hospital, Dublin, Ireland, [5]St. Vincent's University Hospital, Dublin, Ireland

Background: Our earlier research into IgG glycosylation changes associated with rheumatoid arthritis (RA) and other rheumatic diseases has indicated the presence of disease specific glycosylation profiles, which in the case of RA have been shown to correlate with disease activity and to revert to normal in pregnancy induced remission. We have since extended these studies using whole serum to assess the direct diagnostic and prognostic potential of serum sugar biomarkers.

Objectives: Evaluate the influence of anti-TNFα therapy on the serum *N*-glycosylation profile of RA and psoriatic arthritis (PsA) patients and to assess the potential of these sugar biomarkers as a measure of disease response.

Methods: Serum *N*-glycan profile of a cohort of RA (n=24) and PsA (n=18) patients on anti-TNFα therapy, at baseline and 1 year after starting treatment, were investigated. Enzyme released *N*-glycans were analysed by MALDI-TOF mass spectrometry. Direct comparisons of the sugar profiles (mass / charge ratio) indicated significant changes in the profile of several biantennary *N*-glycan structures; distinguished by the presence / absence of galactose (G), fucose (F), bisecting GlcNAc (bis) and sialic acid (A) attached to the core biantennary heptasaccharide [GlcNAc(β1–2)Man(α1–6)] [GlcNAc(β1–2)Man(α1–3)]-Man(β1–4)GlcNAc(β1–4)GlcNAc. The glycans comprised of G0 (non-galactosylated), G2F (fucosylated di-

galactosylated), A1G2F (mono-sialylated G2F), A2 (di- sialylated G2) and A2bisF (fucosylated di-sialylated G2 with a bisecting N-acetylglucosamine).

Results: RA and PsA were found to have distinct serum glycan profiles, which underwent significant changes in response to treatment with anti-TNFα (Figure). Levels of G0 decreased significantly in both RA ($p=0.012$) and PsA ($p=0.028$). This was accompanied by a moderate, but significant, increase in A1G2F (RA; $p=0.018$ and PsA; $p=0.010$).

Anti-TNFα treatment also resulted in significant increase (19–20%; $p<0.05$) in the levels of other glycan structures; G2F and A2G2 in RA, and A2G2bisF in PsA. The G2F glycan values were found to significantly correlate with changes in diseases activity (DAS-28) in RA patients ($n=24$) after one year of anti-TNFa therapy(Pearson; $r(22)=0.421>p>0.04$).

Interestingly, there were also marked differences between Etanercept and Adalimumab, with the RA Adalimumab treated group showing significantly more pronounced changes in G0 and A2 (PsA cohort too small for analysis).

Conclusion: RA and PsA have distinct serum N-glycan profiles which undergo significant changes in response to anti-TNFα therapy. These differential changes which include galactosylation as well as sialylation could be a useful marker of disease response, and may provide a better insight into the different mechanistic action of TNF antagonists currently used for treatment of inflammatory arthritis.

Double-Blind, Randomized, Controlled, Placebo-Included, Pilot Study Comparing Classical Ayurvedic Medicine, Methotrexate, and Their Combination in RA. Daniel E. Furst[3], Manorama M. Venkatraman[4], Mary McGann[1], P. Ram Manohar[1], Cathryn Booth-LaForce[4], Dinesh Khanna[2], K. G. Raveendran[1], Reshmi Sarin[1], Anita Mahapatra[1], Jidesh Gopinath[1] and P. R. Krishna Kumar[1]. [1]The Ayurvedic Trust, [2]UCLA, [3]University of California Los Angeles Medical School, Los Angeles, CA, [4]University of Washington

Background: Classical Ayurveda is a 3000 year old complete system of natural medicine, which is used by millions in India and elsewhere. It is a holistic, multifaceted treatment system which includes complex herbal-mineral formulations, dietary and lifestyle modification, and detoxification routines. Its description of rheumatic diseases is similar to modern descriptions of RA features. Classical Ayurveda for RA has hitherto never been tested in an RCT. The aim of this study was to compare classical Ayurveda, methotrexate (MTX), and their combination in a randomized, double-blind, double dummy pilot trial of RA over 36 weeks.

Methods: In a pilot study, 43 seropositive RA patients by ACR criteria with disease duration ≤7 years were assigned to the following treatment groups: MTX plus Ayurvedic placebo (n= 14), Ayurveda plus MTX placebo (n=12), Ayurveda plus MTX (n=17). DAS28-CRP, ACR20/50/70, and HAQ-DI were obtained every 12 weeks for 36 weeks. Analyses included descriptive statistics, ANOVA, Chi-Square or Student's t-test. The unique features of this study included the development of placebos for each of 7 Ayurvedic pharmacological dosage forms and individualization of Ayurvedic therapy. Neither medications nor placebos contained any heavy metals or foreign substances (e.g., steroids) as shown by HPLC.

Results: All patient groups and physicians were shown to remain blinded throughout. All 3 groups were comparable (p=ns) at baseline (means): age: 45–47.9 years; RA duration: 1.1–2.7 years; RF+: 71–78%; CCP+: 8–29%; % erosions: 61–69%; DAS28-CRP: 6.5 (high disease activity); CRP: 27–42 mg/dl; female: 83–88%. No statistical differences in response were found except in patient pain VAS (see Table 1 & Figure 1). There were no statistically significant differences in the occurrence of Adverse Events (AE) among groups although the groups using MTX had more frequent AE (MTX: 174; Ayurveda: 112; Combination: 176). No deaths occurred.

Conclusion: In this first ever, double dummy, double-blind, randomized, controlled pilot study comparing Ayurveda, MTX, and their combination, MTX and Ayurvedic treatments were approximately equivalent although the trial size and pilot nature of the trial precludes definitive conclusions. AE were numerically but not statistically fewer in the Ayurveda group. These results also show that double-blind, placebo-included, randomized controlled studies are possible when testing classical Ayurvedic versus allopathic treatment in ways acceptable to western standards and to Ayurvedic physicians.

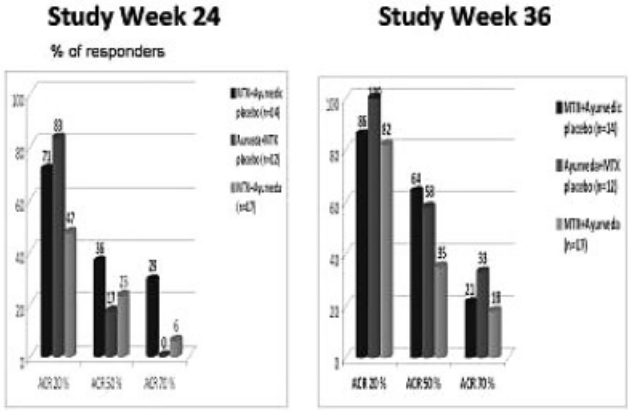

Table 1. Mean Differences (+/− SD) from Baseline to 36 weeks*

	MTX + Ayurvedic placebo (n = 14)	Ayurveda + MTX placebo (n = 12)	MTX + Ayurveda (n = 17)	*p value by ANOVA*
Outcome Measure	**0–36 wks**	**0–36 wks**	**0–36 wks**

HM-A42, a Novel Inhibitor of IKKβ Kinase Reverses Clinical and Histological Disease Parameters in Multiple Autoimmune Disease Models. Yu Cai[1], Xinrong Wang[1], Ping Ren[1], Changwu Lu[1], Jianlin He[1], Xiaoming Dai[3], Qianqian Dong[1], Jun Yu[3], Lei Fang[2], Xiaoning Yang[1], Lei Jiang[3], Jia Li[1], Weifang Xue[1], Pingmin Tang[1], Jian Wang[1], Fang Yin[3], Yongjuan Yu[3], Jingshui Li[3], Yang Sai[3], James Yan[3], Jianguo Ji[3], Weiguo Qing[3], Weiguo Su[3] and Haoran Zhao[1]. [1]Hutchison MediPharma Ltd, Shanghai, China, [2]Hutchison MediPharma Ltd, Shanghai, China, [3]Hutchison MediPharma Ltd

Purpose: NF-κB activation has been demonstrated to be involved in the pathogenesis of multiple inflammatory diseases including rheumatoid arthritis

(RA), multiple sclerosis (MS), and respiratory diseases such as asthma and chronic obstructive pulmonary disease (COPD). The central role that IκB kinase β (IKKβ) plays in regulating NF-κB signaling in response to inflammatory stimuli has made this enzyme as an attractive target for therapeutic intervention. Here we report the identification and preclinical characterization of HM-A42, a potent, selective, and orally bioavailable inhibitor of IKKβ kinase.

Methods and Results: HM-A42 is a potent and highly selective inhibitor of IKKβ kinase (IC50 = 0.006–0.058uM) and demonstrated 127-fold selectivity against IKKα kinase. In OVA-induced asthma model in BN rat, HM-A42 treatment led to reduced inflammatory cell number in the BAL fluid with an ED50 of 0.49 mg/kg. In an acute PLP139–151 peptide-induced EAE mouse model of MS, HM-A42 treatment resulted in rapid and substantial regression of EAE relapses. It also significantly reduced EAE clinical score in a dose dependent manner over a 6 week period with an ED50 of 3.7 mg/kg. Histopathological examination of the spinal cords showed that disease scores for inflammation and the area of demyelination were all significantly lower in HM-A42 treated animals versus vehicle control group. HM-A42 was also tested in a murine collagen-induced arthritis model of RA in a prophylactic setting. Oral administration of HM-A42 resulted in significant reduction of disease symptom that continued through the course of treatment with an ED50 of 4.3mg/kg. In addition, HM-A42 exhibited favorable pharmacokinetic profile including good oral absorption and bioavailability in various species and low potential for CYP450 inhibition. Moreover, from safety point of view, HM-A42 had low affinity for hERG and was negative in AMES test. Its no adverse effect level (NOAEL) was 500 mg/kg in rat, showing a big safety window over efficacy doses in multiple disease models.

Conclusion: The administration of HM-A42, a potent and highly selective IKKβ kinase inhibitor, resulted in substantial efficacy in aggressive models of asthma, rheumatoid arthritis (RA) and multiple sclerosis (MS). These studies support further development of HM-A42 in clinical studies.

Impact of Genetic Interactions on Response to Adalimumab Plus Methotrexate Versus Methotrexate Alone: Six Month Results of the OPTIMA Trial. Alla Skapenko[3], Kaushik Patra[2], Hartmut Kupper[1] and Hendrik Schulze-Koops[3]. [1]Abbott GmbH & Co. KG, Ludwigshafen, Germany, [2]Abbott Laboratories, Abbott Park, IL, [3]University of Munich, Munich, Germany

Background: Identification of genetic factors that affect rheumatoid arthritis (RA) disease severity and response to treatment can guide personalized therapeutic approaches.

Objective: To explore the impact of candidate genetic factors on changes in disease activity following treatment with adalimumab (ADA) plus methotrexate (MTX) or MTX alone.

Methods: OPTIMA is an ongoing 78-week study with 26- and 52-week periods. Eligible patients had RA <1 year, DAS28 >3.2, ≥6 SJC, ≥8 TJC. ESR ≥28 mm/h or CRP ≥1.5 mg/dL, and ≥1 of the following: >1 erosion, RF+, or anti-CCP+. MTX-naive patients were randomized to ADA 40 mg every other week+MTX or placebo (PBO)+MTX. Patients were genotyped by allele-specific polymerase chain reaction (PCR) and direct sequencing as needed for the presence of the HLA-DRB1 shared epitope (SE), the FcγRIIb I232T single nucleotide polymorphism (SNP), and the IL4R I50V SNP. Clinical responses to 26 weeks of treatment were examined by genetic background for each allele independently, and in the allele combinations of SE and IL4R.

Results: Subjects in the treatment groups demonstrated a comparable distribution of 0, 1, or 2 copies of the HLA-DRB1 SE (PBO+MTX: 37%, 48%, 15%; ADA+MTX: 33%, 49%, 19%, $P=0.28$). Likewise, the IL4R alleles, AA, AG, and GG, were distributed similarly between treatment groups (PBO+MTX: 29%, 52%, 20%; ADA+MTX: 33%, 47%, 20%, $P=0.38$). The FcγRIIb alleles, however, were dissimilarly appropriated between treatment groups, and no further analysis was conducted on this SNP. Presence of the SE did not affect treatment response to MTX alone (e.g., ACR50 of 40%, 33%, and 29% for 0, 1, or 2 copies, $P=0.23$). Conversely, treatment response rates were correspondingly enhanced with increasing copies of the SE in subjects receiving ADA+MTX (ACR50 of 42%, 53%, and 65% for 0, 1, 2 SE, $P=0.004$). Thus, presence of 1 copy of the SE afforded a 20% increase in ACR50 for ADA+MTX subjects relative to the PBO+MTX group ($P<0.001$), and 2 copies of SE increased ACR50 in ADA+MTX by 36% over PBO+MTX ($P<0.001$). Similarly, clinical responses to MTX were not affected by IL4R alleles, while treatment outcomes with ADA+MTX was enhanced in subjects with AA or AG IL4R alleles. Examination of treatment responses for the SE and IL4R allele combinations in the PBO+MTX group shows no alteration in responses by genotype, supporting results from analysis of the individual alleles. In the absence of the SE, IL4R genotype affects treatment response to ADA+MTX, while presence of the SE masks effects of the IL4R alleles (table).

		HLA-DRB1 SE copy #		
ACR50, n/N (%)	**IL4R allele**	**0**	**1**	**2**
PBO+MTX	AA	15/34 (44%)	23/56 (41%)	7/23 (30%)
	AG	33/78 (42%)	34/92 (37%)	12/32 (38%)
	GG	18/38 (47%)	14/35 (40%)	1/2 (50%)
ADA+MTX	AA	27/46 (59%)	32/57 (56%)	16/23 (70%)
	AG	24/55 (44%)	58/94 (62%)	28/40 (70%)
	GG	10/26 (39%)	24/41 (59%)	9/12 (75%)

Conclusion: Clinical responses to adalimumab plus methotrexate are independently affected by both the HLA-DRB1 shared epitope and IL4R alleles, while there was no impact of genotype on the response to methotrexate monotherapy. There appears to be an interaction between the HLA-DRB1 shared epitope and IL4R alleles in response to treatment with adalimumab plus methotrexate.

Improved Disease Control in Response to Tocilizumab Therapy Is Accompanied by Decreased Platelet Reactivity in Patients with Rheumatoid Arthritis. Paul A. MacMullan[3], Anne M. Madigan[1], Paola Bagaglia[2], Dermot Kenny[3] and Geraldine M. McCarthy[1]. [1]Mater Misericordiae Univ. Hosp, Dublin, Ireland, [2]Mater Misericordiae Univ. Hosp, Dublin, Ireland, [3]RCSI, Dublin, Ireland

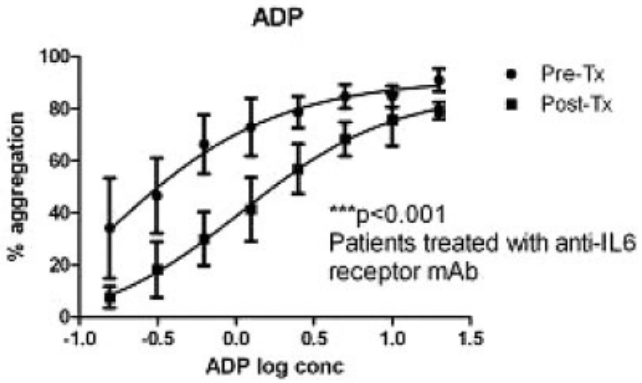
Background: Patients with rheumatoid arthritis (RA) die prematurely of cardiovascular disease (CVD). Platelets play a crucial role in the pathogenesis of CVD. Our previous work demonstrates increased platelet reactivity in patients with active inflammatory arthritis, mediated by the adenosine diphosphate (ADP) pathway [1]. Interleukin 6 (IL-6) plays a key pathogenic role in both inflammation and CVD.

Objective: To prospectively evaluate the impact of IL-6 receptor inhibition on platelet function in patients with RA.

Methods: This work was conducted alongside a PHASE IV study evaluating IL-6 receptor inhibition with tocilizumab in patients with RA. Patients with seropositive RA who had failed conventional and biologic treatment were recruited. Those receiving anti-platelet therapy or with a history of CVD were excluded. All were treated with intravenous infusions of tocilizumab(8mg/kg) at 4-weekly intervals for a minimum of 6 months. 2 patients discontinued treatment due to dermatitis and raised transaminases, respectively. Pre and post-treatment platelet function analyses were performed using a modification of light transmission aggregometry. The *ex vivo* aggregation responses to arachidonic acid, collagen, ADP, epinephrine and thrombin receptor activating peptide (TRAP) were tested. Disease activity was measured using standard inflammatory biomarkers (ESR, CRP, fibrinogen) and the internationally validated DAS-28 Score (<2.6=remission, >5.1=severe disease). The direct effect of elevated IL-6 on platelet ADP responsiveness was examined *in vitro* in samples obtained from 6 healthy volunteers. Platelet-rich plasma (PRP) was incubated with 10ng/ml of IL-6 or vehicle control and the aggregation responses to increasing concentrations of ADP were tested.

Results: Pre and post-treatment data from n=6 female patients were analysed. Disease activity improved significantly in the entire cohort (Mean DAS-28 Scores:5.1+/−0.37 at baseline, and 2.9 +/−0.47 at 6 months, $p<0.01$). Platelet reactivity decreased across a range of agonists in most

subjects, with all subjects displaying a significant decreased response to ADP ($p<0.001$)-see figure. The addition of IL-6 to PRP samples from healthy volunteers increased the platelet response to all concentrations of ADP compared to vehicle control ($p<0.001$).



Control of inflammation *decreases* platelet response to ADP (n=6 RA patients).

Conclusion: Improved disease control with IL-6 receptor inhibition is accompanied by significantly decreased platelet reactivity in patients with refractory RA. This is a novel demonstration of a potential cardioprotective benefit in a cohort of patients at high risk of CVD.

In Patients with Early Inflammatory Polyarthritis, ACPA Positivity and Inefficacy of the First DMARD Are Associated with the Need To Start a Biologic Later on: Results from the Norfolk Arthritis Register (NOAR).

S. M. M. Verstappen[1], M. Lunt[1], D. K. Bunn[2], D. G. I. Scott[2] and D. P. M. Symmons[1]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]Norfolk Arthritis Register, Norfolk and Norwich University Hospital, Norwich, United Kingdom, United Kingdom

Background: Biologics have been available for the management of rheumatoid arthritis (RA) and inflammatory polyarthritis (IP) for almost a decade. Very few data are available on possible predictors, obtained early in the disease, of the need to start a biologic later on. The objectives of this study were (i) to identify baseline disease related predictors in patients with early IP for starting a biologic and (ii) to determine if patients who fail their first non-biologic DMARD within six months are more likely to need a biologic later on.

Methods: Consecutive patients with early IP ($\geq$ 2 swollen joints for $\geq$ 4 weeks) from a primary-care based inception cohort (NOAR), recruited between 2000 and 2004, with a disease duration $\leq$24 months at registration and using at least one DMARD during follow-up were included in this study. Baseline clinical assessments included the DAS28 and the HAQ-score. Blood was collected to determine CRP, RF and ACPA. The use of, including start and stop dates and reason for stopping, DMARDs and biologics was recorded at each visit. DMARD failure was defined as: first DMARD stopped due to inefficacy within six months and/or a second DMARD was started within six months after starting the first DMARD, except if the first DMARD was stopped because of an adverse reaction. The association of baseline disease characteristics and failure of the first DMARD with the start of a biologic was assessed using Cox proportional hazards regression models. Hazard ratios (HRs, 95%CI) were adjusted for age, gender and symptom duration at inclusion. For the association between failure of the first DMARD and the use of a biologic, the survival time started six months after starting the first DMARD.

Results: 45 of 420 (10.7%) patients started to use a biologic during follow-up; the median age of patients at symptom onset in the biologic group was 51 [45 – 55] yrs and 58 [48 – 70] in the non-biologic group and, respectively, 78% (31/40) and 41% (138/334) were ACPA positive. 8.8% patients failed their first DMARD within six months, respectively 17.8% in the biologic group and 7.7% in the non-biologic group. On average, patients started to use a biologic 45 (SD 26) months after symptom onset and used 2.6 (SD 0.9) DMARDs before starting the first biologic. Younger patients and ACPA positive patients were more likely to receive a biologic (see Table).

	HR (95% CI)*
Age (/yr)	**0.97 (0.95, 0.99)**
Gender (female)	1.62 (0.80, 3.28)
Symptom duration at inclusion (/month)	0.97 (0.91, 1.03)
DAS28 score (/unit)	1.25 (0.97, 1.62)
HAQ-score (/unit)	1.52 (1.00, 2.31)
Rheumatoid factor (positive)	1.40 (0.72, 2.70)
ACPA (positive)	**4.87 (2.29, 10.36)**
First DMARD failure within 6 months	**2.52 (1.16, 5.46)**

*age, gender and disease duration at inclusion adjusted HRs (95% CI)

Although not significant, there was a trend towards an association between worse disease activity at inclusion and the need to start a biologic. Furthermore, patients who failed their first DMARD due to inefficacy, within six months of starting, were more likely to need a biological later on.

Conclusion: In this cohort of patients with early IP, ACPA positive patients and those who failed their first DMARD due to inefficacy were more likely to need a biologic during follow-up. These data would support the earlier use of biologics in patients with primary non-response to their first DMARD.

Increasing Chance of Remission in Patients with Rheumatiod Arthritis.

Anja Strangfeld[1], Maria Eveslage[3], Martin Aringer[4], Rainer Dockhorn[5], Matthias Schneider[6], Joachim Listing[3] and Angela Zink[2]. [1]German Rheumatism Research Center, Berlin, Germany, [2]German Rheumatism Research Center and Charité University Medicine Berlin, [3]German Rheumatism Research Center, Berlin, [4]Rheumatologist, Dresden, Germany, [5]Rheumatologist, Weener, Weener, Germany, [6]Scientific Advisory Board, Düsseldorf

Background: During the last years treatment aims in patients with rheumatoid arthritis (RA) have changed. Nowadays, achieving remission is a major goal. We therefore analyzed if the proportion of patients who achieved remission in DAS28 after several years of treatment with biologic agents changed during the last years.

Methods: The analysis was based on RA patients enrolled in the German biologics register RABBIT at start of an anti-TNF treatment. Remission rates (DAS28 $<$ 2.6) after three years of follow-up were compared between patients enrolled from 2001 to 2003 (n = 841) and those recruited from 2004 to 2006 (n = 1,290). Logistic regression was applied to compare both groups after adjustment for prognostic factors.

Results: Crude remission rates at 36 months were significantly higher in patients enrolled between 2004–2006 than in those enrolled between 2001–2003 (26% vs. 19%). Higher rates were observed especially in patients with highly active disease (DAS28 $>$ 6) at baseline (19.7% vs. 12.4 % in remission). The increase could not be explained by differences in baseline status.

The short term treatment response (DAS28 after 6 months) was the most distinct predictor for being in remission after 3 years. Additionally, male patients, younger patients, patients with better functional capacity and patients with a low disease activity at baseline had a higher chance of remission. When adjusting for these factors by multiple logistic regression the beneficial effect for patients enrolled between 2004–2006 was associated with the activity of the RA 6 months after start of treatment (Table).

Patients with an active disease 6 months after start of treatment had a higher chance of remission when they were enrolled in the later period (table). This was not due to more treatment changes in patients registered later (37% vs. 37% patients who started another biologic) but was possibly caused by more frequent use of novel biologics with different mechanisms of action (14% vs. 3%).

Table 1. Probability of remission after 3 years estimated by multiple logistic regression stratified by enrollment period and level of disease activity after 6 months of the initial treatment.

DAS28 after 6 months	n	2001–2003 remission (%)	n	2004–2006 remission (%)
≤ 3.2	217	40.3	427	38.5
> 3.2 & ≤ 4.1	180	19.6	308	25.4
> 4.1 & ≤ 5.1	200	11.0	271	18.8
> 5.1	244	3.6	284	10.0
total	841	18.3	1,290	25.0

Conclusion: The availability of more treatment options accompanied with changes in treatment strategies increases the chance for RA patients to achieve remission.

1112

Influence of ESR on EULAR Response Rates in Patients Treated with Tocilizumab. Results from the German Biologics Register RABBIT.

Anja Strangfeld[1], Maria Eveslage[1], Joachim Listing[1], Peter Herzer[5], Anke Liebhaber[4], Brigitte Krummel-Lorenz[3] and Angela Zink[2]. [1]German Rheumatism Research Center, Berlin, Germany, [2]German Rheumatism Research Center and Charité Berlin, Berlin, Germany, [3]Rheumatologist Frankfurt/M, Frankfurt, Germany, [4]Rheumatologist Halle/S, Halle/Saale, Germany, [5]Scientific Advisory Board, Munich, Munich, Germany

Background: Tocilizumab, a biologic agent newly approved for the treatment of rheumatoid arthritis (RA), is a human anti-interleukin (IL-)-6 receptor antibody. Clinical studies reported high response and remission rates in patients treated with this agent. Blocking the IL-6 receptor directly inhibits the production of acute-phase reactant proteins (including CRP) in hepatocytes. CRP or ESR are important components of the disease activity score (DAS) used to measure the effectiveness of a treatment.

We therefore investigated the contribution of the single components of the DAS28 to treatment response in tocilizumab treated patients in daily rheumatologic care.

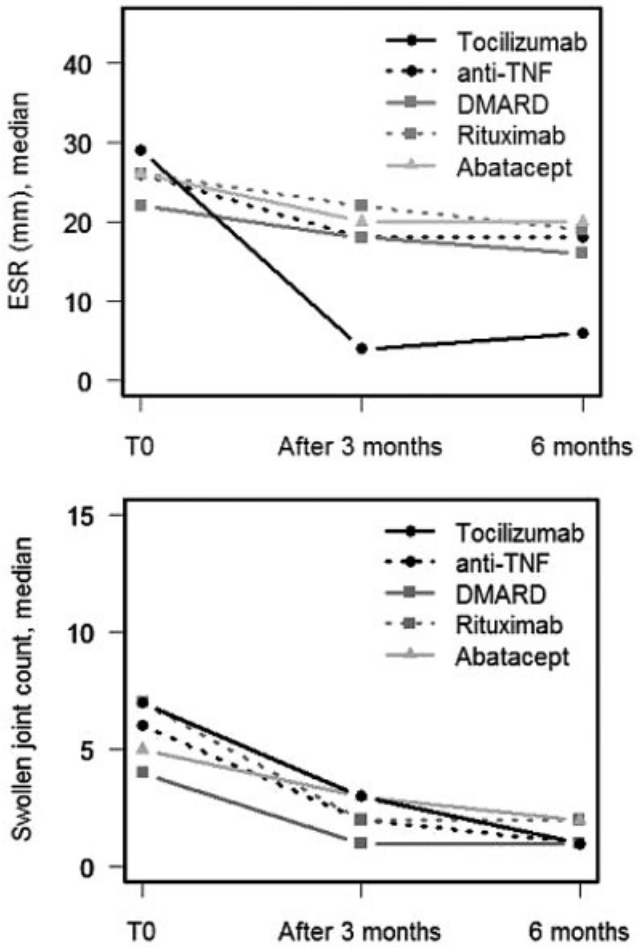
Methods: The German biologics register RABBIT is a prospective cohort study observing all licensed biologic agents applied in RA patients since 2001. In January 2009, tocilizumab was approved in Germany and patients starting this treatment were enrolled in the register. All patients included in the register will be followed up for at least 5 years with regular assessments including clinical status as well as therapy. Disease activity is measured with the DAS28 using the ESR.

Results: A total of 6,861 patients were enrolled in the register, 243 patients were treated with tocilizumab. Their mean age at start of tocilizumab was 57 years and the median disease duration 10 years.

Of 119 patients with a three months follow-up, 36% achieved a good and additional 29% a moderate EULAR response. 27% of the patients were in remission (DAS28 < 2.6). After 6 months (n = 55) the proportion of patients reaching a good EULAR response was 49%, a moderate response was reached by additional 29%. 40% of the patients were in remission.

Separating the DAS28 into its components, significant changes in swollen and tender joint counts and patient global assessment were observed in patients treated with tocilizumab. Compared to patients receiving other biologics the decrease in ESR levels was significantly higher (figures).

Conclusion: Treatment with tocilizumab improves RA in a substantial proportion of patients, response and remission rates are high. However, when considering EULAR response rates, changes in DAS28 scores or DAS28 remission rates the high impact of ESR changes on these measures has to be taken into account.



Figures. Components of the DAS28 (ESR and swollen joint count) and their change after 3 and 6 months after start of treatment with various biologic agents.

1113

Joint Space Narrowing Has a Stronger Impact on Physical Function Than Joint Erosion: Results from 8-Year Longitudinal Analyses.

Desiree M. Van Der Heijde[2], Robert Landewe[3], Benoit Guerette[1], Sanjoy Roy[1], Kaushik Patra[1] and Ed C. Keystone[4]. [1]Abbott Laboratories, [2]Leiden University Medical Center, Meerssen, The Netherlands, [3]Univ Hosp Maastricht, Maastricht, The Netherlands, [4]University of Toronto, Toronto, ON, Canada

Background: Structural damage, assessed by the modified Total Sharp Score (mTSS), has been shown to be related to physical function. Thus far, it remains unclear to what extent the individual components of the mTSS contribute to long-term physical function.

Objective: To characterize the longitudinal relationship between physical function and Joint Space Narrowing (JSN) or Joint Erosion (JE) in patients with advanced RA.

Methods: DE019 was a 52-week, randomized, placebo-controlled trial for the treatment of moderate to severe advanced RA, in which patients with an inadequate response to methotrexate (MTX) were randomized to MTX, adalimumab (ADA) 20 mg every other week (eow) + MTX, or ADA 40 mg eow + MTX. Patients completing the double-blind study were eligible to receive open-label ADA 40 mg eow + MTX for an additional 7 years. This post hoc analysis evaluated the 8-year completers cohort with radiographs at baseline and years 5, 6, and 8. 28-joint Disease Activity Score (DAS28) was used to assess clinical levels of disease activity. Physical function was assessed through the Health Assessment Questionnaire (HAQ). Radiographic damage was assessed using the modified Total Sharp Score (mTSS). Longitudinal generalized linear modeling was used to characterize the dependence of the HAQ on concurrent DAS28, total mTSS, JSN, and JE

values, following adjustment for baseline age and gender and for concurrent CRP.

Results: Over time, DAS28 was linearly associated with the HAQ ($P < 0.001$). Similarly, the mTSS was significantly associated with the HAQ throughout treatment duration ($P < 0.001$). A 1 unit increase in DAS28 and a 20 unit increase in mTSS were associated with 0.22 and 0.044 increases in the HAQ, respectively. A breakdown of mTSS into the individual components revealed that JSN more strongly impacted the HAQ over time than JE, although both were significant determinants ($P < 0.001$ for both). A 20 unit increase in JSN and JE were associated with 0.1 and 0.06 increases in the HAQ, respectively. Interestingly, negative changes in mTSS trended towards lower HAQ values over time.

Conclusions: For patients with advanced disease, long-term physical functioning is associated with both the level of disease activity (DAS28) and the extent of radiographic damage (mTSS). Of the contributors to the mTSS, JSN had a greater impact on the HAQ over time than JE, suggesting that therapies with high potency for inhibiting both the progression of JSN and JE should be considered.

Magnetic Resonance Imaging Assessments of Patients with RA and Their Association with Clinical and Radiographic Outcomes. Paul Emery[3], Desiree M. Van Der Heijde[6], Mikkel Østergaard[5], Philip G. Conaghan[4], Mark C. Genovese[7], Ed C. Keystone[9], Roy M. Fleischmann[8], Weichun Xu[1], Stephen Xu[1], Elizabeth C. Hsia[2] and Mahboob U. Rahman[2]. [1]Centocor Research and Development, Inc., [2]Centocor Research and Development, Inc./Univ. of Pennsylvania School of Medicine, Malvern, PA, [3]Chapel Allerton Hospital, Leeds, United Kingdom, [4]Chapel Allerton Hospital, Leeds, United Kingdom, [5]Copenhagen University Hospital at Glostrup and Hvidovre, [6]Leiden University Medical Center, Meerssen, The Netherlands, [7]Stanford University, Sunnyvale, CA, [8]University of Texas SW Medical Center, Dallas, TX, [9]University of Toronto, Toronto, ON, Canada

Objective: To evaluate the relationship between changes in inflammation and structural damage detected by MRI and clinical and radiographic outcomes in RA pts.

Methods: Data from 2 large study populations were evaluated: 1) GO-BEFORE evaluated (MTX)-naïve pts with active RA and 2) GO-FORWARD evaluated pts with active RA despite MTX. In both studies, pts were randomly assigned to receive placebo(PBO)+MTX, GLM100mg+PBO, GLM50mg+MTX, or GLM100mg+MTX. GLM and PBO were administered SC q4wks. A subset of study sites capable and willing participated in MRI substudies. All pts from each site were eligible to participate in the substudies (n=318 GO-BEFORE; n=240 GO-FORWARD). MRIs of pt's dominant wrist and metacarpophalangeal joints were obtained at baseline and wks12,24,52&104. Results through wk24 are presented here. Images were scored by 2 independent expert readers blinded to image time point or sequence, pt identity, or treatment group. Readers scored synovitis(0–21), bone erosions(0–230), and bone edema(0–69) using Rheumatoid Arthritis MRI Scoring (RAMRIS) system. Preliminary assessments of relationships between RAMRIS system scores and clinical and radiographic measures were done using Spearman correlation coefficients. Disease activity was measured using 28-joint count Disease Activity Score calculated using CRP (DAS28-CRP). Structural damage was measured using the van der Heijde modification of the Sharp (vdH-S) score.

Results: Analysis results are summarized in the Table. In both studies, statistically significant correlations were observed between baseline synovitis, bone edema, and bone erosion scores and baseline vdH-S scores; strongest correlations were between baseline RAMRIS bone erosion and baseline vdH-S scores. Changes in DAS28-CRP scores at wks12&24 correlated with changes at wks 12&24, respectively, in RAMRIS synovitis, RAMRIS bone edema (wk24 only), and RAMRIS erosion scores among MTX-naïve pts in GO-BEFORE, but only with changes at wks12&24, respectively, in RAMRIS synovitis and RAMRIS bone edema scores among MTX-inadequate responders in GO-FORWARD;correlations were generally weak or moderate. Percent changes from baseline in CRP levels correlated with changes in RAMRIS synovitis and RAMRIS bone edema scores at all time points but not with changes in RAMRIS bone erosion scores. Although statistically significant in both study populations, these correlations were generally weak or moderate. Correlations observed between changes in vdH-S scores and changes in RAMRIS synovitis, RAMRIS bone edema, and RAMRIS bone erosion scores were inconsistent and weak.

Conclusion: Strong and significant correlations were observed between baseline MRI scores and baseline radiographic scores. Correlations observed between changes in RAMRIS scores and changes in clinical and radiographic measures were generally weak or moderate.

Optimal Dose Prediction by Pharmacokinetic and Biomarker Response of Subcutaneous Tocilizumab Treatment – A Phase I/II Study Evaluating the Safety, Pharmacokinetics and Clinical Response in Patients with Rheumatoid Arthritis. Shuji Ohta[8], Tomomi Tsuru[5], Kimio Terao[2], Seiji Mogi[7], Midori Suzaki[4], Hitoshi Nakashima[3], Eisuke Shono[6], Eriko Tarumi[1] and Masato Imai[6]. [1]Chugai Clinical Research Center Co., Ltd, [2]Chugai Pharmaceutical Co., Ltd., Tokyo, Japan, [3]Fukuoka University, [4]Med Co LTA PS Clinic, [5]Med Co LTA PS Clinic, Fukuoka, Japan, [6]Shono Rheumatism Clinic, [7]Taga General Hospital, Hitachi, Ltd, Japan [8]Taga General Hospital, Hitachi, Ltd, Japan

Background: Interleukin-6 (IL-6) plays pathologic roles in immune-inflamatory disease as rheumatoid arthritis. Tocilizumab is a humanized monoclonal antibody which inhibits IL-6 signal transduction by binding with both soluble and membranous IL-6 receptor. It has been shown IL-6 inhibition therapy by tocilizumab is effective in RA, JIA and Castleman's disease. Previous data is established by tocilizumab by one hour infusion. Regarding with ease of use, we evaluated the safety, pharmacokinetics, biomarker response and clinical response in patients with rheumatoid arthritis using a tocilizumab new formulation for subcutaneous injection.

Objective: To evaluate the safety, pharmacokinetics and efficacy of tocilizumab subcutaneous injection.

Method: This study is an open label, multicenter, dose ascension, combined single dose (Step1) and multiple dose study (3 doses: Step2) with a 6 month extension (Step3) for two of three treatment arms and last treatment arm entered into study for 6 month multiple dose study followed by three times repeated administration. Eight, 12 and 12 patients eligibly enrolled in cohort 1, 2 and 3, respectively. And they received tocilizumab at 81 mg Q2W treatment in cohort1, 162mg Q2W in cohort2, and 162mg QW in cohort3. Total duration of treatment is 33 weeks for cohort 1and 2, and 27 weeks for cohort 3.

Result: No treatment related serious adverse event were obserbed, and there are also no serious injection site reaction.

Cmax and AUC was 4.9 μg/mL and 444 μg hr/mL at 81mg, and 10.9 μg/mL and 2300 μg hr/mL at 162mg after 1st administration.

CRP is decreased after single dose within first week for all three dose groups. However, the CRP returned back to baseline for 81 mg Q2W dose group from Week 2, 3, 5, 7 and 9 at just before the injection. After week 9, dose was switch to 81 mg QW, then mean CRP decreased slowly. At 162 mg Q2W dose level, CRP retuned to baseline at the end of week 3. Repeated administration (Step2,3) mean CRP decreased progressively going below ULN and remained over the period of this study. In the 162 mg QW group, the CRP decreased below ULN at the end of Week 1 and remained.

Eight out of 12 patients(66%) serum tocilizumab levels in 162mg Q2W group was maintained above 1 μg/mL at week2, CRP was completely normalized in these patients. The normalization of CRP indicated that tocilizumab concentration, which is capable binding of IL-6R, was sufficient to inhibit IL-6 signal.

At week 9, ACR20/50/70 response are 12.5%, 0% and 0% at 81mg Q2W, 75.0%, 16.7% and 16.7% at 162mg Q2W, At the week25, ACR20/50/70 response are 37.5%, 37.5% and 37.5% at 81mg Q2W, 83.3%, 83.3% and 58.3% at 162mg Q2W, 91.7%, 83.3% and 66.7% at 162mg QW, respectively. CDAI at the end of this study is 11.21(18.19 at baseline), 3.76(25.55 at baseline), and 2.03(27.13 at baseline) at 81mg/QW, 162mg Q2W and 162 mg QW respectively.

Conclusion: Tocilizumab subcutaneous injection is well tolerated upto 162mg QW and is associated with good clinical response both 162 mg Q2W and QW.

Preclinical Development of Autologous, Autoantigen-Loaded Dendritic Cells Modified with Bay11–7082 for Tolerizing Immunotherapy in Anti-Citrullinated Peptide Antibody Positive Rheumatoid Arthritis Patients Bearing the HLA-DR Shared Epitope. Sakoontalla Ramnoruth[2], Marion Brunck[2], Claire Hyde[2], Shayna Street[2], Geoffrey Strutton[1], Christelle Capini[2], Sebastien Bertin-Maghit[2], Brendan O'Sullivan[2] and Ranjeny Thomas[2]. [1]Queensland Health Pathology, [2]University of Queensland Diamantina Institute

Background: Effective antigen-specific suppression of pathogeneic T cells in rheumatoid arthritis (RA) patients might be anticipated to provide durable tolerance with low toxicity, suitable for suppression of early disease or prevention in individuals at risk. We showed previously that bone marrow derived dendritic cells modified with the irreversible short-acting NF-kB inhibitor, Bay11–7082 (Bay-DC), exposed to arthritogenic antigen, express low levels of MHC class II and costimulatory molecules and transfer antigen-specific suppression of established antigen-induced arthritis in mice, through induction of regulatory T cells. We undertook preclinical development of human autologous peripheral blood (PB) monocyte-derived Bay-DC pulsed with four SE-restricted citrullinated peptides, to establish feasibility and potential toxicity prior to a phase I trial in anti-citrullinated peptide antibody (ACPA)+ RA patients.

Methods: Under good laboratory practice conditions, we elutriated monocytes from 250 ml PB from RA patients, then generated DC in the presence of 10% human serum, GM-CSF, IL-4, and varying concentrations of Bay11–7082. We compared Bay DC and DC for surface markers and intracellular indoleamine 2,3 dioxygenase (IDO) expression by flow cytometry, the capacity to stimulate T cells in mixed lymphocyte responses, and the ratio of trypophan to kynurenine in culture medium by HPLC. We tested DC proliferation in vitro and in vivo, as well as standard cytoxicity, mutagenesis and clastogenesis assays. In vivo toxicity was tested by s.c. adoptive transfer of peptide-loaded human Bay-DC into SCID mouse recipients followed by hematology, biochemistry and organ pathology.

Results: From 9 RA patients, we elutriated an average of $10 \pm 2.5 \times 10^6$ (mean ± SEM) monocytes and generated $3 \pm 1.3 \times 10^6$ Bay-DC from 250 ml PB. Addition of Bay11–7082 dose dependently reduced expression of DC surface HLA-DR and CD86 and their capacity to stimulate allogeneic T cells. IDO expression and catabolism of tryptophan to kynurenine increased in Bay-DC after lipopolysaccharide exposure. SCID mice recipient of peptide-loaded Bay-DC showed no hematological effects or organ pathology relative to saline-treated mice after 1 week or 1 month, except a reduction in blood glucose from 7.5 to 5 umol/L.

Conclusions: Bay-DC with poor T cell costimulatory capacity and activity of the immunosuppressive enzyme IDO in response inflammatory signaling, can be feasibly generated from PB monocytes of RA patients. Transfer studies suggest Bay-DC loaded with SE-restricted citrullinated peptides have innate immune effects on glucose metabolism. A phase I trial of citrullinated antigen-specific immunotherapy using autologous Bay DC in ACPA+ RA patients is in progress to test safety, and effects on innate and adaptive immunity.

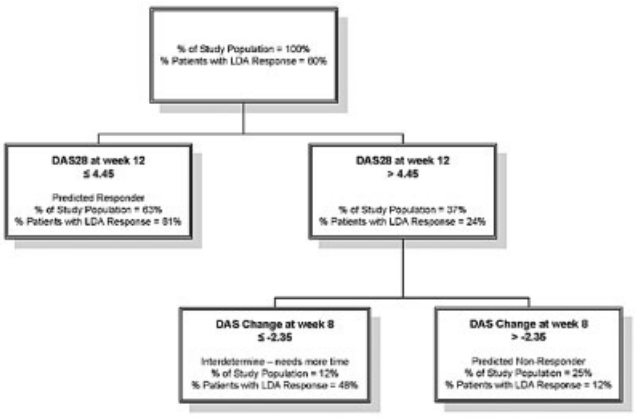
Prediction of One-Year Response to Etanercept and Methotrexate in Rheumatoid Arthritis Patients in TEMPO. Jeffrey R. Curtis[4], Shuo Yang[7], Lang Chen[6], Grace S. Park[1], Bojena Bitman[2], Brian C. Wang[3], Iris Navarro-Millan[5] and Arthur Kavanaugh[8]. [1]Amgen Inc., Thousand Oaks, CA, [2]Amgen Inc., South San Francisco, CA, [3]KForce Clinical Research, South San Francisco, CA, [4]University of Alabama - Brimingham, Birmingham, AL, [5]University of Alabama at Birmingham, Vestavia, AL, [6]University of Alabama at Birmingham, Birmingham, AL, [7]University of Alabama at Birmingham, [8]University of California-San Diego, La Jolla, CA

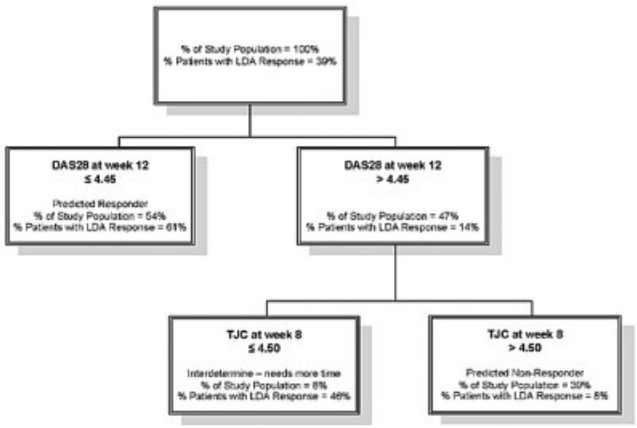
Background: The ability to predict which rheumatoid arthritis (RA) patients (pts) will respond to biologic therapy is a challenging but important endeavor. TEMPO (Trial of Etanercept and Methotrexate with Radiographic Patient Outcomes) data were used to evaluate moderate to severe RA pts initiating etanercept (ETN) with or without methotrexate (MTX) to derive and validate a decision tree that would predict which pts would have a good response after 1 year of therapy, determine which pts could have a treatment decision made at week (wk) 12, and identify pts who needed additional time on therapy.

Methods: Pts were included if they had disease activity scores (DAS28) at 52 (or 48) wks of therapy with either ETN 25 mg twice weekly with MTX (n = 193) or ETN alone (n = 172). Pts were classified as responders if they had low disease activity (LDA) at wk 52, i.e., DAS28 ≤ 3.2. Pts who dropped out for safety reasons were excluded. Classification and Regression Trees (CART) software [Salford Systems], which identifies variables affecting the outcome and partitions data accordingly, was used to develop and validate decision trees on clinical and demographic variables, stratified by TEMPO treatment arm. Tenfold cross-validation was used to guard against overfitting.

Results: Sixty percent (115/193) of pts in the ETN + MTX arm (Figure 1) and 39% (67/172) of pts in the ETN arm (Figure 2) achieved LDA response at wk 52. As shown in Figure 1, LDA was predicted by DAS28 at wk 12 and DAS28 change from baseline values at wk 8. Pts were categorized into 3 groups by 12 wks: 1) high-likelihood responders, such that 63% (121/193) of pts were able to be classified as responders by wk 12 with 81% accuracy (98/121 correctly classified as responders); 2) non-responders, 25% (49/193) of pts with 88% (43/49) accuracy; and 3) uncertain likelihood of response for the remaining 12% (23/193) of pts.



In the ETN only arm, results were similar (Figure 2). Response to therapy in this cohort was predicted by DAS28 at wk 12 and tender joint count at wk 8. By wk 12, 53% (92/172) of pts were able to be classified as responders, 39% of pts as non-responders (67/172), and the remaining 8% were not able to be classified well.



Conclusion: Most TEMPO pts initiating ETN with or without MTX could be classified within 12 wks of starting therapy as likely to have a good response or not at wk 52. However, approximately 10–15% of pts needed additional time on therapy to decide whether to continue ETN. This preliminarily validated decision tree needs replication and may help physicians in deciding whether to continue or change anti-TNF therapy at 12 wks.

Predictors of Response to Rituximab in Patients with Active Rheumatoid Arthritis and Inadequate Response to Anti-TNF Agents or Traditional DMARD. Javier Narvaez[4], Cesar Díaz Torné[2], Jose Miguel Ruiz[3], Maria Victoria Hernández[1], Vicens Torrente[2], Sergio Ros[3], Cesar Díaz López[2], Arturo Rodriguez de la Serna[2], Raimon Sanmartí[1] and Joan Miquel Nolla[4]. [1]Department of Rheumatology, Hospital Clinic, Barcelona, Spain, [2]Department of Rheumatology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [3]Department of Rheumatology, Hospital de Viladecans, Barcelona, Spain, [4]Department of Rheumatology, Hospital Universitario de Bellvitge, Barcelona, Spain

Objective: Identifying early predictors of response to biological agents is important for both the individual patient and health economics. The aim here was to identify clinical variables that are easily assessed in clinical practice associated with a major response to rituximab (moderate-to-good EULAR response, according to DAS28 values) in patients with active rheumatoid arthritis (RA) and inadequate response to anti-TNF agents or traditional DMARD.

Methods: Rituximab (2 × 1 g, two weeks apart) was administered to 108 patients in four different Spanish centres. The primary efficacy endpoint was the percentage of patients who achieved a major response at six months. Potential predictors of a major response were identified using multivariate binary logistic regression models.

Results: Ninety-eight patients (91%) received RTX after the failure of ≥ 1 anti-TNF agent (number of previous anti-TNF agents used: 1.4 ± 0.8). Primary or secondary inefficacy, rather than development of side effects, was the reason for the anti-TNF failure in the large majority of cases (70.2%). Seven of these patients had also failed to respond to other biological agents (abatacept or tocilizumab). In ten patients (9%), RTX was administered as a first-line biological therapy due to contraindications for anti-TNF therapy.

The mean age of patients (86 women) was 58.4 ± 12.2 years and the median disease duration was 9.8 ± 9.4 years (range: 1–36). Rheumatoid factor (RF) and/or anti-CCP antibodies were positive in 84.3% of cases; only 15.7% of patients were seronegative for both antibodies. The mean number of previous DMARDs used was 2.9 ± 1.4. RTX was administered alone in 31 (28.7%) patients and in combination with one DMARD (mainly methotrexate or leflunomide) in the other 77 (71.3%) cases. The mean DAS28 score at baseline was 5.8 ± 1.1 and the mean HAQ value was 1.500 ± 0.67.

At six months of treatment 75.9% of patients achieved a major response (good: 24.1%; moderate: 51.8%). Comparing the clinical features at baseline between patients who did or did not achieve a major response, significant differences were found in RF and anti-CCP positivity, as well as in the number of failed anti-TNF agents prior to RTX.

While RTX delivers clinical benefit in seronegative patients, the presence of RF and/or anti-CCP consistently enriches clinical responses. In the multivariate analysis the only predictors of a major response were anti-CCP antibodies ($p=0.045$) and the number of previous anti-TNF agents used ($p=0.028$). Thus, patients with an anti-CCP titre > 300 were 3–4 times more likely to achieve a major EULAR response (OR: 3.38, 95% CI: 1.025 – 11.17). By contrast, those patients who had failed to respond to more than one anti-TNF agent had a 72.5% lower probability of achieving a moderate-to-good EULAR response (OR: 0.275; 95% CI: 0.087 – 0.871) than did patients who had only failed to respond to one such agent.

Conclusion: Anti-CCP titre and a lower number of previously-failed TNF blockers can help select the best candidates for RTX therapy in patients with RA.

Proof of Concept Study for a Potent p38 MAPK Dual Action Inhibitor BMS-582949 in Subjects with RA Receiving Concomitant Methotrexate. Mark C. Genovese[6], Ling Gao[3], Jie Yin[3], Stefani Smith[3], Michael E. Weinblatt[1], Josef S. Smolen[5], Xiaoning Wang[3], Gary Schieven[3], Juan A. Garcia-Meijide[4], Robert Latek[3], Richard Pasternak[3], Sanjeev Kaul[3], Amit Roy[3], Ralph Raymond[3], Ulrich Thienel[3] and Jingsong Wang[2]. [1]Brigham & Womens Hospital, Boston, MA, [2]Bristol-Myers Squibb, Wayne, PA, [3]Bristol-Myers Squibb, [4]Hospital Clínico Universitario de Santiago, Santiago de Compostela, Spain, [5]Krankenhaus Lainz, Vienna, Austria, [6]Stanford University, Sunnyvale, CA

Background/Purpose: BMS-582949 is a potent and selective dual action inhibitor of p38 MAPK. It inhibits both p38 kinase activity and activation in cells. Previous studies showed BMS-582949 to be well tolerated in both healthy and RA subjects for up to 28 days.

Methods: This 16 week, randomized, double-blind, placebo-controlled study consisted of a 12-week treatment, and a 4-week follow-up period. One hundred and twenty one (121) subjects with active RA, with an inadequate response to MTX, were randomly assigned in a 1:1 ratio to once daily oral treatment with placebo or BMS-582949 300 mg. Efficacy, safety, PK and PD endpoints were monitored throughout the study. The ACR20 response at Day 85 was defined as the primary endpoint. Secondary endpoints were ACR50/70, ACR-N, HAQ-DI and changes in DAS28 on Day 85.

Results: Sixty and 61 subjects with RA, treated concomitantly with MTX, received BMS-582949 300 mg and placebo once daily. The proportion of BMS-582949 300 mg treated subjects (53.3%) who achieved an ACR20 response at Day 85 (Week 12) was significantly higher than the placebo group (32.8%) ($p = 0.036$). At Day 85, the mean treatment group difference for DAS28, favoring active arm, was −0.83 (95% CI: −1.29, -.036). The study also met its secondary endpoints in changes in DAS28, ACR-N and HAQ-DI scores.

Endpoints at Week 12	ACR20 (%)	ACR50 (%)	ACR70 (%)	Mean Change from Baseline in DAS28
BMS-582949 (N=60)	53	15	2	−1.81
Placebo (N=61)	33	10	7	−0.98

BMS-582949 led to a decrease in CRP, with the active treatment group having a larger median decrease in hs-CRP compared with placebo at week 12. Additional post-hoc analyses revealed that efficacy appeared to be related to exposure (Cmin) and that higher responses were observed in patients with baseline CRP levels >10 mg/L.

There were 5 discontinuations due to an AE; 2 subjects treated with BMS-582949 (diarrhea, and fatigue) and 3 subjects treated with placebo (ALT elevation, presyncope and panniculitis). No deaths were reported, and only 1 serious adverse event (SAE) of polyarthritis deterioration (placebo) was reported. Most AEs were mild to moderate in intensity. No significant increase in the frequency of subjects developing abnormal liver function tests, elevated CPK, dizziness and skin rashes was seen compared to placebo.

Conclusions: BMS-582949 300 mg significantly increased the proportion of ACR20, DAS28, and HAQ-DI responders in patients with active RA who had an inadequate response to MTX compared to placebo. BMS-582949 was safe and well tolerated in subjects with RA who were receiving concomitant therapy with MTX. The effect on biomarker (CRP) and clinical efficacy observed with this dual action p38 inhibitor indicate that this approach to

targeting the p38 MAPK pathway may be possible for the treatment of inflammatory diseases.

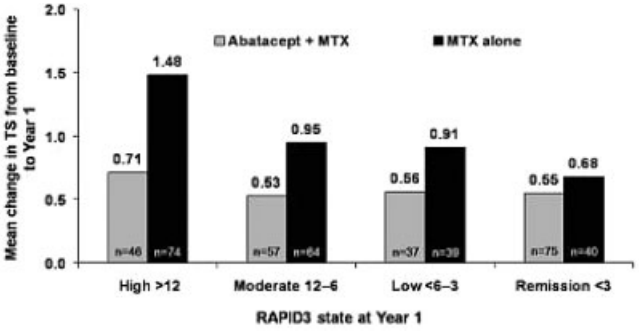
Radiographic Progression Correlates Well with Patient-Reported RAPID3 Disease Activity Levels in Methotrexate (MTX)-Naive Patients with Early Rheumatoid Arthritis (RA): Insights from the AGREE Study. Edward C. Keystone[3], Rene Westhovens[4], Diane Moniz Reed[1], Allison Covucci[1] and Alvin F. Wells[2]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]Rheum & Immunotherapy Center, Oak Creek, WI, [3]University of Toronto, Toronto, ON, Canada, [4]UZ Gasthuisburg, Leuven, Leuven, Belgium

Background: Structural damage early in (RA) can translate into long-term disability; however, assessment of radiographic progression is not routinely performed in clinical practice. Consequently, a patient-derived instrument that correlates with radiographic progression would be helpful in therapeutic decision making. Here we investigate the relationship between X-ray progression and patient-derived RAPID3 disease activity, as well as physical function alone, in patients treated with abatacept (ABA) and/or MTX.

Methods: Patients with early (≤2 years) RA and poor prognostic factors were randomized (1:1) to ABA plus MTX or placebo plus MTX (MTX alone) in the double-blind Phase III AGREE study[1]. X-ray progression at Year 1 assessed by change in Genant-modified Sharp total score (TS) was a co-primary endpoint. In this *post-hoc* analysis, mean change in TS from baseline to Year 1 was analyzed by RAPID3-assessed disease activity (high >12; moderate 12–6; low <6–3; near-remission <3) and HAQ-DI score (high ≥1.5; moderate 0.8–<1.5; low 0.5–<0.8; remission <0.5) at Year 1. Data are for patients who had data available at the visits of interest (as-observed).

Results: Patients had high baseline disease activity (mean DAS28 [CRP] 6.3) and short disease duration (6.5 months); TS was 7.1, HAQ-DI was 1.7 and 86.1% of patients were seropositive for RF and anti-CCP2. In the ABA plus MTX and MTX alone groups, respectively, 215 and 217 patients had data available for the X-ray+RAPID3 analysis, and 215 and 218 had data available for the X-ray+HAQ-DI analysis. In the MTX alone arm, greater X-ray progression was seen with RAPID3-assessed high/moderate disease activity at Year 1 compared with patients in low activity or near-remission; for the ABA plus MTX arm, greater progression was seen for patients in high disease activity compared with moderate/low disease activity states (Figure). Regardless of RAPID3 state, smaller changes from baseline in TS were seen for patients treated with ABA plus MTX versus MTX alone. Similar trends were seen for HAQ-DI scores: mean TS changes for patients with high, moderate, low HAQ-DI and remission, respectively, were 0.53 (n=33) vs 1.64 (n=46), 0.69 (n=55) vs 0.92 (n=71), 0.39 (n=29) vs 0.77 (n=28), and 0.59 (n=98) vs 0.97 (n=73) for ABA plus MTX versus MTX alone.



Conclusions: Radiographic progression in patients with early RA receiving MTX showed good agreement with RAPID3 assessed disease activity state. The association between RAPID3 and radiographic progression with ABA plus MTX was not seen to the same degree, as TS change was consistently low regardless of RAPID3 driven disease activity state. Similar results were observed with HAQ-DI. The agreement observed between RAPID3 and X-ray progression in MTX patients supports the use of the RAPID3, based on patient-reported outcomes, as a guide to management of RA in routine care.

REGN88/SAR153191, a Fully-Human Interleukin-6 Receptor Monoclonal Antibody, Reduces Acute Phase Reactants in Patients with Rheumatoid Arthritis: Preliminary Observations from Phase 1 Studies. Allen R. Radin[1], Scott J. Mellis[1], Martine Jasson[3], Douglas Nadler[2], Pavel Belomestnov[2], Richard Wu[2], Stephanie Biedermann[2], Damir Skific[2] and Jennifer Hamilton[2]. [1]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [2]Regeneron Pharmaceuticals, Inc., [3]Sanofi-aventis, SA

Background: REGN88/SAR153191 (REGN88), a fully human IgG1 monoclonal antibody directed against the interleukin-6 receptor alpha (IL-6Rα), is being evaluated as a new therapeutic modality for rheumatoid arthritis (RA). We report the effects of REGN88 on markers of inflammation and its safety after subcutaneous (SC) administration in RA patients in phase 1 clinical trials.

Methods: Three phase 1, randomized, double-blind, placebo-controlled trials were conducted; RA patients received REGN88 or placebo (PBO) with concomitant methotrexate. Study 801 evaluated single ascending doses of 50, 100, or 200 mg REGN88 or PBO (n=15). In study 803, patients with active RA were administered parallel single doses of 50, 100, or 200 mg REGN88 or PBO (n=32). Study 802 evaluated patients with RA receiving 5 weekly or 3 biweekly doses of 50, 100, 150, 200 mg REGN88 or PBO (n=60). High-sensitivity C-reactive protein (hsCRP), serum amyloid A (SAA), erythrocyte sedimentation rate (ESR), hepcidin and interleukin-6 (IL-6) were measured to assess pharmacodynamic response. Safety and tolerability were evaluated by combining data from all 3 studies (REGN88 n=83; PBO n=24).

Results: Suppression of hsCRP, SAA, hepcidin and ESR was observed in a dose-dependent manner in REGN88 groups; at day 8, a single 200 mg dose of REGN88 was associated with median reductions of 91.7% in hsCRP, 92.5% in SAA, 66.2% in hepcidin and 33.8% in ESR. For hsCRP, reductions were observed through day 15 ($p<0.005$ vs PBO). Reductions in inflammatory markers were paralleled by increases in serum IL-6 levels that peaked at day 8 after the 200 mg dose (median increase 647%) before returning to baseline by day 22. Four patients withdrew due to adverse events; 3 on REGN88 and 1 on PBO. The most commonly reported adverse events were upper respiratory infection, increase in alanine aminotransferase (ALT) levels, and RA flare. One patient on REGN88 50 mg in Study 803 reported a serious adverse event of RA flare requiring hospitalization, as per Russian standard of care. During a maximum 16-week exposure/follow-up period, 1 patient each in REGN88 and PBO groups had a transient elevation of ALT 3–5x upper limit of normal (ULN), and 1 patient who received REGN88 had ALT >5x ULN. Also during this period, 5 patients on REGN88 and 0 on PBO had a transient decrease in neutrophil count (0.5–1.0 $\times 10^3$/uL); no patients had neutrophils <0.5 $\times 10^3$/uL. No changes in neutrophils or liver enzymes were associated with adverse clinical outcomes.

Conclusion: IL-6Rα inhibition with SC REGN88 in active RA patients resulted in dose-related reductions in hsCRP, SAA, ESR and serum hepcidin with concomitant increases in IL-6. The clinical significance of these changes has not been evaluated. SC REGN88 was well-tolerated in these patients, with no dose-limiting toxicities observed. REGN88 is being investigated in a Phase 2 program in RA and ankylosing spondylitis.

Results from a Phase I Study of MLTA3698A, a Novel Anti-Lymphotoxin-a Monoclonal Antibody: Safety, Tolerability and Biologic Activity in Patients with Active Rheumatoid Arthritis. Brinda Emu[2], Diana Luca[3], Carolyn Offutt[3], Jane Grogan[3], John Davis[3], Bernadette Rojkovich[1], Marna Williams[3], Meina Tang[3] and June Lee[3]. [1]Budai Irgalmasrendi, [2]Genentech, Inc., South San Francisco, CA, [3]Genentech, Inc.

Background: Lymphotoxin (LT)-α is a cytokine transiently expressed by subsets of activated lymphocytes that are implicated in the pathogenesis of RA/autoimmunity including T-helper cells (Th1, Th17) and B cells. The biologic agent MLTA3698A is a humanized monoclonal antibody directed against the cytokine LTα, and has several distinct mechanisms of action, including blocking soluble and membrane-bound LTα from interacting with its receptors and selectively depleting subsets of activated immune cells. We report a randomized, double-blind, placebo-controlled trial designed to assess safety, tolerability, pharmacokinetics, impact on biomarkers, and preliminary evidence of biologic activity after single and multiple doses of either intravenous or subcutaneous administration of MLTA3698A in RA patients.

Methods: The first stage of the study consisted of a single dose escalation of MLTA3698A or placebo at 6 doses (0.3 IV, 1.0 IV, 1.0 SC, 3.0 IV, 3.0 SC, and 5.0 mg/kg; n=30) in patients with stable RA. The second stage of the study consisted of a multiple dose escalation phase in which patients with active RA (on stable regimen for RA, with $\geq$ 5 swollen joints, >5 tender joints and CRP $\geq$ 1.0) received 3 doses of MLTA3698A or placebo every 2 weeks (1.0 SC, 3.0 SC, or 5.0 IV mg/kg; n=35). Safety and tolerability were assessed in patients in both single and multiple dose escalation stages. CXCL-13, a downstream chemokine in LTa signaling pathway, was measured prior to and after dosing. Clinical activity endpoints were measured at multiple time points in patients in the multiple dose escalation stage.

Results: Baseline characteristics of patients who received MLTA3698A or placebo were similar with respect to demographics and RA disease status (median age of 57 years, median CRP of 1.21, and median DAS28-CRP of 4.21). The majority of adverse events were mild to moderate. There were no serious adverse events or dose-limiting toxicities in the trial. There were no serious infections or notable changes in peripheral lymphocyte subsets. Pharmacokinetic profiles were linear and clearance was independent of dose. Substantial reductions in levels of serum CXCL-13 were observed. Preliminary evidence of clinical activity was seen in the multiple dose stage as evidenced by ACR20, ACR50, and ACR70 response rates as well as reduction in DAS28CRP scores and C-reactive protein (CRP) levels.

Conclusions: Blockade of LTα pathway is a promising mechanism of action for the treatment of RA. MLTA3698A was generally well tolerated and demonstrated preliminary evidence of clinical activity.

1123

Safety of a Novel Modified-Release (MR) Prednisone Formulation: Results of the "Circadian Administration of Prednisone in Rheumatoid Arthritis" (CAPRA) Studies. Frank Buttgereit[1], Jacek Szechinski[5], Gisela Döring[6], Stephan Witte[2], Christine Knauer[3], Amy Grahn[4], Kenneth G. Saag[8] and Rieke Alten[7]. [1]Charite University Med-Berlin, Berlin, Germany, [2]Horizon Pharma GmbH, Mannheim, Germany, [3]Horizon Pharma GmbH, Mannheim, Germany, [4]Horizon Pharma, Inc., Northbrook, IL, [5]Med. Uni. Department of Rheumatology, Wroclaw, Poland, [6]Merck KGaA, [7]Schlosspark-Klinik, UnivMed, Berlin, Germany, [8]University of Alabama-Birmingham, Birmingham, AL

Background: In patients with rheumatoid arthritis (RA), nocturnal increases in proinflammatory cytokines are implicated in the typical early morning symptoms, joint stiffness and pain. Glucocorticoid (GC) chronotherapy with a novel modified-release (MR) prednisone tablet enables delivery of prednisone during the night to specifically target the nocturnal rises in inflammatory mediators and symptoms. This novel approach showed both clinically relevant reduction of morning stiffness (MS) compared to conventional, immediate-release (IR) prednisone, as well as clinically relevant improvements according to the ACR response criteria. The data here describes the safety and tolerability of low-dose prednisone chronotherapy in patients from two phase 3 clinical studies.

Methods: The CAPRA studies investigated safety and efficacy of MR prednisone in patients with RA, not adequately controlled by disease-modifying antirheumatic drug (DMARD) therapy. The CAPRA-1 study compared the novel formulation (3–10 mg/day, average of 6.8 mg/day) in 288 patients to conventional immediate release prednisone over 12 weeks, the CAPRA-2 study compared 5 mg/day MR prednisone + DMARD in 350 patients to placebo + DMARD over 12 weeks. An open-label extension of CAPRA-1 provided safety data for up to 12 months. In addition, the effect of MR prednisone on the Hypothalamus-Pituitary-Adrenal (HPA) axis was investigated in a CRH test subgroup study, as part of CAPRA-1 (62 tests in 28 patients under treatment with MR prednisone or IR prednisone). All Adverse Events (AEs) from these studies were collected by neutral questioning in a standardized manner.

Results: The incidence of serious adverse events (SAEs) and adverse events (AEs) in all treatments was low and comparable between MR prednisone and IR prednisone and comparable to the placebo arm, with more AEs related to RA signs and symptoms (arthralgia and RA flare) in the PBO arm than in the MR prednisone arm. In all studies MR prednisone was shown to be safe and well tolerated. The most frequent AEs are shown in Table 1. CRH tests in patients on treatment with MR prednisone or IR prednisone showed no evidence for a different effect on the HPA axis.

Table 1. Adverse Events occurring in ≥2% of MR Prednisone in patients of the CAPRA studies.

	CAPRA-2 (3 Months)		CAPRA-1 (3 Months)		CAPRA-1 (9 Months)
Preferred term	Prednisone MR 5mg (%) N=231	Placebo (%) N=119	Prednisone MR 3–10mg (%) N=144	Prednisone IR 3–10mg (%) N=144	Prednisone MR 3–10mg (%) N=249
Worsening of rheumatoid arthritis	6.5	9.2	7.6	9.0	14.5
Arthralgia	10.4	20.2	0.7	2.1	2.4
Nasopharyngitis	4.8	3.4	2.8	5.6	2.4
Headache	3.9	4.2	4.2	2.8	1.2
Abdominal pain upper	0.4	1.7	3.5	5.6	1.6
Bronchitis	1.3	4.2	0.7	3.5	2.4
Upper respiratory tract infection	0.4	0.8	0.7	2.1	2.8
Hypertension	2.2	0.8	2.1	2.1	<1
Back pain	1.3	0.8	<1	<1	2.8
Nausea	1.3	0.0	3.5	2.8	<1
Chest pain/discomfort	0.4	0.0	2.1	2.1	<1
Hypercholesterolemia	0.4	1.7	<1	<1	2.4
Feeling hot	0.0	0.0	<1	<1	2.0
Weight increased	0.0	0.0	<1	<1	2.8

Conclusion: Two large phase 3 clinical trials established a favorable safety profile of low-dose chronotherapy with MR prednisone. MR Prednisone has been shown to reduce duration of morning stiffness and to be more effective than placebo with regard to standard RA outcome parameters.

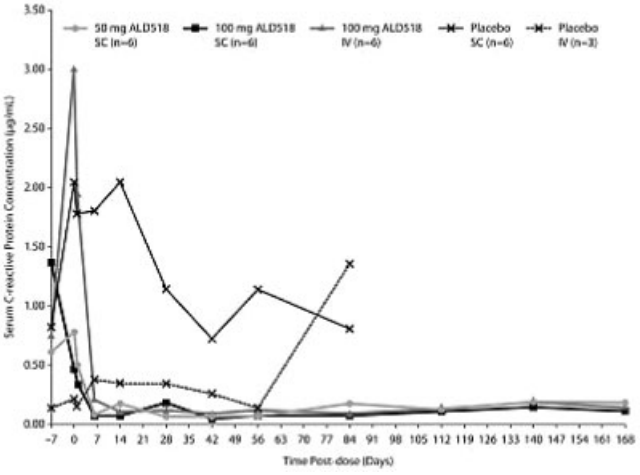
Safety, Pharmacokinetics and Pharmacodynamics of ALD518 (BMS-945429), a High-Affinity Monoclonal Antibody Directed Against Interleukin-6 (IL-6) Administered by Subcutaneous Injection: A Phase I Trial. Sepehr Shakib[2], Barbara Francis[1] and Jeffrey Smith[1]. [1]Alder Biopharmaceuticals Inc., Bothell, WA, [2]Royal Adelaide Hospital, Adelaide, Australia

Background: ALD518 (BMS-945429) is an asialated, humanized anti-IL-6 monoclonal antibody with a half-life of ~30 days. ALD518 binds to IL-6 with high affinity, preventing interaction and signalling mediated via IL-6R. Rapid and significant treatment responses have been demonstrated with intravenous (IV) ALD518 in patients with RA[1]; here we report the safety, pharmacokinetics and pharmacodynamics of subcutaneous (SC) ALD518 in healthy subjects.

Methods: In this Phase I, double-blind, placebo-controlled study, 27 subjects were randomized 2:1 to receive a single dose of ALD518 or placebo in the following groups: ALD518 50 mg SC, ALD518 100 mg SC or

ALD518 100 mg IV (n=6 active and n=3 placebo per group). The primary objective was to assess safety of SC ALD518 versus placebo over 12 weeks. Plasma concentrations of ALD518 and serum concentrations of C-reactive protein (CRP) were assessed as secondary objectives. Assessments were performed daily in Week 1 and then on Day 10, Weeks 2, 4, 6 and 8, and then monthly to Week 12. The study was unblinded at Week 12, and ALD518 subjects were monitored to Week 24.

Results: Over 24 weeks, there were no deaths or serious AEs, and no withdrawals due to AEs. Nearly all subjects (89%) experienced AEs, which were mild or moderate except one event of severe gastroenteritis in the ALD518 SC 50 mg group. Injection site reactions occurred in 5/12 ALD518 SC subjects, 1/6 placebo SC subjects and 1/3 placebo IV subjects (none were reported in ALD518 IV subjects). These were mild except one case of moderate erythema and pruritis in the ALD518 100 mg SC group. Increases in direct bilirubin and neutrophil counts below the limit of normal were more common in subjects receiving ALD518 than placebo; all were CTC Grade 1 or 2. The half life of ALD518 was similar across all groups (mean range: 30.7–33.6 days). The median T_{max} of ALD518 was longer after SC (~1 week) than after IV administration (~end of infusion). The PK of SC ALD518 was dose-proportional in terms of AUC and C_{max} at doses of 50 mg and 100 mg. Based on $AUC_{0-\infty}$ (day*μg/mL) of 237, 452 and 764 for the ALD518 50 mg SC, 100 mg SC and 100 mg IV groups, respectively, the bioavailability of ALD518 was ~60% for the SC versus IV groups. Subjects receiving ALD518 experienced rapid and sustained reductions in serum CRP (Figure).



Conclusions: In this Phase I study, the anti-IL-6 antibody ALD518 was well tolerated when administered in a single SC dose; injection site reactions were generally mild. The bioavailability of SC ALD518 was ~60% of IV ALD518, and the half life was ~30 days. Rapid and significant reductions in CRP were observed, which were sustained over 24 weeks of assessment.

Selective Activation of Naturally Occurring Regulatory T Cells (Tregs) by the Monoclonal Antibody (mAb) BT-061. Markers of Clinical Activity and Early Phase II Results in Patients with Rheumatoid Arthritis (RA).
Anatoliy Rudnev[1], Sukanya Ragavan[6], Christina Trollmo[6], Vivianne Malmstroem[6], Christian Becker[5], Helmut Jonuleit[5], Vibeke Strand[7], Silke Aigner[1], Niklas Czeloth[1], Benjamin Daelken[1], Andre Engling[1], Helga Koch[1], Gabriele Niemann[1], Frank Osterroth[1], Christoph Uherek[1], Andrea Wartenberg-Demand[1], Olga Ershova[4], Tatiana Sotnikova[2] and Alexander Orlov-Morozov[3]. [1]Biotest AG, Dreieich, Germany, [2]Botkin Clinical Hospital, Moscow, Russian Federation, [3]City Clinical Hospital Nr. 23 n.a. Medsantrud, Moscow, Russian Federation, [4]Clinical Hospital for Emergency Medical Care, Yaroslavl, Russian Federation, [5]Johannes-Gutenberg University, Mainz, Germany, [6]Karolinska Institute, Stockholm, Sweden, [7]Stanford University, Portola Valley, CA

Naturally occurring Tregs are essential for maintaining normal immune homeostasis in healthy individuals. In patients with autoimmune diseases reduced numbers or functional impairment of Tregs has been observed. A humanized agonistic mAb, BT-061 selectively activates Tregs. It binds to a unique epitope of the CD4 molecule, leading to induction of Treg specific signaling events. While freshly isolated and resting Tregs do not inhibit T cell proliferation, pre-treatment of Tregs with BT-061 leads to suppression of CD4 and CD8 T effector cell proliferation, reduction of pro-inflammatory cytokines and a moderate increase in the anti-inflammatory cytokine TGF-beta.

To further assess the potential of BT-061 to modulate immune responses, *in vitro* studies with synovial fluid derived mononuclear cells from patients with active RA were performed. Addition of BT-061 at concentrations between 0.01 and 50 micro g/mL to isolated CD4-positive cells derived from the highly inflammatory milieu of RA synovial fluid suppressed proliferation as well as IFN-gamma production following antigen-specific stimulation.

In a Phase I/IIa trial in patients with psoriasis, a single dose of BT-061 resulted in PASI 50/75 responses for up to 90 days at doses of 0.5, 2.5, 10, 20 mg iv and 12.5, 25 mg sc. A Phase IIa, multicenter, randomized placebo-controlled trial with BT-061 monotherapy was performed in 96 patients with active RA and inadequate responses to one or more traditional DMARD despite 3 months or more of treatment. Patients were randomized to 12 treatment groups: from 1.25 – 100 mg sc, or 0.5 – 25 mg iv, once weekly for 6 weeks: 6 patients received BT-061 and 2 received placebo in each group.

Initial data analysis confirmed the clinical activity of BT-061 by ACR20/50/70 responses in a meaningful proportion of patients despite the short duration of therapy. No major safety signals were identified. Final analyses of safety and efficacy data are ongoing and will be presented.

Phase II multiple dose trials with BT-061 are underway to further evaluate the clinical benefit of BT-061 in patients with RA and psoriasis.

Serum Cytokine Profile Predicts Response to Rituximab Therapy in Rheumatoid Arthritis.
Edward M. Vital[4], Richard J. Cuthbert[4], Shouvik Dass[1], Rekha Parmar[4], Andrew C. Rawstron[3], Frederique C. Ponchel[1] and Paul Emery[2]. [1]Leeds, West Yorkshire, United Kingdom, [2]Chapel Allerton Hospital, Leeds, United Kingdom, [3]Leeds Teaching Hospitals NHS Trust, Leeds, West Yorkshire, United Kingdom, [4]University of Leeds, Leeds, West Yorkshire, United Kingdom

Background: Response to B-cell depletion with rituximab in rheumatoid arthritis is variable. Several factors have been shown to have predictive value at baseline: RF and CCP status, IgG titre, circulating memory B cell numbers, synovial expression of CD79a, as well as persistence of circulating plasmablasts and synovial plasma cells after treatment. These data suggest it may be possible to select patients for therapy based on parameters indicating greater active B-cell involvement. However, parameters identified to date are not accurate and many are not suitable for routine clinical practice. We therefore studied serum cytokines that have a hypothetical role in B-cell function in RA to better understand the determinants of response, and as convenient biomarkers.

Patients and Methods: 85 patients were treated with rituximab and clinical response was evaluated at 6 months by EULAR criteria. Relapse was determined by rise in DAS28 $\geq$ 0.6. Serum was tested for BAFF (n=85 at baseline, 29 serial samples), IL6 (n=46) and IL10 (n=26) by ELISA (R&D Systems). B cell subsets were measured by 6-parameter flow cytometry using CD19, CD20, CD3, CD14, CD27 and CD38. The strength of correlations was tested by Spearman's log rank test and relationships between cytokine titres and categorical variables by either Mann Whitney U test or log transformation and Student's t test, as appropriate.

Results: Baseline Cytokines and disease activity: IL6 was correlated with CRP at baseline as expected ($R = 0.591$, $p < 0.001$) but there was no relationship of BAFF or IL-10 with DAS28 or CRP, nor any interrelationship between cytokines.

Cytokine changes after therapy: 6 months after B-cell depletion, BAFF significantly increased ($p<0.001$) and IL-6 significantly reduced ($p=0.001$) but there was no substantive or significant change in IL10. As expected, IL-6

was higher in non-responders at 6 months ($p<0.001$). Levels of each cytokine correlated between baseline and 6 months after therapy (BAFF, $R=0.735$, $p<0.001$; IL-6, $R=0.541$, $p<0.001$; IL-10, $R=0.675$, $p=0.008$).

Predictive value of baseline cytokines: Baseline DAS28, its components, and CRP/ESR did not differ between responders and non-responders. Most importantly, levels of IL-6 and BAFF were predictive of response at baseline: in responders BAFF was higher ($p=0.03$) and IL-6 was lower ($p=0.014$).

No relationship of serum cytokines with B cell depletion or repopulation: No relationship was identified between IL6, IL10 or BAFF levels at baseline or follow up and baseline B-cell number, degree of depletion at 2 or 6 weeks or rate of repopulation of any subset.

Conclusions: Serum BAFF and IL-6 titres are predictive of response to rituximab in rheumatoid arthritis and may have utility as biomarkers. However, this effect appears to be independent of B cell depletion, and the hypothesis that BAFF inhibits B cell depletion, as suggested by animal models, is not supported by these results. These relationships may differ in the synovium or other tissues.

Serum Markers Associated with Structural Damage in Methotrexate Naïve Rheumatoid Arthritis Patients Treated with MTX in Combination with Placebo or Golimumab, a Human Anti-TNFa Monoclonal Antibody. Carrie Wagner[2], Dion Chen[1], Hongtao Fan[1], Sudha Visvanathan[5], Elizabeth C. Hsia[3], Paul Emery[4], Roy M. Fleischmann[6], Michael Mack[1] and Mahboob U. Rahman[3]. [1]Centocor Research and Development, Inc., [2]Centocor Research and Development, Inc., Malvern, PA, [3]Centocor Research and Development, Inc./Univ. of Pennsylvania School of Medicine, Malvern, PA, [4]Chapel Allerton Hospital, Leeds, United Kingdom, [5]Hoffmann La Roche, [6]University of Texas SW Medical Center, Dallas, TX

Purpose: Little is known about biomarkers that are correlated with structural damage endpoints in rheumatoid arthritis (RA). The purpose of this study is to evaluate whether there are serum markers associated with structural damage in MTX naïve RA patients treated with MTX in combination with either placebo (PBO) or an anti-TNF antibody, golimumab (GLM).

Methods: In the GO-BEFORE study, 637 patients were randomly assigned in a 1:1:1:1 ratio to receive placebo (PBO) + methotrexate (MTX), GLM 100 mg+ PBO, GLM 50 mg + MTX, or GLM 100 mg + MTX. Sera were collected at wks 0, 4 and 24 from a subset of approximately 100 patients for testing select markers of inflammation and bone/cartilage metabolism and protein profiling using multi-analyte profiles (Rules Based Medicine). The baseline, absolute change and percent change from baseline to wk 4 in these markers were compared between the PBO+MTX and the combined GLM group [GLM+MTX (50 mg + 100 mg) and GLM+PBO groups] against changes in van der Heijde modified Sharp (vdh-S) score, erosion score and joint space narrowing score at wks 28 and 52 using Spearman's correlations. Significant biomarker correlations with efficacy in the GLM group relative to the PBO treatment group were evaluated using Fisher Z-transformation test.

Results: Biomarker correlations with structural damage endpoints were predominantly observed for only the PBO+MTX treatment group and very few correlations were observed with GLM treatment. With PBO+MTX treatment, only IL-1ra was observed to be repeatedly correlated with the structural damage endpoints at wks 28 and 52. However, there were a number of more consistently observed structural damage correlations in the PBO+MTX treatment group using either absolute change from baseline or percent change from baseline in biomarker levels. Absolute change or percent change from baseline markers that were repeatedly correlated with changes in structural damage endpoints at wks 28 and/or 52 included CD-40 ligand (CD40-L) and epidermal growth factor (EGF). There were repeated, but less frequent structural damage correlations with change or percent change in matrix metalloproteinase 3, MIP-1β and Col 2–3/4C long neoepitope. The only biomarker that was repeatedly correlated with structural damage endpoints in the GLM treatment group was IL-1ra.

Conclusions: Biomarker correlations with structural damage endpoints were predominantly observed in the PBO+MTX treatment group, but rarely in the GLM+MTX treatment group, likely reflecting the reduced structural damage observed following anti-TNF treatment. Change and percent change from baseline to wk 4 in levels of certain markers were repeatedly associated with structural damage endpoints at wks 28 or 52 in the PBO+MTX treatment. Markers that were repeatedly associated with structural damage measures at wks 28 and/or 52 included EGF and CD40-L. CD40-L has been reported to regulate osteoclastogenesis and EGF has been implicated in bone remodeling. Additional studies are needed to confirm whether these markers would be similarly correlated with structural damage measures in MTX-refractory patients.

Targeting Potassium Channels for the Treatment of Rheumatoid Arthritis. Xueyou Hu[2], Teresina Laragione[4], Liang Sun[2], Shyny Koshy[2], Karlie R. Jones[2], Frank T. Horrigan[2], Percio S. Gulko[3] and Christine Beeton[1]. [1]Baylor College of Medicine, Houston, TX, [2]Baylor College of Medicine, [3]Feinstein Institute for Medical Research, Manhasset, NY, [4]Feinstein Institute for Medical Research

Background: Activated fibroblast-like synoviocytes (FLS) in the rheumatoid arthritis (RA) synovium (RA-FLS) are major players in inflammation, synovium and bone destruction, angiogenesis, and hyperplasia. However, no currently-approved therapies specifically target these cells. Potassium channels regulate cell signaling and thus a large number of functions of non-excitable cells such as fibroblasts, lymphocytes, or astrocytes. We therefore hypothesized that targeting the potassium channels expressed by RA-FLS may represent an attractive target for the treatment of RA.

Methods: We have used four complementary methods (RT-PCR, western blot, immunocytochemistry, and patch-clamp electrophysiology) to identify the potassium channels expressed by RA-FLS isolated from 5 different patients. We next used selective blockers of KCa1.1 channels (paxilline and iberiotoxin) to probe their roles on RA-FLS proliferation, invasion, and production of cytokines, chemokines, angiogenic factors, and matrix metalloproteinases (MMPs).

Results: We have identified KCa1.1 channels (BK, Maxi-K, Slo-1) as the major potassium channels expressed by RA-FLS. Blocking KCa1.1 channels inhibited the proliferation of RA-FLS and their ability to produce vascular endothelial growth factor (VEGF), IL-8, and MMP-2 without inducing cytotoxicity or affecting the production of IL-6. In keeping with these data, blocking KCa1.1 channels also inhibited the invasion of RA-FLS in matrigel assays.

Conclusions: KCa1.1 channels play a major role in the pathogenic functions of RA-FLS. These channels are therefore attractive targets for the treatment of RA.

Tasocitinib (CP-690,550), an Orally Available Selective Janus Kinase Inhibitor, Exhibits Sustained Safety and Efficacy in the Treatment of Rheumatoid Arthritis over 24 Months. Carol A. Connell, Richard Riese, Susan Wood, John Bradley and Samuel H. Zwillich. Pfizer Inc

Background: Tasocitinib (CP-690,550) is an orally available, small molecule Janus kinase inhibitor that has previously demonstrated efficacy and acceptable safety in patients with active rheumatoid arthritis (RA) in randomized studies of up to 24 weeks of treatment. Here we report the safety and tolerability of tasocitinib and the durability of response beyond 24 weeks in patients with RA.

Methods: In this Phase 2/3, open label study of 1070 patients who had participated in a prior randomized study of tasocitinib (PRST), treatment was initiated with either 5 or 10 mg tasocitinib twice daily. The baseline is that of the PRST for patients who enrolled within 14 days of PRST participation; if enrollment was >14 days after PRST participation, baseline was the start of this study. The primary endpoints were laboratory safety and adverse event (AE) reports. Secondary endpoints included ACR20, ACR50 and ACR70 response rates, Disease Activity Score using the erythrocyte sedimentation rate (DAS28-4 [ESR]), and the Health Assessment Questionnaire-Disability Index (HAQ-DI). Results are reported for all patients (ALL) and stratified according to those who completed Month 12 (M12) and Month 24 (M24) visits.

Results: 1070 patients were treated for a total duration of 1295.7

patient-years; median days of treatment were 518.5 (ALL, n=1070), 655.0 (M12, n=648), and 796.0 (M24, n=207). Seventy patients discontinued from the study due to AEs. A total of 929 treatment-related AEs (TRAEs) were reported; the most frequently reported classes of events were infections and infestations (197, 18.4%), gastrointestinal disorders (109, 10.2%), and investigations [laboratory] (79, 7.4%). 188 serious AEs (SAEs) were reported, of which 48 (25.5%) were considered possibly related to treatment. The most frequently reported class of SAEs was infections (34, 18.1%, 2.62/100 patient-years of tasocitinib treatment).

Mean DAS28-4(ESR) at baseline was 6.41 (ALL); at month 12, 3.70 (ALL) and at month 24, 3.55 (ALL). ACR20, ACR50, and ACR70 percent responders were similar through month 24 in all groups, as seen in Figure 1.

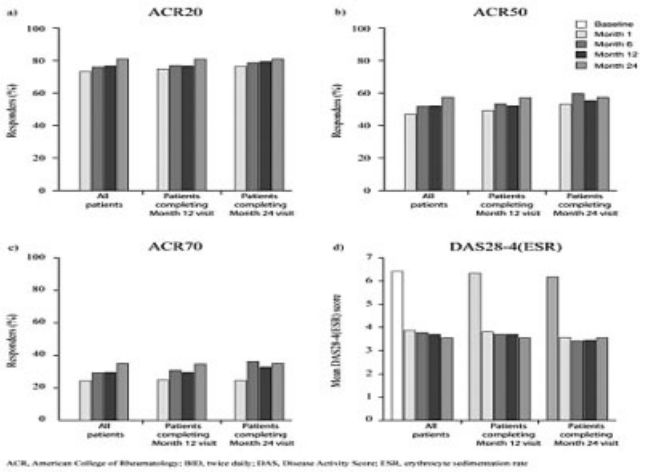

Figure 1. % responders for (a) ACR20, (b) ACR50, (c) ACR70 and (d) mean DAS28-4(ESR) score for patients initially treated with tasocitinib 5 or 10 mg BID.

Mean HAQ-DI scores were improved compared with baseline and remained consistent over time for ALL patients: 1.46 (baseline), 0.86 (Month 12), and 0.76 (Month 24) and M24 patients: 1.38 (baseline), 0.74 (Month 12), and 0.76 (Month 24).

Conclusion: Tasocitinib is effective in the long-term treatment of RA with a manageable safety profile. Efficacy is demonstrated by sustained improvement in ACR response rates, DAS28-4(ESR), and HAQ-DI over a 24-month period.

The Bacterial Effector Protein YopM Reduces Bone Destruction in Rheumatoid Arthritis (RA). Jessica Bertrand[1], Christian Rüter[3], Julia Scharnert[3], Alexander Schmidt[3] and Thomas Pap[2]. [1]Institute for Experimental Musculoskeletal Medicine, Münster, Germany, [2]Institute for Experimental Musculoskeletal Medicine, [3]Institute for Infectiology ZMBE

Background: Bone marrow macrophages (BMM) are precursors of osteoclasts, which mediate the degradation of bone during rheumatoid arthritis (RA). The yersinia outer protein M (YopM) is an effector protein of Yersinia species that is able to enter host cells by membrane penetration. In the cell YopM mediates down-regulation of inflammatory responses. We investigated whether YopM has the potential to act as a "self-delivering" immune therapeutic agent by reducing the inflammation and joint destruction linked to RA.

Methods: We analysed the penetration of recombinant YopM into BMMs by confocal laserscanning microscopy and studied the effects of YopM on osteoclastogenesis using an in vitro osteoclast formation assay. To unravel the signaling pathways involved in the effects of YopM, we investigated the activation of MAP-kinases (ERK, AKT and p-38) and NF-KB signaling by Western Blot analysis. With respect to a potential in vivo application of YopM, we injected YopM intra articular and intravenous of wildtype and hTNFtg mice and monitored its distribution by fluorescence reflection imaging (FRI). Additionaly, we treated hTNFtg mice, as animal model for RA, with YopM and recorded clinical parameters (weight, grip strength and paw swelling). Finally, we analysed the destruction of bone and cartilage histologically compared to untreated hTNFtg mice and wildtype mice.

Results: As seen in confocal scanning microscopy, YopM penetrated the cell membrane of BMMs and accumulated near the nucleus. Studying the signaling pathways affected by YopM, we found that YopM reduced the TNF alpha induced activation of NF-KB by reducing the phosphorylation of IkB alpha. TNF alpha mediated phosphorylation of MAP kinases were not altered by YopM. Most interestingly, we found a strong reduction of osteoclast formation by YopM. Incubation of BMMs with YopM led to a 90% reduction in osteoclasts precursors and osteoclasts. YopM-Cy5 injected intra-articular into the knee joints of a mouse was detectable whithout a systemic distribution of YopM during a time period of 72 hours. Analysing the clinical parameters of RA in hTNFtg mice, we observed a delay of onset of paw swelling in mice treated with YopM. At histological analysis of the hind paws, we found reduced bone destruction and inflammation in YopM treated hTNFtg mice in comparison to untreated hTNFtg mice.

Conclusion: These results suggest that YopM has the potential to reduce inflammation and bone destruction in vivo. Therefore YopM may constitute a novel therapeutic principle for the treatment of RA.

The Effects of Manzamine A on Rheumatoid Arthritis Synoviocyte Cytokine Secretion. Kyle Chong[1], Karolina Klosowska[1] and James M. Woods[2]. [1]Midwestern University, Downers Grove, IL, [2]Midwestern University

Purpose: Manzamine A (MZA) is a marine alkaloid isolated from sponges on the ocean floor known to have anti-inflammatory properties on activated macrophages. The complete synthesis of this complex compound has recently been reported. Rheumatoid Arthritis (RA) is characterized by increased production of pro-inflammatory cytokines by a variety of synovial cells found in the synovial tissue (ST) including fibroblast-like synoviocytes (FLS). We hypothesized that MZA would decrease the levels of pro-inflammatory cytokines secreted by RA cell types.

Methods: RA FLS and RA synovial tissue (ST) explants collected from patients with IRB approval were treated with MZA (10 μM, 1 μM, 0.1 μM, 0.05 μM, and 0.01 μM MZA) or vehicle control, to observe for alterations in pro-inflammatory cytokine production and to observe any cytotoxic effects. Condition media (CM), with or without IL-1β stimulation was collected at various time points. Toxicity was determined using trypan blue exclusion while cytokine levels were analyzed using antibody microarrays and ELISAs.

Results: Toxicity studies on RA FLS suggest that concentrations of 10 μM, 1.0 μM and 0.1 μM MZA had no toxic effects after 24 hours of incubation. However, after 48 and 72 hours, the 10 μM and 1.0 μM MZA concentrations appear to significantly decrease FLS viability. Using an antibody microarray, 24 hour CM with 10 μM MZA appeared to decrease the production of several pro-inflammatory mediators in both RA FLS and RA ST. Proteins decreased include monocyte chemoattractant protein (MCP)-1 (CCL2), interleukin (IL)-8 (CXCL8), growth related oncogene (Gro)-α (CXCL1), regulated on activation of normal T cell expressed and secreted (RANTES/CCL5), IL-6, and epithelial neutrophil activating peptide (ENA)-78 (CXCL5). To confirm data obtained from the cytokine microarray analysis, the level of protein expression was further examined by ELISA. At 24 hours, 10 μM, 1.0 μM and 0.1 μM MZA significantly decreased the production of MCP-1 by 57%, 37 % and 44% respectively ($n=5$; $p<0.05$). Additionally 0.1 μM MZA decreased MCP-1 by 43% at 48 hours ($n=5$; $p<0.05$). MCP-1 production, when stimulated with IL-1β, was significantly decrease with 10 μM, 1.0 μM, 0.1 μM, 0.05 μM and 0.01 μM MZA by 87%, 84%, 57%, 62%, and 67%, respectively, at 24 hours ($n=5$; $p<0.05$). RANTES production was significantly decreased with 10 μM and 1.0 μM MZA by 79% and 69%, respectively, at 24 hours, and also by 54% with 0.1 μM MZA at 72 hours ($n=5$; $p<0.05$). IL-1β stimulated RANTES production was significantly decreased with 10 μM and 1.0 μM MZA by 86% and 75%, respectively, at 24 hours, and also by 59% with 0.1 μM MZA after 72 hours ($n=5$; $p<0.05$). Also, IL-1β stimulated Gro-α production was significantly decreased by 0.01 μM MZA by 26% after 24 hours ($n=5$; $p<0.05$).

Conclusions: While some concentrations of MZA applied appeared toxic to RA FLS, we identified a number of significant effects of MZA at non-toxic concentrations and time points. Our data suggest that MZA decreases RA-associated inflammation by reducing pro-inflammatory cytokines and appears to have solid pharmacological potential to serve as a novel therapeutic in RA therapy.

The Hawthorne Effect, Sponsored Trials, and the Overestimation of Treatment Effectiveness. Frederick Wolfe[1] and Kaleb D. Michaud[2]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Univ of Nebraska Med Ctr, Omaha, NE

Objective: Improvement in rheumatoid arthritis (RA) clinical trials is often greater than improvement seen in the clinic. But follow-up clinical trial studies by sponsors almost invariably show sustained improvement (durability of response). We investigated whether sponsored trial participation influenced study results to determine if the result of clinical trials are upwardly biased by the Hawthorne effect.

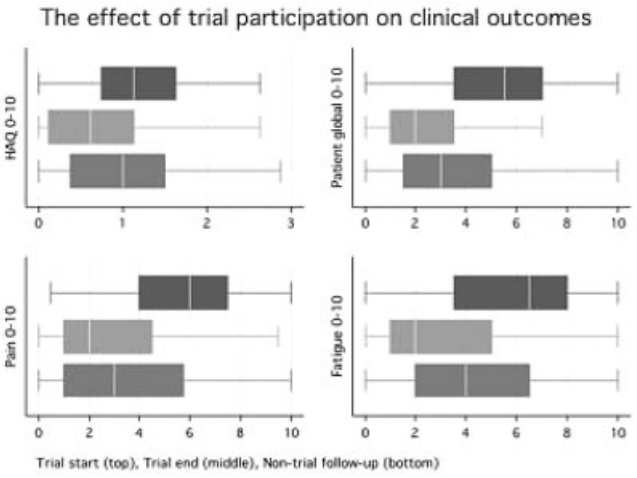
Methods: We studied 264 RA patients who completed a commercially sponsored 3-month, open label, phase 4 trial of a Food and Drug Administration approved RA treatment. We evaluated changes in the Health Assessment Questionnaire disability index (HAQ) and VAS scales for pain, patient global, and fatigue during three periods: Pretreatment in the trial, on treatment at the close of the trial, and by a trial-unrelated survey 8 months after the close of the trial, but while the patients were receiving the same treatment. The study forms were the same for the trial and post-trial assessments.

Results: The HAQ score (0–3) improved by 41.3% during the trial, but only by 16.5% when the end point was the post-trial result. Similar results for the other variables were patient global (0–10): 51.9% and 34.6%; pain (0–10) 51.7% and 39.7%; fatigue (0–10) 45.6% and 24.6%. Worsening between the trial end and the first survey assessment was: HAQ 0.29 units, pain 0.8 units, global 0.8 units, and fatigue 1.1 units. These values are documented in Table 1 and Figure 1.

Changes in Study Variables According to Study Time and Setting.

	Trial Start	*Trial end*		*Post-trial follow-up*	
Variable	Mean (SD)	Mean (SD)	Positive ES (95% CI)	Mean (SD)	Negative ES (95% CI)
ACR20 (%)		63.1			
ACR50 (%)		43.4			
ACR70 (%)		20.2			
HAQ (0–3)	1.21 (0.60)	0.71 (0.61)	0.83 (0.72, 0.95)	1.01 (0.71)	0.44 (0.60, 0.26)
Global (0–10)	5.2 (2.3)	2.5 (2.1)	1.22 (1.07, 1.38)	3.4 (2.5)	0.38 (0.49, 0.25)
Pain (0–10)	5.8 (2.3)	2.8 (2.4)	1.29 (1.12, 1.45)	3.5 (2.7)	0.30 (0.41, 0.19)
Fatigue (0–10)	5.7 (2.7)	3.1 (2.7)	0.93 (0.78, 1.09)	4.3 (2.9)	0.41 (0.54, 0.27)

Trial start: pre-treatment; trial end (6 months later); Post-trial follow-up (0.8 years later).
Differences between trial end and trial follow-up are significant at $p < 0.001$.
Positive=clinical improvement, negative=clinical worsening.
ES=Effect Size



Conclusions: Almost half of the improvement noted in the clinical trial HAQ score disappeared on entry to a non-sponsored follow-up study, and from 23%-44% of improvements in pain, patient global, and fatigue also disappeared. These changes can be attributed to the Hawthorne effect. The difference between the clinical trial HAQ and the community (clinic) HAQ is important because HAQ values are commonly used to map to utility scores and then in the calculation of cost effectiveness. If clinical trial results overstate HAQ scores, then the true effectiveness—the real functional status — is overstated. Based on our data, we hypothesize that the absolute values of RA outcome variables in clinical trials are upwardly biased, and that that treatment effect is less than observed. Our results suggest that 3rd party (non-sponsored) follow-up studies, removed from the trial assessment, can and should be used to estimate actual clinical improvement.

The Relationship of Serum Cytokine Levels with Disease Activity Parameters and Ultrasonographic Findings in RA Patients before and after Treatment with TNF Antagonists. Nevsun Inanc[2], Atilla Bulur[2], Meryem Can[2], Onder Ergonul[1], Pamir Atagunduz[2], Sule Yavuz[2] and Haner Direskeneli[2]. [1]Marmara University Medical School, Department of Infectious Diseases, [2]Marmara University Medical School, Division of Rheumatology

Background: Although effective in most patients, response to TNF antagonists is heterogenous and unpredictable in rheumatoid arthritis (RA). Bio-markers like serum cytokine levels or imaging methods like ultrasonography (US) might be helpful in predicting response to treatment with TNF-antagonists.

Methods: Levels of IL1, IL1Ra, IL6, MCP, TNF, VEGF, IFN gamma, IL10, IL12, IL13 were measured by a Luminex multiplex technology, VEGF-R1 and ANG-1 by quantitative sandwich ELISA in 26 RA patients (72 samples) before and after TNF antagonist therapy at 3 and 6 months. Tender and swollen joint counts, ESR, CRP, DAS28, patient and physician's global assessment were recorded at each visit. US evaluation included GrayScale (0–3)(GS) and PowerDoppler (0–3)(PD) semiquantitative examination with a My Lab 70 XVG (Esaote Biomedica, Italy) equipped with 6–18 and 3–9 broad band linear transducer in 28 joints to calculate total GS and PD scores.

Results: Mean (SD) age was 49(11) and disease duration 9.7(6.2) years. Mean DAS28(SD) score was 5.3(0.6) at baseline and 3.3(1.3) at 6 months' follow-up. The number of patients in remission was 2(8%) at 3 months and 9(35%) at 6 months' visit, respectively. Although levels of all selected cytokines decreased at 6 months' visit, only the changes at levels of MCP ($p=0.009$), IL10 ($p=0.005$) and IFNgamma ($p=0.005$) reached statistical significance. IL6 levels correlated with DAS28 at all visits ($r=0.334$, $p=0.003$). The baseline levels of VEGF, TNFalpha, IL6 and IL12 were found to be predictors of remission at 6 months according to DAS28 with an AUROC of 0.64 (95% confidence interval (CI) 0.4–0.9), 0.58 (95% CI: 0.4–0.8), 0.59 (95% CI: 0.4–0.8), 0.58 (95% CI: 0.3–0.8) respectively. Total GS score decreased significantly at both 3 (12.3 ± 7.2)($p<0.001$) and 6 months' visits (9.9 ± 6.6)($p<0.001$) compared to the baseline visit (21.2 ± 15.3). Similarly total PD score changes at both 3 (7.5 ± 4.4)($p=0.001$) and 6 months' visits (5.9 ± 4.1) ($p<0.001$) differed significantly from the baseline (16.7 ± 13.5). Total GS ($r=0.402$, $p<0.001$) and PD (0.455 $p<0.001$) scores correlated with DAS28 in all visits. However, only the levels of IL6 correlated with total GS ($r=0.544$, $p=0.009$) and total PD scores ($r=0.523$, $p=0.006$) among the selected biomarkers.

Conclusion: US findings and DAS28 correlated in all visits in our study, suggesting that both clinical and imaging follow-up is useful in monitoring RA patients before and after taking TNF antagonists. Although MCP, IFNgamma and IL10 serum levels decreased significantly at 6 months, IL6 seem to be the best cytokine for follow-up, correlating both with DAS28 and US findings. Baseline levels of VEGF, TNFalpha, IL6 and IL12 might also be appropriate for the prediction of remission during TNF antagonists.

Therapeutic Potential of Human Umbilical Cord Mesenchymal Stem Cells in the Treatment of Rheumatoid Arthritis. Yanying Liu, Rong Mu, Shiyao Wang and Zhanguo Li. Peking University People's Hospital

Introduction: Rheumatoid arthritis (RA) is a T-cell-mediated systematic autoimmune disease, characterized by synovium inflammation and articular destruction. Bone marrow mesenchymal stem cells could be effective in the treatment of several autoimmune diseases. However, there has been thus far no report on umbilical cord (UC)-MSCs in the treatment of RA. Here, potent immunosuppressive effects of human UC-MSCs in RA were evaluated.

Methods: The effects of UC-MSCs on responses of FLSs and T cells in RA patients were explored. The possible molecular mechanism mediating this immunosuppressive effect of UC-MSCs was explored by addition of inhibitors to indoleamine 2,3-dioxygenase (IDO), Nitric oxide (NO), prostaglandin E2 (PGE2), transforming growth factorβ1 (TGF-β1) and interleukin 10 (IL-10). The therapeutic effects of systemic infusion of human UC-MSCs in collagen-induced arthritis (CIA) in mice model were explored.

Results: In vitro, UC-MSCs were capable of inhibiting proliferation of FLSs from RA patients, via IL-10, IDO and TGF-β1. Furthermore, the invasive behavior and IL-6 secretion of FLSs were also significantly suppressed. Albeit inducing hyporesponsiveness of T cells mediated by PGE2, TGF-β1 and NO, UC-MSCs could promote the expansion of $CD4^+$ $Foxp3^+$ regulatory T cells from RA patients. More importantly, systemic infusion of human UC-MSCs reduced the severity of CIA in mice model. Consistently, there were reduced levels of proinflammatory cytokines and chemokines (TNF-α, IL-6 and MCP-1) and increased levels of the anti-inflammatory/regulatory cytokine (IL-10) in sera of UC-MSCs treated mice. Moreover, such treatment shifted Th1/Th2 type responses and induced Tregs in CIA.

Conclusions: In conclusion, human UC-MSCs suppressed the various inflammatory effects of FLSs and T cells of RA in vitro, and attenuated the development of CIA in vivo, strongly suggesting that UC-MSCs might be a therapeutic strategy in RA.

TRA-8 (CS-1008), a Novel Anti-Arthritic Biologic Agent That Targets Macrophages with Low Toxicity. Jun Li[1], Hui-Chen Hsu[2], PingAr Yang[2], Qi Wu[2] and John D. Mountz[1]. [1]Division of Clinical Immunology and Rheumatology, Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, [2]Division of Clinical Immunology and Rheumatology, Department of Medicine, University of Alabama at Birmingham, Birmingham, AL

Background: Macrophages contribute to joint inflammation and destruction in both the acute and chronic phases of rheumatoid arthritis (RA). However, biologic agents that can selectively eliminate pathogenic macrophages in RA have not been identified. Death receptor 5 (DR5) is a pro-apoptotic protein, which mediates apoptosis upon binding to a novel anti-human DR5 antibody, TRA-8 (humanized, CS-1008). We have found that macrophages isolated from both synovium and peripheral blood of RA patients express DR5 and are susceptible to TRA-8 mediated killing. The purpose of this study is to use a humanized DR5 transgenic mouse to evaluate the therapeutic efficacy of TRA-8 by eliminating pathogenic macrophages in a chicken collagen II (CII)-induced arthritis (CIA) model.

Methods: A chimeric human/mouse DR5 transgenic mouse was generated using a 3kb mouse promoter/*Floxed* STOP/humanized mouse DR5 construct in which the extracellular domain of mouse DR5 was replaced by the human counterpart. Macrophages specific expression of chimeric DR5 is achieved by crossing the DR5 mice with lysozyme M-Cre mice. Arthritis was induced by AdIL-17 at day −2 plus intradermal injection of CII in CFA/IFA on day 0 and day 30. TRA-8 (0.2 mg per mouse) was administrated I.V. every 3–7 days starting on day 0 (early treatment) or on day 30 (late treatment) until mice were sacrificed 3 months after the primary CII injection. Enumeration of macrophages before and after CII injection was determined by FACS analysis. *In vivo* joint macrophage activity was quantitated using an infrared cathespin B *in vivo* imaging analysis. Clinical scoring and histologic assessments were performed to evaluate the severity of arthritis.

Results: There was a higher percentage of $CD11b^+$ macrophages in the spleen of CII immunized mice (12.08%) compared to naïve mice (2.5%). Chimeric DR5 is highly expressed on $CD11b^+$ macrophage. TRA-8 treatment resulted in 60% and 48% reduction of $CD11b^{high}$ activated macrophages isolated from the spleen for early and late TRA-8 treatment, respectively. For both early and late TRA-8 treatments, joint histopathology showed a significantly decreased severity of inflammatory cell infiltration, synovial hyperplasia, cartilage damage, and bone erosion. Immunohistochemistry staining further demonstrated a dramatically reduced $Mac\text{-}3^+$ macrophages in the synovium after TRA-8 treatment. *In vivo* live imaging of joints revealed that there was a significantly decreased macrophage activation-induced cathepsin B activity in chimeric DR5 Tg mice that received TRA-8 treatment. The arthritis clinical scores were highly correlated with the abundance of macrophages in synovium and spleen. Neither systematic toxicities nor increased incidences of infections and malignancies were found in TRA-8 treated DR5 Tg mice.

Summary: This study demonstrated that TRA-8 (CS-1008) is a novel anti-arthritic biologic agent with high safety. Importantly, since the DR5 molecule is expressed on macrophages, our results suggest that TRA-8 can be developed into a novel therapy to either prevent the onset or suppress established arthritis via elimination of macrophages.

Treat-To-Target for the Management of Rheumatoid Arthritis: A Validation Using Patient Reported Outcomes Data from Two Phase III Clinical Trials of Golimumab. Ed C. Keystone[6], Roy M. Fleischmann[4], Chenglong Han[3], Paul Emery[2], Mark C. Genovese[5], Timothy Gathany[3], Elizabeth C. Hsia[1] and Mahboob U. Rahman[1]. [1]Centocor Research and Development, Inc./Univ. of Pennsylvania School of Medicine, Malvern, PA, [2]Chapel Allerton Hospital, Leeds, United Kingdom, [3]Johnson and Johnson Pharmaceutical Services, LLC, [4]Rheumatology Associates, Dallas, TX, [5]Stanford University, Sunnyvale, CA, [6]University of Toronto, Toronto, ON, Canada

Objectives: To assess the impact of disease remission, a treatment target in the management of rheumatoid arthritis (RA) recommended by the International Task Force, on patient reported outcomes [1].

Methods: The efficacy and safety of golimumab (GLM) were assessed in methotrexate (MTX)-naïve RA patients (GO-BEFORE, N=637), and RA patients with inadequate response to MTX (GO-FORWARD, N=444). In both trials, patients with active RA were randomly assigned to placebo (PBO) +MTX, GLM 100mg+PBO, or GLM (50 or 100mg) +MTX, q 4 weeks. Clinical remission was defined as DAS28 (ESR) <2.6. Patient reported outcomes included physical function, quality of life, fatigue, pain and work productivity as measured using instruments of Health Assessment Questionnaire (HAQ), 36-item short-form health survey (SF36 PCS and MCS), Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), Pain Severity Score of Brief Pain Inventory (BPI-Pain) and a visual analogue scale of daily work productivity. An ANOVA on van der Waerden normal scores or Chi-square test were performed for between-group comparisons.

Results: At week 24, a greater proportion of patients treated with GLM+MTX achieved DAS28<2.6 compared to patients treated with PBO+MTX (22.3% vs. 11.3% in GO- BEFORE, and 21.4% vs. 6.0% in GO-FORWARD, all $p<0.01$). GLM+MTX treated-patients had a greater improvement in patient reported outcomes than patients treated with PBO+MTX. The overall distribution of SF36-PCS shifted significantly towards a distribution observed in the normal population at week 24 through 104. Compared to patients without remission, more patients in remission at week 24 achieved a normal physical function (HAQ$\leq$0.5) (75.3% vs. 27.3%), a SF-36 PCS$\geq$50 (median value of general population) (48.3%, vs. 7.6%) and a SF-36 MCS$\geq$50 (median value of general population) (66.3% vs. 40.3%), regained employability (43.5% vs. 27.6%) and achieved significant improvement in work productivity (80% vs. 28.3%) from baseline (all p-values<0.01). Greater improvements (median) in FACIT-Fatigue (week 24: 12.0 vs. 4.0) and in BPI-Pain score (week 14: 2.1 vs. 0.8) were observed among patients in remission than patients without remission.

Conclusion: This analysis indicates that controlling disease activity in patients with RA is crucial to regaining a normal life. Thus DAS28 remission may be a reasonable target in the management of RA.

Validation of an Algorithm Using Genome-Wide SNP Analysis for Prediction of Responders, Non-Responders, and Adverse Events of Tocilizumab-Treated RA Patients Using Two Population Samples from Multiple Medical Cohorts. Tsukasa Matsubara[5], Satoru Koyano[10], Keiko Funahashi[10], Takafumi Hagiwara[6], Takako Miura[5], Kosuke Okuda[5], Akira Sagawa[11], Takeo Sakurai[2], Hiroaki Matsuno[7], Tomomaro Izumihara[3], Eisuke Shono[12], Kou Katayama[4], Toyomitsu Tsuchida[13], Mitsuhiro Iwahashi[1], Tomomi Tsuru[9] and Motohiro Oribe[8]. [1]Higashi-hiroshima Memorial Hospital, Higashihiroshima, Japan, [2]Inoue Hospital, Takasaki, Japan, [3]Izumihara Rheumatic and Medical Clinic, Kagoshima, Japan, [4]Katayama Orthopedic Reumatology Clonic, Asahikawa, Japan, [5]Matsubara Mayflower Hospital, Kato, Japan, [6]Matsubara Mayflower Hospital, Kato, Japan, [7]Matsuno Clinic for Rheumatic Diseases, Toyama, Japan, [8]Oribe Rheumatism and Internal Medicine Clinic, Oita, Japan, [9]PS Clinic, Fukuoka, Japan, [10]Research Institute of Joint Diseases, Kobe, Japan, [11]Sagawa Akira Rheumatology Clinic, Sapporo, Japan, [12]Shono Rheumatology Clinic, Fukuoka, Japan, [13]Tsuchida Clinic, Chiba, Japan

Purpose: Tocilizumab, a human anti-IL-6 receptor antibody, is an effective biologic agent for inflammatory diseases such as RA. However, there is no method for prediction of responders, non-responders, and adverse events which can occur during the treatment. We established and validated an SNP algorithm for prediction of responders or non-responders, and adverse events among tocilizumab-treated RA patients by using multiple medical cohorts.

Patients and Methods: Samples were obtained from RA patients who failed to the treatment with DMARDs including MTX. The first population sample included 106 RA patients and the second included 93 patients: a total of 199 patients from 11 hospitals in different regions of Japan. The efficacy was determined by Clinical Disease Activity Index (CDAI) within 24–30 weeks after the initial treatment. The efficacy of tocilizumab was judged by the scores of CDAI (remission and low disease activity group—'responders', moderate and high disease activity group—'non-responders'). Adverse events such as leukopenia, high total cholesterol, fever, and skin manifestations were documented. Genome-wide SNP genotyping was performed by Illumina HumanHap300K chip technology. Case-control analyses between 277,141 SNPs and responsiveness or occurrence of adverse events were examined by Fisher's exact tests. We selected 10 SNPs associated with tocilizumab-responsiveness, or adverse events which were common in analyses of both the first and second population ($p < 0.02$). We then scored the relationship between each SNP and responsiveness, the estimated total score of 10 SNPs (estimated scoring in each SNP was as follows: homo allele in the majority in responders: +1 point, hetero allele: 0 point, and homo allele in the majority of non-responders: −1 point), and examined relationships between responders and non-responders, or occurrence of adverse events plus or minus, and the total score.

Results: Accuracy ((true positive+true negative)/total), specificity (true negative/(false positive+true negative)) and sensitivity (true positive/(true positive+false negative)) of the algorithm for responsiveness of tocilizumab ranged from 87–92%. For adverse events, accuracy, specificity and sensitivity of the algorithm ranged from 85–91%. It is therefore suggested that the SNP algorithm can predict responders and adverse events prior to the initiation of treatment with tocilizumab.

Conclusion: This highly accurate algorithm using SNP analysis may be useful in the prediction of responsiveness and adverse events before treatment with tocilizumab, and in this way can contribute to future tailor-made treatment with biologic agents.

1α,25-Dihydroxyvitamin D3 Suppresses Differentiation, Maturation and Activation of Dendritic Cells from Patients with Systemic Lupus Erythematosus. Hai Jing Wu, Chak Sing Lau and Mo Yin Mok. The University of Hong Kong, Queen Mary Hospital, Hong Kong

Background: Dendritic cells (DC), professional antigen presenting cells, are believed to play a crucial role in the pathogenesis of systemic lupus erythematosus (SLE). 1α,25-Dihydroxyvitamin D3 (VitD3), in addition to its effect on bone metabolism, has been increasingly recognized to have immunomodulatory action.

Objective: To examine the effect of VitD3 on the differentiation, maturation and activation of DCs in SLE patients.

Method: CD14+ monocyte derived-DCs from SLE patients and age- and sex- matched controls were derived from growth medium cultured with IL-4 and GM-CSF. Mature DCs were induced by addition of lipopolysaccharide (LPS) and tumour necrosis factor-α (TNF-α) in the presence or absence of VitD3 (1×10−10 M) and/or dexamethasone (1×10−6 M). The expression of CD1a and co-stimulatory molecules was examined by flow cytometry. After stimulation of DCs with CD40L transfected cell line for 24h, the production of pro-inflammatory cytokines including IL-12 and IL-6, were measured by ELISA kits.

Results: 50 SLE patients and 32 normal controls were studied. VitD3 was found to suppress differentiation of monocytes into DCs with lower level of expression of CD1a for both controls ($p<0.05$) and SLE patients ($p<0.01$) compared to untreated condition. With or without dexamethasone, VitD3 inhibited up-regulation of maturation markers, including CD86, CD40 and CD83 ($p<0.05$), but not CD80 and HLA-DR (Table 1&2). In terms of pro-inflammatory cytokine production, stimulated and unstimulated DCs produced less IL-12p70 and IL-6 in SLE patients as well as controls under the effect of VitD3 with or without dexamethasone compared to pre-treatment DCs.

Conclusion: VitD3 is found to inhibit differentiation, maturation and activation of DCs in vitro in both SLE patients and controls and may be considered as immunomodulatory agent in the treatment of SLE.

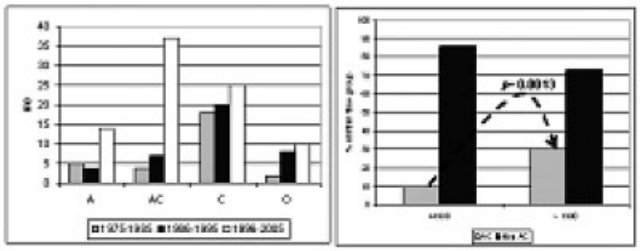
30-Year Follow-Up of Lupus Nephritis in a Single Clinic—Outcome, Serology and Ethnicity. Sara C. Croca[2], Teresa Rodrigues[1] and David A. Isenberg[3]. [1]Faculdade de Medicina de Lisboa, Laboratory of Biomathematics, Lisboa, Portugal, [2]Hospital de Santa Maria, Department of Medicine 1, Lisboa, Portugal, [3]UCL Div of Medicine, London, United Kingdom

Objectives: Although lupus nephritis (LN) represents one of the most common and potentially severe complications of systemic lupus erythematosus (SLE), there are few data on the very long-term follow up of these patients. Our aim was to characterize a LN cohort followed at a single centre for 30 years and assess its evolution over time.

Methods: Between 1975 and 2005, 156 patients were diagnosed as having LN at University College Hospital London (UCLH). We divided the cohort into 3 groups (1975–1985, 1986–1995 and 1996–2005), allowing for a minimum 5-year follow-up. The 3 groups were compared in terms of their clinical, demographic and serological characteristics, as well as disease outcome. Outcomes were defined as the 5-year mortality rate or end-stage renal disease (ESRD) development.

Results: Clinical characteristics were comparable between groups; however the proportion of Afrocaribbean (AC)-origin patients rose significantly over time accompanied by an increased prevalence of anti-ENA antibodies (ENAab). No other clinical association was found between the ENAab subgroups and ethnicity. In terms of outcome, AC-origin was associated with a poorer overall prognosis whereas no significant influence was linked to the other factors considered. The 5-year mortality rate decreased by 60% between the first and second decades and stabilised throughout the third. Disappointingly, the 5-years ESRD rate remained constant during time. An increasing number of renal transplants (RTx) was performed (n= 16, in table) with encouraging results, particularly when a living-related donor graft was used. The prognosis for the ESRD group was poorest for AC patients, with no other factors showing any influence.



Conclusions: LN is associated is a common complication of SLE associated with increased mortality and morbility, particularly among AC-origin patients. Despite encouraging results for RTX, once ESRD is established the prognosis is relatively poor and no improvement was achieved in preventing its development. Moreover, although a significant decrease in mortality was noted over the 3 decades, it has remained stable for 10 years. This result suggests that we have maximised the benefits of conventional therapies and, if further improvement is to be achieved, novel drug regimens must be considered.

A Flow Cytometric Receptor Occupancy Assay Demonstrates Dose-Dependent Blockade of B7RP-1 by AMG 557 on Circulating B Cells from SLE Subjects. Barbara A. Sullivan[1], Cherie L. Green[2], Ming Zhang[1], Christina Abbott[1], Shelley Belouski[1], John Thomas[1], Kevin Gorski[1], Gerald Siu[3], James B. Chung[1] and John Ferbas[1]. [1]Amgen, Thousand Oaks, CA, [2]Amgen, Thousand Oaks, CA, [3]GlaxoSmithKline, Stevenage, United Kingdom

Background: Assessment of RO (receptor occupancy) is useful in drug development to confirm physical target coverage and support dose selection when combined with PK modeling. We describe a B7-related protein-1 (B7RP-1, B7h, ICOSL) FACS RO assay from initial experiments in SLE mouse models to validation and application to whole blood samples from subjects treated with a fully human IgG2 anti-B7RP-1 clinical candidate (AMG 557). B7RP-1 blockade in SLE is supported by the role of ICOS: B7RP-1 engagement in germinal center formation, B cell class switch recombination and antibody affinity maturation. Establishment of a correlation of B7RP-1 occupancy and efficacy with in vivo studies, including a murine lupus model, provided a rationale for incorporation of RO in an AMG 557 clinical trial.

Methods: *Preclinical*: NZB/W F1 mice were injected with 8, 1.5, or 0.3 mg/kg of 1B7-V2, 8 mg/kg mouse IgG1 isotype control or PBS once weekly for 23 weeks. RO was measured 3 months after starting treatment and just prior to the next dose; serum anti-dsDNA antibody levels were measured by ELISA as one measure of disease at 6 months. *Clinical:* Whole blood was collected from subjects in a Phase 1a single dose-escalating study of AMG 557. A four-color flow cytometric whole blood assay was constructed and validated to measure B7RP-1 on human circulating B cells. Antibody reagents directed against B7RP-1 were generated in-house according to standard procedures in mice and rats; all other antibodies were commercially available (Becton Dickinson, Inc, Immunotech S.A.).

Results: B7RP-1 RO on circulating B cells correlated with efficacy in the NZB/NZW F1 mouse model of lupus. For the clinical assay, two monoclonal antibodies from two immunization campaigns (mouse and rat) were chosen: one that competed with AMG 557 for B7RP-1 (Ab 1.64.1) and one that did not (Ab 3.7.1). These antibodies were fluorescently labeled for use in a 4-color FACS assay. The assay was validated by initially demonstrating selective inhibition of 1.64.1 binding to B cells in vitro (by AMG 557), followed by analysis of specimen stability and biological variability from ten healthy volunteers across three sequential visits. The RO assay was next implemented in the Phase 1a single dose-escalating study of AMG 557. The RO data from the clinical trial showed a reversible, dose-dependent coverage of B7RP-1 by AMG 557 in this single dose study. Moreover, measurement of receptor levels with antibody 3.7.1 indicated a dose-dependent transient rise in total B7RP-1 on circulating B cells in the treated subjects.

Conclusions: The RO assay demonstrated coverage of B7RP-1 on circulating B cells from SLE subjects after single dose administration of AMG 557 in a dose-dependent and reversible manner. Total receptor levels on the B cells increased in association with increasing occupancy in a dose dependent manner in keeping with preclinical observations in mouse studies. The relationship of receptor occupancy and pharmacodynamic effects in mouse models provides an important consideration for interpreting the RO results from the Phase 1 study and for guiding dose selection in future clinical trials of AMG 557.

A Longitudinal Study of the Prolongation of the Corrected QT Interval in Anti-Ro/SSA Positive Adults with Systemic Lupus Erythematosus. Josiane Bourré-Tessier[3], Thao Huynh[5], Ann E. Clarke[4], Sasha R. Bernatsky[1], Lawrence Joseph[3], Patrick Belisle[3] and Christian A. Pineau[2]. [1]McGill UHC/RVH, Montreal, QC, Canada, [2]McGill Univ Health Center, Montreal, QC, Canada, [3]McGill University, [4]Montreal General Hospital, Montreal, QC, Canada, [5]Montreal General Hospital

Background: Electrocardiographic (ECG) abnormalities such as congenital heart block (CHB), bradycardia and prolongation of the corrected QT interval (QTc) are known to occur in newborns who passively acquired anti-Ro/SSA antibodies through maternal transfer. In adults, studies of the association between QTc prolongation and anti-Ro/SSA are conflicting. The goal of our study was to examine whether anti-Ro/SSA antibodies are associated with an increased risk of corrected QT (QTc) prolongation in a large systemic lupus erythematosus (SLE) cohort and to examine the stability of this relationship over a longitudinal follow-up period.

Methods: Two cross-sectional studies were conducted. Patients fulfilling ACR criteria for SLE were invited to undergo a 12-lead resting ECG between March 2002 and March 2005 in study 1, and between April 2005 and March 2006 in study 2. QTc's greater than or equal to 440msec were considered prolonged. Multivariate logistic regression models were performed to assess the association between anti-Ro/SSA and prolonged QTc. Other potentially associated factors examined included age, sex, disease duration, lupus activity (SLEDAI), damage (SLICC/ACR DI), potassium and magnesium levels and medications with the potential to prolong QTc interval (antimalarials, beta-blockers, antiarrhythmics, antibiotics, tricyclics and tetracyclics, selective serotonin reuptake inhibitors [SSRI], domperidone and human immunodeficiency virus [HIV] protease inhibitors).

Results: Study 1 included 150 subjects and study 2, 278 subjects. 118 subjects had participated in both studies, with a mean time (SD) of 505 (256) days between the 2 ECGs and of 512 (258) days between anti-Ro/SSA measurements. For these 118 subjects, most (92.4%) were female, the mean age at baseline was 45.4 years (14.2) and the mean lupus duration was 13.0 years (10.8). Mean SLEDAI was 3.3 (3.8) and median SLICC/ACR DI was 1.0 (interquartile range 0, 3). Cross-sectional analysis of prolonged QTc's on the presence of anti-Ro/SSA showed an OR (95%CI) of 12.6 (2.3–70.7) for the study 1, and of 5.1 (1.5–17.4) for the study 2. In the majority of subjects (75.4%), the anti-Ro/SSA and QTc status did not change over the observation interval. For 2 patients (1.7%), both QT and anti-Ro decreased and for one patient (0.9%), both increased. 25 patients (21.2%) changed only one of their status, and only a single participant (0.9%) had anti-Ro/SSa and QTc statuses that changed in an opposite direction (anti-Ro/SSA increased and QTc decreased).

Conclusion: The presence of anti-Ro/SSA antibodies was associated with QTc prolongation in a large SLE cohort. This cross-sectional relationship was preserved upon longitudinal follow-up. Since prolongation of the QTc is known to increase the risk of ventricular arrhythmias and sudden death, patients with anti-Ro/SSA may be exposed to a prolonged period of increased risk of cardiac events. ECG screening should be considered, so that patients

with QTc prolongation could receive appropriate counseling to avoid drugs that may put them at risk for life-threatening arrhythmias.

Allogeneic Mesenchymal Stem Cells Transplantation in Severe and Refractory Systemic Lupus Erythematosus. Lingyun Sun[1], Dandan Wang[1], Huayong Zhang[1], Jun Liang[1], Xuebing Feng[1] and Yayi Hou[2]. [1]Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, [2]Immunology Laboratory, Nanjing University Medical School

Objective: To assess the long-term efficacy and safety of allogenic bone marrow (BM) or umbilical cord (UC) mesenchymal stem cells transplantation (MSCT) for patients with severe and refractory systemic lupus erythematosus (SLE).

Methods: A single-arm trial involved 82 SLE patients, aged from 12 to 56 years old, average disease duration was 44 months. 24 patients were infused once with BM MSC, 50 patients received once UC MSC, while the other 8 patients received both MSC twicely. Allogeneic MSC were administered $\geq 1.0\times10^6$/body weight(KG)intravenously. BM MSC were aspirated from related healthy donors and expanded in vitro, and UC MSC were obtained from Stem Cell Center of Jiangsu Province of China. The clinical manifestations and laboratory parameters were compared pre- and post-MSCT, with a mean follow-up of 16.5 months (range, 3 to 36 months). Side effects were monitored all the time during and post-MSCT.

Results: Complete remission (CR) of disease activity (SLEDAI less than 3 and prednisone dose≤10mg/d) was seen in 9/41 (22%) patients 1 year post-MSCT and up to 9/16 (56%) and 3/5 (60%) at 2 and 3 years point respectively. Probability of disease relapse (DR) or unresponsive to MSCT (SLEDAI increased ≥3 and an increase in prednisone or immunosuppressive drug) was 8/41 (20%) at 1 year and 4/16 (25%) at 2 years visit. Of 5 patients completed 3 years visit, 2 of which with DR, and both were unresponsive to a second MSCT. The other 6 patients, who received second MSCT, reached to complete or partial remission. Significant improvements in SLEDAI score were examined 3 months (9.4±0.5) post-MSCT (n=82, $p<0.01$ *vs* pre-MSCT 14.0±0.6), and further decline in 1 and 2 years visit (4.9±0.4 *vs* 14.1±0.6, n=41 in 1 year, 3.6±0.6 *vs* 18.4±1.5, n=16 in 2 years, $p<0.01$). SLEDAI score <3 in 3 patients at 3 years visit. Amelioration of lupus nephritis was identified by the obvious decline of 24-hour proteinuria in 3 (1771±157mg *vs* 2799±152mg, n=64, $p<0.05$) and 6 months (1353±153mg *vs* 2584±179mg, n=31, $p<0.05$) visit, with further decline at 1 year visit (945±177mg *vs* 2045±112mg, n=20, $p<0.05$), and for 11 patients completed 2 years visit (989±289mg, $p<0.05$). Serology index showed serum albumin and complement C3 increased combined with decline of serum autoimmune antibodies. In addition, of 22 patients with moderate to severe hematological disorders, haematoglobin and/or platelet count reached to almost normal levels post-MSCT. Furthermore, 4 patients had central nervous system involvement (seizures, cerebralgia) with improvement and no relapsed post-MSCT. Significant improvements of glomerular filtration rate were found for 3 patients 12, 12, 20 months after MSCT respectively (from 65.23, 71.86, 23.45 ml/min to 94.45, 100.07, 69.82 ml/min). There was no difference in efficacy between BM and UC MSCT. Four patients died 5, 6, 6, 10 months post-MSCT respectively, due to uncontrolled infection or disease relapse. No transplant related mortality or any significant toxicity was observed and overall 3 years survival rate was 95% (78/82).

Conclusion: Allogeneic MSCT is safe and results in amelioration of disease activity. These data provide a foundation for conducting BM or UC MSCT for severe and treatment-refractory SLE.

Analysis of the Use of Rituximab in the Treatment of Lupus Nephritis. Sara C. Croca[1] and David A. Isenberg[2]. [1]Hospital de Santa Maria, Department of Medicine 1, Lisbon, Portugal, [2]UCL Div of Medicine, London, United Kingdom

Background: Lupus nephritis (LN) represents one of the most common and potentially severe complications of systemic lupus erythematosus (SLE). Classical serological markers of disease activity include the erythrocyte sedimentation rate (ESR) and the levels of anti-dsDNA antibodies and C3. Other serological markers with potential prognostic value such as the anti-ENA antibodies (ENAab) have also been studied. As traditional therapies show their limitations in achieving rapid disease control and damage prevention, novel treatment approaches have emerged. Rituximab (RTX) is an anti-CD20 monoclonal antibody that has been widely reported to be effective in treating renal disease flares. Our published data (Lu et al, Arthritis Rheum 2009) indicates that clinical benefit is related to the period of B-cell depletion. In this study we have analysed this period in detail, trying to determine if there are correlations to standard lupus tests and ethnicity.

Methods: Between July 2001 and December 2009, 40 LN patients were treated with RTX at the University College Hospital London (UCLH). A minimum follow-up of 12 months was required for this study ($n=38$). Patients were assessed at baseline and at 6 months after RTX in terms of serological and renal profile. Response to treatment was defined as an absolute CD19 count < 0.005 and values above this were considered evidence of repopulation.

Results: Following the first RTX cycle, 89.47% ($n=34$) were successfully depleted (CD19< 0.005). After 6 months, only 32.35% ($n=11$) of these remained depleted. When comparing the depleted *vs.* the repopulated group, no differences were found in terms of the classical disease activity markers (ESR, anti-dsDNA and C3). Other serological markers such as the anti-C1q antibodies, ENAab and anti-cardiolipin antibodies also showed no association with depletion status. However, analysis of the ENAab subgroups showed that anti-Sm negative patients tend to remain depleted at 6 months. The baseline proteinuria and serum creatinine level also failed to influence response. In terms of ethnicity, Afro-caribbean origin patients were more likely to have repopulated at 6 months.

Conclusions: In the last 10 years, RTX has progressively shown its potential as an effective drug in the treatment of SLE flares. However, its use in the context of LN is not as well documented. Despite the limitations imposed by the small size of our sample, a few interesting results have emerged. Renal disease background and classical disease activity markers did not predict response to treatment. Other serological markers such anti-C1q antibodies, anticardiolipine antibodies and ENAab status are also irrelevant. However, anti-Sm positive patients seem to be more likely to repopulate. In addition, AC patients tend to have higher rates of repopulation. Thus, classical serological markers are of no use in predicting response to RTX, apart from anti-Sm antibodies which may be associated with earlier repopulation. Finding predictors of response is important in order to select the patients more likely to respond and identify those with a probable shorter term response allowing for closer monitoring.

Anti-Mullerian Hormone in Systemic Lupus Erythematodes – Is Fertility Affected? Joerg C. Henes[1], Melanie Henes[4], Tanja Fehm[4], Diethelm Wallwiener[4], Lothar Kanz[2], Ina Koetter[2] and Barbara Lawrenz[3]. [1]Department for Internal Medicine II; University Hospital Tuebingen, Tuebingen, Germany, [2]Department for Internal Medicine II; University Hospital Tuebingen, Germany, [3]Department of Gynecology and Obstetrics; University Hospital of Tuebingen, Germany, [4]Department of Gynecology and Obstetrics; University Hospital Tuebingen, Germany

Introduction: Systemic lupus erythematodes (SLE) usually manifests in women during their childbearing age. Women with SLE have a lower number of births compared to healthy controls although fertility is considered not to be reduced. Anti-Mullerian hormone is expressed in granulosa cells of growing follicles, reflects the size of the primordial follicle pool and therefore is used to assess fertility potential.

Method: Serum samples of 40 patients with SLE without previous cytotoxic – especially cyclophosphamid – treatment and 40 age matched, healthy controls were collected. All patients gave written informed consent and filled out a questionnaire on menstrual irregularities, lifestyle, pregnancy outcomes and contraception. AMH was quantified using a standard ELISA with standard value 1–8μg/l; values $< 1\mu$g/l defined as reduced, $< 0{,}4\mu$g/l as severely reduced fertility. Systemic lupus erythematosus disease activity index (SLEDAI) and European Consensus Lupus Activity Measurement (ECLAM) were used for clinical disease activity assessment.

Results: Median age was 29,5 (20–39) years. Disease activity was low to moderate with a median SLEDAI of 2 (0–17) and ECLAM of 1,75 (0–5). The median AMH level was 1,7 (0,01 – 15μg/l) and thus lower compared to historic control groups with 2,1 and 2,3 (1). In 30% (12 patients) AMH level

was below 1μg/l and in 6 even < 0,4μ/l. 8 patients were pregnant at the time of sample acquisition and patients had an average of 0,55 children.

Discussion: This is the first study to examine AMH levels in women with SLE. Lupus patients seem to have a reduced ovarian reserve and a reduced period of reproduction. As cytotoxic therapy is still standard for some SLE manifestations this data has an impact on fertility preservation strategies. Ovary protection during cytotoxic treatment is even more important in SLE patients.

Belimumab, a BLyS-Specific Inhibitor, Significantly Reduced Autoantibodies, Normalized Low Complement, and Reduced Selected B-Cell Populations in Patients with Seropositive Systemic Lupus Erythematosus (SLE): The Phase 3 BLISS Studies.

W. Stohl[12], F. Hiepe[1], M. Thomas[8], M. A. Scheinberg[2], A. E. Clarke[9], C. Aranow[10], R. Jimenez[4], F. Wellborne[5], C. Abud-Mendoza[3], D. Hough[6], L. Pineda[7], T. S. Migone[7], W. Freimuth[7], W. W. Chatham[11] and on Behalf of the BLISS-52 and -76 Study Groups. [1]Charité Universitätsmedizin, Berlin, Germany, [2]Hospital Abreu Sodré Pesquisa Clínica, Sao Paulo, SP, Brazil, [3]Hospital Central y Facultad de Medicina, San Luis Potosi, Mexico, [4]Hospital G. Fricke, Vina del Mar, Vina del Mar, Chile, [5]Houston Institute for Clinical Research, Houston, TX, [6]Human Genome Sciences, Inc, Rockville, MD, [7]Human Genome Sciences, Inc, Rockville, Rockville, MD, [8]Kerala Institute of Medical Sciences, Trivandrum, India, [9]McGill University Health Centre, The Montreal General Hospital, Montreal, QC, Canada, [10]The Feinstein Institute for Medical Research, Manhasset, Manhasset, NY, [11]UAB Arthritis Clinical Intervention Program, Birmingham, AL, [12]USC Keck School of Medicine, Los Angeles, CA

Purpose: To assess the effects of belimumab on biomarkers, and B- and T-cell populations in patients with seropositive SLE.

Methods: In 2 randomized, double-blind, placebo-controlled phase 3 studies (BLISS-52, NCT00424476; and BLISS-76, NCT00410384),1684 seropositive (ANA ≥1:80 and/or anti-dsDNA ≥30 IU/mL) SLE patients with SELENA-SLEDAI ≥6 on stable standard-of-care (SOC) therapy ≥30 d received belimumab 1 or 10 mg/kg, or placebo, plus SOC, on d 0, 14, and 28, then q28d for 48 wk in BLISS-52 and 72 wk in BLISS-76. Immunoglobulin (Ig), complement (C), and autoantibodies (anti-dsDNA, ANA, anti-Sm, anti-CL, anti-ribosomal P) were evaluated. In addition, B- and T-cell subsets were evaluated in BLISS-76.

Results: Overall, belimumab treatment reduced autoimmune antibody titers and promoted conversion from antibody seropositive to seronegative status (table). More patients treated with belimumab converted from positive to negative for anti-dsDNA, anti-Sm, anti-ribosomal P, and aCL-IgG compared with placebo. Belimumab-treated patients had significantly greater increases in C3 and C4 levels with a dose response; patients receiving 10 mg/kg had significantly greater increases at every visit through wk 52 and a greater % achieved normalized levels (table). Normalization of hypergammaglobulinemia (≥16.2 g/L) occurred in significantly more patients in the 2 belimumab groups vs placebo (49.2% vs 19.7%; table). Belimumab significantly reduced various circulating B-cell subsets, but not T-cell subsets. Reductions in naïve B-cells and short-lived plasma cells ($CD20^{-}/27^{BRIGHT}$), as well as the SLE B-cell subset ($CD19^{+}/27^{BRIGHT}/38^{BRIGHT}$), were observed as early as wk 8 with the 10-mg/kg dose. Memory B-cells increased ~100% by wk 8 and gradually decreased toward baseline levels through wk 52. A modest expansion of T-cell subsets was observed at wk 52, but this is considered to be a secondary effect of the B-cell reductions.

Conclusions: In these phase 3 studies, belimumab treatment led to rapid, significant, and sustained reductions in autoantibodies, and normalization of C3, C4, and hypergammaglobulinemia compared with placebo. These findings, and the selective reduction of B-cell and short-lived plasma cell subsets, are all consistent with the mechanism of action of belimumab.

Table. Biomarker Data at Wk 52

1147

Comparison of Serum Free Light Chains, Interferon and Interleukins as Biomarkers of Disease Activity in Systemic Lupus Erythematosus (SLE).

Serene Francis[4], Rohit Aggarwal[6], Rachel Mikolaitis[4], Timothy B. Niewold[5], Susanna Chubinskaya[4], Joel A. Block[1], Winston Sequeira[2] and Meenakshi Jolly[3]. [1]Rush University Medical Center, Chicago, IL, [2]Rush University Medical Center, Chicago, IL, [3]Rush University Medical Center, Section of Rheumatology, Chicago, IL, [4]Rush University Medical Center, Section of Rheumatology, [5]University of Chicago, Section of Rheumatology, Chicago, IL, [6]University of Pittsburgh Medical Center

Background: SLE may affect any organ and is associated with significant morbidity and mortality. Other than DsDNA in the context of Lupus nephritis, studies thus far exploring a biomarker for disease flare have been equivocal. We previously reported superior utility of serum free light Chains (FLC) compared to DsDNA and IgG as biomarkers for disease activity in SLE. We also reported that Total FLC (TFLC) elevation was greater in SLE as compared to rheumatoid arthritis, and that its association with disease

activity was stronger in SLE than rheumatoid arthritis. There have been studies by other authors showing association of Interleukin-6 (IL-6), Interleukin-10 (IL-10) and Interferonα (IFN-α) with SLE disease activity. Herein, we compare the utility of total FLC with IL-6, IL-10 and IFN- α for disease activity in SLE.

Aims: To determine the association of (1)serum TFLC with IL-6, IL-10 and IFN-α (2)to compare their association of disease activity, demographic variables (age. gender and ethnicity), immunosuppressive agents and ACR criteria.

Methods: This is a cross-sectional study of 134 SLE patients (ACR criteria) recruited from a University Center from 2008–2010. PGA and SLEDAI were assessed by the same physician. Adjusted SLEDAI was calculated by deleting DsDNA and complement items from the SLEDAI. Serum was tested for TFLC (The Binding Site U.K), IL-6, IL-10 and IFN-α. Chart review was done for demographics, clinical and serological characteristics and treatment. Statistical analysis performed included correlation analysis, Mann Whitney test.

Results: Mean age of the patients was 43$\pm$12 yrs; females composed 91% of the study group; African American 50%, Caucasians 24%,Hispanic 16%. PGA (Mean$\pm$SD, Median) was 0.5$\pm$0.6, 0, while SLEDAI was 4$\pm$4, 2. Forty eight percent patients were on prednisone. The (mean$\pm$SD, median) values were: TLC (58$\pm$64, 43), IL-6 (6$\pm$7, 4), IL-10 (16$\pm$20, 13) and IFN-α (21$\pm$39, 4). TFLC was correlated with IFN-α (r=0.37, p=0.0001) and IL-6 (r=0.25, p=0.009). IFN-α correlated with IL-6 (r=0.20, p=0.05).

TFLC showed a moderate correlation with PGA (r=0.39, p=0.002), SLEDAI (r=0.35, p=0.001) and adjusted SLEDAI (r=0.34, p=0.005). IL-10 was moderately associated with adjusted SLEDAI (r=0.32, p=0.02). IL-6 weakly correlated with SLEDAI (r=0.23, p=0.04) but not with adjusted SLEDAI. IFN-α was not associated with either of them.

IFN-α correlated with age (r=0.22, p=0.02), while IL-6 correlated with height (r=0.22, p=0.04). TFLC, IFN- α and IL-6 showed correlation with ethnicity. TFLC correlated with use of prednisone (r=0.30, p=0.001) while IFN-α correlated with use of methotrexate (r=0.20, p=0.04).

Conclusion: Serum TFLC is moderately correlated with PGA and adjusted SLEDAI. Strength of TFLC association with adjusted SLEDAI is greater than observed with IL-10. Longitudinal studies to determine if changes in disease activity result in changes in TFLC are now indicated.

Coronary Calcification in SLE: Comparison with Multi-Ethnic Study of Atherosclerosis (MESA). Adnan N. Kiani[3], Wendy Post[4], Moyses Szklo[2], Joan M. Bathon[4], Laurence S. Magder[6], Russell Tracy[8], Pamela Schreiner[7], Daniel O'Leary[5] and Michelle A. Petri[1]. [1]Timonium, MD, [2]Johns Hopkins University, Department of Epidemiology, [3]Johns Hopkins University, School of Medicine, Baltimore, MD, [4]Johns Hopkins University, School of Medicine, [5]Tufts University, [6]University of Maryland, [7]University of Minnesota, [8]University of Vermont

Objectives: Women with lupus (SLE) have been demonstrated to have a marked increase in risk for myocardial infarction compared with the general population. CT coronary artery calcium (CAC) is a measure of subclinical atherosclerosis associated with risk for cardiovascular (CV) events in women with SLE. The purpose of this study was to determine whether the prevalence of CAC is higher in female SLE patients compared with the participants in the Multi-Ethnic Study of Atherosclerosis (MESA) who were free of CV events and SLE at the baseline exam.

Methods: CAC was measured in 88 female SLE patients enrolled in the Lupus Atherosclerosis Prevention Study (LAPS) and 583 female MESA controls from the Baltimore Field Center aged $\geq$ 45 years without evidence of clinical cardiovascular disease. Poisson regression with robust variance estimation was used to estimate the ratio of CAC prevalence between SLE and MESA controls, controlling for demographic and CV risk factors.

Results: Mean ages were 53.8 (SD=7.1) years (SLE) and 63.3 (SD=10.1) (MESA). 28 percent of SLE and 55 percent of controls were African-American. Sixty percent of SLE and forty seven percent of MESA controls had coronary calcification. In all age groups, SLE patients had a higher prevalence of CAC than MESA controls (Table1).

Table 1. Proportion (%) with coronary artery calcium (>0), by study group and age

Age Group	SLE Patients (n=88)	MESA Controls (n=583)
45–54	33/57 (58%)	31/144 (22%)
55–64	13/22 (59%)	52/144 (36%)
65–74	5/7 (71%)	120/211 (57%)
75+	2/2 (100%)	70/84 (83%)

After controlling for age, ethnicity, diabetes, hypertension, hyperlipidemia, smoking, education, and BMI, SLE patients had a significantly higher prevalence of CAC than controls (Prevalence Ratio 1.8 (1.5, 2.3)) (Table 2).

Table 2. Association between predictors and presence of coronary calcium based on a multivariable prevalence-ratio regression model.

Variable	Prevalence Ratio (95% CI)	P-value
SLE patients vs. MESA controls	1.8 (1.4, 2.3)	<0.0001
Age (per 10 years of life)	1.5 (1.4, 1.6)	<0.0001
Caucasian vs. NonCaucasian	1.3 (1.1, 1.5)	0.0013
Diabetes	1.2 (1.0, 1.5)	0.042
Total cholesterol >200 mg/dl	1.0 (0.9, 1.2)	0.65
Hypertension	1.2 (1.0, 1.4)	0.020
Ever smoked	1.3 (1.2, 1.5)	0.0001
BMI 25–29 vs. <25	1.0 (0.9, 1.3)	0.67
BMI 30+ vs. <25	1.1 (0.9, 1.4)	0.24

Conclusion: SLE is associated with a greater prevalence of CAC in women than MESA controls even after adjusting for traditional cardiovascular risk factors. We previously demonstrated that inflammatory markers and degree of disease activity are not associated with CAC in SLE. Future studies are needed to determine the etiology of increased subclinical atherosclerosis in this population.

Decrease in Complement (C3) Levels during Systemic Lupus Erythematosus Pregnancy Is Associated with Higher Rates of Pre-Eclampsia. Aisha Lateef[2], Laurence S. Magder[3] and Michelle A. Petri[1]. [1]Johns Hopkins Lupus Center, School of Medicine, Johns Hopkins University, Timonium, MD, [2]National University Health System, Singapore, Singapore, [3]University of Maryland Medical School, Baltimore, MD

Objective: To determine the changes in complement (C3 and C4) levels during pregnancy in women with systemic lupus erythematosus (SLE), and to evaluate the association between these changes and adverse pregnancy outcomes.

Methods We reviewed all pregnancies in a cohort of SLE patients who were observed prospectively from 1987 to 2009. Four hundred and twenty nine pregnancies were recorded in 352 women. We calculated the mean value of C3 and C4 during the first and second halves of the pregnancy. The change in C3 and C4 was evaluated by subtracting the mean C3 and C4 during the first half from the mean C3 and C4 during the second half of pregnancy. This analysis is based on 296 pregnancies, with both a first-half and second-half value of C3 and C4.

We investigated if pregnancy outcomes, including miscarriage, pre-eclampsia, gestational age, birth weight, pre-term birth and intra-uterine growth restriction(IUGR) were associated with the change in C3 and C4 levels during pregnancy.

Results: C3 levels increased (greater than 3 point rise) during the second half of pregnancy in 211 (71%), decreased (greater than 3 point drop) in 50 (17%) and remained stable in 35 (12%) of pregnancies. C4 levels increased (greater than 1 point rise) in 115 (39%), decreased (greater than 1 point drop) in 93 (31%) and remained stable in 88 (30%) of pregnancies.

Pre-eclampsia was noted in 12 out of 50 (26%) pregnancies where C3 levels decreased during pregnancy. In contrast, only 15 out of 211 (7%) pregnancies were complicated by pre-eclampsia if the C3 levels increased during pregnancy. The difference reached statistical significance (p <0.01), after adjusting for age, race, use of steroids, plaquenil and immunosuppressants. There was a trend towards lower gestational age at birth, (35.9 weeks in group with lower C3 versus 37.0 weeks with higher C3 in second half of pregnancy), but the difference was not statistically significant (p=0.16). Miscarriages, pre-term births, IUGR and birth weight were similar among the different groups (Table). No significant differences in pregnancy outcomes were noted among groups with increased or decreased C4 levels during pregnancy.

Conclusion: Complement levels generally rise during normal pregnancies. Similarly, SLE pregnancies with stable disease tend to have higher levels of complement during pregnancy. In our cohort, 71% of the pregnancies had

a rise in C3 levels, while only 17% had a decline.Decreasing C3 levels during pregnancy were predictive of a higher rate of pre-eclampsia, compared to stable or rising C3 levels. The risk of pre-eclampsia is higher in SLE pregnancies, occurring in 22–30% of pregnancies, compared to 5–7% of normal pregnancies. Earlier studies have suggested renal disease, thrombocytopenia and anti-phospholipid antibodies to be the predictors of pre-eclampsia in SLE. Our study suggests that a declining trend of C3 level is another risk factor for pre-eclampsia.

	Number (%) with the outcome, by change in C3			
Outcome	Decrease in C3 more than 3 points (n=50)	Change of 3 or fewer points (n=35)	Increase in C3 more than 3 points (n=211)	P-value
Miscarriage	3 (6%)	4 (11%)	3 (1%)	Too few
Preterm	16 (37%)	9 (28%)	70 (35%)	.34
Pre-eclampsia	12 (26%)	1 (3%)	15 (7%)	.0061
IUGR	4 (9%)	2 (6%)	13 (6%)	.82
OLIGO	6 (14%)	2 (6%)	21 (10%)	.55

Dendritic Cells and Regulatory T CD4+CD25^{Bright} in Pregnant Patients with Systemic Lupus Erythematosus. Luis J. Jara[1], Griselda Teresa Romero-Sánchez[1], Laura A. Montiel-Cervantes[1], Gabriela Medina[1], Polita Cruz-Cruz[2], Jorge Vela-Ojeda[1], Rafael Arias-Flores[1], Olga Vera-Lastra[1] and Miguel A. Saavedra Salinas[1]. [1]Hospital de Especialidades Centro Medico La Raza, IMSS, Mexico City, DF, Mexico, [2]Hospital de Gineco-Obstetricia No.3, Centro Medico La Raza, IMSS, Mexico City, DF, Mexico

Introduction: During pregnancy, dendritic cells (DC) participate in the shift from T-helper 1 (Th1) to T-helper 2 (Th2) activity. Myeloid DC induce Th1 cell differentiation, and plasmacytoid DC induce Th2 cell differentiation. On the other hand, CD4+ CD25^{bright} + FOXP3+ T regulatory cells (Treg cells) are CD4+ T cells with suppressive properties. An inadequate expression of Treg cells is associated with obstetric complications. Therefore, Treg/DC maintain maternal-fetal tolerance. However, their role in systemic lupus erythematosus (SLE) and pregnancy remains unknown.

Objective: To analyze the changes of DC and Treg cells in the peripheral blood of pregnant SLE patients in comparison with normal pregnancy. To correlate these alterations with clinical activity and maternal-fetal complications of SLE patients.

Material and Methods: Fifty pregnant, 25 with SLE (mean age 26.6+−6 years), and 25 pregnant healthy as controls (mean age 27.8+−5 years) were enrolled in the study. The majority of SLE patients were treated with low doses of prednisone (96%) and chloroquine (68 %). Mononuclear cells of peripheral blood were obtained during pregnancy (each trimester) and postpartum. The subtypes of DC and Treg cells from whole blood samples were analyzed as previously described. A total of 100 microlitres of whole blood was incubated with 20 microlitres of monoclonal specific antibodies: For DC Lin1-FITC, CD123-PE, HLADR-PERCP, CD11C-APC for determination of CD1(Myeloid DC), and CD2 (plasmacytoid DC). For Treg: FoxP3, CD4 PerPC, CD25 APC. The antibodies and cells were incubated for 25 min at room temperature in a dark room. Labeled cells were analyzed with the program Cell Quest pro, using FACSCalibur BD flow cytometer. We used SLAM-M modified to measured SLE activity during pregnancy. Statistic analysis: Mann-Whitney U test, Spearman correlation, and logistic regression.

Results: Fetal loss (2), pre-eclampsia (2), and abortion (2) were observed in SLE patients. No maternal-fetal complications were observed in controls. During pregnancy, decrease tendencies of percentages of CD1, and Treg were observed in SLE patients vs controls: CD1, 35.2+−42 vs 58.3+ −44 ($p<0.06$), and Treg, 53.9+ −56 vs 89.8+ −133 ($p<0.2$), with a significant decrease of CD2, 9.9+−8 vs 26.6+−25 ($p< 0.003$), respectively. In postpartum, a significant decrease of CD1 was observed in SLE patients: pregnancy SLE, 40.2+−35 vs postpartum SLE, 17.7+−17 ($p< 0.05$) without significant differences in CD2 and Treg. A direct correlation between CD1 and CD2 ($r=0.58$, $p< 0.001$), CD1 and Treg ($r=0.65$, $p< 0.0001$), and CD2 and Treg ($r= 0.27$, $p<0.05$) was found in SLE patients. In normal controls we did not observed a correlation among subpopulations of CD, and Treg. We did not observe a direct correlation among CD1, CD2, and Treg with SLAM-M in SLE patients.

Conclusions: The significant decrease of CD2 during pregnancy, and CD1 in postpartum of SLE patients, with positive correlation among CD1, CD2, and Treg without correlations with SLE activity may reflect the immunological and subclinical activity of SLE. These alterations may be associated with maternal-fetal complications observed in these patients despite of treatment.

Distinctions in the ISN/RPS 2003 Subclasses of Class IV Lupus Nephritis. Suhail Hameed[2], Kun Chen[2], Surya Seshan[3] and Michael D. Lockshin[1]. [1]Hosp for Spec Surgery, Cornell, New York, NY, [2]Hospital for Special Surgery, Cornell, New York, NY, [3]Weill Cornell Medical Center

Purpose: We hypothesized that the ISN/RPS 2003 classification subclasses of Class IV Lupus Nephritis (LN) better correlate with respect to clinical, morphological and prognostic distinctions. The distinction between the subclass IV-Segmental (IV-S) and IV-Global (IV-G) has been the subject of a few prior studies without a consensus in conclusions. Whether this distinction between IV-S and IV-G will be retained in future iterations of ISN/RPS classification will depend on how distinct these subclasses prove to be.

Methods: This is a single institution retrospective study comparing the ISN/RPS 2003 Class IV LN subclasses. 95 SLE patients who had biopsy diagnosed Class IV LN from 1990 to 2007 and had clinical follow-up at our institutions were included.

All renal biopsies were reclassified according to the ISN/RPS 2003 LN classification by a single renal pathologist. Relevant clinical data was collected from the medical records of the subjects. The investigators were blinded to the histopathologic and clinical data of the subjects until all data collection was complete. A comparison of IV-S and IV-G with respect to clinical, morphological and pre-defined outcome measures was made. Independent samples t-test for means, Fischer's exact test and Kaplan-Meier survival curves were performed for statistical analysis.

Results: Out of the 95 Class IV LN patients, there were 58 G (61%) and 37 S (39%). Overall, there were 82.8% females and 17.2% males with 16.7% Caucasians, 30.8% African Americans, 34.6% Hispanics and 17.9% Asians. 53.7% had Medicaid and 46.3% had private medical insurance.

The mean duration of follow-up since renal biopsy was 93.79 months and mean duration of SLE at diagnosis of lupus nephritis was 50.30 months. The mean age at diagnosis of SLE was 22.13 years and mean age at diagnosis of LN was 26.42 years. Significant clinical and histopathologic distinctions in ISN/RPS 2003 subclasses of Class IV LN were noted as shown in figure 1.

Figure 1. Shows significant clinical and histopathologic distinctions in ISN/RPS 2003 Subclasses of Class IV LN

Clinical Distinctions	ISN/RPS 2003 Class IV LN Subclass		
Mean baseline clinical characteristics	Segmental	Global	p-value
Hematocrit (%)	31.90	29.59	0.057
Lymphocyte (%)	13.12	20.59	0.001
Neutrophil (%)	79.93	71.20	0.001
Serum abumin (G/dl)	2.72	2.49	0.034
Urine protein (gm/24hr)	3.44	4.78	0.055
C3 (mg/dL)	62.26	47.42	0.003

Histopathologic Distinctions	ISN/RPS 2003 Class IV LN Subclass		
Histopathologic characteristics (% Present)	Segmental	Global	p-value
Segmental Cellular Proliferation	91.9	6.9	<0.001
Global Cellular Proliferation	2.7	94.8	<0.001
Segmental Glomerulosclerosis	45.9	13.8	0.001
Global Glomerulosclerosis	45.9	29.3	0.099
Fibrous Crescerts	43.2	22.4	0.032
Interstitial Fibrosis	64.9	43.1	0.038
Tubular Atrophy	67.6	50.0	0.092
Wire Loops	27.0	81.0	<0.001
Hyaline Thrombi	2.7	41.4	<0.001

Activity and Chronicity Distinctions	ISN/RPS 2003 Class IV LN Subclass		
Mean Activity and Chronicity Indices Scores	Segmental	Global	p-value
Activity Index	8.22	10.55	0.004
Chronicity Index	3.43	1.83	0.001

Subclass G had hypocomplementemia, hypoalbuminemia, increased proteinuria, hyaline thrombi, wire loops and higher activity index, implying an immune complex etiopathogenesis. Subclass S had higher hematocrit, relative lymphopenia and neutrophilia, higher chronicity, glomerulosclerosis and fibrosis suggesting more of a pauci-immune and relapsing process. Subclasses S and G had similar outcomes and there was no statistically significant difference in any of the pre-defined outcome measures including remission, relapse, doubling of serum creatinine, ESRD and death.

Conclusion: S and G are clinically and morphologically distinct subclasses of Class IV LN suggesting different underlying pathogenetic mechanisms. Currently the 2003 ISN/RPS classification does not distinguish the prognosis of subclass S from G. Therapeutic advances targeting the different pathogenetic mechanisms for these subclasses, might yield a change in their prognosis.

Does Smoking Influence Disease Manifestations and Disease Severity in Systemic Lupus Erythematosus? Nayef Al Ghanim[2], Aqeel Ghanem[2], Ebrahim Nahar[1], John M. Esdaile[2] and Diane Lacaille[2]. [1]Mubarak Al Kabeer Hospital, Vancouver, BC, Canada, [2]University of British Columbia, Vancouver, BC, Canada

Objective: Several studies have established that smoking is a risk factor for Systemic Lupus Erythematous (SLE). However, few studies have evaluated whether smoking influences disease manifestations or disease activity and severity.

The objective of our study was to evaluate whether smoking is associated with differences in pattern of organ involvement and with greater disease severity, as measured by the SLICC.

Method: A retrospective medical chart review was conducted between 2002 and 2005 of all SLE patients seen since 1990 from eight rheumatology practices. All patients included met the 1982 ACR criteria for SLE. Data were extracted on: demographics, SLE duration, SLE treatment, SLICC, and organ involvement using predefined criteria derived from the SLAM, and current smoking status at baseline (ie time of first rheumatologist visit). Smokers and non-smokers were compared using Chi-square for categorical variables and Student t-test for continuous variables. To take into account the multiple comparisons tested, we considered $p < 0.01$ as statistically significant. SLICC score, because of its skewed distribution, was analyzed as a binary variable with a cut off of 2 (i.e. values of 0 or 1 vs. values of 2 or greater). Multivariable binary logistic regression analysis was performed with SLICC score as the dependent variable, controlling for SLE duration, age, gender, and ethnicity.

Results: Our sample included 306 patients, 52 were smokers and 254 non-smokers (92% women, mean (SD) age 43.3 (12.9) years, disease duration 12.2 (8.8) years). No significant differences were observed in the pattern of organ involvement between smokers and non-smokers (Table 1). A trend was observed with smokers having increased frequency of antiphospholipid syndrome (APLS) compared to non-smokers (31.4% vs 16.9%, respectively. $p = 0.03$). However, it did not reach statistical significance at the preselected level of $p < 0.01$. No difference was observed in the medications received for SLE, such as glucocorticosteroids or immunosuppressant medications (data not shown). After adjusting for age, gender, disease duration and ethnicity, the likelihood of severe disease, as measured by SLICC >= 2, was not increased in smokers compared to non-smokers (OR: 1.18, 95% CI: 0.56–2.46).

Conclusion: In our sample of SLE patients, there was no association between smoking and the pattern of organ involvement or disease severity measured by SLICC.

Organ involvement	Non - smokers (n=254)	Smokers (n=52)	p value
Mucocutaneous	216 (85%)	47 (92%)	0.26
MSK	228 (90%)	46 (90%)	1
Renal	89 (36%)	12 (25%)	0.13
CNS	140 (55%)	30 (59%)	0.64
Hematological	220 (87%)	38 (75%)	0.03
APLS	43 (17%)	16 (31%)	0.03
Pulmonary	85 (34%)	23 (45%)	0.14
Cardiac	52 (21%)	8 (16%)	0.56
GI	8 (3%)	1 (2%)	1

Abbreviations: MSK: Musculoskeletal; CNS: Central Nervous System; APLS: Antiphospholipid syndrome; GI: Gastrointestinal

Early Treatment with Rituximab (RTX) in Newly Diagnosed Systemic Lupus Erythematosus (SLE) Patients: A Steroid Sparing Regimen. Amara N. Ezeonyeji[2] and David A. Isenberg[1]. [1]UCL Div of Medicine, Room 331, 3rd Floor, London, United Kingdom, [2]University College London Hospital NHS Trust, London, United Kingdom

Introduction: The efficacy of a RTX as induction therapy enabling long-term steroid therapy reduction or withdrawal has recently been reported in patients with lupus nephritis by Pepper et al.[1] We describe a RTX/Azathiaprine (AZA) based steroid sparing regimen given in 9 newly diagnosed mostly non-renal patients with SLE.

Patients and Methods: Nine female patients fulfilling at least 4 of the revised ACR criteria for the diagnosis of SLE were treated. Mean age at time of B cell depletion therapy was 39 years, Mean duration of symptoms prior to treatment was 16.5 months (range 4–96). Eight were treated with two intra-venous (iv) infusions of RTX (1000mg) and methylprednsiolone (2 × 100mg) and one iv 750mg infusion of cyclophosphamide (CYC). One patient received 375mg/m^2 equivalence RTX over 3 weeks with CYC. Post treatment all patients received AZA and any steroid treatment rapidly weaned [table 1]. The British Isles Lupus Assessment Group (BILAG) disease activity index was used for both individual organ system assessment and as a global index. The patients full blood count, serum creatinine (Cr), serum C3, immunoglobulin G (IgG), erythrocyte sedimentation rate (ESR), anti-dsDNA and circulating B lymphocytes (CD19+) count were tested at baseline, 1, 3, 6 and 12 months post treatment.

Table 1. Patient characteristics: prednisolone; pred, weeks; wks

Patient	Disease manifestation at baseline	Therapy pre-RTX	Therapy post-RTX
1	Headache, rash, pleurisy, proteinuria	Pred 30 mg ↓ over 8 weeks for flare	Pred 40 mg ↓ over 4 wks
2	Rash, lymphadenopathy, angioedema, fevers, ↑ anti-dsDNA, lymphopenia, ↓ C3	Depomedrone 120mg i.m.	Pred 20mg ↓ over 8 wks at 2 months for flare
3	Rash, headache, alopecia, aicca symptoms, ↓ C3, lymphopenia,	None	None
4*	Rash, headache, thrombocytopenia, anaemia, proteinuria ↑ anti-dsDNA, lymphopenia, ↓ C3	AZA (stopped) & Pred 2.5 mg Pred 30mg ↓ over 2 wks for thrombocytopenia	Pred 60mg ↓ over 8 wks
5	Rash, livido reticularis, serositis, oral ulcers, proteinuria, ↑ anti-dsDNA, lymphopenia, ↓ C3.	Pred 40mg stat	Pred 40mg ↓ over 12 wks AZA
6	Polyarthritis, ↑ anti-dsDNA, lymphopenia, ↓ C3	Pred 7.5mg for 2 wks	AZA
7	Skin rash, raynauds, alopecia, pleurisy, ↑ anti-dsDNA, lymphopenia.	Pred 7.5mg for 12 wks	AZA
8	Rash, alopecia, raynands, arthralgia, ↓ C3	None	AZA
9	Polyarthritis, ↑ anti-dsDNA, lymphopenia	AZA for colitis	AZA

Results: All patients achieved B cell depletion (CD 19 < 0.005 $\times 10^9$/l. at 1 month). Patient 3 re-populated at 6 months but did not flare. The mean BILAG global score fell from 12.1 (SD 8.6) (n=9) at baseline to 7.4 (SD 4.7) (n=7) at 1 month, 3.9 (SD 2.3) (n=7) at 3 months, 3.5(SD 1.3) (n=4) at 6 months, and 1.5 (SD 0.7) (n=2) at 1 year. Patients 7 achieved improvement of BILAG grades A→D for mucocutaneous manifestations by 3 months and patient 2 and 8 by one year although patient 2 had a musculoskeletal flare at 2 months requiring steroid treatment. No patient developed any major sustained deterioration i.e. new A or D→B scores. Manifestations such as rash, arthritis, fever, thrombocytopenia and pleurisy responded well. Mean ESR fell from 76 to 32.9 at 1 month (n=9). Anti-dsDNA antibody levels fell by >50% in 3 patients. Serum C3 level did not change significantly except for patient 7 where it rose from 0.4 to 1.04 (NR 0.8 to 1.8g/l) by 3 months. Cr was stable throughout. In patient 1 and 5, urine protein: creatinine ratio (PCR) was stable at 6 and 3 months respectively although patient 5 required a renal biopsy as the PCR was 236 mg/mmol at 3 months. PCR fell from 104 to 15 mg/mmol by 1 month in patient 4. Mean total serum IgG fell modestly from 20.3 to 13.8 g/l.

Adverse Events: Treatment was safe and well tolerated. There were no adverse events on follow up.

Conclusions: A RTX/AZA protocol as a steroid sparing regimen is safe and effective in newly diagnosed patients with SLE.

Evidence of Peripheral B Cell Depletion in Subjects with Controlled Systemic Lupus Erythematosus (SLE) Following Subcutaneous Administration of SBI-087. Roy M. Fleischmann[3], Stanley B. Cohen[7], Patricia Pardo[4], Marianne L. Shaw[1], Megan E. B. Clowse[2], Kyri Dunussi-Joannopoulos[6], Indranil Bhattacharya[6], Sudhakar T. Sridharan[5], Annette Diehl[6] and Ian Gourley[6]. [1]Altoona Center for Clinical Research, Duncansville, PA, [2]Duke University, Durham, NC, [3]Metroplex Clinical Research Center, Dallas, TX, [4]Miami Research Associates, [5]Pfizer Inc, Collegeville, PA, [6]Pfizer Inc, [7]Rheumatology Associates, Dallas, TX

Background: Preclinical data have shown a critical role of B cells in murine SLE models. Positive results from several open-label trials with CD20+ depleting agents and other B cell directed therapies support targeting B cells in human SLE. There have been two negative controlled studies of rituximab in SLE; however methodologic issues may have contributed to these results. SMIP™ biologics are disulfide bonded single chain polypeptides comprising binding, hinge, and effector domains designed to meet predetermined therapeutic specifications for diseases such as SLE. SBI-087 is a humanized SMIP biologic directed against the CD20 antigen located on B cells. SBI-087 is structurally different from rituximab, and has shown enhanced B cell depleting activity in the blood, bone marrow, and lymph nodes in cynomolgus monkeys. SBI-087 is being developed for subcutaneous (SC) administration that will eliminate the need for intravenous (IV) infusions and premedication with IV corticosteroids.

Objectives: To examine the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of ascending single doses of SBI-087 in subjects with controlled SLE.

Methods: Twenty-four subjects (23 females) received a single IV (0.5 mg/kg) or SC (25, 75, or 200 mg) dose of SBI-087 in this phase 1 open-label study. Each cohort contained 6 subjects. Blood was drawn for PK, PD (CD19+ B cells using a high-sensitivity assay), immunogenicity, and clinical safety assessments. Follow-up of subjects and data acquisition are ongoing.

Results: B cell depletion has been observed in the IV and all SC cohorts. Between wks 2 and 4, one subject in the 25 mg SC cohort, 5 subjects in the 75 mg SC cohort, and 4 subjects in the 200 mg SC cohort achieved B cell depletion to <5 cells/uL. 2 subjects in the 75 mg SC cohort and 1 subject in the 200 mg SC cohort achieved complete B cell depletion to the lower limit of quantitation (0.3 cells/uL) between wks 2 and 4. The 75 mg dose depleted peripheral blood B cell levels in all subjects to below 20 cells/uL by wk 4. SBI-087 has been generally well tolerated. Treatment-emergent adverse events (AEs) in more than 1 subject were upper respiratory tract infection, back pain, diarrhea, headache, fatigue, anxiety, chills, flushing, muscle spasms, nasopharyngitis, pain in extremities, and somnolence. Serious AEs included pregnancy, ankle fracture, spinal stenosis, diverticular perforation, and urinary tract infection. Chills occurred in 2 subjects after administration of 25 mg SC, and were abrogated in the 75 mg SC cohort with a day-of-treatment oral steroid regimen. 2 subjects in the 200 mg SC cohort had moderate flushing on the day of injection that was self-limiting. Injection site reactions have not been seen in any subject. Immunoglobulin levels have remained within normal limits in all subjects.

Conclusions: SBI-087 given as a single SC dose with a day-of-treatment oral steroid regimen appears to be generally well tolerated with an acceptable safety profile. B cell depletion has been observed in all SC cohorts dosed to date. Data from later timepoints for the 200 mg SC cohort will be necessary to fully explore the exposure/B cell response relationship and to select doses for future studies in SLE.

Background: Phosphatonins are involved in phosphate homeostasis, Vitamin D metabolism, and bone mineralization. FGF23, the master phosphatonin, acts through FGFr1 present in kidney, vessels and heart; its levels are high in chronic renal disease, and association between FGF23 levels and high death a part of other risk factors has been reported. JSLE is associated with high risk of atherosclerosis and cardiovascular disease. Endothelial dysfunction, by autoantibodies, ICC and cytokines play a role in vascular injury.

Objectives: 1.To evaluate the serum level of intact FGF23 in JSLE pts. 2.To correlate FGF23 values to lipid profile, renal function, renal biopsy, and cardiac data.

Patients and Methods: 53 consecutive pts (46 F 7 M, mean age at diagnosis 13.3±5.6) with SLE onset before 18 yrs entered the study. 12/53 had renal disease (GN) at onset while 13/53 developed GN signs over time. Steroids were the first drug in all pts, then hydroxychloroquine, AZA, CyA, and MMF while antiCD20 was applied to 3 pts. At study entry, the disease was controlled by hydroxychloroquine in 28/53, while in 25/53 with low dose prednisone, MMF or AZA; 1 pts developed renal failure and went on dialysis. All pts with GN were biopsied 6 mths from renal manifestations onset: 4 WHO IIA, 6 IIB, 10 III, 5 IV. 35 sex and age matched subjects acted as controls. Serum intact FGF23 levels were measured with an ELISA assay (Immunotopics Inc. San Clemente, CA, USA).

Results: FGF23 serum levels resulted higher in JSLE pts than in controls (t-student:67.1±40SD *vs* 5±3.2SD pg/ml). By Mann-Whitney U Test; GN pts had FGF23 values higher than those without (45.3±20 *vs* 13,77±9.2 SD pg/ml; p=0.0001). By Ancova analysis pts with severe disease (WHO III-IV) had higher levels than patients with biopsies WHO IIA-IIB (52,5±21 and 58,5±15 pg/ml respectively vs 13.7±9 and 35±10 pg/ml p=0.004). No significant correlation was found among serum FGF23 levels, lipid profile and cardiac function. A trend characterized by an inverse correlation between FGF23 and HDL was found (r−0.07;p=n.s.).

Conclusion: Serum FGF23 levels are higher in JSLE pts and seem to correlate with renal damage. FGF23 serum values should be a helpful biomarker for assessing the risk of renal damage, and helpful in pts with early kidney disease in whom FGF23 levels firstly increase. Data in a larger cohort of pts are needed to define the role of FGF23 in renal disease of JSLE pts.

Fracture Risk Assessment and Prevalence of Low Bone Mass in Canadian Females Living with Systemic Lupus Erythematosus (SLE). Jennifer J. Lee[6], Angela M. Cheung[6], Ellie Aghdassi[6], Stacey Morrison[6], Valentina Peeva[6], Carolyn Neville[1], Sarah Hewitt[4], Janet E. Pope[3], Deborah DaCosta[2] and Paul R. Fortin[5]. [1]McGill University, Montreal, QC, Canada, [2]McGill University, [3]St Joseph Health Care London, London, ON, Canada, [4]St. Joseph's Health Care, [5]University Health Network, Toronto, ON, Canada, [6]University Health Network

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease with many complications. SLE patients are at risk of osteoporosis (OP) and fractures due to the disease and/or long-term steroid use.

Objective: To estimate in SLE females: 1) low bone mass prevalence and 2) fracture probability in those over the age of 40 using the Fracture Risk Assessment Tool (FRAX).

Methods: 271 SLE females with no OP fracture history were enrolled from 3 Canadian centres. Demographic data including age, SLE duration, body mass index (BMI), smoking status, OP risk factors, and medications were collected. Bone mineral density (BMD) of the lumbar spine, hip, and femoral neck were determined using DEXA. OP was defined as t-scores <−2.5 for those >50 years, and low bone mass as z-scores <−2 for those

<50. For those >40, the 10 year probabilities of a major OP event (FRAX Major) and hip fracture (FRAX Hip) were calculated using age, sex, BMI, past fractures, family history, smoking, alcohol, presence of rheumatoid arthritis, steroid use and femoral neck BMD. Risks high enough to warrant pharmacological treatments are >20% for FRAX Major and >3% for FRAX Hip.

Results: Subjects had a mean (SD) age of 43.8 (13.1) years, SLE duration of 11.6 (10.4) years, BMI (kg/m^2) of 26.3 (6.3), 57% consumed alcohol, 44% were smokers, 38% were postmenopausal, 28% had a prior fracture, 24% were on steroids >7.5 mg, and 41% were on steroids for at least 3 months. Calcium and vitamin D were used by 48% and 39% respectively. There was a significant correlation between BMD of the femoral neck ($r=-0.26$, $p=0.001$) and hip ($r=-0.35$, $p<0.01$) with the duration of steroid use.

In females ≥50 years (32.8%), the mean t-scores of the spine, hip, and femoral neck were −0.73, −0.52, −0.78 respectively. OP was diagnosed overall in 4.8%, and in 11.5%, 4.2%, and 5.7% in spine, hip, and femoral neck respectively.

In females <50 (67.2%), the mean z-scores of the spine, hip, and femoral neck were −0.22, 0.11, and −0.19 respectively. Low bone mass was at the spine, hip, and femoral neck in 52.7%, 39%, and 2.8% of the participants.

Overall, there was no difference in BMDs based on calcium and vitamin D intake. However, spine BMD was significantly lower in those who took steroids longer than 3 months [1.1 (0.1) vs. 1.0 (0.1), $p=0.006$].

Of those ≥40 (63.5%), the mean FRAX Major was 10.2% (6.3) and FRAX Hip was 1.8% (3.3). FRAX Major ≥20% was seen in 7% (n=12) of whom only half were on OP treatment. FRAX Hip ≥3% was noted in 15.8% (n=27) where 2/3 were on treatment. OP treatment was given to 22% and 16.7% of females who had low FRAX Major (<20%) and FRAX Hip (<3%) scores respectively. FRAX Major correlated significantly with: steroid duration ($r=0.31$, $p=0.03$) and age ($r=0.21$, $p=0.01$). Similarly, FRAX Hip correlated significantly with: steroid duration ($r=0.32$, $p=0.03$), age ($r=0.23$, $p=0.01$), and SLE duration ($r=0.20$, $p=0.01$).

Conclusion: Low bone mass is prevalent in SLE females without prior OP fractures. This is important for females <50 years, where routine BMD monitoring is not currently part of standard care. FRAX scores may provide additional insight to the level of risk and identify those who may benefit from OP treatments. This may help reduce future morbidity and mortality.

Immunosuppression in the Treatment of Systemic Lupus Erythematosus Associated Pulmonary Arterial Hypertension: Improvement in Functional and Exercise Capacity. Judith Ashouri[2], Yon Sung[2], Roham Zamanian[2] and Lorinda Chung[1]. [1]Stanford Univ Medical Center, Palo Alto, CA, [2]Stanford University School of Medicine

Purpose: Accumulating evidence suggests that autoimmunity and inflammation are important in the pathogenesis of systemic lupus erythematosus associated pulmonary arterial hypertension (SLE-APAH). Several case reports and series have described improvement in dyspnea, exercise capacity, and hemodynamics with aggressive immunosuppression (IMM), both alone and in combination with PAH-specific therapies. We aimed to assess the effects of IMM in combination with PAH-specific therapies on the clinical outcomes of SLE-APAH patients followed at our center.

Methods: We identified 13 patients from Stanford's PAH database diagnosed with PAH by right heart catheterization between 1999–2009. All patients fulfilled ACR criteria for a diagnosis of SLE based on medical record review, and patients who fulfilled ACR criteria for another connective tissue disease were excluded. All patients received PAH-specific therapies according to standard of care. Patients who underwent aggressive IMM for a minimum of 8 months between the baseline and follow-up evaluations were compared with those receiving PAH-specific therapies alone. Cumulative probability of freedom from worsening New York Heart Association functional class (FC) was calculated using the Kaplan-Meier estimator, and compared using the log-rank test. Follow-up time was calculated from the time of the baseline evaluation. The mean changes in clinical parameters were compared between the IMM and non-immunosuppression (non-IMM) groups using Student's t-test.

Results: All patients were female, 69% Asian, 15% white, with a mean age of 38±9 years and mean SLE disease duration at PAH diagnosis of 5.6±6.1 years. 46% had a history of renal disease, 46% had Raynaud's, and 38% a history of serositis. 100% were ANA+, 85% anti-dsDNA+, 71% anti-RNP+, 40% anti-Smith+, and 29% antiphospholipid antibody+. 4 (30%) patients were treated with aggressive IMM (3 with high dose steroids and mycophenolate mofetil, 1 with hematopoietic stem cell transplant) during a mean follow-up time of 14.8±4.3 months. At baseline, there were no significant differences in demographics, SLE clinical features or autoantibodies in patients treated with or without IMM, except for increased prevalence of oral ulcers in the IMM group (23% vs. 8%, $p=.02$). Baseline PAH disease duration (9±15 vs. 35±42 months), hemodynamics (mean right atrial pressure 11.3±6.1 vs. 7.5±4.9 mmHg, mean pulmonary arterial pressure 46±12.7 vs. 51.3±16.1 mmHg, cardiac index 2.6±0.7 vs. 2.3±0.6, peripheral vascular resistance 10.1±2 vs. 12.4±6.1 WU), FC (3.3±0.5 vs. 2.7±0.9), 6 minute walk distance (6MWD, 276±168 vs. 397±177 m), and PAH-specific therapies did not differ significantly between the IMM and non-IMM groups. At follow-up, hemodynamics and PAH-specific therapies did not differ between the groups. No patients in the IMM group had worsened FC compared with 22% and 45% at 1- and 3-years in the non-IMM group ($p=.2$). Mean improvements in FC (−2±1 vs. 0±1, $p=.01$) and 6MWD (+206±46 vs. +52±200 m, $p=.054$) were higher in the IMM group.

Conclusion: Immunosuppression in addition to PAH-specific therapies may improve functional and exercise capacity in patients with SLE-APAH.

Immunosuppressive Drugs for Systemic Lupus in the Michigan Lupus Cohort: Increased Requirement for Cyclophosphamide and Mycophenolate Mofetil in Men. Emily E. Lewis[3], Emily Crooks[4], Zhichao Sun[4], Patricia C. Cagnoli[3], Tania Gonzalez-Rivera[4], Mariana J. Kaplan[3], Wendy Marder[2], Panduranga Rao[4], Emily C. Somers[1] and W. Joseph McCune[3]. [1]U of Michigan Health System, Ann Arbor, MI, [2]Univ of Michigan, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI, [4]University of Michigan

Purpose: Male lupus patients have been reported to have more aggressive disease, including more rapid accrual of damage, and increased mortality when compared to females. We examined sex differences in the use of immunosuppressive agents to treat systemic lupus erythematosus (SLE), hypothesizing that first line drugs for severe lupus, cyclophosphamide (CYC) and/or mycophenolate mofetil (MMF), are more frequently prescribed for men than women, reflecting more severe disease activity in men.

Methods: An extensive retrospective chart review was conducted on the records of 764 patients, including 91 men and 673 women, enrolled in the Michigan Lupus Cohort (MLC) from 2000 – present, to determine the frequency of administration of immunosuppressive drugs. The evaluation included all University of Michigan electronic records spanning 1992 – present, in addition to any available outside records. Chart review confirmed that patients satisfied ≥4 ACR criteria for SLE. An electronic medical search engine (EMERSE) was used to scan patient records for use of immunosuppressive drugs; all records were then carefully assessed to confirm that the immunosuppressive was prescribed to treat SLE. The use of CYC, MMF, azathioprine (AZA), and/or methotrexate (MTX) was then recorded if the drug was prescribed to treat SLE and the patient began treatment.

Results: Of the 764 patients enrolled, the majority of patients received treatment with at least one immunosuppressive drug including 81.3% of men and 72.1% of women. CYC was used by 52.7% men vs. 37.7% women ($p=0.006$). MMF was used by 69.2% of men vs. 51.1% of women ($p=0.001$). In contrast, AZA was used by 36.3% of men vs. 41.8% of women, and MTX was used by 16.5% of men vs. 26.6% of women ($p=0.0375$). Approximately 75% of men in the MLC received at least one first line drug as treatment for their SLE.

IMS Medications	Female n=673	Male n=91	P - value
CYC	254 (37.7)	48 (52.7)	0.0060
MMF	344 (51.1)	63 (69.2)	0.0012
CYC or MMF	388 (57.7)	68 (74.7)	0.0018
AZA	281 (41.8)	33 (36.3)	NS
MTX	179 (26.6)	15 (16.5)	0.0375
None	188 (27.9)	17 (18.7)	NS

( )=percent

Conclusions: There is a highly significant increase in the proportions of men who receive first line drugs for severe lupus, cyclophophamide and

mycophenolate mofetil, compared with women. These data highlight the importance of fully characterizing pathogenic mechanisms contributing to the increased severity of lupus in men vs. women.

Increased Recruitment of Brain Activation within the Hippocampus in SLE Patients as Shown by Functional MRI May Be a Compensatory Mechanism To Cope with Memory Impairment. Daphna Paran[3], Ifat Glikmann-Johnston[2], Talma Hendler[2], Irena Litinsky[3], Eli Vakil[1], Dan Caspi[3] and Irit Shapira-Lichter[2]. [1]Department of Psychology and Gonda Multidisciplinary Brain Research Center, Bar-Ilan University, [2]Functional Brain Center, Wohl Institute for Advanced Imaging, Tel-Aviv Sourasky Medical Center, [3]Rheumatology Department, Tel-Aviv Soursky Medical Center

Objectives: The hippocampus has been shown to have a major role in memory processes. Atrophy of the hippocampus has been correlated to cognitive impairment in SLE and other diseases. This study aimed to assess neural correlates of memory impairment within the hippocampus in SLE patients by functional MRI.

Methods: Twelve female SLE patients (mean age: 30±5.9 years; mean education: 14.6±1.7 years; disease duration 9.5±3.4 yrs; SLE disease activity index 6.3±6.4; SLICC damage index: 0.9±1.0) without clinically overt NPSLE and 11 female healthy controls (mean age: 29.8±6.8 years; mean education: 15.1±1.3 years) underwent fMRI testing using an auditory verbal memory test. The paradigm consisted of three blocks of verbal encoding and repeated free recall steps followed by a recognition test. During retrieval blocks subjects indicated by pressing a key when a word was recalled or recognized. Brain activation patterns were evaluated within the hippocampus in both groups using this paradigm. Hippocampal volume was measured using Brain Voyager QX.

Results: Free recall was impaired in SLE patients as compared with healthy subjects ($p<0.05$). Among SLE patients, learning was correlated with hippocampal responsiveness to the encoding task, reflected in the percent signal change in activation from baseline to each of the encoding blocks (EB) (left hippocampus: EB1: $r=0.38$, $p<0.05$; EB2: $r=0.39$, $p<0.05$; EB3: $r=0.4$, $p<0.05$; right hippocampus: EB1: $r=0.4$, $p<0.05$; EB2: $r=0.36$, $p<0.05$; EB3: $r=0.37$, $p< 0.05$). No such correlation was seen in the healthy controls. Furthermore, greater activations were evident within both the right and left hippocampus in SLE patients compared to controls during the encoding, free recall and recognition tests. The left hippocampus was significantly smaller in SLE patients as compared to controls ($p<0.05$), however there was no correlation between hippocampal volume and learning abilities (i.e. number of learned words).

Conclusions: SLE patients demonstrated memory difficulties along with greater activity in the hippocampus as compared to healthy controls. This increased activity correlated with learning performance. These findings suggest that increased brain activation within the hippocampus during learning in SLE patients, may reflect compensatory mechanisms required to overcome impaired memory and learning abilities and cope with memory tasks.

1160

Inhibition of Complement Activation by Heparins but Not Fondaparinux on Alternative, Mannose/Mannan Binding Lectin (MBL) and Classical Pathways in Active SLE with Low C3/C4. Andrea A. Ramirez[1], Ankur A. Kamdar[2] and Barry L. Myones[1]. [1]Baylor College of Medicine/ Texas Children's Hospital, Houston, TX, [2]University of Texas Medical School at Houston, Houston, TX

Background: Activation of 1 or more of the complement cascades has been implicated in disease pathogenesis in several autoimmune disease processes including SLE and antiphospholipid antibody syndrome (APS). Low molecular weight heparins (LMWH) have been used to treat thrombosis, microangiopathic processes and anecdotally in the therapy of giant coronary aneurysms in Kawasaki Disease. Unfractionated heparin (UFH) and LMWH have also been implicated in classical pathway complement inhibition in APS. We have previously demonstrated complement inhibition only at supra-pharmacologic levels of heparin (5 to 10x the accepted therapeutic cutoff).

Purpose: Evaluate the effect of UFH, LMWH, and a factor Xa inhibitor (fondaparinux) on cell membrane-associated classical (CP), MBL, and alternative pathway (AP) activation *in vitro* utilizing serum with normal and very low C3/C4 (simulating active SLE).

Methods: AP hemolytic assay was modified to 100% lysis. Unsensitized rabbit erythrocytes (RaE) (direct activator of human AP) @1.25 $\times 10^8$ in GVB/MgEGTA (blocks CP activation by calcium chelation) were utilized per tube. Sheep erythrocytes (ShE) were sensitized with mannan by CrCl3 incubation in MBL assay (GVB/Ca++/Mg++). ShE were sensitized with hemolysin (anti-ShE IgM) in CP hemolytic assay. Varying doses of UFH or enoxaparin (0.5–10 IU/ml final concentration) or fondaparinux (1.25 – 6.25 mg/ml) were added to normal human serum (C3 120–140 mg/dL; C4 >15 mg/dL) and active/inactive SLE (C3 25–50 mg/dL; C4 0–10 mg/dL) as complement sources. (C3/C4 ascertained by Mancini immunodiffusion; C4 allotyping performed on test sera). Mixtures were incubated up to 30 minutes @37°C. Supernatants were read at OD541 and expressed as % lysis against controls.

Results: Escalating doses of enoxaparin or UFH (up to 20 IU/ml) resulted in increased % inhibition of complement-mediated RaE or ShE lysis (1mg enoxaparin ~100 IU anti-Factor-Xa activity) whereas fondaparinux had no appreciable inhibition of lysis in control or patient serum. A small % inhibition (<20%) of membrane-associated complement activation was noted at anti-factor-Xa activity levels achievable with standard therapeutic anticoagulant regimens of UFH or LMWH, but LMWH > UHF achieved inhibition at higher (>2 IU/ml) dosing levels for CP > AP components for both controls and SLE patients with normal C3/C4 (only 50–70% even at 5 IU/ml). Sera with higher C3/C4 (>140 mg/dL; >20 mg/dL) were much harder to inhibit. Sera with limited C3 /C4 levels (<30 mg/dL; <5 mg/dL) resulted in significantly more inhibition of complement-mediated RaE or ShE lysis at lower dosing levels of UFH or LMWH (1 to 2 IU/ml).

Conclusions: UFH and LMWH inhibit membrane-associated complement activation via all 3 pathways *in vitro* while fondaparinux, a factor Xa inhibitor, had no effect. Anticoagulation effects were again discordant from complement inhibitory effects in controls and SLE patients with normal C3/C4 levels. Active SLE sera with very low C3/C4 levels resulted in inhibition by heparins at 1.5 to 2 IU/ml dosing levels (lower bleeding risk). These data suggest heparins as an additional therapeutic modality in very active SLE patients with limited complement supply.

Long-Term Outcome of Autologous Hematopoietic Stem Cell Transplantation (AutoHSCT) Using Lymphoablative Conditioning in Treatment-Resistant Systemic Lupus Erythematosus. Gabor G. Illei[11], Sarfaraz A. Hasni[7], Nikolay P. Nikolov[1], Francis Hakim[2], Susan Leitman[2], James Balow[9], Howard Austin[4], Juan Gea-Banacloche[2], Unsong Oh[10], Jeanie Odom[2], Donna Hardwick[8], Claude Sportes[2], Ronald Gress[2], Steven Pavletic[2], Cheryl Yarboro[6], Paolo Muraro[5] and Peter Lipsky[3]. [1]Bldg. 22, Room 3335, HFD-570, Silver Spring, MD, [2]National Cancer Institute, [3]National Institue of Arthritis, Musculoskelatal and Skin Diseases, [4]National Institue of Dibetes, Digestive and Kidney DIseases, [5]National Institue of Neurological Diseases and Stroke, [6]National Institute of Arthritis, Musculoskelatal and Skin Diseases, [7]National Institute of Arthritis, Musculoskelatal and Skin Diseases, Bethesda, MD, [8]National Institute of Arthritis, Musculoskeletal and Skin Diseases, [9]National Institute of Diabetes, Digestive and Kidney Diseases, [10]National Institute of Neurological Disroders and Stroke, [11]NIDCR, NIH #10 1N114, Bethesda, MD

Background: Despite improvements in the outcomes of SLE patients with major organ involvement, treatment failure and relapse continue to affect significant proportion of patients. In this pilot study we tested if intensive lymphoablation followed by autoHSCT can lead to sustained, complete, treatment-free remission in severe, recalcitrant SLE and whether this approach fundamentally changes abnormal immune response.

Methods: Patients were enrolled with active SLE despite prior treatment with IV cyclophosphamide (CYC). Of the 8 patients treated, 2 had transverse myelitis, 1 retinal vasculitis and 5 WHO Class IV nephritis. Stem cell mobilization regimen consisted of 2,000 mg/m^2 CYC, 750 mg/m^2 rituximab (RTX) and G-CSF. Conditioning regimen consisted of 750 mg/m^2 RTX, 4.8 g/m^2 CYC and 120 mg/m^2 fludarabine, followed by CD34+ selected stem cell infusion and G-CSF.

All immunosuppressive medications and hydroxychloroquine (HCQ)

were stopped at the start of mobilization and steroids were rapidly tapered off after the transplant. Clinical response was evaluated by organ specific response criteria. Disease activity indices (SLEDAI and SLAM) were used to assess overall lupus activity. The primary endpoint was complete response (CR) at 24 months defined as no lupus activity and no treatment for lupus (including HCQ and steroids).

Results: Among the 8 patients, there were 2 early deaths (one from diffuse alveolar damage, one from mycobacterial meningoencephalitis). One patient had lupus flare (retinal vasculitis responding to corticosteroids) 6 months post-transplant. Five patients were tapered off corticosteroids, achieved CR criteria within 6 months of transplant and SLEDAI scores of 0. One of these patients had SLE relapse 18 months post-transplant which responded to standard treatments, whereas 4 continue to be in CR beyond 4 (n=2) to 5 years (n=2). The reconstituted immune system of long-term responders showed a significant shift from a phenotype dominated by memory and activated effector T and B cells at baseline to a predominantly naïve phenotype post-transplant. In contrast, the patient who flared had an early recurrence of memory B cells and circulating plasma cells preceeding the flare.

Conclusions: Our data indicate that lymphoablative autoHSCT leads to sustained (over 5 years) clinical and serologic remission, without the use of any maintenance therapy in a subset of otherwise recalcitrant SLE patients. This clinical benefit is associated with marked normalization of the immune repertoire. Reducing the intensity of conditioning and/or exclusion of patients with multiple organ dysfunction may decrease short term toxicity and would make this approach an acceptable alternative for the treatment of severe SLE.

1162

Microembolic Signals Detected by Transcranial Doppler Ultrasound Corresponds to Persistence of Foramen Ovale in Neuropsychiatric Lupus with Brain MRI Abnormalities.

Melissa Padovan[2], Alessandra Bortoluzzi[2], Cristiano Azzini[1], Alessandro De Vito[1], Maria Rosaria Tola[1], Francesco Trotta[3] and Marcello Govoni[3]. [1]Neurology Unit, Department of Neurosciences, Azienda Ospedaliero-Universitaria Sant'Anna, Ferrara, Italy, [2]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Ferrara and Azienda Ospedaliero-Universitaria Sant'Anna - Ferrara, Ferrara, FE, Italy, [3]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Ferrara and Azienda Ospedaliero-Universitaria Sant'Anna - Ferrara (Italy)

Background: Magnetic resonance imaging (MRI) abnormalities, as small punctuate hyperintense lesions in subcortical and periventricular brain white matter areas (WMHL) are a frequent but not specific finding in systemic lupus erythematosus (SLE) patients with and without neuropsychiatric (NP) involvement. Their pathogenesis is not fully understood yet, being recurrent cerebral micro-embolism - detectable through transcranial Doppler ultrasound (TCD) - one of the hypothesized mechanism. In general population micro-embolic signals (MES) may be detected with a reported frequency of about 15 % often due to the persistence of foramen ovale.

Aim: To assess the frequency of microembolic signals (MES) by using transcranial Doppler (TCD) ultrasound in SLE patients with and without brain MRI abnormalities.

Methods: A TCD registration to detect MES from the middle cerebral artery was carried out accordingly to a local standardized protocol in 21 SLE patients (mean age of 42,2 years, range 32–55) with and without NP involvement lupus, after exclusion of aortic and/or carotid atheromatous disease. In all patients brain magnetic resonance imaging (MRI) and trans-esophageal echocardiography were performed. Patients were stratified in two groups, with and without MRI WMHL and compared. Antiphospholipids antibodies (APL) and lupus anticoagulant (LA) status were checked too.

Results: MES were detected in a total of 11 patients (52,3%), 4 APL/LA+ and 7 APL/LA-, 9 out of 15 patients (60 %) with abnormal MRI and history of NP SLE had MES compared with 2 out of 6 patients (33.3 %) with normal MRI (1 NPSLE and 5 without NP involvement). No correlations between MES and APL or LA were found. The persistence of foramen ovale was confirmed in almost all case of MES detection. However with abnormal MRI only one case did not show persistence of foramen ovale.

Conclusion: Compared with what has been reported in general population, MES is a frequent finding in SLE patients irrespective of their previous history of NP involvement and more prevalent in patients with MRI abnormalities compared with patients with normal MRI. These finding either suggest caution in the interpretation of MRI pictures and a careful evaluation of MES in patients with MRI abnormalities which should be included in the work-up of SLE patients prompting further investigations for micro-embolic sources (i.e. carotid plaques and/or right-left shunt due to the persistence of foramen ovale).

1163

Multivariate Analysis of Vitamin D Insufficiency and Deficiency in SLE: The SOLD (Systemic Lupus Associates of Low Vitamin D) Project.

Caroline D'Souza[2], Kayode Jibril Bello[2], Hong Fang[2], Laurence Magder[3] and Michelle A. Petri[1]. [1]Timonium, MD, [2]Johns Hopkins University, [3]University of Maryland

Purpose: Vitamin D is an important immunomodulator in animal models of autoimmune diseases. In humans, in addition to its role in bone health, it may be important in the prevention of diabetes, cardiovascular disease, and certain cancers. We explored clinical and laboratory associates of Vitamin D insufficiency (<32 ng/mL) and deficiency (<15 ng/mL) in SLE.

Methods: 810 SLE patients (mean age 44.94, 49.54% Caucasian, 40.36% African-American, 92.07% female) were included. 25 OH Vitamin D was measured from July 20, 2009 to April 22, 2010.

Results: Univariate analyses suggested that age, ethnicity, hypertension, diabetes, physician global assessment of SLE activity (PGA), urine protein/creatinine ratio (>0.5), systolic blood pressure, cholesterol, and obesity were associated with both Vitamin D insufficiency and Vitamin D deficiency.

Table 1. Association between various factors and deficiency/insufficiency of Vit D in patients with SLE based on a multivariable logistic regression model

Variable		Odds Ratio (95% CI) with Vit D Deficiency	P-Value	Odds Ratio (95% CI) with Vit D Insufficiency	P-Value
Age	18–30	1.00 (reference)		1.00 (reference)	
	31–49	0.83 (0.47; 1.47)	0.524	1.20 (0.77; 1.85)	0.419
	50+	0.40 (0.21; 0.78)	0.007	0.63 (0.39; 0.99)	0.048
Race	White	1.00 (reference)		1.00 (reference)	
	Black	5.92 (3.76; 9.33)	0.001	2.18 (1.57; 3.04)	0.001
	Other	1.89 (0.80; 4.51)	0.149	1.22 (0.68; 2.18)	0.501
Urine Pr/Cr Ratio	<0.5	1.00 (reference)		1.00 (reference)	
	>=0.5	1.01 (0.54; 1.91)	0.967	1.71 (0.90; 3.24)	0.102
BMI	<=30	1.00 (reference)		1.00 (reference)	
	>30	1.85 (1.23; 2.78)	0.003	2.51 (1.79; 3.53)	0.001
Cholesterol	<=200	1.00 (reference)		1.00 (reference)	
	>200	1.43 (0.93; 2.21)	0.102	1.79 (1.26; 2.55)	0.001
Systolic BP	<140	1.00 (reference)		1.00 (reference)	
	>=140	1.60 (0.97; 2.63)	0.065	1.60 (1.02; 2.51)	0.039
Diabetes	No	1.00 (reference)		1.00 (reference)	
	Yes	2.05 (1.13; 3.69)	0.017	1.49 (0.85; 2.61)	0.165

However, in the best multivariate logistical regression model (see table 1), age, ethnicity, and obesity remained statistically significant, but urine protein/creatinine ratio did not. In the best multivariate linear regression model (see table 2), urine protein/creatinine ratio was significantly associated with Vitamin D levels.

Table 2. Association between various factors and Vit D levels in patients with SLE based on a multivariate linear regression model

Variable	Effect on Mean Vit D	P-value
Age (per year)	0.11 ± 0.04	0.005
Race (Black vs White)	−6.32 ± 1.04	0.001
Systolic BP (per mmHg)	−0.09 ± 0.03	0.004
Diabetes	−2.43 ± 1.71	0.156
Urine Pr/Cr Ratio	−1.55 ± 0.78	0.047
BMI	−0.29 ± 0.07	0.001
Cholesterol (per mg/dL)	−0.04 ± 0.01	0.001

Conclusion: Younger age, African-American ethnicity and obesity are associated with both Vitamin D insufficiency and deficiency, after adjustment for other variables, in multiple variable models. The apparent association with disease activity in univariate analyses did not remain in multiple variable models. The association with urine protein/creatinine ratio, however, did remain in the multivariate linear regression model. This suggests that Vitamin D deficiency may play a role in renal lupus.

Network Analysis of Associations between Serum Interferon Alpha, Serology, and Clinical Features in Systemic Lupus Erythematosus in a Large Multi-Ancestral Cohort. Corinna E. Weckerle[6], Beverly S. Franek[7], Jennifer Kelly[2], Marissa Kumabe[7], Rachel Mikolaitis[5], Stephanie Green[7], Gail R. Bruner[3], Tammy O. Utset[6], Meenakshi Jolly[4], Judith A. James[1], John B. Harley[8] and Timothy B. Niewold[9]. [1]Oklahoma Med Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, [3]Oklahoma Medical Rsrch, Oklahoma City, OK, [4]Rush University Med Ctr, Chicago, IL, [5]Rush University Med Ctr, [6]Univ of Chicago Med Ctr, Chicago, IL, [7]Univ of Chicago Med Ctr, [8]Univ of OK Hlth Sci Ctr, Oklahoma City, OK, [9]University of Chicago, Chicago, IL

Background: Interferon-alpha (IFN-α) is a primary pathogenic factor in systemic lupus erythematosus (SLE), and high IFN-α levels may be associated with particular clinical manifestations. The prevalence of individual clinical and serologic features differs significantly by ancestry. We used logistic regression modeling to establish the network of associations between clinical and serologic manifestations and serum IFN-α in SLE patients from multiple ancestral backgrounds.

Methods: We analyzed the presence or absence of ACR clinical criteria for SLE, autoantibodies, and high serum IFN-α in 1089 SLE patients (387 African-American, 186 Hispanic-American, and 516 European-American). Iterative multivariate logistic regression was performed in each background separately to establish associations between variables, and network diagrams were constructed illustrating associations that were significant following Bonferroni correction.

Results: We found 14 unique associations forming network maps of relatively sparse density in each background. Of those, only 7 associations were shared by more than one ancestral background. Network maps of the interactions between clinical criteria were different in different ancestral backgrounds. In contrast, associations between autoantibodies and IFN-α were very similar in different backgrounds. In all backgrounds, high IFN-α was associated with presence of anti-Ro and anti-dsDNA antibodies (p-values 4.6×10^{-18} and 2.9×10^{-16} respectively). IFN-α and serology were not associated with ACR clinical features in these multivariate models.

Conclusions: Serum IFN-α was strongly and consistently associated with serology, and not independently associated with clinical features in SLE. Our study suggests that IFN-α may be more relevant to humoral tolerance and initial disease pathogenesis than ongoing late clinical disease manifestations.

Peripheral Neuropathy in Patients with Systemic Lupus Erythematosus. Brandusa Florica[2], Jiandong Su[1], Ellie Aghdassi[1], Dafna D. Gladman[1], Murray B. Urowitz[1] and Paul R. Fortin[1]. [1]University Health Network, [2]University of Toronto, Toronto, ON, Canada

Background: Peripheral neuropathy (PN) is a common feature of neuropsychiatric syndromes in Systemic Lupus Erythematosus (SLE) that can affect the quality of life of these patients. Currently the studies describing the clinical features of SLE patients with PN are scarce.

Objective: To determine in SLE patients: 1) the prevalence, the clinical course of PN and the impact on quality of life, 2) the clinical features and sub-classes of PN, and 3) whether there is an association between PN and any other clinical feature.

Methods: Patients who met at least 4 of the ACR classification criteria and met the ACR case definition criteria for peripheral neurological SLE were selected from the database registry of the University of Toronto Lupus Clinic. Chart review was performed to confirm clinical findings, determine the contributing factors and outcome of PN. PN found to be due to non-SLE causes were analyzed but kept in a separate group than SLE-related PN. Demographic data including age, gender and SLE duration, as well as SLE related clinical and investigational data at the time of the first appearance of PN were extracted by chart review. Disease activity and damage were assessed by SLE- Disease Activity Index (SLEDAI-2K) and SLICC Damage Index (SDI) at the time of the first appearance of PN. Quality of life was determined using the SF-36 questionnaire and scored for the physical (PCS) and mental (MCS) component summary scores. Data were analyzed using SAS statistical program.

Results: Out of 1520 patients in the database, 210 (14%) with a mean (SD) ACR criteria of 5.7 (2.0) met the inclusion criteria. Subjects had mean (SD) for age of 44 (14.4) years and SLE duration of 9.2 years (10.2); median (IQR) for SLEDAI of 6.0 (IQR: 2.0, 12.0) and SDI of 1.0 (IQR: 0.0, 2.0); and 86.6% were female. Among patients, 66.9% had at least one SLE-related or possible SLE-related PN including mononeuritis multiplex (14.2%), sensory PN (27%) and mononeuropathy (25.8% including cranial neuropathy in 7.4%). Asymmetric presentation was most common (62.8%), and distal weakness occurred in 31.8% of patients. Peroneal nerve (61.4%), sural nerve (51.8%) and median nerve (40.9%) were frequently involved. Associated SLE features were: 85% arthritis, 69.3% rash, 47.8% CNS involvement. ANA titer of 1:320 or higher was significantly more prevalent in patients with SLE-related PN than non-SLE related PN (43.5% vs. 21.4%; p=0.028). EMG/NCS was performed in 67.7% of patients and indicated axonal neuropathy in 76.8% and demyelination in 18.3% of patients. Treatment included oral steroid in 85.4%, cyclophosphamide in 19.3% and pulse steroids in 7.9 % of patients. Chart review completed in 130 of the patients, showed that 67.7% of patients improved and 28.4% had no response to treatment, within a mean (SD) follow up period of 5.4 (7.6) years. SF-36 PCS was low in those with PN with a mean (SD) of 35.8 (10.7).

Conclusion: PN is relatively prevalent in SLE, may occur at any time after SLE diagnosis and with different presentations. This manifestation of SLE has a big impact on patient's quality of life.

Predictors of Mortality in Diffuse Alveolar Haemorrhage (DAH) Associated with Systemic Lupus Erythematosus. Marco U. Martínez-Martínez[2], Eufrates Hernández-Núñez[3], Enrique Cuevas-Orta[3], Ricardo Moreno-Valdés[3], Martin Saldaña-Barnad[3], Martin Magaña-Aquino[3], Juan C. Rizo-Rodríguez[2] and Carlos Abud-Mendoza[1]. [1]Rheumatology Unit, Hospital Central and Faculty of Medicine, University of San Luis Potosí, San Luis Potosi, Mexico, [2]Rheumatology Unit, Hospital Central and Faculty of Medicine, University of San Luis Potosí (México), [3]Rheumatology Unit, Hospital Central and Faculty of Medicine, University of San Luis Potosí (Mexico)

Objectives: Evaluation of clinical, demographic and treatment-associated mortality factors in patients with DAH associated with SLE.

Methods: Clinical, laboratory test, SLEDAI-2K, predictors of mortality (APACHE II) and different treatments including cyclophosphamide, methylprednisolone and rituximab were evaluated in SLE patients who were diagnosed with DAH, to determine potential association with factors that could be predictive of mortality.

Results: Twenty nine episodes of DAH in 22 SLE patients were included (one patient with 4 episodes, 4 patients with two episodes (7 recurrences)), 15 died. Mean age was 25.1 years and 1.5 years of SLE evolution with haemoglobin drop 3.4 g/dl. In 4 of 22 patients, the DAH diagnosis was confirmed by autopsy. Six episodes were in patients under 18 years of age (2 patients with recurrence). DAH was the initial manifestation of SLE in 10 patients. Of the 22 patients, 17 were women and 22/29 DAH episodes. Through evaluation of all included factors, only thrombocytopenia, renal failure, requirement for mechanical ventilation and high APACHE II were associated with higher mortality. In 3 patients mycoses were diagnosed, all died. There is benefit using cyclophosphamide in selected patients (not statistically differences). Table 1 show the main characteristics evaluated in the 29 episodes.

Table 1. Characteristics evaluated at admission.

	All (mean ± SD)	Alive (mean)	Deceased (mean)	p
hsCRP (*)	9.9 ± 8.1	7.3	12.4	0.137
Leukocytes (†)	10.8 ± 8.9	10.4	11.1	0.832
Lymphocytes (†)‡	0.72 (0.1–4.6)	0.98	0.54	0.252
Haemoglobin (§)	6.9 ± 1.7	7.0	6.8	0.772
Platelets (†)‡	162 (4–496)	224	144	0.055
Creatinine (*)‡	1.2 (0.3–31.9)	0.79	2.54	0.016
GFR (‖)	73.4 ± 51.9	104.1	42.9	0.001
SLEDAI-2K	17.1 ± 7.5	15.9	18.3	0.416
APACHE II	18.4 ± 6.1	15.7	21.1	0.015
Renal failure (%)	41.4	6.9	34.5	0.004
Haemodialysis (%)	27.6	6.9	20.7	0.215
MV (%)	72.4	24.1	48.3	0.014
Cyclophosphamide (%)	58.6	34.5	24.1	0.176

(*): mg/dl, (†): × 10^3/mm^3, ‡ Median (minimum-maximum), (§): g/dl, (‖): ml/min/1.73 m^2, SD: standard deviation, hsCRP: high sensitivity C reactive protein, GFR: Glomerular filtration rate, SLEDAI-2K: Systemic Lupus Erythematosus Disease Activity Index 2000, APACHE II: Acute Physiology And Chronic Health Evaluation. MV: Mechanical ventilation

Conclusions: Mortality of DAH associated with SLE has continued being high in spite of intensive treatment. Thrombocytopenia, renal failure, requirement of mechanical ventilation and high APACHE II are factors associated with higher mortality. Cyclophosphamide would be useful to diminish mortality related to DAH associated with SLE. Patients should receive therapy against prevalent and opportunistic infectious agents.

Prefrontal Lobe Volume Could Reveal Working Memory Function in Patients with System Lupus Erythematosus. Yongfei Fang[2], Haitao Lii[1], Qinghua Zou[3] and Yun Lin[1]. [1]Department of Radiology, Southwest Hospital, Third Military Medical University, Chongqing, China, [2]Department of Rheumatology, Southwest Hospital, Third Military Medical University, Chongqing, China, [3]Department of Rheumatology, Southwest Hospital, Third Military Medical University, Chongqing, China

Background: As a disease found with multiple organ involvement, cerebral atrophy in systemic lupus erythematosus has been reported by recent studies. The aim of the current study is i) to localize cerebral areas affected by SLE, and ii) to find any clinical index significantly correlated with cerebral atrophy.

Methods: 45 patients with SLE and 30 age, gender and education matched healthy controls were included, patients first underwent a working memory test named Paced Visual Serial Adding Test (PVSAT) and then scanned in a 3.0 Tesla MRI scanner for whole brain by 3D MPRAGE sequence. Images were process by Statistical Parametric Mapping (SPM8) software using a voxel based morphometry (VBM) through a newly improved Diffeomorphic Anatomical Regstration Through Exponentiated Lie algebra (DARTEL) approach, which mainly included segmenting brain images into grey matter, white matter and cerebral spinal fluid; estimating the deformations that best align the images together by iteratively registering the segmented images with their average, and generating spatially normalised and smoothed Jacobian scaled grey matter images, by using the deformations estimated in the previous step; and finally a two sample t test to depict cerebral areas of SLE patients with significant atrophy compared with controls. Then SLEDAI score, duration of disease, daily corticosteroid dosage and working memory test results were correlated with individual volume of these atrophied areas.

Results: diffuse grey matter atrophy was found in patients with SLE, mainly involved with prefrontal, temporal lobe, and cerebellum. By extracting individual volume of these cerebral areas, prefrontal lobe volume was positively correlated with test score of working memory test, and whole brain volume was negatively correlated with disease duration. No other clinical indexes were found to be in significant correlation with cerebral atrophy of SLE.

Conclusion: in consistence with previous researches, diffuse grey matter atrophy was found in patients with SLE. Further more, correlation between cognitive impairment and prefrontal lobe atrophy was discovered, indicating that i) cognitive impairment in SLE could be reflected by individual prefrontal lobe volume; ii) prefrontal lobe volume may be served as an marker of cognitive function in SLE. Nevertheless, negative correlation between disease duration and whole brain volume demonstrated a significant and chronic impact of SLE on human brain. However, as such results were generated based on a limited number of subjects, further research is required to depict the insights of the profile in the future.

Preliminary Results: Baseline Nutritional Vitamin D Level Does Not Predict Progression of Subclinical Atherosclerosis in Women with SLE. Apinya Lertratanakul[2], Peggy Wu[2], Alan R. Dyer[2], Craig Langman[1], William Pearce[2], Kim Sutton-Tyrrell[4], George Kondos[3], Daniel Edmundowicz[4], James Carr[2] and Rosalind Ramsey-Goldman[2]. [1]Childrens Memorial Hospital, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]University of Illinois, Chicago, IL, [4]University of Pittsburgh, Pittsburgh, PA

Background: CV events and subclinical atherosclerosis are increased in women with SLE. Low levels of 25(OH)D have been associated with disease activity and cardiovascular (CV) risk factors in SLE. CV events and subclinical atherosclerosis are increased in women with SLE.

Objective: Determine if baseline 25(OH)D level predicts progression of subclinical atherosclerosis in women with SLE.

Methods: Demographic, traditional CV risk factors, disease activity (SLEDAI) and severity (ACR/SLICC-DI), medications and imaging to assess subclinical atherosclerosis by carotid B-mode ultrasound to measure carotid plaque index (PI), intima-media thickness (IMT) and electron beam or multidimensional computed tomography to measure coronary artery calcification (CAC), and aortic calcification (AC) were measured at baseline and 3 yrs later in the Study of Lupus Vascular and Bone Long-Term Endpoints (SOLVABLE). Abnormal PI, CAC, and AC were defined as PI≥1, CAC>10 and AC>100. Progression at 3y was defined as abnormal and an increase in PI, CAC>10 and AC>100 with an increase of >10% in CAC and AC. Hypertension (HTN) was defined as SBP≥140 or DBP≥90 or on treatment. Regression models investigated the relationship between PI, CAC, AC, and IMT and traditional CV risk factors, SLEDAI and ACR/SLICC-DI as well as baseline 25(OH)D (adjusted for age, race, & season) and progression of each imaging marker.

Results: In 118 women, mean±SD age, disease duration, SLEDAI, ACR/SLICC-DI, and 25(OH)D levels at baseline were 44.3±9.6 yrs, 12.6±8.8, 3.6±3.2, 1.7±1.7 and 28.2±11.6 ng/mL, respectively. Preliminary imaging data at baseline and 3y followup were available on 118 women for IMT and PI, 91 with CAC, and 56 with AC. The frequency at baseline (#, %) of abnormal PI, CAC, and AC was 45 (38%), 21(23%), and 16 (29%), respectively. The frequency of progression at 3y followup (#, %) of PI, CAC, and AC was 34 (29%), 23 (25%), and 24 (61%), respectively. 13, 5, and 9 patients progressed from normal to abnormal at 3y followup visit for PI, CAC, and AC, respectively. The mean (SD) for IMT at baseline and 3y followup was 0.61 (0.12) and 0.64 (0.15), respectively. IMT change was associated with triglycerides (p=0.035, β=0.019,95% CI 0.001–0.037). PI, AC, and CAC progression were associated with HTN (p=0.045,OR=3.96,95% CI 1.14–18.41), (p=0.038,OR=2.91,95% CI 1.09–8.30), (p=0.017,OR=3.59,95% CI 1.32–10.98), respectively. AC and CAC progression were associated with ACR/SLICC-DI (p=0.003, OR=1.61,95% CI 1.20–2.26), (p=0.002, OR=1.63,95% CI 1.22–2.25). CAC progression was also associated with fibrinogen (p=0.039,OR=1.64,95% CI 1.03–2.70).

Vitamin D and Progression of PI, CAC, AC, and IMT

Imaging Type	Adjusted vitamin D model β	OR	95% CI	p
PI		0.73	0.33,1.48	0.40
CAC		0.95	0.51,1.74	0.88
AC		1.18	0.62,2.26	0.62
IMT	−0.02		−0.04,0.002	0.08

Conclusion: These preliminary results suggest that baseline 25(OH)D levels did not predict progression of PI, CAC, AC, or IMT over 3 yrs in women with SLE. However, traditional CV risk factors and SLE-related markers may be important in predicting progression of vascular bed abnormalities.

1169

Progression of Carotid Atherosclerosis and Its Determinants in Lupus Patients. Rosa Weiss Telles[3], Cristina Costa Duarte Lanna[3], Tulio Pinho Navarro[3], Adriano Jose Souza[1], Rodrigo Citton Padilha Reis[4], Fabiana Lemos Sousa[2], Luciana Andrade Rodrigues[3] and Antonio Luiz Ribeiro[3]. [1]Clinica Radiologica CONRAD, Brazil, [2]Hospital das Clinicas, Universidade Federal de Minas Gerais, Brazil, [3]School of Medicine - Universidade Federal de Minas Gerais - Brazil, [4]Statistics Department - Universidade Federal de Minas Gerais - Brazil

Objective: to determine the rate and risk factors of carotid atherosclerosis progression in patients with Systemic Lupus Erythematosus (SLE)

Patients and Methods: carotid intima-media thickness (IMT) and plaque were obtained by ultrasound at an interval of 39(37–42) months in 157 lupus patients out of 181 patients initially included in a prospective study. Progression of atherosclerosis was defined by either an increase of common carotid IMT>0.15mm or a higher plaque score. Traditional risk factors for coronary heart disease (CHD) and SLE-related factors were assessed longitudinally. Poisson regression was used to assess the predictors of atherosclerosis progression, given robust relative risk (CI95%) for each independent variable.

Results: The cohort was 96.2% female, 75.8% non-white, with a median (IR) age at baseline of 38(29–46) years. Median (IR) age at lupus diagnosis and disease duration was 27.3(21.5–34.7) years and 7.72 (4.31–11.44) years, respectively. A common carotid IMT increase of 0.06(−0.01–0.14)mm was detected, with a mean annual increase of 0.018(−0.003–0.015)mm. Forty three patients (27.4%) had progressive atherosclerosis: nine(5.7%) had higher plaque score, 31(19.7%) increase in IMT>0.15mm and 3(1.9%) both. Univariate determinants of atherosclerosis progression were age at baseline (p=0.017), SLE duration (p=0.004) and triglycerides level (p=0.024). Nephrotic proteinuria (p=0.063) and the use of prednisone for a longer period (p=0.056) were more frequent in patients with progression, although not statistically significant. Multivariate determinants of atherosclerosis progression were duration of SLE (p=0.007; RR=1.06 CI95%=1.03–1.10) and nephrotic proteinuria (p=0.021; RR=4.22 CI95%=2.18–8.15). Traditional risk factors for CHD were not independently related to atherosclerosis progression.

Conclusion: Atherosclerosis progresses in a substantial number of young SLE patients during short-term follow up. SLE-related risk factors were associated with IMT and plaque progression after controlling for the traditional risk factors for CHD.

Regional Brain Diffusion Abnormalities in Systemic Lupus Erythematosus. Simone Appenzeller[3], Leticia Rittner[4], Gabriel Leonard[1], Martin Vielleux[2], Bruce Pike[1] and Ann Clarke[1]. [1]McGill University, Canada, [2]McGill University, Canada [3]State University of Campinas, Brazil, [4]State University of Campinas, Brazil

Objective: To determine regional brain diffusion abnormalities and to evaluate the relationship between diffusion parameters [fraction anisotropy (FA) and mean diffusivity (MD)] and cognitive impairment and mood disorders in systemic lupus erythematosus (SLE).

Method: We screened consecutive female SLE patients followed in a longitudinal cohort between 2007/2008. We excluded patients with any factors associated with cerebral atrophy or vasculopathy [i.e., age ≥ 50 years, hypertension, renal insufficiency, transient ischemic attack or stroke, scleroderma features, diabetes, drug abuse, or malignancy] or not educated primarily in English or French. Healthy age-matched women were selected as controls. All underwent a standardized neuropsychological evaluation assessing the following: simple attention, complex attention, memory, visuospatial processing, language, reasoning/problem solving, psychomotor speed, and executive functions. Individual results were converted into standard scores and compared to normative data. Subjects with a total score in any of the 8 domains ≤2 SD below the normative value were considered impaired. Mood disorders were determined by Becks Depression and Becks Anxiety Inventory (BDI and BAI). Magnetic resonance imaging (MRI) was performed on a Siemens 3 Tesla scanner and volumetric T1, T2 and PD weighted images were used for automatic segmentation of the brain. Diffusion images were acquired in 63 directions (b=1000s/mm2; TR=10900ms; TE=105ms; FOV=256mm). Brain regions of interest (ROI) were overlaid to the diffusion images acquired and FA and MD were calculated for each structure. The FA and MD values were compared between groups using the t-test. Correlation between cognitive impairment, mood disorders and FA and MD was assessed through the Pearson correlation.

Results: Twenty-seven patients (mean age 34.08, SD 8.85) and ten controls (mean age 33, SD 8.3) were included. We observed significantly lower FA and higher MD in SLE when compared to controls in the following white matter structures: bilateral frontal lobe (p=0.01), right temporal lobe (p=0.031), bilateral parietal lobe (p=0.02), in addition to bilateral amigdala (p=0.005) and the thalamus (p=0.01). No difference between diffusion parameters were observed in the hippocampus, left frontal lobe, occipital lobes, cerebellum, corpus callosum, caudate, putamen and parahippocampal region. FA and MD of the amigdalacorrelated with the severity of anxiety (r=0.7; p=0.001) and FA and MD of the frontal lobe with cognitive impairment (r=0.56; p=0.03).

Conclusion: Diffusion abnormalities are not uniform in SLE patients. Increased MD and reduced FA, indicating reduction in myelination and axonal damage were observed in frontal, temporal, parietal white matter and in the amigdala. The severity of anxiety and the presence of cognitive impairment correlated with axonal damage in the amigdala and in the frontal lobe white matter. Diffusion parameters can be used to evaluate SLE patients with central nervous system manifestations and visually normal MRIs.

Renal Biopsy in Systemic Lupus Erithematosus Patients with Low Levels of Proteinuria. Esther Rodriguez, Julio Sánchez, Eva Salgado, Isabel Mateo, María Galindo and Patricia E. Carreira. Rheumatology Department, Hospital 12 de Octubre, Madrid, Spain

Objective: To evaluate the need of performing renal biopsy in SLE patients with low levels of proteinuria.

Patients and Methods: From 443 patients included in our SLE data base (1974–2009), 150 with biopsy proven lupus nephritis were selected. Demographic (sex, age at onset and diagnosis, death), clinical (type of nephritis, proteinuria, urinary casts, creatinine, aDNA, complement, high blood pressure –HBP-), treatment and outcome (renal failure, relapse, death) data, had been previously included in the data base, or were obtained from the charts. In patients with proteinuria <1 g/d, relationship between clinical data and renal histology, and risk factors for relapse and renal failure were analyzed. Clinical and outcome data were compared between patients with proteinuria lower and higher than 1 g/d. Chi square, Student t test and binary logistic regression were used for statistics.

Results: Out of 150 patients, 42 (29%; 39 f, 3 m; age 30±14 a) had proteinuria <1g/d. Ten patients (24%) did not have renal symptoms, 15 (37%) presented HBP, 8 (19%, all with HBP) creatinine elevation, 9 (21%) granular casts, 26 (62%) aDNA and 36 (86%) low complement levels. Renal biopsies showed: minimal changes 1 (2%), mesangial GN 18 (43%), focal proliferative GN 7 (17%), diffuse proliferative GN 12 (29%) and membranous GN 4 (9%). No correlation between clinical characteristics and histological findings were found. One patient did not receive any treatment, 19 received only glucocorticoids, 15 cyclophosphamide, 6 azathioprine and 1 mophetil mycophenolate. Thirty seven (97%) responded well to therapy (28 complete and 9 partial response). After 14±8 years of follow up, 8 patients relapsed, 6 developed renal failure and 6 died. Presence of proliferative/membranous GN was a risk factor for relapse in this group (p<0.0001). Renal failure in patients with low levels of proteinuria was related to the presence of HBP (p<0.001) and creatinine elevation (p=0.006). Compared to 107 patients with higher proteinuria levels, these had more frequently diffuse proliferative GN (p=0.007) and more relapses (p=0.03). Both groups developed renal failure with similar frequency.

Conclusions: More than half SLE patients with low proteinuria levels present severe disease on renal biopsy. Although they present less diffuse proliferative GN and renal relapses than patients with higher proteinuria, may develop renal failure with the same frequency. Our results support the convenience of performing renal biopsy and careful follow-up to patients with low proteinuria levels, especially if HBP and/or creatinine elevation are present.

Safety Profile of Belimumab, a BLyS-Specific Inhibitor, in Patients with Active Systemic Lupus Erythematosus (SLE): Pooled Data from Phase 2 and 3 Studies. D. J. Wallace[1], S. Navarra[12], A. Gallacher[2], R. Gúzman[10], M. Thomas[7], R. A. Furie[8], O. Zamani[9], R. A. Levy[4], R. van Vollenhoven[11], S. Cooper[6], Z. J. Zhong[5], W. Freimuth[6], L. Pineda[6], R. Cervera[3] and for the BLISS-52 and -76 and LBSL02/99 Study Groups. [1]Cedars-Sinai/UCLA, Los Angeles, CA, [2]Hospital Británico de Buenos Aires, Argentina, [3]Hospital Clinic, Barcelona, Spain, [4]Hospital Universitário Pedro Ernesto, Rio de Janeiro, Brazil, [5]Human Genome Sciences, Inc, Rockville, MD, [6]Human Genome Sciences, Inc, Rockville, MD, [7]Kerala Institute of Medical Sciences, Kerala, India, [8]North Shore LIJ Health System, Lake Success, NY, [9]Rheumazentrum Favoriten, Wien, Austria, [10]SaludCoop, Bogotá, Colombia, [11]The Karolinska Institute, Stockholm, Sweden, [12]University of Santo Tomas Hospital, Manila, Philippines

Purpose: To provide phase 2 and 3 clinical trial safety data on belimumab in SLE patients.

Methods: Safety data were evaluated in 2133 patients with seropositive SLE from 1 phase 2 (LBSL02; N=449; NCT00071487) and 2 phase 3 (BLISS-52; N=865; NCT00424476; and BLISS-76; N=819; NCT00410384), multicenter, double-blind, placebo-controlled studies of belimumab (1 and 10 mg/kg in all studies, plus 4 mg/kg in phase 2 only). Belimumab or placebo was infused over 1–2 h on d 0, 14, and 28, and q28d thereafter, for 48 or 72 wk. All patients received SLE standard of care (SOC), including various combinations of corticosteroids, antimalarials, and immunosuppressants. Clinical and laboratory findings were monitored at every scheduled visit and adverse events (AEs) were reported as they occurred. All 3 studies had a 52-wk placebo-controlled phase; only BLISS-76 had a controlled phase to wk 76. Pooled data of belimumab 1 and 10 mg/kg were compared with placebo. Since the 4-mg/kg dose was not used in the phase 3 studies and can only be appropriately evaluated within LBSL02, it was not included in the table.

Results: There were no remarkable differences between the belimumab 1- and 10-mg/kg, and placebo groups when AEs were categorized by severity, seriousness, or whether they resulted in discontinuation of study agent. Rates of different AEs are shown in table. Rates of infections were numerically slightly higher in the belimumab groups, while rates of serious and/or severe infections were comparable across all groups. Rates of infections of special interest (using a composite definition for each), such as sepsis, cellulitis, herpes, fungal, and respiratory infections, were comparable among all treatment groups. Rates of infusion reactions were numerically slightly higher in the belimumab groups. There were no reports of malignancy, death, or serious hypersensitivity/infusion reactions with the 4-mg/kg dose during the double-blind period. The rate of malignancy, excluding nonmelanoma skin cancers, per 100 patient-y in patients exposed to belimumab was similar to the rate in SLE patients reported by Bernatsky et al (2005). The safety profile of the 4-mg/kg dose was comparable to those of the 1- and 10-mg/kg doses, and placebo in LBSL02.

Conclusions: Overall, belimumab plus SOC therapy was generally well tolerated, with a safety profile comparable to placebo plus SOC.

Table. Integrated Safety Data of 52-Wk Double-Blind Phase

		SOC + Belimumab	
	SOC + Placebo (n=675)	1 mg/kg (n=673)	10 mg/kg (n=674)
% patients with ≥ 1:			
AE in general	92.4	93.0	92.7

Second Renal Biopsy in Proliferative Lupus Nephritis. Alberto Allievi[2], Ana Malvar Perrin[2], Bruno Lococo[2], Mariac Cristina Basta[2], Paola Pirruccio[2], Sebastian Andres Muñoz[2], Alejandra Quevedo[2], Bernarda Fazzini[2], Valeria Alberton[2] and Alejandro Iotti[1]. [1]Hospital Britanico, Ciudad Autonoma de Buenos Aires, Argentina, [2]Hospital Juan A Fernandez, Ciudad Autonoma de Buenos Aires, Argentina

Background: Renal biopsy is one of the main diagnostic tools in lupus nephritis. Disease activity and prognosis can be established through a systematic light microscopic and indirect immunofluorescence analysis of renal tissue. Ultrasonographic guided biopsy has made the collection of renal tissue a common and safe procedure in clinical nephrology. Frequently only clinical parameters are used to evaluate therapeutic response. Correlation between clinical response and histopathology is not always present.

Purpose: To compare the predictive value of clinical and histopathological criteria after six month of induction therapy in diffuse proliferative lupus nephritis at two years.

Methods: thirty three SLE patients with diffuse proliferative lupus nephritis were evaluated prospectively between august 2002 and september 2007. A second renal biopsy was performed after induction treatment with six pulses of cyclophosphamide in 29 patients and sodium mycophenolate in four patients. All patients completed 2 years of maintenance treatment. Responders were treated with azathioprine. We compared between clinical parameters and second renal biopsy findings as predictors of clinical outcome after 24 months. Renal biopsies were evaluated by two experienced renal pathologists blinded to clinical data. The ISN/RPS 2003 classification was used. Serum creatinine levels and 24 hr proteinuria were compared with the second biopsy histopathological findings as predictors of clinical outcome after 24 months. Patients were categorized according to their response to treatment. Those patients with complete or partial response were defined as responders. Clinical response was based on increase or decrease of 24 hs proteinuria and creatinine. Histological response was assesses according to the activity and chronicity index. The increase of both parameters was considered no response, the disparity of both was apartial response and the improvement of both parameters was considered response.

Results: Thirty three patients were assessed according to the protocol. We

have biopsy results for all of them and they have been followed for 2 years. Seven patients presented membranous glomerulopathy in the second renal biopsy, 6/7 had good clinical evolution two years later. 19/26 patients with good clinical response after induction treatment were in low concordance with clinical evolution two years after (46.15 %; Spearman's: 0.1785, Kappa: 0.13). Second renal biopsy performed after induction treatment revealed information more accurate about two years clinical evolution with concordance of 73.08 % (Spearman's: 0.57, Kappa: 0,50, p<0,001).

Conclusions: In our experience, membranous nephropathy in the second renal biopsy was coincidental with good clinical evolution. Second renal biopsy revealed more accurate information than clinical evolution.

Seroprevalence of NMO-IgG (Anti-Aquaporin 4 Antibodies) in Patients with Neuropsychiatric Systemic Lupus Erythematosus. Jakub Zavada[4], Petra Nytrova[1], Klaus-Peter Wandinger[2], Svobodova Radka[4], Ivana Putova[4], Dana Tegzova[4] and Jiri Vencovsky[3]. [1]Department of Neurology, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Czech Republic, [2]Institute of Experimental Immunology, Euroimmun, Lübeck, Germany, [3]Institute of Rheumatology, Prague, Czech Republic, [4]Institute of Rheumatology and First Faculty of Medicine, Charles University in Prague, Czech Republic

Background: Neuropsychiatric manifestations are present in up to 60% of patients with systemic lupus erythematosus (SLE) with psychosis, seizures, headaches and cerebrovascular accidents being most common. However, transverse myelitis has also been described in aproximately 1–2% of SLE patients. Neuromyelitis optica (NMO) is an inflammatory demyelinating disease (syndrome) of the central nervous system (CNS), characterized by sequential or concomitant attacks of transverse myelitis (TM) and optic neuritis (ON), and has occasionally been reported in conjunction with SLE. The distinction between myelitis associated with NMO-IgG and myelitis of another etiology may be difficult but crucial for futher treatment and prognosis of the involved patients. The serum autoantibody NMO-IgG (anti-aquaporin 4 antibody) is considered to be a sensitive and specific marker for NMO. The antigenic target of these antibodies is aquaporin-4 (AQP4), the most abundant water channel in the CNS. Although the prevalence of NMO-IgG antibodies was examined in minor cohorts of patients with established SLE, only one very recent study reported data on SLE patients with established neuropsychiatric involvement. That is why we decided to evaluate the NMO-IgG seroprevalence in another larger cohort of patients with diagnosed neuropsychiatric lupus (NPSLE).

Patients and Methods: We have retrospectively studied NMO-IgG (anti-AQP4 Ab) in sera of 50 patients with NPSLE. All of the patients fulfilled the American College of Rheumatology (ACR) criteria for SLE and suffered from neuropsychiatric involvement as defined by the ACR nomenclature for NPSLE. Only one of them was treated for TM. ON was not documented in this strictly defined cohort. NMO-IgG (anti-AQP4 Ab) has been tested by indirect immunofluorescence on AQP-4 transfected HEK cells

Summary of the Results: Only one of the examined sera (in the patient with TM who has not fulfilled the criteria for NMO) has been positive for NMO-IgG (anti-AQP4 Ab). None of the remaining 49 NPSLE patients without documented concomittant ON or TM has been found to be seropositive for NMO-IgG (anti-AQP4 Ab) antibodies.

Conclusion: These findings support the notion that NMO-IgG (anti-AQP4 Ab) could play a role in the pathogenesis of some cases of TM and/or ON. NMO-IgG (anti-AQP4 Ab) are not detectable in NPSLE patients without TM and/or ON. However, in patients with SLE and concomitant ON/TM, it is very useful to assess the NMO-IgG (anti-AQP4 Ab) in serum due to selection of a suitable treatment regimen.

1175

Serum Free Light Chains and Disease Activity in Systemic Lupus Erythematosus. Meenakshi Jolly[1], Rohit Aggarwal[4], Rachel Mikolaitis[3], Joel A. Block[2] and Winston Sequeira[1]. [1]Rush University Medical Center, Chicago, IL, [2]Rush University Medical Center, Chicago, IL, [3]Rush University Medical Center, [4]University of Pittsburgh Medical Center, Pittsburgh, PA

Purpose: We previously reported the superiority of using Total Free Light Chains (TFLC) as a biomarker of disease activity as compared to high sensitivity DsDNA and IgG in 75 patients with Systemic Lupus Erythematosus (SLE). Herein we report our experience with the use of TFLC in 205 SLE patients as a biomarker for disease activity.

Methods: 211 consecutive consenting SLE patients attending an outpatient Rheumatology clinic at a University Hospital were enrolled. Disease activity was assessed using physician global assessments (PGA) and Selena-SLEDAI. Adjusted SLEDAI (adjSLEDAI= SLEDAI – [C3C4 and Ds-DNA score]) was obtained. Serum FLC (Kappa (κ), Lambda (λ) and total FLC ($\kappa + \lambda$)) was measured using nephelometry (Binding site, UK). Additional data on DsDNA (positivity {n=182} and titres {n=171}) and complement (C3 & C4 abnormality {n=171} and titres {109}) were available from the same blood sample. Spearman correlation was used to correlate total FLC, DsDNA positivity, titre, Complement abnormality and titre with PGA, SLEDAI and adjusted SLEDAI. Mann-Whitney or Kruskall Wallis test was used to compare continuous data.

Results: The mean age was 42±13 yrs. African American 45%, Caucasian 30%, Hispanic 12%, Asian 10% and Others 4%. PGA and SLEDAI were (mean± SD, median) 0.7± 0.8, 0.5 and 4.2 ±4.3, 2 respectively. Fifty six percent were taking prednisone. The TFLC values (mean± SD, median) were 62.5 ± 69.8, 44.3. Correlations are tabulated below.

Table 1. Correlation between markers and disease activity.

	TFLC	DsDNA abnormality	DsDNA titre	Complement abnormality	C3 titre	C4 titre
PGA	0.39 (P=0.0001)	0.39 (P=0.0001)	0.34 (P=0.0001)	−0.14 (P=0.07)	−0.24 (P=0.01)	−0.14 (P=0.16)
SLEDAI	0.44 (P=0.0001)	0.49 (P=0.0001)	0.47 (P=0.0001)	−0.13 (P=0.16)	−0.41 (P=0.0001)	−0.23 (P=0.03)
Adj-SLEDAI	0.39 (P=0.0001)	0.23 (P=0.03)	0.211 (P=0.05)	−0.08 (P=0.45)	−0.15 (P=0.22)	−0.12 (P=0.31)

Conclusions: TFLC is correlated with disease activity, even after removing DsDNA and complement information from the disease activity score. Its correlation with adjusted SLEDAI is the strongest as compared to DsDNA positivity, titres, complement abnormality or complement titres. These data suggest that TFLC may serve as a potential biomarker for SLE, especially in the patients who lack DsDNA antibodies. Longitudinal studies are now indicated.

Shrinking Lung Syndrome Is Associated with Pleuritis. David Allen[3], Zoheir Bshouty[3], Mellissa Moyen[3], David B. Robinson[3], Christine A. Peschken[1], Carol A. Hitchon[3], Hani S. El-Gabalawy[2] and Shikha Mittoo[1]. [1]Univ of Manitoba, Winnipeg, MB, Canada, [2]University of Manitoba, Winnipeg, MB, Canada, [3]University of Manitoba, Winnipeg, MB, Canada

Background: Shrinking lung syndrome (SLS) is a form of pulmonary damage in systemic lupus erythematosus (SLE) characterized by unexplained dyspnea, small lung volumes and restrictive lung physiology with or without diaphragmatic elevation. The pathophysiology of SLS is incompletely understood but is associated with significant morbidity and may require escalation of therapy to avoid fulminant respiratory failure. Pleuritis has been reported in 30–60% of patients with SLS. We set out to determine the frequency of SLS in patients with SLE and if pleuritis is associated with SLS.

Methods: Consecutive patients ≥ 18 years of age who met American College of Rheumatology (ACR) criteria for SLE were enrolled. Demographics, disease duration, smoking status, body-mass index (BMI), self-reported dyspnea, pleuritic chest pain (CP), autoantibodies and measures of disease activity; SLE Activity Measure (SLAM), cumulative organ damage (Systemic Lupus International Collaborating Clinics damage index (SDI), ACR criteria modified to exclude pulmonary variables (mACR) were recorded. All

patients underwent pulmonary function testing (PFTs) and chest imaging (X-ray or CT scan).

Pleuritis was defined as serositis by ACR criteria, relying on the presence of CP, a rub or a history of pleural effusion on chest X-ray. At enrollment, SLS was defined as a forced vital capacity (FVC) or total lung capacity (TLC) <80% predicted without evidence of interstitial/pleural disease on imaging or myositis/myalgia causing impairment.

Univariate and multivariate logistic regression was used to determine factors associated with SLS and the relationship between pleuritis and SLS. Results are reported as mean ± SD unless stated otherwise.

Results: One hundred patients (94% women, 81% Caucasian) with an age at diagnosis of 33.8 ± 13.8 years, disease duration of 13.2 ± 9.2 years, had a mACR of 5.5 ± 1.2, total SDI of 1.2 ± 1.2, and total SLAM of 7.1 ± 3.6. Fifty-four of 99 reported ≥ 1 respiratory symptom; 52/99 had dyspnea and 26/99 had CP. Thirty-four had SLS; 23/33 had dyspnea and 13/33 had CP. Dyspnea and CP was more common in those with SLS [n=25/34 (71%) vs n=27/65 (42%), p=0.006] and [n=15/34 (43%) vs n=11/64 (17%), p=0.007].

Thirty-five patients had pleuritis. SLS was more common among those with pleuritis compared to those without, [26/34 (57%) vs. 14/65 (22%), (p<0.0001)]. As well, disease duration (p=0.05), self-reported dyspnea (p=0.02), anti-RNP (p=0.001), anti-Sm (p=0.002), and mACR (p=0.02) were significantly associated with SLS. However, age at diagnosis, BMI, pCP, ethnicity, smoking status, SDI, SLAM and anti-dsDNA, anti-Ro, and anti-La, were not associated with SLS.

In multivariate analysis controlling for pleuritis, disease duration, self-reported dyspnea, mACR, presence of anti-RNP and Sm antibodies, only pleuritis remained associated with SLS [OR= 3.6, 95% CI of 1.3–10.1, p=0.02].

Conclusions: SLS was a frequent finding in this unselected cohort, occurring in 57% of patients and pleuritis was significantly associated with SLS. This suggests that pleural disease may be important in the etiology of SLS. Further, the presence of pleural disease in patients with SLE should result in an assessment for SLS.

The Metabolic Syndrome in Systemic Lupus Erythematosus: More Than the Sum of Its Parts? Ben Parker[3], Yasmeen Ahmad[4], Joanna Shelmerdine[1], Sahena Haque[2] and Ian N. Bruce[1]. [1]Manchester, United Kingdom, [2]Manchester, United Kingdom, [3]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [4]Manchester Royal Infirmary, Manchester, United Kingdom

Purpose: The metabolic syndrome (MetS) is a clustering of metabolic abnormalities in individuals with increased adiposity and is associated with an increased risk of developing diabetes and coronary heart disease (CHD). The prevalence of the MetS is increased in SLE although rates of obesity are not. Therefore lupus-specific factors and inflammatory disease may be an important contributor to the metabolic derangements observed in those SLE patients with the MetS. The aim of this study is to determine those disease characteristics associated with the presence of the MetS and to investigate whether the MetS is associated with the presence of carotid plaque in patients with SLE.

Methods: Caucasian women with SLE were assessed in a cross-sectional observational study. Disease activity (SLEDAI), disease damage (SLICC-DI) and clinical characteristics were determined. The MetS was defined according to the 2009 Consensus Statement from the IDF and partners. All patients underwent B-mode ultrasound of the common carotid and proximal internal and external carotid arteries to detect plaque. Mutivariate logistic regression was performed to determine the association between disease characteristics and the MetS, and the presence of carotid plaque and the MetS.

Results: 200 women with SLE were assessed of whom 30% fulfilled the criteria for the MetS. Those meeting the MetS definition were older (median (IQR) age 53 (46, 59) years vs. 46.5 (41, 53) years, p = 0.001) and had a longer disease duration (median (IQR) 14 (6–22) years vs. 7 (4–16) years, p = 0.002) than those who did not. In a multivariate model the presence of the MetS was associated with age, disease duration and low C3 but not with average steroid dose.

Table 1. Lupus Features associated with the MetS

Variable	Age-Adjusted OR (95% CI)
Low C3	8.46 (1.25, 57.0))
Age	1.06 (1.01, 1.10)
Disease duration	1.05 (1.01, 1.09)
Steroids Ever	2.46 (0.69, 8.72)
Azathioprine Ever	2.06 (0.89, 4.75)
SLICC	1.35 (0.99, 1.85)
Renal Disease Ever	1.89 (0.63, 5.66)
Average Steroid Dose (6 months)	1.03 (0.97, 1.11)

Carotid plaque was present in 42% of SLE patients with the MetS compared to 23.5 % of patients without (p = 0.01). Overall, the MetS was not independently associated with the presence of carotid plaque (OR 1.7 (95% CI 0.8, 3.4). However, fulfilling IDF criteria for high blood pressure and hypertriglyceridaemia (OR 2.9 (1.3, 6.3) and 2.2 (1.1, 4.4) respectively) were both associated with the presence of carotid plaque.

Conclusions: The MetS is more prevalent with increasing age in SLE. Low complement and disease duration were independently associated with the presence of the MetS in SLE suggesting a role for inflammatory activity in contributing to the syndrome. The MetS was not associated with the presence of carotid plaque overall, although individual criteria were. Therefore a CHD risk assessment strategy attending to these individual risk factors would appear a more important way to modify CHD risk in patients with SLE.

1178

The Prevalence of Liver Abnormalities in Patients with Systemic Lupus Erythematosus. Darryl Huang[2], Ellie Aghdassi[2], Jiandong Su[2] and Paul R. Fortin[1]. [1]Toronto Western Hospital, Toronto, ON, Canada, [2]University Health Network, Division of Rheumatology, Toronto, ON, Canada

Studies reporting on liver involvement in Systemic Lupus Erythematosus (SLE) are limited, often focused on liver transaminases and without inclusion of imaging procedures and/or liver biopsies. Furthermore, the etiology for the abnormal transaminases has not been investigated. This study determined in SLE patients: 1) the prevalence of abnormal liver function tests (LFTs) and whether further investigations were done; 2) the differences in SLE-related and/or metabolic factors in patients with and without abnormal LFTs. Patients who met at least 4 of the ACR classification criteria for SLE and had 1.5 times the upper limit for AST or ALT on two visits within a 2-year period were selected from the database registry of the University of Toronto Lupus Clinic. Demographic, and laboratory data at the time of the first appearance of LFTs abnormality were extracted from these patients as well as the age, gender and SLE duration matched controls who had normal LFTs. Disease activity and damage were assessed by SLE- Disease Activity Index (SLEDAI) and SLICC Damage Index (SDI). Chart review was performed to determine the contributing factors to these liver abnormalities. Data were analyzed using SPSS statistical program. Out of 1533 patients in the database, 135 (8.8%) with a mean (SD) ACR of 6.4 (1.5) met the inclusion criteria. The subjects had mean (SD): age of 40.1 (13.7) years, BMI of 25.9 (5.8) kg/m2, SLEDAI of 6.4 (5.4), SDI of 1.5 (1.8) and 83% were female. Among patients, 65% were Caucasian; 23% smoked; 30% consumed alcohol, 61% had hypertension, 7% had previous cardiovascular involvement and 68% had other autoimmune disorders. Medication profile of the two year period preceding the first abnormal LFT included: prednisone (67% of patients) with a mean (SD) dose of 12.1 (15.3) mg; antimalarial (63%), immunosuppressants (61%), statins (16%), hormone replacement therapy (13%) and anticoagulants (13%). Laboratory findings were normal for CBC, blood glucose and lipid profile except for serum triglycerides that was elevated (2.10 ± 2.04 mg/dl). The mean (SD) levels for AST and ALT were 73 (67) and 88 (79) respectively. Chart review completed in 60 of the patients, showed that only 12 patients were further evaluated by a Hepatologist, 30 had an abdominal ultrasound (US) (15 fatty liver, 3 fibrosis, 11 with suspected drug-induced hepatitis), and only 3 had a liver biopsy. However, only 15 of the US were done specifically for liver investigation. In the nested case control study of 134 matched subjects, cases had higher prevalence of: hypertension (60% VS. 46%, p=0.02); antiphospholipid syndrome (9% VS. 2% p=0.02); and immunosuppressants use (60% VS. 37%, p<0.001), especially azathioprine (39% VS. 22%, p<0.01) and methotrexate (22% VS. 10%, p<0.01) compared to controls. Although, BMI, SLEDAI and SDI were similar, blood biochemistry showed a significantly lower IgM (1.2 (0.7) vs 1.5 (1.0), p=0.03) and higher triglycerides (2.1 (2.1) vs 1.7 (1.2), p=0.05) among cases compared to the controls. Factors associated with the metabolic syndrome, such as obesity, insulin resistance, and hypertension, as well as side-effects of the drugs used in the treatment of SLE may contribute to liver abnormalities in SLE.

Undertreatment of Active Disease May Increase Mortality in Lupus Patients with End Stage Renal Disease. Anna R. Broder[2] and Chaim Putterman[1]. [1]Albert Einstein College of Med, Bronx, NY, [2]Montefiore Medical Ctr, Bronx, NY

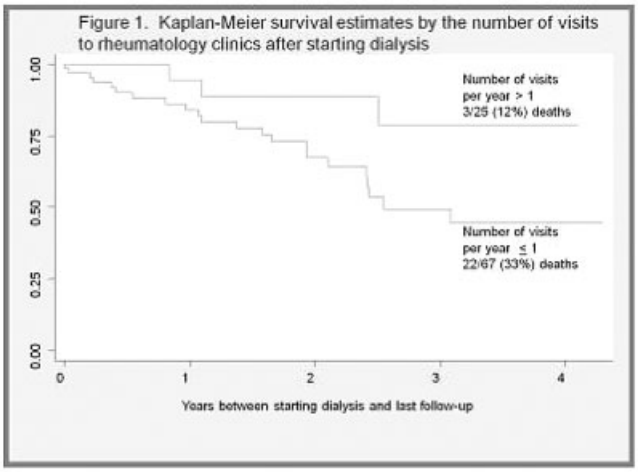
Background: Earlier studies have concluded that SLE becomes quiescent once end stage renal disease (ESRD) develops. However, more recent publications and our clinical experience suggest that SLE can remain active even in patients undergoing dialysis. SLE patients with ESRD receiving chronic dialysis may not be followed as closely by the rheumatologists, and, therefore, active SLE is underdiagnosed and undertreated.

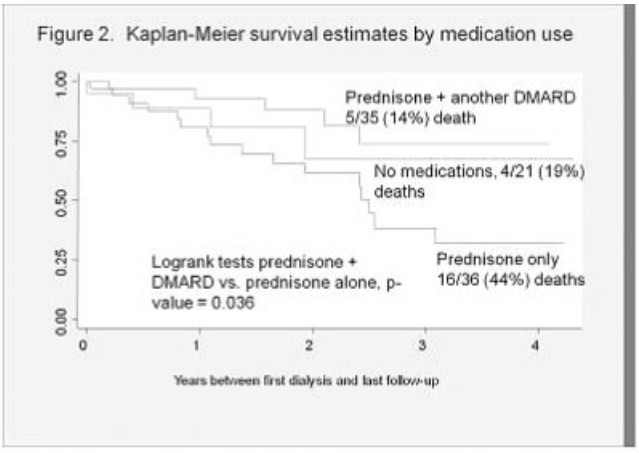
Methods: We identified all patients over 18 years old with SLE who started dialysis between 2000 and 2010 at a large urban tertiary care center. Mortality data was obtained using in-hospital records and Social Security Death Index database.

The number of rheumatology clinic visits was analyzed as 1 or more visits per year ("frequent") or between 0 to 1 visits per year ("infrequent"). Time to event was defined as the number of years from the start of dialysis to the last follow-up date.

Results: We identified 92 ESRD/SLE on dialysis, 79 women and 13 men, mean age 48 (±16) years. The median duration between first dialysis and last follow-up was 1.6 years IQR (0.5, 2.5). Twenty of these patients (22%) died during follow-up from various causes includin infections, GI or CNS hemorrhage, status epilepticus, and heart failure. ESRD/SLE patients seen frequently by rheumatologists were younger compared with patients followed infrequently (35 years old (28, 43) vs. 51 years old (41, 58)). The 2 groups were similar in terms of race/ethnicity and duration of follow-up.

The results of survival analysis are shown in Figures 1 and 2.





ESRD/SLE patients followed frequently in rheumatology clinics at our center had significantly lower mortality rates compared with patients followed infrequently, 3/25 (12%) vs. 22/67 (33%), log rank p-value =0.039; HR 0.24, 95% CI (0.07, 0.83), p=0.041 adjusted for age and the number of rheumatology visits before they began dialysis. Moreover, ESRD/SLE patients treated with prednisone alone had higher mortality rates compared with prednisone in combination with hydroxychloroquine, mycophenolate mofetil, or azathioprine, 16/36 (44%) vs. 5/35 (14%), logrank p = 0.036; adjusted HR 0.36, 95% CI (0.13, 1.0), p=0.05. We did did account for medication doses. Differential selection, misclassification, and medication compliance may have affected the results in this retrospective analysis.

Conclusions: Treatment with prednisone alone in ESRD/SLE patients may be associated with higher mortality rates compared to prednisone in combination with other DMARDS. Active disease in SLE patients on dialysis may be unrecognized and undertreated leading to increased mortality.

Vitamin D Levels Are Positively Associated with Complement among Patients with SLE. Michelle A. Petri[1], Kayode Jibril Bello[2], Hong Fang[2] and Laurence Magder[3]. [1]Timonium, MD, [2]Johns Hopkins University School of Medicine, [3]University of Maryland School of Medicine

Purpose: Vitamin D deficiency is common in SLE. Vitamin D deficiency has been associated with diabetes mellitus, cardiovascular disease, and certain forms of cancer; all represent outcomes increased in SLE patients. In murine SLE models, Vitamin D is an immunomodulator. We investigated whether Vitamin D levels were associated with disease activity in patients who took vitamin D supplements for vitamin D deficiency.

Methods: As part of routine clinical care, 478 SLE patients were determined to have low levels of 25 OH Vitamin D (<32 ng/mL). 50,000 units Vitamin D was then given weekly for 12 weeks, with Ca/D 200 units twice daily. One physician measured the physician's global assessment (PGA) and SLEDAI at all visits. Linear regression models were used to estimate the association between change in vitamin D and change in various measues of disease activity. The dependent variables analyzed in the models were change in PGA, change in SLEDAI, change in Urine Protein/Creatinine Ratio, change in C3, change in C4, and change in anti-dsDNA. The independent variable was change in Vit D. Generalized estimating equations were used to account for the repeated observations from the same patients.

Results: The SLE patients were 91.7% female, mean age 44.9, 53.9% Caucasian, 38.3% African-American, 7.8% other ethnicity. At baseline, the mean PGA (0–3 VAS) was 0.6 ± 0.6 and mean SLEDAI was 2.0 ± 2.8. The mean 25 OH Vit D at baseline was 29.3 ± 14.4 and at 3 months was 35.9 ± 14.9.

Table 1. Effect of change in Vit D on disease activity by univariate analysis

	Estimated change in variable per 10 units increase in Vit D	P-Value
PGA	0.002 ± 0.012	0.9004
SLEDAI	0.029 ± 0.051	0.5680
Urine Pr/Cr Ratio	−0.009 ± 0.011	0.4124
C3	1.739 ± 0.542	0.0013
C4	0.315 ± 0.118	0.0076
Anti-dsDNA	2.281 ± 1.978	0.2487

Vit D levels were not associated with PGA, SLEDAI, urine protein/Creatinine ratio, but were associated with an improvement in C3 and C4.

Conclusion: Change of Vitamin D levels in this outpatient SLE population were neutral in terms of clinical disease activity. Further followup of this population will allow us to determine if there are delayed clinical effects. However, there was a statistically significant effect on both C3 and C4. The effect on C3 might have clinical implications in that low C3 is known to be associated with SLE renal disease and increases the risk of flare. This analysis cannot address the effects of "super" supplementation, since no attempt was made to achieve 25 OH Vit D levels higher than 40 ng/mL. However, the data suggest that clinical trials to achieve higher levels of 25 OH Vit D are indicated.

Acute Flares of Neuropsychiatric Systemic Lupus Erythematosus (NPSLE) Are Sometimes Associated with Spikes of Interferon-alpha Activity in the CSF. Elisabet Svenungsson[2], Clio P. Mavragani[1], Liisa Hopia[3], Mohsen Khademi[3], Anna Laveskog[2], Mary K. Crow[1] and Magnus Andersson[2]. [1]Hospital for Special Surgery, New York, NY, [2]Karolinska Institutet, Stockholm, Sweden, [3]Karolinska Institutet, Sweden

Background: Neuropsychiatric involvement in Systemic Lupus Erythematosus (NPSLE) is a serious complication affecting a large proportion of systemic lupus erythematosus (SLE) patients. Diagnosis and treatment is a challenge as no specific biomarker/investigation for NPSLE is available. Enhanced interferon-alpha (IFN-a) activity has been identified as an important ethiopathogenic factor in SLE, and a previous study reported that IFN-a contributes to NPSLE. We investigated IFN-a activity in the systemic and intrathecal compartments of patients with acute and chronic symptoms of NPSLE.

Methods: 59 NPSLE patients, who fulfilled the ACR 1982 revised criteria for SLE, were evaluated clinically. Lumbar puncture and magnetic resonance imaging (MRI, n=56) was performed. All presented with one or several NPSLE manifestations as defined by the ACR NPSLE case definitions. The majority (n= 49) had chronic NPSLE symptoms but 10 were investigated during acute NPSLE flares. Paired blood and cerebrospinal fluid (CSF) samples were collected from patients and controls (15 Multiple Sclerosis (MS) patients, 22 patients with other neurological diseases (OND)). IFN-a activity was measured as a score with a functional cell reporter assay. mRNA expression of IFN-a was determined in peripheral blood and CSF mononuclear cells (PBMC, CSF-MC) in 39 patients and in a different set of controls (MS=34, OND=24).

Results: On a group level there were no differences between SLE patients and controls with respect to IFN-a activity or IFN-a mRNA expression in PBMCs or CSF-MCs, but IFN-a scores were higher in acute than in chronic NPSLE cases ($p=0.007$). A few patients, but no controls, had very high levels of IFN-a activity in CSF and blood. 4/10 acute vs. 5/49 chronic NPSLE patients had high (>+2SD) IFN-a activity in the CSF ($p=0.02$). A similar trend was observed in blood where 5/10 with acute vs. 5/49 with chronic NPSLE had high IFN-a scores ($p=0.07$). There was no corresponding increase in mRNA expression in CSF-MCs or PBMCs. Two patients had very high mRNA expression in CSF-MCs. One of these patients had an acute NPSLE flare. There was no specific NPSLE symptom (mood disorder, headache, cognitive dysfunction, seizures or previous infarction), CSF aberration or MRI finding, which was convincingly associated with high IFN-a activity or high expression of IFN-a mRNA.

Conclusion: Our results indicate that IFN-a activity in the CSF is high in some patients with NPSLE and is often associated with acute NPSLE symptoms. As a group, patients with chronic NPSLE had similar IFN-a activity in CSF and blood to controls. IFN-a activity may be of diagnostic potential in patients with SLE who present with acute neurological symptoms.

Allogeneic Mesenchymal Stem Cells Inhibited OAZ Expression in Patients with Systemic Lupus Erythematosus. Xuebing Feng[1], Rongliang Li[2], Jing Huang[2], Dandan Wang[2], Xiaolei Ma[2], Betty P. Tsao[3] and Lingyun Sun[2]. [1]Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China, [2]Affiliated Drum Tower Hospital of Nanjing University Medical School, [3]UCLA School of Medicine, Los Angeles, CA

Objective: Allogeneic mesenchymal stem cell transplantation (MSCT) has been applied to successfully treat patients with refractory systemic lupus erythematosus (SLE) (Sun et al A & R, 2010). However, the underlying mechanism is still unclear. Recently we have shown Olf1/EBF associated zinc finger protein (OAZ), a novel lupus susceptibility gene, involves in the production of antinuclear antibody (ANA) that is partly through the regulation of ID genes. This study is to explore whether allogeneic MSCT helps down-regulate elevated OAZ expression in SLE patients.

Methods: Study protocol was approved by the hospital's Ethics Committee. MSCs were isolated and expanded from bone marrow of 5 SLE patients and 6 healthy subjects. After culturing for 3 passages, MSCs were harvested and mRNA levels of OAZ and ID1, ID3, two downstream genes of OAZ, were measured by qRT-PCR. MSCs expanded from umbilical cord (9 cases) or bone marrow cells (1 case) of healthy donors were infused once to 10 refractory SLE patients at 10^6cells/kg of body weight. Peripheral blood cells (PBLs) were collected before and one week as well as four weeks after MSCT, and transcript levels of OAZ and IDs were measured. Concurrently, serum levels of IL-10, IL-12, IL-21, CCL2 and ANA were tested by ELISA. Relationships between gene expressions and cytokine levels as well as ANA values were analyzed. Data were shown as mean +/− SEM.

Results: Compared to PBLs, MSC expression of OAZ transcripts was 150 and 110 times higher in SLE patients and normal controls, respectively. OAZ expressions of MSCs in SLE patients were elevated compared to those in normal subjects ($p = 0.03$), but expressions of ID1 and ID3 were not different. Ten SLE patients (9 female and 1 male, 32.2 ± 3.7 years old) who accepted MSCT had decreased OAZ expressions in PBLs by 42.6% ±17.1% one week after MSCT compared to those before MSCT ($p < 0.05$) with concomitant reduction in disease activity (SLEDAI score was 14.9 ± 0.6 before MSCT, 13.0 ± 0.5 one week later) which continued to drop further four weeks after the transplant (a reduction of 37.6% ±12.4% compared to those at one week, $p < 0.05$). Peripheral gene expressions of ID1 and ID3 were also significantly down-regulated after MSCT ($p < 0.05$). Four weeks after MSCT, serum levels of IL-10, IL-21 and ANA were significantly decreased ($p < 0.05$ in all), while CCL2 level was elevated ($p < 0.05$) compared to the baseline levels. Compared to the value before MSCT, inhibited peripheral OAZ expression four weeks after MSCT was inversely correlated with reduced IL-21 levels ($r = -0.88$, $p < 0.05$) and ANA values ($r = -0.91$, $p < 0.01$) but positively correlated with increased CCL2 levels ($r = 0.92$, $p < 0.01$).

Conclusion: OAZ is highly expressed in MSCs from SLE patients. Allogeneic MSCT helps down-regulate OAZ expression and its downstream components, which may account for the ameliorated SLE disease activity. The differential expressions of ID1 and ID3 in peripheral blood cells but not MSCs support that MSCs could exert their roles through the regulation of other cells types.

Analysis of Vascular Endothelium from Female Systemic Lupus Erythematosus (SLE) Patients Identifies an Interferon Signature That Correlates with Disease Activity. Diana Goldenberg[3], Mikhail Olferiev[3], Duygu Onat[1], Danieli Andrade[3], Mary K. Crow[3], Paolo C. Colombo[1] and Jane E. Salmon[2]. [1]Columbia University College of Physicians and Surgeons, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgery, New York, NY

Background: Accelerated atherosclerosis has emerged as a significant threat to the health of patients with systemic lupus erythematosus (SLE). Endothelial dysfunction represents an important precursor to the development of atherosclerosis. The type I interferons likely influence the relationship between endothelial dysfunction and vascular health in lupus patients. To study the pathogenesis of endothelial dysfunction in SLE, we utilized a novel, minimally-invasive approach to sample venous endothelial cells (ECs) and perform gene expression profiling.

Methods: Venous endothelial cells were sampled from 11 adult SLE patients and 10 healthy controls. ECs were collected from arm veins using endovascular wires. ECs were purified; amplified RNA was hybridized with Affymetrix HG-U133 2.0. Samples were normalized to the baseline median level according to the RMA algorithm. Data was analyzed using GeneSpring GX 11 software. Student T test analysis for multiple samples was performed. Differentially expressed genes with >2.0 fold expression and $p<0.05$ were selected. SLE disease activity was assessed by SLEDAI at the time of endothelial sampling. The interferon score was determined using the mean of the normalized expression values for IFIT1, IFIT3, MX2 and OAS2. To simulate our in vivo findings and to determine whether SLE serum could directly alter endothelial cell gene profiles, we cultured HUVECs with sera from SLE patients and healthy controls and assessed their capacity to induce interferon-inducible genes, IFIT1, IFI44 and MX1 using Real-time quantitative polymerase chain reaction.

Results: Eleven (8 females, 3 males) adult SLE patients meeting American College of Rheumatology criteria for SLE and 10 age-matched controls

were studied. Their mean age was 32.2 ± 10.2 yrs, mean SLEDAI score was 6.82; range 0–20. Ten age-matched healthy subjects were studied. A total of 2013 known genes were differentially expressed (FC ≥2, p<0.05) between all SLE patients and controls while 183 known genes were differentially expressed (FC ≥2, p<0.05) between female SLE patients and matched controls. IFIT1 and IFIT3 were upregulated in the 11 SLE patients compared with controls. In female SLE patients the interferon signature was particularly robust: IFIT1, IFIT3, MX2 and OAS2 were upregulated. The interferon score correlated significantly with SLEDAI in female patients (R=0.75, p = 0.04). Similar to the results of our in vivo venous endothelial samples, HUVECs cultured with sera from SLE patients showed increased expression of the interferon inducible genes compared with those exposed to sera from control patients (109.1 ± 41.42 vs 0.04 ± 0.01).

Conclusions: Microarray analysis of primary venous endothelial cells distinguished SLE patients from healthy controls based on the expression of interferon-inducible genes. In the 8 female SLE patients, SLE disease activity correlated with the interferon score. These results support the possibility that interferon contributes to the pathogenesis of endothelial dysfunction in SLE patients.

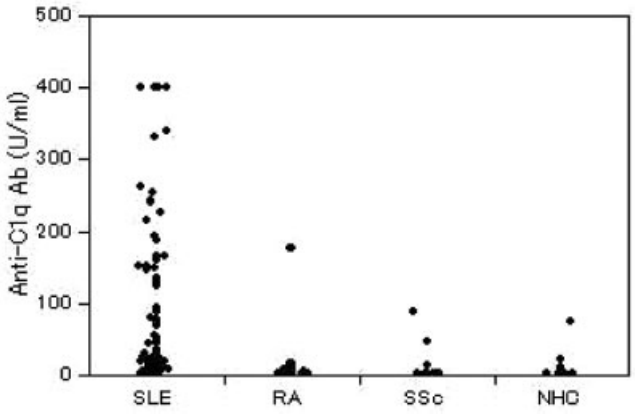
1184

Anti-C1q Antibodies Are Associated with Global Activity of Systemic Lupus Erythematosus, but Not Specifically with Nephritis. Yuko Okamoto[1], Yasuhiro Katsumata[5], Yasushi Kawaguchi[2], Kohei Miyake[5], Manabu Kawamoto[5], Kae Takagi[5], Takahisa Gono[5], Sayumi Baba[5], Yuko Ota[5], Masako Hara[4] and Hisashi Yamanaka[3]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Tokyo Women's Medical University, Tokyo, Japan, [3]Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan, [4]Tokyo Women's Medical University, Kamakura Kanagawa, Japan, [5]Tokyo Women's Medical University

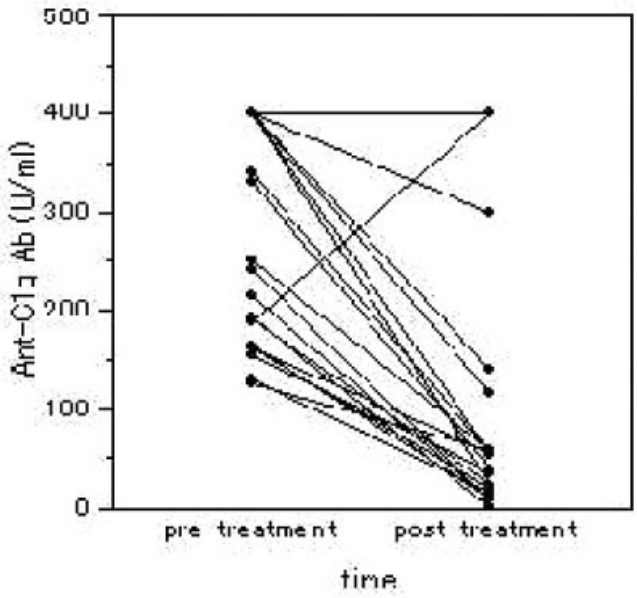
Purpose: Antibodies against complement C1q (anti-C1q Abs) are frequently found in patients with autoimmune diseases such as systemic lupus erythematosus (SLE). It has been reported that they correlate with the occurrence and activity of nephritis and cutaneous vasculitis in SLE. Additionally, their pathogenic role in SLE, such as direct link with apoptosis, has been suggested. However, the significance of anti-C1q Abs in SLE has not been fully characterized. This study was conducted to investigate associations between anti-C1q Abs and clinical and serological parameters of SLE.

Methods: Anti-C1q Abs were measured using ELISA kit (BÜHLMANN Laboratories AG, Schönenbuch, Switzerland) in sera of 126 consecutive active SLE patients who were admitted to our university hospital from 2007 through 2009. Sera of patients with high-titer anti-C1q Abs at initial evaluation were re-evaluated when their disease ameliorated (n = 20). Sera of patients with other autoimmune diseases and normal healthy controls were also assessed (n = 20 in each control group). Associations between anti-C1q Abs and clinical and serological parameters of SLE were statistically analyzed.

Results: The titers and the positivity rate of anti-C1q Abs were significantly higher in patients with active SLE than in patients with rheumatoid arthritis, systemic sclerosis, or normal healthy controls ($p < 0.0001$ in all comparisons).



Anti-C1q Abs were detected in sera of active SLE patients with various manifestations, which yields sensitivity of 63% and specificity of 90%. Inconsistent with previous reports with fewer samples, the titers or the positivity rate of anti-C1q Abs were not associated with active lupus nephritis (n = 23; $p = 0.75$ and 1.00, respectively). However, the titers of anti-C1q Abs were mildly correlated with the values of SLEDAI, anti-dsDNA Abs, C3, C4 and CH50 ($p < 0.0001$ in all comparisons). In addition, the titers of anti-C1q Abs significantly decreased in accordance with clinical amelioration by treatment in the cases with high-titer anti-C1q Abs at initial evaluation (median decrement 85%; $p = 0.0008$).



Conclusions: These findings indicate that anti-C1q Abs are associated with global activity of SLE, but not specifically with active lupus nephritis. Moreover, anti-C1q Ab might be useful as a surrogate marker of SLE in cases with this antibody.

1185

Biomarkers of Oxidative Stress, mTOR Activation, and Treg Depletion Correlate with Disease Activity in Patients with Systemic Lupus Erythematosus. Zhiwei Lai[1], Adam Bartos[1], Tiffany Tekarico[1], Robert Hanczko[1], Gabriella Miklossy[1], Brandon Clair[1], John Jimah[1], Lisa Francis[1], Hajra Tily[1], Ricardo Garcia[1], Maha Dawood[1], David R. Fernandez[1], Paul E. Phillips[2], Ioana Coman[1] and Andras Perl[3]. [1]SUNY, [2]SUNY-Upstate Medical Univ, Syracuse, NY, [3]Upstate Medical Univ, Syracuse, NY

Purpose: Systemic lupus erythematosus (SLE) patients' T cells exhibit persistent elevation of the mitochondrial transmembrane potential ($\Delta\Psi m$) or mitochondrial hyperpolarization (MHP) which predisposes to pro-inflammatory death via necrosis. Persistent MHP has been attributed to the depletion of reduced glutathione (GSH) and increased production of nitric oxide (NO) and reactive oxygen intermediates (ROI). Here, we evaluated metabolic checkpoints of mitochondrial dysfunction as biomarkers of disease activity in patients with SLE.

Patients and Methods: 34 female SLE patients and 34 female healthy controls were studied. 24 patients with stable disease were enrolled in double-blind placebo-controlled treatment trial with N-acetylcysteine (NAC; ClinicalTrials.gov identifier: NCT00775476). 10 patients with uncontrolled disease due to lack of efficacy or tolerance to current medications were enrolled in prospective treatment trial with rapamycin (RAPA; NCT00779194). SLE disease activity was assessed by using the British Isles Lupus Assessment Group (BILAG) and SLE Disease Activity Index (SLEDAI). Peripheral blood lymphocytes (PBL) and untouched T cells (using Dynal negative T-cell isolation kit) were freshly isolated on the same morning from patients and controls matched for ethnicity and age within 10 years and investigated in parallel for $\Delta\Psi m$, mitochondrial mass, glutathione, NO and

ROI production, cytosolic ([Ca2+]c) and mitochondrial calcium levels ([Ca2+]m), and T and B cell subset distribution by flow cytometry after 24 with or without CD3/CD28 co-stimulation. mTOR activity was assessed through the phosphorylation of its substrates by western blot. Spearman's correlation coefficients rho and the two-tailed significance levels were estimated in SPSS version 17.

Results: SLEDAI (8.6 +/− 1.2) and BILAG (24.6 +/−1.8) of 24 patients enrolled in the NAC trial were exceeded by the SLEDAI (16.5 +/− 2.9; p = 0.004) and BILAG (33.0 +/− 4.4; p = 0.04) scores of 10 patients enrolled in the RAPA trial. MHP, increased mitochondrial mass, increased [Ca2+]c, and increased NO production were detected in all T cell subsets irrespective of disease activity. mTOR activity was increased in negatively isolated T cells. Foxp3 expression was reduced CD4+/CD25+ Treg cells. [Ca2+]c was also increased in CD19+ B cells. Across all patients, individual total SLEDAI scores best correlated with glutathione depletion (p=0.002) and ROI elevation in T cells (p=0.008). Within SLEDAI components, anti-DNA titers were correlated with increased [Ca2+]m in CD3+/CD4+, CD3+/CD4-/CD8- (p < 0.008) but not in CD3+/CD8+ T cells. Leukopenia was correlated with diminished CD4+/CD25+ T cells (p=0.003).

Conclusion: While mitochondrial dysfunction is detectable in lupus T cells irrespective of disease activity, oxidative stress characterized by the depletion of GSH and increased ROI production as well as activation of mTOR and Treg depletion may represent biomarkers of disease activity in patients with SLE.

CD138 RNA Can Be Detected in the Circulation of Patients with Systemic Lupus and Correlated to Other Factors Suggestive of Plasma Cell Activation. Ming Chen[3], Joy G. Hutcheson[2], Stan Kamp[2], Danny Walker[2] and Joan T. Merrill[1]. [1]Oklahoma Med Research Foundation, Oklahoma City, OK, [2]OMRF, Oklahoma City, OK, [3]OMRF, Allen, TX

Background: Plasma cells are key components in models of SLE pathogenesis, but are sequestered from easy analysis in humans, being rare and difficult to detect in peripheral blood. We hypothesized that quantification of CD138 RNA by real time PCR of peripheral blood leukocytes might provide a sensitive marker for activation of the plasma cell compartment.

Methods: The following measurements were performed on blood samples from 102 patients with SLE: CD138 RNA by RTPCR, BLyS (BAFF) RNA and protein by RTPCR and ELISA, and immune complexes (CIC/C1Q) by ELISA. Routine blood testing and clinical information were also recorded.

Results: CD138 RNA was detectable in most patient samples. Samples were divided into two groups: Group A was comprised of 39 patients with higher levels of CD138 (5–28 copies/5ng). Group B included 61 patients with CD138 < 5 copies/5 ng. There were no differences in age (median 46 vs 47), gender (% female 89.5 vs 91.3) or ethnicity (% CAUC/AFR/ASIAN 63/26/11 Group A and 61/21/18 Group B). Compared to group B, Group A had greater prevalence of anti-dsDNA (28% vs 6.5%, p=0.008), and C3 below normal (25.6% vs 5.0%, p=0.007). Group A trended to higher levels of immune complexes (median 417 ng/ml vs 189, p=ns) as well as increased BLyS protein (median 3333 ng/ml vs 2805, p=ns) and BLys RNA (median 529 copies/5ng vs 421, p=ns). Levels of CD138 did not impact on disease activity by SLEDAI or BILAG, although CIC were increased in patients with SLEDAI >/= 6 vs those with lower scores (median 1580.7ng/ml vs 132.6, p=0.009) as were levels of BLyS protein (median 3927ng/ml vs 2742, p=0.042). An exploratory multivariate analysis was performed, considering the possibility that circulating CD138 reflects increased global plasma cell activity, which might contribute to autoantibody formation and complement consumption systemically. C3 levels were chosen as the dependent variable by virtue of being the furthest downstream of the elements studied. After adjusting for several potentially confounding factors, CD138 maintained a strong, independent effect on C3 levels (see table).

Variables With Potential Impact on Complement C3

Independent Variables	Univariate p value	Multivariate p value
Anti-dsDNA	<0.001	0.008
CIC/C1Q	ns	ns
CD138 RNA	<0.001	0.005
BlyS protein	0.014	0.059
BlyS RNA	0.022	0.056

Conclusions: CD138 can be measured in peripheral blood from lupus patients and may be related to meaningful upstream B Cell stimulants (such as BLyS) as well as downstream effects of plasma cell activation, including anti-dsDNA antibodies and complement consumption. Since some biologic agents in development are expected to have more impact on plasma cells than others, studies of the few that enter the circulation could provide predictive biomarkers for treatment selection.

1187

Characterisation of Lipid Order in Lymphocyte Subsets from Patients with Systemic Lupus Erythematosus (SLE). Laura Miguel[2], Chrissie Lim[2], David A. Isenberg[1] and Elizabeth C. Jury[2]. [1]UCL Div of Medicine, London, United Kingdom, [2]University College London, London, United Kingdom

Membrane lipid microdomains (lipid rafts) enriched with cholesterol and glycosphingolipid are thought to play an important role in lymphocyte function by forming areas of high lipid order that facilitate the activation process. Patients with SLE have defects in T and B cell receptor-mediated activation pathways involving altered expression and membrane localisation of key intracellular signalling molecules. However, the precise role that lipid rafts play in these abnormalities is not fully understood.

Here, using a new probe, di-4-ANEPPDHQ, to define lipid microdomains, we were able to distinguish areas of high lipid order (lipid rafts) and disorder (non-rafts) in the membrane of T and B lymphocytes from patients with SLE (n=79) compared with healthy volunteers (n=44), and patients with Sjorgrens Syndrome (SS) (9) or rheumatoid arthritis (RA) (n=15) as controls. Lipid order was quantified by calculating a generalized polarization (GP) value from mean fluorescence intensity emissions at 570nm and 630nm using a LSRII flow cytometer. Plasma membrane lipid order was related to naive, memory, regulatory and activated phenotypes using a range of T and B cell surface markers and flow cytometry. In addition membrane lipid order was related to levels of membrane and serum cholesterol, triglycerides, HDL and LDL.

The results revealed that lymphocytes from healthy controls had three distinct populations with relative High, Intermediate and Low membrane lipid order. The majority of T cells had high membrane order, whereas B lymphocytes had an expanded Intermediate order population. Patients with SLE and RA had significantly reduced lymphocyte membrane order compared with healthy controls (p=0.001), except for patients with inactive SLE on prednisolone therapy who had lymphocytes of higher overall order than healthy controls (p=0.01). No significant differences were observed in patients with SS compared with healthy volunteers.

Phenotyping showed that in both healthy and patient samples T cells with High lipid order were predominantly naive and responder cells whilst Low order T cells were associated with activated, regulatory and effector memory phenotypes. Immature B cells tended to be associated with Low membrane order. These results correspond with the increased frequency of activated, regulatory and memory T cells in patients with autoimmune disease. Interestingly, in healthy volunteers, the serum cholesterol:HDL ratio showed a positive correlation with plasma membrane lipid order (p=0.05). However, this relationship was lost in patients with SLE, regardless of therapy, who had increased serum LDL and reduced serum HDL resulting in high cholesterol:HDL ratios.

In conclusion, the correlation between immune phenotype and membrane lipid order supports an important role for lipid microdomains in modulating adaptive immune responses and the contribution of dyslipidaemia to immunopathology. The results support the need for further investigation to define the relationship between serum cholesterol and plasma membrane microdomains in lymphocytes from healthy volunteers compared to patients with autoimmune rheumatic disease.

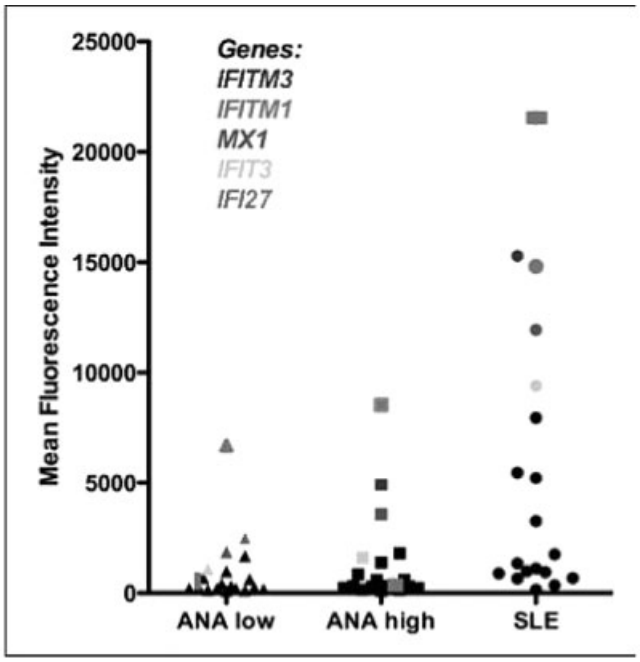
Correlates of ANA Positivity in Healthy Individuals. David R. Karp[2], Quan-Zhen Li[2], Valerie K. Branch[2], Jiexia Quan[3] and Nancy J. Olsen[1]. [1]Univ of TX Southwestern Med Ctr, Dallas, TX, [2]UT Southwestern Med Ctr, Dallas, TX, [3]UT Southwestern Med Ctr., Dallas, TX

The significance of ANA positivity that is observed in up to 25% of the population is unknown. We sought to determine demographic, immunologic and gene expression correlates of elevated ANA values in healthy controls (HC) to provide insights into when this might signal elevated risk for development of autoimmune disease. ANA was measured by ELISA in serum samples from 1159 individuals in the Dallas Regional Autoimmune Disease Registry (DRADR) and autoantibodies in the ENA panel were quantitated by a Luminex-based assay. CCP measurements utlized ELISA. More detailed studies were carried out on a subset of HC with high ANA (N=18) or low ANA (N=18) and SLE patients (N=14) matched for gender and age. A slide-based array was used to measure approximately 100 autoantibodies in IgG and IgM classes. Gene expression profiles were measured in these individuals using RNA isolated from whole blood and analyzed on the Illumina Human-6 V3 Bead Chip. Elevated ANA levels in the HCs were strongly correlated with female gender ($P=0.033$) but not with age ($R^2=0.01$). CCP autoantibodies did not show gender dimorphism in HC or autoimmune individuals, indicating that female gender is not a risk factor for all autoantibodies. Autoantigen arrays identified 12 autoantibodies with SLE-comparable levels in ANA high but not ANA low HC. Of these, 6 (50%) were directed against antigens associated with autoimmune skin disorders (MMP-1, nidogen-1, laminin 5, $\alpha6\beta4$ integrin, desmoglein4, plectin-1) or other autoimmune diseases (dsDNA, aggrecan, thyroglobulin, liver cytosol type-1). A total of 95 genes were significantly ($P<0.01$) dysregulated in ANA high vs ANA low HC, and the vast majority (90) were upregulated in the ANA low group. The highest upregulated gene in ANA high HC was TGM2 which encodes transglutaminase2, a celiac disease autoantigen. Some gene components of the Type I IFN signature were elevated in the ANA high group (MX1, IFITM3, IFITM1, IFIT3) while others, notably IFI27, were only elevated in SLE (Figure).



The findings suggest that early lupus-like autoimmunity might begin in the skin and that some ANA positivity may herald development of other autoimmune diseases. Identification of gene and protein patterns along with ANA and demographic features has potential to predict risk of lupus and other autoimmune diseases in normal individuals.

Dysfunctional, Pro-Inflammatory High Density Lipoproteins Directly Influence Monocyte PDGFRβ Transcript Levels, TNFα Secretion, and Chemotaxis. Brian J. Skaggs[1], Bevra H. Hahn[4], Lori Sahakian[2], Jennifer M. Grossman[3] and Maureen A. McMahon[1]. [1]UCLA School of Medicine, Los Angeles, CA, [2]UCLA School of Medicine, [3]University of California Los Angeles, Sherman Oaks, CA, [4]University of California Los Angeles School of Medicine, Los Angeles, CA

Statement of Purpose: Accelerated atherosclerosis is a major co-morbid condition of women with SLE. Dysfunctional, pro-inflammatory HDL (piHDL), found in half of SLE patients, increase the risk for carotid artery plaque 16-fold. Because monocytes are intimately involved in lipid regulation and are the main immune cell involved in atherosclerosis initiation, we hypothesized that piHDL might directly influence monocyte gene expression and function.

Methods: Peripheral blood monocytes isolated from 54 SLE patients were stratified into three groups: 1) carotid artery plaque+piHDL+ 2) plaque neg-piHDL+ and 3) plaque neg-piHDL neg (n=18/group). Transcript levels of 84 atherosclerosis-specific genes were examined by real-time PCR-based gene arrays. RNA from the human monocyte cell line THP-1 was examined by real-time PCR after 4 hr treatment with 20 μg/ml of either subject-isolated normal, anti-inflammatory HDL (nHDL) or piHDL. THP-1 secretion of TNFα was measured by ELISA after concurrent treatment with lipids and either 1) a peptide mimetic of an anti-inflammatory HDL-associated protein (apoJ) that converts piHDL to nHDL or 2) imatinib (Gleevec), a small molecule platelet-derived growth factor receptor β (PDGFRβ) inhibitor. THP-1 chemotaxis after 2 hr treatment with lipids and inhibitors (as described above) was also examined.

Summary. PDGFRβ was upregulated in primary monocytes from plaque+piHDL+ patients versus monocytes from the other two groups (3.4 fold, $p<0.01$ versus plaque neg-piHDL neg; 2.5 fold, $p=0.02$ versus plaque neg-piHDL+) and in THP-1 monocytes treated in vitro with piHDL compared to normal HDL (2.8 fold, $p=0.03$). TNFα transcript levels were significantly upregulated in primary monocytes from both piHDL+ groups. THP-1 cells treated with piHDL (vs. nHDL) secreted significantly greater amounts of TNFα and exhibited greater migration to chemotactic signals. TNFα levels and increased chemotactic responses were both reduced to normal after apoJ-mimetic peptide or imatinib treatment.

Conclusions: Dysfunctional piHDL has profound pro-inflammatory effects on human monocytes. These effects can be neutralized by blocking the PDGFRβ receptor. Therefore, piHDL directly influences monocyte biology and could promote accelerated atherosclerosis in SLE patients Imatinib or an apoJ-mimetic peptide could be used as targeted therapy in piHDL+ SLE subjects at risk of atherosclerosis as determined by the presence of plasma piHDL.

Dysregulation of the Microvascular as Assessed by Expression of Protective and Injury Associated Markers Is Reflected in the Non-Lesional Non-Sunexposed Skin of Patients with Lupus Nephritis. Peter M. Izmirly[1], Shane Meehan[2], Sherry X. Xu[2], Anca D. Askanase[1], Joan T. Merrill[3], Jill P. Buyon[1] and Robert M. Clancy[4]. [1]NYU School of Medicine, New York, NY, [2]NYU School of Medicine, [3]Oklahoma Med Research Foundation, Oklahoma City, OK, [4]Tisch Hospital 4–407, New York, NY

Purpose: Coagulation is one of the first pathways to be elicited by vascular injury, and its activation is followed by proinflammatory phenomena, in part due to loss of the anti-inflammatory activity of both the Protein C pathway and membrane Endothelial Protein C receptor (mEPCR). It has been recently demonstrated that mEPCR is highly expressed in the cortical peritubular capillaries of kidneys from patients (pts) with active lupus nephritis compared to normal human kidney. Profound upregulation of mEPCR was observed even in areas absent tubulointerstitial damage. This study addressed the hypothesis that changes in the microvasculature extend beyond the clinically targeted organ and that dysregulation is a fundamental characteristic of SLE.

Methods: The study included SLE pts in whom renal disease was considered active as assessed by proteinuria and urinary sediment. Renal biopsies were performed in all pts. Thirty skin biopsies from non-lesional non-sunexposed skin (buttocks) were obtained in 26 pts (23 females, 3 males)

and five healthy controls (4 females, 1 male). The paraffin skin sections were individually stained with specific antibodies against mEPCR and adiponectin (protective markers), ICAM-1 (proinflammatory) and CD31 (pan endothelial marker). Immunohistochemistry (IHC) was scored by counting peroxidase-brown labeled blood vessels (10–20 microns in diameter) without knowledge of the clinical information associated with the biopsy. The number of blood vessels with an intensity of at least 1+ were quantitatively scored with ranges 1–12. To account for the number of blood vessels per slide, the CD31 count had to be 12 to be included in the analysis.

Results: The 28 renal biopsies comprised the following ISN/RPS classifications: 4 Class III, 7 Class IV, 8 Class V, I Class VI, 3 Class III/V, 3 Class IV/V. Nineteen percent of the pts had a GFR <60 (mean GFR, 82 ml/min). Abnormal laboratory values for complement and anti-dsDNA antibodies were reported in 72% and 75% of pts, respectively. Nephrotic range proteinuria was present in 37%. For IHC skin assessments of the controls, the mean score for mEPCR was 1 (highest 2), ICAM-1 was 4 (highest 7) and adiponectin was 1 (highest 2). In 17/25 (68%) of the SLE non-lesional non-sun exposed skin sections, mEPCR was expressed above the highest control. In 16/30 (53%) ICAM-1 staining exceeded 7. In contrast, only 6/25 (19%) expressed adiponectin above 2. For each specific stain there were no apparent differences between biopsy class, degree of proteinuria, presence of anti dsDNA or low complement levels. However, pts with mEPCR staining above 2 had higher GFR measurements than those with staining < 2 (88 ml/min ± 31 versus 53 ± 32, p= 0.0168). In contrast, GFR was unrelated to ICAM-1 and adiponectin expression.

Conclusion: These data are consistent with the notion that there is widespread activation of the microvasculature. The capacity of endothelial cells to utilize anticoagulation pathways is not restricted to the kidney and expression of mEPCR in the microcirculation likely represents an attempt to limit microvascular inflammation in kidney and skin.

Evidence of N-methyl-D-aspartate Receptor (NMDAR) Expression on Primary Human Endothelial Cells. Cagri Yildirim-Toruner[3], Paola Mina-Osario[2] and Betty Diamond[1]. [1]Feinstein Institute for Medical Research, Manhasset, NY, [2]Feinstein Institute for Medical Research, [3]Morgan Stanley Children's Hospital of NewYork- Presbyterian Columbia University Medical Center, Feinstein Institute for Medical Research, New York, NY

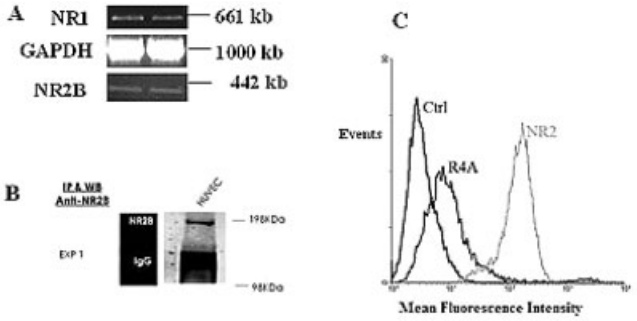
Background: A subset of anti-DNA antibodies has been implicated in neuropsychiatric lupus. These antibodies bind NMDARs and mediate excitotoxic neuronal death, but cause no appreciate neuronal damage when present in the circulation unless there is a breakdown in the blood-brain barrier (BBB). Thus, the BBB is the limiting step for the onset of neurotoxicity. Identifying the mechanisms of antibody transfer through the BBB has important prophylactic and therapeutic implications. It has recently been proposed that anti-NMDAR antibodies modify the permeability of BBB, but presence of NMDARs on BBB is controversial. In order to address this controversy, we studied two different human endothelial cells (EC) considered as in-vitro models of human BBB, Human Umbilical Vein Endothelial cells (HUVEC) and human brain microvascular endothelial cells (HBMEC), to determine the presence of the NMDAR in EC.

Methods: After HUVEC cells were grown to confluency, total RNA was isolated with the RNeasy RNA isolation kit (Qiagen) and reverse-transcribed by using the iScript RT-PCR System (BioRad). Resulting cDNA was amplified with NR1 and NR2B primers. PCR amplicons were visualized in a 1% agarose gel.

For immunoprecipitation, cells were trypsinized, lysed with and then centrifuged at 14,000 rpm. The supernatants were incubated overnight with 2 μg/ml of a polyclonal anti-NR2B antibody. The lysates were then incubated for 1h at 4°C with protein-A agarose. The beads were pelleted by a short centrifugation, washed several times and resuspended in Laemli sample buffer. Then immunoprecipitates were separated by PAGE under non-denaturing conditions.

HUVEC were grown to confluency on gelatin-coated culture dishes. After trypsinization, cells were fixed in 1% PFA, permeabilized in Triton-X100 0.1%/PBS for 10 min, washed and incubated with the indicated antibodies or an isotype control for 1 hour at 4°C followed by a PE-conjugated secondary antibody for 30 min at 4°C. Cells were subsequently analyzed in a FACS-Calibur flow cytometer.

Results: Human endothelial cells express NMDAR and bind anti-DNA/NMDAR cross-reactive antibodies RT-PCR experiments demonstate the expression of NMDAR subunits, NR1 and NR2B, are expressed in HUVEC **(Fig1A)**. We were also able to immunoprecipitate the NR2B subunit of NMDAR from total cell lysates of HUVEC (**Fig1B**). Finally, the anti-NMDAR antibody R4A and two human anti-NMDAR antibodies (clone E2 and G11) bound to HUVEC and HBMEC as determined by flow cytometry (**Fig1C**).



Conclusion: NMDARs are expressed in in-vitro models of human BBB. The demonstrated physical interaction of these anti-NMDAR antibodies with NMDAR raises the possibility of a role for the antibodies in modulating the permeability of BBB through antibody- receptor interaction in the pathogenesis neuropsychiatric lupus. Functional and expression assays are ongoing to elucidate the role of anti-NMDAR antibodies on BBB.

Expession of B Cell Subsets in SLE Pregnancy: Correlation with Preterm Birth. Megan E. B. Clowse[1], Sara Sparks[2], Sallie Allgood[2], Mark Lanasa[2] and David S. Pisetsky[3]. [1]Duke Univ Med, Durham, NC, [2]Duke University, Durham, NC, [3]Duke University Medical Ctr, Durham, NC

Background: Pregnancy demands significant shifts in immunologic function to maintain tolerance to the fetus. Women with systemic lupus erythematosus (SLE), particularly active SLE, have a several-fold higher rate of preterm birth and miscarriage compared to healthy women, suggesting that immune systems changes in SLE affect maternal-fetal tolerance and thereby promote pregnancy complications. To investigate this possibility, we tested whether alterations in the B cell compartment associated with SLE (increased plasmablasts and plasma cells and decrease naïve B cells) are associated with SLE activity and pregnancy outcomes.

Methods: Pregnant women with rheumatologic disease were consecutively enrolled in a prospective cohort. Disease activity using the SLE pregnancy disease activity index (SLEPDAI), and blood for autoantibody levels and peripheral blood mononuclear cells were collected in the first trimester, at a mid-pregnancy visit (between 20–26 weeks gestation) and at least 6 weeks post-partum. Flow cytometry was performed and data analyzed using Flowjo. Plasmablasts were identified as CD27++, CD38++, and IgD- cells. Plasma cells, memory B cells, and naive B cells were delineated based on the degree of CD27 positivity. T tests and Fisher's exact test were used to determine statistical significance.

Results: The cohort included 25 pregnant women: 19 with SLE and 6 with rheumatoid arthritis (RA). Extractable nuclear antigens were identified in 68% and the anti-dsDNA antibody was positive in 42% of the women with SLE. Five women had active disease, determined by a SLEPDAI ≥8. Three of the SLE pregnancies resulted in a pregnancy loss. Of the live births, 37% of SLE pregnancies were delivered preterm (<37 weeks gestation). All of the RA pregnancies resulted in a live birth at term.

Pregnant women with RA had a higher percentage of naive B cells than women with SLE both at mid-pregnancy (RA 88% vs SLE 80%, p=0.07) and post-partum (RA 88% vs SLE 80%, p=0.007). Women with a positive anti-dsDNA antibody had a higher percentage of plasmablasts (p=0.03), plasma cells (p=0.07), and memory B cells (p=0.08), but fewer naive B cells (p=0.09) than other women with SLE. Compared to values post-partum, in the 1st trimester women with SLE had a trend toward fewer lymphocytes, a higher percentage of B cells, fewer memory B cells and more naive B cells (see Table).

Table. Comparison of B cell subsets for pregnant women with SLE.

	1st trimester	Post-partum	P-value
Total white blood cell count	6.7×10^9 cells/mm^2	6.3×10^9 cells/mm^2	0.65
Lymphocyte count	1.5×10^9 cells/mm^2	2.2×10^9 cells/mm^2	0.07
B cells (% of lymphocytes)	5.3%	3.3%	0.09
Memory B cells (% of B cells)	9.5%	12%	0.07
Naïve B cells (% of B cells)	85%	80%	0.03
Plasma cells (% of B cells)	0.56%	0.69%	0.89
Plasmablasts (% of B cells)	0.55%	0.53%	0.67

The week of delivery correlated negatively with the percentage of plasmablasts in the 1st trimester ($r -0.7$, $p=0.02$) and trended towards a negative correlation with plasma cells ($r -0.5$, $p=0.07$). SLE activity and pregnancy loss were not correlated with any B cell subset.

Conclusion: Women with SLE have altered B cell homeostasis in the 1st trimester which may reflect the immunologic changes of pregnancy that allow fetal tolerance. In women with SLE, increased numbers of plasmablasts in the first trimester were associated with preterm delivery.

Increased Male Fetal Loss and Fewer Male Siblings in a Cohort of Systemic Lupus Erythematosus Families. Rachna Aggarwal[1] and Robert H. Scofield[2]. [1]OUHSC, [2]OUHSC, OMRF, VA

Purpose: A sex bias has been found absent in sibships of non-female predominant diseases like diabetes. We undertook this study to enhance our understanding of sex ratios in live sibships and lost fetuses in a large cohort of Systemic lupus erythematosus (SLE).

Methods: Families were collected through the Lupus Family Registry and Repository. All patients met atleast four of the 1982 ACR classification criteria for SLE. All families had atleast one member with SLE. Collective sibling gender data were obtained for the SLE cohort studied. Spontaneous miscarriage and abortion information was assessed, when self-reported, on a standard questionnaire filled by the patient. Male to female sex ratios were calculated.

Results: Collectively, 282 SLE affected male patients had 314 male siblings and 415 female siblings. The 2296 SLE affected female patients had 3113 male siblings and 3772 female siblings. Thus the ratio of male to female siblings= $(314+3113) / (3772+415) = 0.82$. SLE affected females reported 36 events of male fetal loss and 20 events of female fetal loss. Thus, ratio of male to female fetal loss was found to be 1.8:1.

Conclusions: There is a trival explanation for too few male siblings in this cohort. Sibships with lots of girls are more likely to have SLE because of the excess girls with SLE and, therefore are more likely to be included in the study. So, to correct for the ascertainment bias, we left out the SLE patients. Even when doing this, the male/female ratio is 0.8 and live births and fetal loss is nearly twice more common in males. The most parsimonious and perhaps the only explanation is a gene on X where a mutation or allele is lethal for males in utero and gives girls risk for SLE as we have discussed. This means this gene should be on the maternal X chromosome of patients in families where the sibship containing the SLE patient has excess girls and/or there are reports of male fetal loss.

Low Levels of Atheroprotective Natural IgM Antibodies Against Phosphorylcholine and Increased Prevalence of Vulnerable Atherosclerotic Plaques in Patients with SLE. Cristina Anania[2], Thomas Gustafsson[2], Xiang Hua[2], Jun Su[2], Mikael Heimbürger[1], Tomas Jogestrand[2] and Johan Frostegård[2]. [1]Abbot, [2]Karolinska Institutet

Background: We recently reported that natural antibodies against phosphorylcholine (anti-PC) are negatively associated with atherosclerosis and cardiovascular disease (CVD) in the general population: low IgM anti-PC levels predict increased risk of CVD and high levels protect against increase in atherosclerosis over time. We have determined two potential mechanisms: anti-inflammatory effects of anti-PC (inhibiting inflammatory phospholipids which are implicated in both atherosclerosis and RA) and decreased uptake of oxidized lipids in macrophages. According to our hypothesis, an immune deficient state – low levels of anti-PC –predispose to chronic inflammatory diseases. We here study atherosclerosis as determined by carotid ultrasound in systemic lupus erythematosus (SLE) and the role of traditional and non-traditional risk factors for atherosclerosis and CVD.

Methods: One hundred fourteen patient with SLE were compared with one hundred twenty two age- and sex matched population-based controls. Common carotid intima-media thickness (IMT), calculated intima-media area (cIMa) and plaque occurrence were determined by B-mode ultrasound as a surrogate measure of atherosclerosis. Plaques were graded according to echogenicity and grouped as 1–4, with 1 being echoluscent, and considered most vulnerable. Osteoporosis was studied by DXA and anti-PC by ELISA.

Results: IMT and cIMa did not differ significantly between groups. However, plaques were more often found in SLE patients ($p=0.029$). Age, LDL and IgM anti-PC (lowest tertile) were independently associated with plaque occurrence in SLE. Further, in the left carotid arteries echoluscent plaques (grade 1) were more prevalent in SLE as compared to controls $p<0.016$).

Triglycerides, insulin resistance (determined by homeostasis model assessment of insulin resistance) hypertension, and C-reactive protein (CRP) were increased in SLE ($p<0.01$) while smoking, LDL and HDL did not differ between groups. Low levels of anti-PC IgM (lowest tertile) were more common in SLE patients than in controls ($p=0.0022$). Osteoporosis was more prevalent in the hip in SLE-patients as compared to controls ($p<0.05$) but not otherwise. 18.4% of SLE patients and 1.6% of controls ($p<0.01$) exhibited a history of CVD (myocardial infarction, angina, heart valve disease, stroke or claudication).

Conclusion: Plaque occurrence and the frequency of vulnerable plaques in the carotid arteries are increased in SLE. Anti-PC could be a novel risk marker also with a therapeutic potential in SLE.

Presence of HMGB1 (High Mobility Group Box 1) and Antibodies to HMGB1 in Systemic Lupus Erythematosus (SLE). Deena Abdulahad, Johanna Westra, Pieter Limburg, Cees Kallenberg and Marc Bijl. UMCG

Background: Apoptotic cells accumulate in SLE and are considered to play an important role in the pathogenesis. High mobility Group box 1 is a non-histone nuclear protein, that can be secreted actively by inflammatory cells, and is released passively from apoptotic and necrotic cells where it may act as an autoantigen and as a pro-inflammatory mediator. There is increasing evidence that HMGB1 contributes to the pathogenesis of chronic inflammatory and auto-immune diseases. Indeed, presence of HMGB1 in serum of mice with SLE has been reported in the serum of lupus mice.

Objectives: In this study we determined levels of HMGB1 and anti-HMGB1 in SLE patients compared to healthy controls (HC).Also their relation with clinical and biochemical parameters was assessed.

Methods: The study population consisted of 69 SLE patients and 35 age and sex matched HC. Of the 69 SLE patients 35 were visiting the outpatient clinic and randomly chosen. The other 34 patients were selected for active disease and paired samples of these patients were selected during inactive phase of the disease. Eighteen of 34 patients had renal involvement and remaining 16 patients had other organ involvement. HMGB1 levels were measured with a Western blot and anti-HMGB1 levels were measured with an in-house developed ELISA using recombinant HMGB1 as antigen. Clinical and biochemical parameters of all patients were assessed routinely.

Results: HMGB1 levels in all SLE patients were significantly increased compared to HC. HMGB1 levels were relatively more increased in patients with renal involvement compared to non renal patients. HMGB1 levels were correlated with disease activity, as determined by SLEDAI. HMGB1 levels were correlated with anti-dsDNA levels and showed a negative correlation with C3. Anti-HMGB1 levels were significantly increased in all SLE patients compared to HC and were correlated to HMGB1 levels in all SLE patients.

Conclusions: In SLE patients serum HMGB1 levels are significantly increased, in particular in patients with renal involvement, and are related to disease activity. Furthermore, in SLE patients increased levels of anti-HMGB1 antibodies were detected. Whether HMGB1, and HMGB1-anti-HMGB1 immune complexes play a role in the pathogenesis of SLE, in particular in patients with renal involvement needs to be established.

Reversal of CD3+/CD4+/CD25+/Foxp3+ Treg Depletion in Active SLE Patients with Rapamycin. Zhiwei Lai[1], Tiffany N. Telarico[1], Adam Bartos[1], Gabriella Miklossy[1], Robert Hanczko[1], John Jimah[1], Brandon Clair[1], Lisa Francis[1], Hajra Tily[1], Ricardo Garcia[1], Paul E. Phillips[2], Irene Ramos[1] and Andras Perl[3]. [1]SUNY, [2]SUNY-Upstate Medical Univ, Syracuse, NY, [3]Upstate Medical Univ, Syracuse, NY

Purpose: Activation and death pathway selection of T cells are regulated via the mitochondrial transmembrane potential ($\Delta\Psi m$). Systemic lupus erythematosus (SLE) patients' T cells exhibit persistent $\Delta\Psi m$ elevation or mitochondrial hyperpolarization (MHP) and ATP depletion which predispose them to pro-inflammatory death via necrosis. Here, we examined the role of the mammalian target of rapamycin (mTOR), which serves as a sensor of MHP, in activation and death signal processing of lupus T cells.

Patients and Methods: 34 female SLE patients and 34 female healthy controls were studied. 24 patients with stable disease were enrolled in double-blind placebo-controlled treatment trial with N-acetylcysteine (NAC; ClinicalTrials.gov identifier: NCT00775476) and only baseline values were evaluated. 10 patients with uncontrolled disease due to lack of efficacy or tolerance to current medications were enrolled in prospective treatment trial with rapamycin (RAPA; NCT00779194) and both pre and post-treatment data were evaluated. SLE disease activity was assessed by using the British Isles Lupus Assessment Group (BILAG) and SLE Disease Activity Index (SLEDAI). Peripheral blood lymphocytes and untouched T cells (using Dynal negative T-cell isolation kit) were freshly isolated on the same morning from patients and controls matched for ethnicity and age within 10 years and investigated in parallel for $\Delta\Psi m$, mitochondrial mass, glutathione, production of nitric oxide (NO) and reactive oxygen intermediates (ROI), cytosolic ([Ca2+]c) and mitochondrial calcium levels ([Ca2+]m), and T and B cell subset distribution by flow cytometry and for mTOR activity by western blot.

Results: SLEDAI (8.6 +/− 1.2) and BILAG (24.6 +/− 1.8) of 24 patients enrolled in the NAC trial were exceeded by the SLEDAI (16.5 +/− 2.9; p = 0.004) and BILAG (33.0 +/− 4.4; p = 0.04) scores of 10 patients enrolled in the RAPA trial. MHP and mitochondrial mass were elevated, most robustly in CD3+/CD4-/CD8- cells (1.6- to 2-fold) both among NAC and RAPA study patients. The prevalence of annexin V+/propidium iodide+ necrotic cells was only increased in RAPA patients. Likewise, the prevalence of Foxp3+ cells within the CD4+/CD25+ compartment was only reduced in RAPA patients (37.05 +/− 3.0 %) relative to controls (48.37 +/− 2.5 %; p = 0.0014). mTOR activity, as measured by the accumulation of pS6 protein, was increased > 1.5-fold in CD3+ T cells (p=0.012) and CD19+ B cells (p=0.006) in RAPA patients. Relative to healthy controls (3.18 ± 0.39%), the frequency of Foxp3+/CD4+/CD25+ cells was reduced in RAPA patients (1.70 ± 0.42%; p=0.021) prior to RAPA treatment. In vivo treatment with RAPA increased the frequency of Tregs from 1.50 ± 0.45% to 2.8 ± 0.59% (p=0.040) while the SLEDAI scores were reduced in 5 SLE patients from 22.4 ± 5.7 to 16.7 ± 2.8 (p=0.017).

Conclusion: While mitochondrial dysfunction was detectable in lupus T cells irrespective of disease activity, predisposition to necrosis and Treg depletion were confined to "RAPA" patients with high disease activity. The data identify the in vivo expansion of Tregs as a potential mechanism of action that may contribute to the therapeutic efficacy of RAPA in SLE.

Strong Viral Associations among Filipinos with Systemic Lupus Erythematosus. Evan Glenn Vista[6], Michael H. Weisman[3], Mariko L. Ishimori[1], Jourdan Anderson[5], Robelle Tanangunan[8], Noga Gal[2], John B. Harley[7], Guthridge Joel[5], Sandra Navarra[8] and Judith A. James[4]. [1]Cedars Sinai Medical Center, Los Angeles, CA, [2]Cedars-Sinai, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]Oklahoma Med Research Foundation, Oklahoma City, OK, [5]Oklahoma Medical Research Foundation, [6]Oklahoma Medical Research Foundation, Oklahoma City, OK, [7]Univ of OK Hlth Sci Ctr, Oklahoma City, OK, [8]University of Santo Tomas Hospital

Background: Specific environmental determinants could determine development of SLE among susceptible individuals. Among potential viral environmental agents, the ubiquitous Epstein Barr virus (EBV) has been associated with SLE through seroprevalent exposure in pediatric and adult populations, viral DNA association, increased viral loads in the peripheral blood of SLE patients and increased evidence of viral reactivation. SLE patients have also been shown to have abnormal humoral and T cell responses against EBV. Filipinos, compared to other populations, could have potential major differences in terms of genetic risk, environmental exposure and disease causation brought about by their location as an archipelago separated from other Asian nations and a strong history of racial admixture.

Methods: Filipinos with written and informed consent belonging to the University of Santo Tomas Hospital lupus cohort and fulfilling the 1997 American College of Rheumatology criteria (ACR) for SLE (233 cases) along with 544 unaffected first degree relatives (FDRs) and 220 unrelated controls were studied. Sera were tested for seroconversion to EBV, Cytomegalovirus (CMV) and Herpes simplex viruses (HSV1 and HSV2) by standardized ELISAs for IgG responses to EBV early antigen (EA), EBV viral capsid antigen (VCA), EBNA1, CMV immediate early antigen, HSV-1 (strain F) and HSV-2 (strain G). Correlation statistics (Fisher's exact test, student's t-test, and one-way ANOVA) were done to determine associations between patients and their controls and FDRs.

Results: Filipino patients have significantly higher seroconversion for EBV EA (92.3%), EBV VCA (99.6%), CMV (94.4%), HSV1 (87.5%) and HSV2 (79.4%). Seroconversion against EBV-EA (a measure of reactivation) was dramatically higher in SLE patients compared to controls (92.3% vs 40.4%; OR=17.6, p <0.0001) or compared to FDRs (92.3% vs 49.4%; OR=12.2, p< 0.0001). For VCA, the cases have higher seroconversion than controls (OR 7.62, p 0.03). The cases have higher seroconversion for CMV than controls (OR 4.85, p<0.0001). Higher seroconversion for HSV1 was also seen for cases than controls (OR 7.2, P< 0.0001). Lastly, the cases have higher seroconversion for HSV2 compared among controls (OR 7.9, p <0.0001) and FDRs (OR 2.17, p <0.0001). Significantly higher antibody titers were seen for all viruses among the cases compared to controls and FDRs (p <0.0001).

Conclusions: This study shows strong viral associations among Filipinos with SLE by the significantly higher seroconversion for EBV-EA, EBV-VCA, CMV, HSV1 and 2. Exposure to these environmental determinants could predispose Filipinos with high susceptibility in developing clinical disease.

TNFα Expression in Peripheral Blood Mononuclear Cells of Cutaneous Lupus & Dermatomyositis Patients. Adam S. Nabatian[2], Maria Wysocka[4], Muhammad M. Bashir[1] and Victoria P. Werth[3]. [1]Philadelphia VAMC, University of Pennsylvania, [2]UMDNJ-Robert Wood Johnson Medical School, Philadelphia VAMC, University of Pennsylvania, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Pennsylvania

Background: There has been data published regarding TNFα in skin lesions and serum of patients with cutaneous lupus erythematosus (CLE) and dermatomyositis (DM). TNFα is increased in lesional skin of patients with discoid lupus erythematosus (DLE), subacute cutaneous lupus erythematosus (SCLE), and DM compared to controls. TNFα has been measured in sera from patients with systemic lupus erythematosus (SLE), DLE, SCLE, and DM and is elevated in patients with SLE, DLE, SCLE, but not DM. In vitro production of TNFα by unstimulated peripheral blood mononuclear cell (PBMCs) from juvenile DM patients was measured and it was found that PBMCs from children who had disease course ≥36 months produced more TNFα compared to PBMCs from juvenile DM patients who had disease <36 months. Since there has been minimal data published on TNFα expression in PBMCs of CLE and DM patients, the purpose of our experiments was to evaluate TNFα production in PBMCs of DLE, SCLE, tumid lupus erythematosus (TLE), and DM patients.

Methods: PBMCs were separated from heparanized venous blood of 21 DLE, 10 SCLE, 10 TLE, and 18 DM patients and 18 healthy controls. A subset of these cells were placed in culture and an ELISA was performed to measure TNFα protein levels. In another subset, Real-Time-PCR was performed to measure TNFα and ADAM17 (TACE) transcription. Lastly, flow cytometry was performed on another subset of cells to determine which cell type is secreting TNFα.

Summary of the Results: The transcription of TNFα and ADAM17 and the TNFα protein production in DLE patients (55.9±11.1, 5.3±0.46, 31.6±8.9 pg/mL, respectively), but not SCLE (15.8±0.9, 2.4±0.3, 5.5±1.2 pg/mL), TLE (8.9±1.2, 3.7±1.0, 4.3±0.8 pg/mL), or DM, (11.6±2.7, 1.4±0.2, 2.0 ±0.2 pg/mL) was significantly greater than controls (3.2±0.7,

2.1±0.09, 1.5±0.37pg/mL, respectively) ($P < 0.001$). TNFα was predominately produced from monocytes and myeloid dendritic cells (mDCs). There was a significantly greater percentage of cells with TNFα intracellular staining in mDCs of DLE (28.5±7.1) ($P < 0.01$) and DM (21.6±4.1) ($P < 0.05$) patients when compared to controls (3.14±1.7). The mean fluorescence intensity of both monocytes (1569.8±485.8) and mDCs (1,044.5±185.4) from DLE patients was significantly greater ($P < 0.05$) when compared to healthy controls (470.9±82.6 and 293.6±138.1, respectively). Lastly, the total number of both monocytes (11.8±1.5%) ($P < 0.001$) and mDCs (1.14±0.4%) ($P < 0.01$) was significantly greater in DLE patients compared to healthy controls (5.2±1.1% and 0.37±0.09%). The total number of monocytes was also significantly greater in DLE patients (11.8±1.5%) compared to DM patients (6.5±2.8) ($P < 0.01$).

Conclusion: TNFα may be critically important in the induction and development of DLE as these patients have significantly greater TNFα transcription and protein production. Myeloid DCs and monocytes may also have a greater role in the pathogenesis of DLE than was previously believed.

Type I IFN Signature in Pregnant Patients with Lupus. Danieli Andrade[3], Gloria C. Koo[3], Patricia Redecha[3], Kyriakos A. Kirou[3], Mimi Kim[1], Mary K. Crow[3] and Jane E. Salmon[2]. [1]Albert Einstein College of Medicine, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgery, New York, NY

Purpose: The cytokine milieu in SLE pregnancy is skewed towards a tolerant anti-infammatory state. Type I interferon (IFN) pathway is activated in many SLE patients and is associated with increased disease activity. That IFN-α has anti-angiogenic effects raises the possibility that it may be deleterious for pregnancy. We hypothesized that an IFN type I signature in pregnant lupus patients would be suppressed and if present, it would correlate with poor pregnancy outcomes.

Methods: We performed a nested case-control study of SLE patients in the PROMISSE Study- **P**redictors of Pr**e**gnancy **O**utcome: Bio**m**arkers **I**n Antiphospholipid Antibody **S**yndrome and **S**ystemic Lupus **E**rythematosus. Exclusions were: prednisone >20mg, proteinuria >1gm/24 hr and creatinine >1.2 mg/dl. Subjects were evaluated and blood collected monthly beginning at <12 wks' gestation. Poor pregnancy outcome was defined as: fetal death >12 wks (n=3); placental insufficiency or preeclampsia (PE) (n=9), severe IUGR (n=4) or disease activity (n=2). Each of 18 patients with SLE and poor pregnancy outcomes (SLE/outcome) were matched 1:1:1 by age and ethnicity to an SLE patient with an uncomplicated pregnancy (SLE/no outcome) and a pregnant healthy control (HC). A total of 324 samples prospectively collected during pregnancy were tested. Serum samples from the 3 matched pregnancies were assayed simultaneously for IFN-α activity using a reporter cell assay (WISH assay) based on expression of IFN-regulated genes (MX1, IFIT1 and IF144). Data were compared between disease groups at each gestational time window with an ANOVA model. To examine the influence of PE in type I IFN signature in patients without autoimmune disease, we analyzed a second group of samples collected through pregnancy in 6 patients who developed PE and 6 controls with uncomplicated pregnancies.

Results: Type I IFN signature was present throughout pregnancy in SLE patients compared to controls. Type I IFN score was higher in SLE patients without poor outcomes compared to controls (29.4 ± 14.73 vs 16.2 ± 6.71,18 pairs of patients, 230 samples, p=0.03) and it trended to be higher in SLE patients with poor outcomes compared to controls (38.4 ± 21.68 vs 16.2 ± 6.71, n= 18 pairs of patients, 209 samples, p=0.06). The two SLE groups did not differ significantly with respect to IFN signature. Mean SLEPDAI scores at enrollment were also not different between SLE with or without poor outcomes (4.1±3.4 vs. 2.1±2.9, respectively. SLE patients with PE showed a trend for increase in Type I IFN signature compared to non-autoimmune patients with PE, respectively. (55.13 ± 145 vs 8.93 ± 6.10, p= 0.09). In the non-autoimmune patients, the IFN signature did not differ between patients with and without PE (8.60 ± 6.36 vs 9.82 ± 2.52, p=0.91).

Conclusions: Pregnancy does not abrogate the IFN signature in lupus patients. PE, in and of itself, is not associated with increase in type I IFN signature. The onset of proteinuria and increased blood pressure in pregnancy that is accompanied by a high Type I IFN score is suggestive of SLE flare rather than PE. Elevated type I IFN may help distinguish SLE from PE in pregnant patients.

Vitamin D and Vascular Stiffness in Patients with Systemic Lupus Erythematosus. John A. Reynolds[3], Sahena Haque[4], Jacqueline L. Berry[4], Lee-Suan Teh[2], Pauline Ho[1], Rachel Gorodkin[1] and Ian N. Bruce[4]. [1]Central Manchester University Hospitals NHS Foundation Trust, [2]East Lancashire Hospitals NHS Trust, [3]University of Manchester, Manchester, United Kingdom, [4]University of Manchester

Background: Vitamin D deficiency is highly prevalent amongst patients with systemic lupus erythematosus (SLE) and is associated with increased disease activity. Low vitamin D levels are associated with increased cardiovascular events in the general population. We hypothesised that in patients with SLE, lower vitamin D levels would be associated with increased vascular stiffness (measured by aortic pulse-wave velocity, aPWV), and subclinical atherosclerosis (carotid intima-media thickness (cIMT) and plaque presence).

Methods: Patients with SLE who fulfilled 4 or more ACR 1997 criteria were recruited from regional outpatient clinics. Clinical assessment and serum collection occurred between Jan 2007 and Jan 2009. Serum 25-hydroxyvitamin D (25(OH)D) was measured by ELISA and 25(OH)D deficiency was defined as <20ng/ml. Aortic pulse-wave velocity was measured (Micro Medical PWV) and cIMT and plaque measured using B-mode Doppler ultrasound.

Results: We studied 75 female patients with SLE with a median (IQR) age and disease duration of 53 (46, 60) and 16 (8, 27) years respectively. Thirty three (52%) of patients had inactive disease (SLEDAI score=0). The median (IQR) serum 25(OH)D was 19.7 (15.1, 29.6) ng/ml, and 39 (52%) of subjects were vitamin D deficient.

Vitamin D levels were significantly lower (median [IQR] 12.88 [12.0, 16.2] ng/ml) in patients with the most active disease (SLEDAI score ≥75th centile) compared to less active disease (20.5 [16.5, 30.8] ng/ml) (p=0.0187).

Serum 25(OH)D was significantly associated with increased aPWV (p=0.010), but not carotid plaque presence (p=0.205) or cIMT (p=0.571). The association with aPWV remained significant after adjustment for traditional CVD risk factors (age, systolic blood pressure, smoking, body mass index (BMI) and season sample taken) (p=0.04), but this association did not remain following adjustment for lupus disease activity (p=0.16).

Table. Serum 25(OH)D and subclinical markers of cardiovascular disease

	Unadjusted 25(OH)D Model				Adjusted 25(OH)D Model 1[1]				Adjusted 25(OH)D Model 2[c]			
Marker	**β**	**OR**	**95% CI**	**p**	**β**	**OR**	**95% CI**	**p**	**β**	**OR**	**95% CI**	**p**
Aortic pulse wave velocity*	−0.022		−0.04, −0.01	0.010	−0.028		−0.06, −0.00	0.048	−0.020		−0.03, 0.01	0.175
Carotid plaque presence#		1.03	0.96, 1.08	0.206		0.99	0.90, 1.09	0.860		1.00	0.91, 1.11	0.928
Carotid intima-medial thickness*		1.02	0.96, 1.07	0.571		0.99	0.92, 1.07	0.889		0.95	0.85, 1.07	0.402

β = β coefficient, CR=odds ratio, 95% CI=95% confidence interval, p=p-value
* linear regression model of log(aPVW)
# logistic regression model
c logistic regression model cIMT above upper quartile
1 Adjusted for age, season (summer or winter), body mass index (BMI), systolic blood pressure, pack-years smoking, disease duration
2 As model 1 plus disease activity score (SLEDAI)

Discussion: Vitamin D deficiency was highly prevalent within our study population. Lower levels of 25(OH)D were associated with increased vascular stiffness, but not cIMT or plaque presence. This association may be mediated by increased disease activity, and prospective studies are now required to determine whether treatment of vitamin D deficiency can modify CVD risk in patients with SLE.

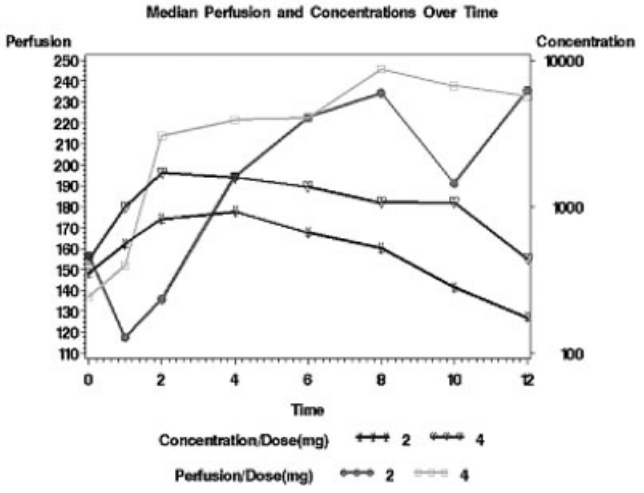
A Pilot Study To Evaluate Digital Perfusion in Scleroderma Patients Treated with Oral Treprostinil. Ami A. Shah[2], Laura K. Hummers[2], Kristan D. Rollins[4], Susan Walker[4], Mike Wade[4], Cynthia Anderson[3], Robert Wise[3], Francesco Boin[2] and Fredrick M. Wigley[1]. [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins University, [4]United Therapeutics

Background: Raynaud's phenomenon and a small vessel obliterative vasculopathy in scleroderma frequently lead to ischemic digital ulcers (DU). Previous studies have demonstrated a therapeutic effect of intravenous prostacyclin analogs for ischemic DU, but oral prostacyclin analogs have had limited success. During a Phase I pharmacokinetic (PK) trial of an oral treprostinil formulation, we sought to quantify changes in perfusion as assessed by laser Doppler imaging (LDI) and to determine whether improvements in perfusion correlated with drug concentration.

Methods: Ten patients with scleroderma and a history of recent or active ischemic DU were enrolled into the study. All subjects received oral treprostinil and titrated the dose up to 4mg twice daily (BID) as tolerated over 6–8 weeks. Assessments were performed when subjects achieved the 2mg and 4mg (or maximally tolerated) doses. Subjects who did not reach a dose of 2 mg BID during the study had assessments performed only at the end of study visit. Eight serial measures of digital perfusion and drug concentration were obtained at each of the 2 study visits. Repeated measures analyses using random effects models were performed using perfusion and skin temperature as dependent variables of interest and perfusion obtained at drug trough, log-transformed drug concentration, visit number, individual timepoints of Doppler assessment at each PK visit, and left/right hand as potential explanatory variables. Covariates with p-values <0.15 were retained in the statistical model.

Results: Ten subjects with a mean age of 44.3 years and mean scleroderma disease duration of 12.2 years were studied. Seventy percent had limited cutaneous scleroderma. Nine subjects tolerated the 2mg BID dose by the first PK visit, and 6 subjects tolerated the 4mg BID dose by the 2nd PK visit. Two subjects completed the study at 0.5mg BID and 1mg BID, respectively. Subjects experienced transient adverse effects typical of prostacyclin therapy: headache, jaw pain, photosensitivity, fatigue, leg pain, nausea, emesis, diarrhea, abdominal bloating, and flushing.



Perfusion was positively associated with log-transformed plasma concentration at the 4mg visit (but not the 2mg visit), after adjusting for the individual time points of Doppler assessment at each PK visit ($p=0.015$). Digital skin temperature was positively associated with log-transformed plasma concentration at the 4mg visit (but not the 2mg visit), after adjusting for the individual time points of Doppler assessment at each PK visit ($p=0.013$).

Conclusions: An increase in digital perfusion was observed with increased treprostinil blood concentrations, suggesting a dose-response relationship. Further investigation with a larger sample size and a control population is needed to confirm this association, to correct for individual subjects' natural perfusion variations, and to evaluate for dose effects.

An Analysis of Agreement of Guidelines for Management in SSc from a Large Database (CSRG: Canadian Scleroderma Research Group). Janet E. Pope[3], Sarah Harding[4], Sarit Khimdas[4], Ash Bonner[2], Murray Baron[1] and The CSRG. [1]Jewish General Hospital, Montreal, QC, Canada, [2]McMaster University, [3]St Joseph Health Care London, London, ON, Canada, [4]University of Western Ontario

Objective: We determined congruence with recently published guidelines from EULAR/EUSTAR, for SSc investigations and treatment practices within the Canadian Scleroderma Research Group (CSRG)

Methods: Investigations and medication use for SSc complications were obtained from SSc patients in the CSRG to determine adherence to guidelines.

Results: The CSRG database of 938 SSc patients demonstrated that annual echocardiograms for PAH screening were done in 86.5%; for PAH treatment one quarter were receiving warfarin which has no recommendations, all diagnosed with PAH Class III/IV were on PAH specific treatment (9% of total CSRG patients had PAH). For Raynaud's: 47% were on calcium channel blockers and some sites used PDE5 inhibitors more than others. Iloprost is not approved in Canada, so its use for severe RP and digital ulcers was low. In the guidelines it is recommended that all SSc patients with GERD be recommended for PPIs. In the CSRG database, PPIs were used in 86%, and one quarter with GI symptoms were on prokinetic drugs. In those with SRC ever: 77% were on current ACE inhibitors, one third were on dialysis and 10% had received kidney transplants. It is recommended that ACE inhibitors not be discontinued post SRC. 19% of MRSS >10 were on methotrexate whereas only 3% were using D-penicillamine which was not recommended in the guidelines. In severe ILD, there was significant variability in use of cyclophosphamide. There was also variation between centers with >50 patients for treatment for inflammatory arthritis (with hydroxychloroquine and D-penicillamine). The rate of ordering some investigations such as HRCT was different at some centers, but obtaining echocardiograms annual did not differ and was at a rate of $>90\%$.

Eular guideline	Medication	% of CSRG patients
Raynaud's phenomenon		
1. Calcium channel blockers should be considered for first-line therapy for SSc-related RP and intravenous iloprost, or other available i.v. prostanoids, should be considered for severe SSc-related RP.	Calcium channel blockers	47.3
	Iloprost	0.3
Digital ulcers (active)		
2. Intravenous prostanoids, (particularly iv iloprost) should be considered for the treatment of active digital ulcers.	Iloprost	<1%
3. Bosentan should be considered in treatment of diffuse SSc patients with multiple DU, after failure of CCBs and, usually, prostanoid therapy.	Bosentan	9.2
PAH		
4. Bosentan should be strongly considered in the treatment SSc-related PAH.	Bosentan	19
5. Sitaxentan may be considered in treatment of SSc-related PAH.	Sitaxentan	11.9
6. Sildenafil may be considered in treatment of SSc-related PAH.	PDE5 inhibitors	14.3
7. Intravenous epoprostenol should be considered for the treatment of severe SSc-related PAH.	Epoprostenol	6
Skin involvement (mRSS>10)		
8. Methotrexate may be considered in the treatment of skin involvement in early diffuse SSc.	Methotrexate	18.8
ILD		
9. Cyclophosphamide should be considered in the treatment of SSc-related ILD.	Cyclophosphamide)	16.2
Renal crisis		
10. Angiotensin converting enzyme inhibitors should be used in the treatment of scleroderma renal crisis.	ACE inhibitors	77.1
Gastrointestinal involvement		
12. Proton pump inhibitors should be used for prevention of SSc-related GERD, esophageal ulcers and strictures.	PPIs (GERD)	85.5
13. Prokinetic agents should be used for the management of SSc-related symptomatic motility disturbances (dysphagia, GERD, delayed gastric emptying, bloating, pseudoobstruction, etc.)	Promotility agents (GERD)	24.6
	Promotility agents (delayed gastric emptying)	27.8
	Promotility agents (pseudo-obstruction)	40.3
	Promotility agents	26.8

* P-values measure variation among centers

Conclusions: Although the guidelines were not published until after our standard of care was established, the SSc experts were mostly practicing in accordance with EULAR/EUSTAR recommendations. Methotrexate use for skin was only 19% for current use, but we did not study ever use so it may have been higher if studied in that way. CSRG practices were generally comparable to recently published guidelines; however, use of iloprost for digital ulcers and severe RP differed from guidelines as this drug is not approved in Canada. The CSRG adherence is a 'best case' scenario as these are centers with an interest in SSc and queries for non-adherence to recommended tests occur in the database. The adherence to EULAR/EUSTAR SSc guidelines in general rheumatology practice is likely far less than in SSc centers.

Are SSc Experts Doing What They Should Do? An Analysis of Practice Variability in Large SSc Centers within the Canadian Scleroderma Research Group (CSRG) Shows Practice Differences. Sarah Harding[4], Sarit Khimdas[4], A. Bonner[2], Murray Baron[1] and Janet E. Pope[3], [1]Jewish General Hospital, Montreal, QC, Canada, [2]McMaster University, [3]St Joseph Health Care London, London, ON, Canada, [4]University of Western Ontario

Objective: There is currently no consensus on best practice in SSc. To determine if variability in treatment and investigations exists, practices among Canadian Scleroderma Research Group (CSRG) centers were compared.

Methods: Prospective clinical and demographic data from adult SSc patients are collected annually from 15 CSRG treatment centers. Laboratory parameters, self-reported socio-demographic questionnaires, current and past medications and disease outcome measures are recorded. For centers with >50 patients enrolled, treatment practices were analyzed to determine practice variability.

Results: Data from 640 of 938 patients within the CSRG database met inclusion criteria, where 87% were female, the mean ± SEM age was 55.3 ± 0.5; 49% had limited SSc and 48% had diffuse SSc (and 3% uncharacterized). Several investigation and treatment practices were inconsistent among 6 centers including proportion receiving PDE5 inhibitors for Raynaud's phenomenon (p=0.036); cyclophosphamide (p=0.037) and azathioprine (p=0.037) for treatment of ILD; hydroxychloroquine (p=0.023), D-penicillamine (p=0.008), and steroids (p=0.039) for inflammatory arthritis; hyperalimentation (p=0.000) and esophageal dilatations (p=0.000) among centers analyzed. Where negative trails exists, there were differences in use of D-penicillamine (although infrequent) for MRSS >10 (p=0.004), Between site performing of: chest X-rays (72–98%,p=0.000), HRCTs (11–41%,p=0.000) and ECGs (75–98%p=0.000) were different. Annual echocardiograms (91–100%, p=0.2) and PFTs (85–97%, p=0.17) were usually performed annually and did not vary among sites.

* P-values measure variation among centres

Conclusions: There is site variation in SSc with respect to investigations and management among CSRG centers suggesting a need for a standardized approach to the investigation and treatment of SSc. One would speculate that more variability would occur between rheumatologists who did not have a critical mass of SSc and were not given reminders of annual tests to be performed (ex. echocardiograms) as we looked only at practices within a database.

Assessing Health Status in Patients with Systemic Sclerosis: Construct Validity of the Karnofsky Performance Status Score. Christelle Nguyen[2], Alice Bérezné[2], François Rannou[3], Caroline Mestre-Stanislas[2], Sandrine Morell-Dubois[1], Loïc Guillevin[2], Serge Poiraudeau[3] and Luc Mouthon[2]. [1]Universite Lille 2; Service de Medecine Interne; Centre de Reference Pour la Sclerodermie Systemique; Hopital Claude Huriez; Lille; France, [2]Universite Paris Descartes; Faculte de Medecine Paris Descartes; Pole de Medecine Interne, Centre de Reference Pour les Vascularites Necrosantes et la Sclerodermie Systemique; Hopital Cochin; Assistance Publique-Hopitaux de Paris (AP-HP); [3]Universite Paris Descartes; Faculte de Medecine Paris Descartes; Service de Medecine Physique et Readaptation; Hopital Cochin AP-HP; Inserm, Institut Federatif de Recherche sur le Handicap, Paris

Purpose: Systemic sclerosis (SSc) is a connective-tissue disease, responsible for skin, tendon, joint, and vessel damage, which can ultimately lead to disability, compromised health-related quality of life and poor health status. However, available instruments assessing global, patient's perceived and location-specific disabilities do not specifically survey patient global health status. An example of a score that surveys global health status is the Karnofsky Performance Status (KPS) score. Previous data support the use of the KPS score to predict outcome in SSc. Nevertheless, before considering the KPS score as a suitable outcome measure in SSc, its relevance should be definitely established. Therefore, we aimed to assess the construct validity of the KPS score in the assessment of health status in patients with SSc, by determining its convergent and divergent validity.

Methods: Three-hundred-and-sixty-two SSc patients fulfilling the American College of Rheumatology and/or the Leroy and Medsger criteria were assessed for visceral involvement, handicap and health-related quality of life (HRQoL). Global health status was evaluated by the KPS score. KPS score convergent and divergent validities were assessed using the Spearman's rank correlation coefficient.

Results: Mean age and disease duration at the time of evaluation were 55.7 (13.3) and 9.6 (7.9) years, respectively. Thirty-three (9.3%) patients had limited SSc, 179 (50.7%) limited cutaneous SSc, and 141 (39.8%) diffuse cutaneous SSc. Mean total score of the KPS score was 77.6 (11.7). The KPS score had fair convergent validity with disease duration ($r=-0.361$), dyspnea (NYHA classification, $r=-0.308$), perceived handicap as assessed by McMaster-Toronto Arthritis Patient Preference Disability Questionnaire ($r=-0.479$) and global disability as assessed by the Health-Assessment Questionnaire (HAQ, $r=-0.337$), and no correlation with hand-located disability as assessed by the Cochin Hand Functional Scale ($r=-0.278$), mouth-located disability as assessed by the Mouth Handicap In Systemic Sclerosis Scale ($r=-0.003$), anxiety and depression symptoms as assessed by the Hospital Anxiety and Depression Scale ($r=-0.053$), aesthetic impairment assessed on an 11-point scale ($r=-0.071$), and HRQoL as assessed by SF-36 mental and physical component scores ($r=0.064$ and $r=0.168$, respectively).

Conclusion: For assessing global health status in patients with SSc, the KPS score has acceptable construct validity. The weak correlation between KPS score and previously validated outcome measures in SSc suggests that the KPS score adds useful information for assessing the global health status in patients with SSc and that it may be a suitable instrument for daily practice or clinical trials in SSc.

Association of Gastrointestinal Involvement and Depressive Symptoms in Patients with Systemic Sclerosis. Vijay Bodukam[1], Ron D. Hays[2], Paul Maranian[2], Daniel E. Furst[2], James R. Seibold[3], Ann Impens[4], Maureen D. Mayes[5], Philip J. Clements[2] and Dinesh Khanna[2]. [1]Interfaith Medical Center, Brooklyn, Los Angeles, CA, [2]UCLA, [3]Univ of Connecticut, [4]University of MIchigan, [5]University of Texas Houston

Background: Systemic sclerosis-associated gastrointestinal tract involvement (SSc-GIT) is an important predictor of depressive symptoms. UCLA Scleroderma Clinical trial Consortium Gastrointestinal tract 2.0 (UCLA SCTC GIT 2.0) is a 34 item instrument that captures GIT symptom severity and impact on quality of life. This instrument is feasible, reliable and valid. It has seven scales—reflux, distension/bloating, diarrhea, fecal soilage, constipation, emotional well-being and social functioning and a total GIT score.

Objective: To assess 1) whether there is an association between depressed mood with GI symptoms as assessed by the UCLA SCTC GIT 2.0 instrument, and 2) to explore which GI specific symptom scales are associated with depressed mood in patients with SSc.

Methods: 152 patients with SSc completed the UCLA SCTC GIT 2.0 and the Center for Epidemiologic Studies Short Depression scale (CES-D 10; 0–30). Patients were divided into depressed (CES-D $\geq$ 10) or non-depressed group (CES-D $<$ 10) and compared using t-test or Chi-Square test. Multiple linear regression was used to determine associations between GI scales and depressed mood (CES-D).

Results: Study participants were 84% female, 78% Caucasian and 40% had depressed mood (CES-D10 $\geq$ 10). Patients with depressed mood had statistically worse GI scale scores (except fecal soilage) and worse total GIT score ($P<0.05$). In the multivariable model, reflux and constipation scales were independently associated with worse CES-D scores ($P=0.01$ to 0.06)

Conclusion: SSc-GIT involvement is associated with depressed mood. Reflux and constipation scales of UCLA-SCTC GIT 2.0 were independently associated with CES-D. Future studies should assess if treatment of GIT symptoms will improve depressed mood in patients with SSc-GIT.

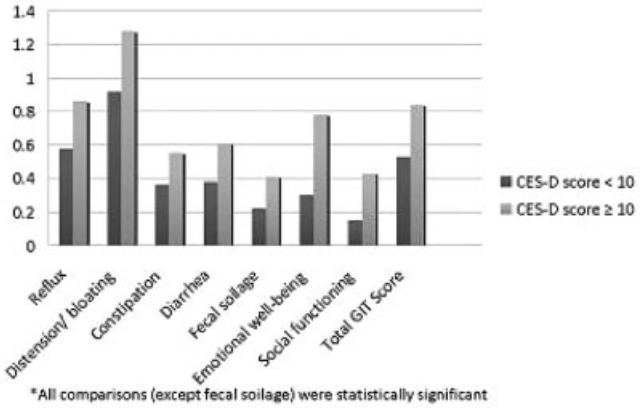

Figure. UCLA SCTC GIT 2.0 scale scores in patients with and without depressed mood.

Bone Mineral Density and Body Composition in Systemic Sclerosis: A Case-Control Study. Chi Chiu Mok, Ling Yin Ho, Chi Hung To and Kwok Man Ma. Tuen Mun Hospital

Background: Whether bone mineral density (BMD) is lower in patients with systemic sclerosis (SSc) than age-matched population is controversial. We conducted a case-control study on BMD and body composition (BC) in a group of southern Chinese patients with SSc.

Method: Consecutive patients who fulfilled the ACR criteria for SSc were invited for this cross-sectional study on BMD and BC (fat and lean mass), which was measured by dual energy X-ray absorptiometry (DXA) scan (Hologic, Belford USA). Exclusion criteria were: (1) Age $<$18 years; (2) Presence of other underlying rheumatic diseases (overlap syndrome); (3) Informed consent could not be obtained. An equal number of age and gender matched healthy controls were also recruited for the same measurements.

Results: 46 patients with SSc and 46 controls were studied. The mean age of patients at the time of DXA study was 48.4 ± 9.7 years. The mean duration of SSc since diagnosis was 5.5 ± 3.2 years. Thirteen (28%) patients had diffuse SSc while the others had limited SSc. Only 2 (4%) patients were currently receiving bisphosphonates. According to the World Health Organization (WHO) criteria, 5 (11%) patients with SSc had osteoporosis (T score ≤-2.5) at the hip and 16 patients (35%) had osteoporosis at the lumbar spine. 61% and 30%, respectively, of the patients had osteopenia at the hip and spine (T score between -1 and -2.5). One patient (2%) had vertebral fractures on radiological screening but no patients had a personal history of non-vertebral fractures. The body mass index (BMI) of patients with SSc was significantly lower than that of controls (20.9 ± 3.2 vs 26.1 ± 2.4kg/m^2; $p<0.001$). After adjustment for age, BMI and other risk factors for osteoporosis by ANCOVA, BMD of the total hip (0.778 ± 0.135 vs 0.838 ± 0.106g/m^2; $p=0.02$) and femoral neck (0.671 ± 0.127 vs 0.721 ± 0.106g/m^2; $p=0.04$) were significantly lower in patients with SSc than that of normal controls. The BMD of the lumbar spine (L2–4) was lower in SSc patients (0.903 ± 0.167 vs 0.944 ± 0.135g/m^2; $p=0.19$) but the difference was not statistically significant. The total bone mineral content (BMC) (1.73 ± 0.34 vs 1.85 ± 0.24g; $p=0.04$), fat mass (15.15 ± 5.34 vs 17.34 ± 4.09kg; $p=0.04$), lean mass (31.58 ± 4.61 vs 34.66 ± 3.95kg; $p=0.002$) were significantly lower in patients with SSc than controls. Among patients with SSc, linear regression analysis revealed that the whole body lean mass correlated positively with hip BMD ($p=0.02$), but age correlated negatively with BMD at the hip ($p=0.004$), after adjustment for sex, major organ complications and other common risk factors for osteoporosis. On the other hand, both lean mass and fat mass correlated positively with spinal BMD ($p<0.05$), whereas increasing age correlated with a significantly lower BMD at the lumbar spine ($p<0.001$).

Conclusions: Patients with SSc have significantly lower BMD at the hip than age-matched healthy controls, which is probably contributed by a significantly lower body lean mass.

Clinical Significance of Defined ANCA Positivity in Systemic Sclerosis. Emma C. Derrett-Smith[2], Svetlana Nihtyanova[2], Jennifer Parker[1], Christopher Bunn[1], Aine Burns[1], Mark A. Little[1] and Christopher P. Denton[3]. [1]Centre for Immunology, Royal Free Campus, UCL Medical School, London, [2]Centre for Rheumatology and Connective Tissue Diseases, Royal Free Campus, UCL Medical School, London, [3]Royal Free Hospital, London, United Kingdom

Purpose: While an atypical ANCA is reported in 20–30% of patients who have systemic sclerosis (SSc), this is not usually clinically significant. Conversely, patients with systemic sclerosis who have confirmed ANCA positivity with either myeloperoxidase (MPO) or proteinase-3 (PR3) antibodies on ELISA and clinical vasculitis are rarely reported in the literature. We have interrogated our database of patients with SSc who also have listed a clear clinical or histological diagnosis of vasculitis to look for the prevalence of overlap disease with ANCA-associated vasculitis (AAV) and whether these patients have altered disease features.

Methods: We examined a clinical database of 2200 patients with either limited or diffuse cutaneous SSc. Patients who had a clear clinical or histological diagnosis of vasculitis of any description had their serology investigations reviewed and repeated if possible to look for ANCA positivity with either MPO or PR3 reactivity. The clinical features, serology and histology of those patients who had both SSc and AAV were examined in detail.

Results: From our SSc cohort, 35 patients (1.6%) had a current or previous history of vasculitis, in whom the distribution of antibodies characteristically associated with the SSc features of their disease was comparable to those previously published from our cohort. For example, 20% were anti-centromere positive, 20% anti-topoisomerase-1 positive and 6% anti-fibrillarin antibody positive. Of these 35 patients, 8 (0.4% of total cohort) were either anti-MPO or anti-PR3 antibody positive. Both patients from the 35 who carried anti-fibrillarin antibodies, usually associated with overlap disease and increased incidence of renal and cardiac complications, were ANCA positive. No patients with vasculitis and anti-centromere antibodies were ANCA positive. Of the 8 ANCA positive patients, 7 had limited cutaneous SSc and anti-MPO antibodies and one had diffuse disease with anti-PR3 antibodies. The latter patient had clinical features of microscopic polyangiitis with renal, neurological and skin involvement. None of the MPO positive patients had granulomatous disease. All but one had glomerulonephritis, and 6 had pulmonary fibrosis.

Conclusions: SSc in overlap with ANCA-associated vasculitis is rare, and clinical features are more mixed than when either of these two conditions occurs separately. From our database, anti-fibrillarin antibodies may be more associated with overlap AAV than the other scleroderma-specific antibodies.

Cognitive Impairment in Systemic Sclerosis. Neslihan Yilmaz[2], Aynur Mollahasanoglu[1], Meryem Can[2], Müge Koçak[1], Nese Tuncer[1], Nevsun Inanç[2] and Sule Yavuz[2]. [1]Marmara University, Faculty of Medicine, Neurology Department, Istanbul, Turkey, [2]Marmara University, Faculty of Medicine, Rheumatology Department, Istanbul, Turkey

Background and Aim: Systemic sclerosis (SSc) is a connective tissue disorder that is characterized by microvascular damage and tissue fibrosis. Although nervous system involvement is unusual in SSc, cerebral hypoperfusion has been shown in imaging studies. Here, we aimed to evaluate cognitive functions in SSc patients who had no previous or current history of neurological involvement.

Methods: Thirty-one scleroderma patients (24 limited SSc, 4 diffuse SSc, 3 overlap) were examined. Fifteen rheumatoid arthritis patients (RA) and 20 healthy subjects(HC) were selected as aged and sex matched controls. To evaluate of different areas of cognition six neuropsychological tests was performed.

Results: Five out of 6 test scores including Wechsler Memory Scale digit span (WMS), Wisconsin card sorting test(WSCT),Stroop color-word interference test,Controlled oral word association tes(COWAT), California verbal learning test (CVLT) were different among the groups ($p<0.005$). WSCT categories completed test (HC vs SSc and RA vs SSc, $p<0.0001$), WSCT perseverative responses (HC vs SSc, $p<0.0001$; RA vs SSc, $p=0.005$), WSCT percentage perseverative errors (HC vs SSc, $p<0.0001$; RA vs SSc, $p=0.003$), WSCT percentage conceptual level responses (HC vs SSc, $p<0.0001$; RA vs SSc, $p= 0.001$) and CVLT perseveration (HC vs SSc, $p<0.0001$; RA vs SSc, $p=0.001$) test scores were significantly impaired in Ssc patients compared to both RA patients and HC subjects.

Table 1. Neuropsychological performances of SSC and RA patients vs healthy controls

	HC	RA	SSc
WSCT categories completed test	6 ± 0.0	5.6 ± 0.7	3.9 ± 1.2 □
WSCT perseverative responses	14.6 ± 7.8	21.7 ± 12.2	36.5 ± 17.5 □
WSCT percentage perseverative errors (%)	13.1 ± 4.5	16.3 ± 6.6	25.0 ± 10.2 □
WSCT percentage conceptual level responses (%)	73.5 ± 6.5	66.9 ± 13.5	47.4 ± 16.6 □
CVLT perseveration	1.7 ± 1.7	2.2 ± 1.3	4.58 ± 2.4 □

Kruskal Wallis test $p<0.0001$, Post hoc analysis; □ vs RA and HC $p<0.005$

On the other hand, WMS, Stroop test, COWAT and CVLT scores were found to be impaired in both SSc and RA patients compared to healthy controls ($p<0.005$).

Conclusion: This is the first extensive study showing cognitive impairment in SSc patients. WSCT might be considered a useful tool for detection of cognitive dysfunction in SSc patients.

1209

Coronary Artery Calcification in Systemic Sclerosis: There Was No Difference between SSc and Healthy Control Groups. Young-Eun Park[2], Seong-Hu Park[2], Seung-Hoon Baek[2], Jun-Hee Lee[2], Joung-Wook Lee[2], Geun-Tae Kim[2], Yeon-Ju Jeong[3], Su-Yeon Choi[4], Wan-Hee Yoo[1] and Sung-Il Kim[2]. [1]Chonbuk National University Medical School, Jeonju, Jeonbuk, South Korea, [2]Department of Internal Medicine, School of Medicine, Pusan National University, Busan, South Korea, [3]Department of Radiology, School of Medicine, Pusan National University, Busan, South Korea, [4]Seoul National University Hospital Healthcare System Gangnam Center, Seoul, South Korea

Background: Several systemic autoimmune diseases are associated with an increased prevalence of coronary artery disease. In systemic sclerosis (SSc), microvascular abnormality is well recognized, but previous studies about macrovascular disease including coronary artery disease showed conflicting results. Measurement of coronary calcification score (CCS) by a multi-detector computed tomography (MDCT) is an accurate and non-invasive method to detect coronary atherosclerosis, and the high level of CCS can predict coronary events.

Objective: To investigate the CCS in patients with SSc by using MDCT and to evaluate the risk of coronary artery disease.

Methods: We investigated the clinical and laboratory characteristics in patients with SSc (41 patients, all were women, mean 50 years, 22 with limited and 19 with diffuse type). The CCS was measured by MDCT and the risk of coronary events were evaluated by CCS and Framingham risk score (FRS). We selected sex and age-matching controls (123 controls) among the historical healty control group in South Korea, who were scanned by same CT scanner with our group, and analysed data statistically between SSc and control groups. We also assessed whether disease specific factors of SSc were correlated with CCS.

Results: The mean CCS of SSc was not significantly increased compared with healthy control (7.0 ± 26.3 vs 5.5 ± 41.2, $p=0.829$). The frequency of CCS>0 was not significantly different between SSc and control groups (17% vs 13%, $p=0.339$) (figure 1). There was also no difference in coronary

calcification between SSc and control groups after correction for the confounders high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, triglyceride, fasting glucose, body mass index and waist measurement. The CCS had no significant correlations with disease specific factors. The FRS was evaluated in 36 patients, all patients were categorized into low-risk group (FRS<10%).

Statistics of coronary calcification scores in 41 patients with systemic sclerosis

	CCS, Mean ± SD	CCS>0, no. (%)
Control (n=123)	5.5 ± 41.2	16 (13.0)
SSc-total (n=41)	7.0 ± 26.3	7 (17.1)
p-value	0.829	0.339
SSc-limited (n=22)	12.0 ± 35.3	5 (22.7)
SSc-diffuse (n=19)	1.1 ± 3.2	2 (11.2)
p-value	0.161	0.217

Conclusion: These results imply that the risk of coronary events due to coronary atherosclerosis might not be high in patients with SSc.

CXCL4, a Novel Marker for Systemic Sclerosis That Clearly Correlates with the Clinical Hallmarks and Pathological Events. Timothy Ruben Radstake[3], Lenny van Bon[2], Jasper Broen[2], Romy Beatriz-Christmann[1], Alsya Affandi[1], Madelon Vonk[2], Mike York[1], Cindy Collins[1], Mark Wenink[2], Roger Hesselstrand[7], Dirk Wuttge[7], Sandeep Agarwal[6], John Reveille[6], Joost Drenth[2], Jaqueline de Graaf[2], Martin Den Heijer[2], Cees Kallenberg[5], Marc Bijl[4], Wim van den Berg[2], Joosten Leo[2], Waander van Heerde[2], Piet van Riel[2] and Robert Lafyatis[1]. [1]Boston Medical Center, [2]Radboud University Nijmegen Medical Center, [3]Radboud University Nijmegen Medical Center/Boston Medical Center, Nijmegen, The Netherlands, [4]University Hospital Groninge, [5]University Hospital Groningen, [6]University Hospital Houston, TX, [7]University Hospital Lund, Sweden

Background: Despite recent advances in our understanding of systemic sclerosis (SSc) many patients still suffer from progressive disease leading to severe complications and premature death. Currently predictors for disease phenotype and prognosis are lacking.

Methods: We exploited proteome-wide analysis (SELDI-TOF) of secreted proteome from plasmacytoid dendritic cells (pDCs) from clinically well-defined groups of SSc patients (n = 214) to study the differential expression of proteins between SSc subsets. We confirmed the presence of the most predominant protein CXCL4 by ELISA in the supernatant and plasma of SSc patients in comparison with healthy individuals (n=129) and other autoimmune (SLE, n = 109), auto-inflammatory (AS, n = 93) and fibrosing (liver fibrosis, n = 93) clinical conditions. Using SSc phenotypic data including the presence of autoantibodies, skin- and lung fibrosis and pulmonary arterial hypertension (PAH) we examined the potential correlation between these clinical hallmarks and circulating CXCL4 levels. Finally, we studied the direct effects of CXCL4 on skin fibroblasts and HUVEC by investigating COMP expression and secretion of endothelin-1, respectively.

Results: Circulating pDCs were found at higher frequencies in SSc patients but did not spontaneously produce higher levels of IFNa compared to controls. Proteome-wide analysis of SSc pDC supernatants revealed the chemokine CXCL4 as the most abundant protein detected, seen predominantly in patients having early diffuse disease. Validation using ELISA confirmed this observation and also showed that circulating CXCL4 levels were significantly higher in SSc patients compared to controls and other conditions such as SLE, AS and liver fibrosis. CXCL4 levels were higher in diffuse SSc compared with limited SSc but showed by far the highest levels in those patients having early diffuse SSc. CXCL4 levels correlated well with the extent of skin fibrosis and the presence of lung fibrosis and PAH. These correlations could be explained by the ability of CXCL4 to induce myofibroblast transformation of skin fibroblasts and the secretion of endothelin-1 by human endothelial cells (HUVEC).

Conclusion: The anti-angiogenic chemokine CXCL4 is highly expressed in SSc patients and correlates well with the clinical hallmarks of SSc skin- and lung fibrosis and PAH and therefore provides a novel biomarker for SSc phenotype but also other fibrosing diseases.

Determinants of Work Disability in Patients with Systemic Sclerosis: A Longitudinal Study of the GENISOS Cohort. Roozbeh Sharif[2], Maureen D. Mayes[8], Perry M. Nicassio[1], Emilio B. Gonzalez[6], Hilda T. Draeger[5], Terry A. McNearney[7], Deepthi K. Nair[3], John D. Reveille[4], Frank C. Arnett[9] and Shervin Assassi[2]. [1]Department of Psychiatry, University of California, Los Angeles, CA, [2]Division of Rheumatology and Immunogenetics, University of Texas Health Science Center at Houston, Houston, TX, [3]Division of Rheumatology and Immunogenetics, University of Texas Health Science Center at Houston, Houston, TX, [4]Univ Texas Health Sci Ctr, Houston, TX, [5]University of Texas Health Science Center at San Antonio, San Antonio, TX, [6]University of Texas Medical Branch at Galveston, Galveston, TX, [7]University of Texas Medical Branch at Galveston, TX, [8]University of Texas-Houston, Houston, TX, [9]UT Medical School, Houston, TX

Background: Systemic sclerosis (SSc) is associated with substantial morbidity and mortality. SSc can have profoundly detrimental impact on the patients' personal and professional life. There are no published data on the prevalence of the work disability (WD) in patients with SSc in the United States, nor longitudinal studies examining long-term predictors of WD in general. The goal of this study was to determine the prevalence and correlates of WD at enrollment and to investigate the longitudinal determinants of WD in the patients enrolled in the Genetic versus Environment in Scleroderma Outcome Study (GENISOS) cohort.

Methods: Patients were subdivided into three groups based on their employment status at enrollment: work disabled, working, and retired or homemakers. The latter group was excluded from further analysis. Utilizing logistic regression analysis with a forward hierarchical variable selection strategy, we evaluated the independent socio-demographic, clinical, and quality of life measure correlates of WD at enrollment. Furthermore, patients working at enrollment were included in the longitudinal study. We used a Cox regression proportional Hazard's model with a similar variable selection strategy to determine the predictors of WD on follow up visits. All quality of life measures demonstrated adequate internal consistency reliability in the current study.

Results: At the time of analysis, 284 patients with mean age of 48.7 (±13.2) years were enrolled in the GENISOS cohort. There were 237 (83.5%) female; 133 (46.8%) Caucasian, 83 (28.9%) Hispanic, 58 (20.4%) African American, and 10 (3.5%) from other ethnic groups. Overall; 162 (57.0%) patients had diffuse cutaneous involvement; the disease duration at enrollment was 2.5 (±1.6) years. Patients were followed for 3.9 (±3.6) years; in 1438 consecutive visits. At entry; 124 patients (43.7%) were WD, 131 (46.1%) working, and 29 (10.2%) retired or homemakers. In a multivariate regression model, older age (p=0.012), educational level below associate degree (p<0.001), higher Fatigue Severity Score (p=0.045), lower SF-36 physical component scores (p<0.001) and lower % predicted FVC (p=0.009) were independently associated with WD at the cross sectional level.

At mean follow-up of 4.4 (±3.8) years (range up to 12 years) of those working at baseline, 96 (73.3%) were still working while 35 (26.7%) became disabled. Using multivariate Cox regression analysis, lower coping skills as measured by higher IBQ scores (p=0.004), lower % predicted DLCO (p=0.047), and the presence of joint contractures in small joints (p=0.004) were the independent predictors of WD on follow up visits.

Conclusion: Socio-demographic, lung involvement, fatigue severity, and SF-36 physical component scores were the strongest independent correlates of WD in patients with SSc at early stages of the disease. Whereas small joint contracture, lung involvement, and higher IBQ scores, reflecting lower coping skills are the main predictors of the WD at the later stages of the disease.

1212

Developing a Disease Activity and Therapeutic Response Index in Connective Tissue Disease Related Interstitial Lung Disease (CTD-ILD): Rationale, Aims, Design and Results from Tier 0, the Pre-Delphi Exercise. Lesley Ann Saketkoo[4], Dörte Huscher[2], Dinesh Khanna[12], Paul F. Dellaripa[1], Kevin Flaherty[15], Eric L. Matteson[5], Chester V. Oddis[16], Kristine Phillips[14], David Pittrow[3], Athol Wells[8], Christopher P. Denton[9], Oliver Distler[11], Otylia M. Kowal-Bielecka[6], Vibeke Strand[10], Kevin K. Brown[7] and James R. Seibold[13]. [1]Brigham & Womens Hospital, Boston, MA, [2]German Rheumatism Research Centre - Berlin, Germany, [3]Institute of Clinical Pharmacology, Medical Faculty, University of Dresden, Germany, [4]Louisiana State University Health Sciences Center - New Orleans, LA, [5]Mayo Clinic, Rochester, MN, [6]Medical University of Bialystok, Poland, [7]National Jewish Health, Denver, CO, [8]Royal Brompton Hospital and National Heart and Lung Institute, London, United Kingdom, [9]Royal Free Hospital, London, United Kingdom, [10]Stanford University; Palo Alto, Portola Valley, CA, [11]University Hospital Zurich, Switzerland, [12]University of California Los Angeles, [13]University of Connecticut Health Center, Farmington, CT, [14]University of Michigan, Ann Arbor, MI, [15]University of Michigan, Ann Arbor, [16]University of Pittsburgh, PA

Background: There are currently no licensed therapies for interstitial lung disease (ILD). There is no consensus on measures of disease activity or therapeutic responsiveness, thus hampering effective drug development and regulatory evaluation of candidate therapies. We present the first phase of a multi-tiered investigation to identify consensus on provisional criteria to measure disease activity and therapeutic response in CTD-ILD and Idiopathic Pulmonary Fibrosis (IPF).

Methods: A multi-disciplinary steering committee (authors) engaged in extensive literature review and agreed upon the following methodology: Pulmonary, rheumatology and cardiology specialists with ILD expertise were identified by literature review, task force membership in international societies and peer recommendation. Each was invited to participate in a 3-Tier Delphi project with a preceding 'Tier 0' exercise. The goal of 'Tier 0' was to engage the participants in a brainstorming exercise to identify *qualities that are important to measure* ('domains') in CTD-ILD and IPF and '*instruments'* to measure these domains. The goal of contrasting CTD-ILD and IPF is to distinguish similarities and differences between these entities. Additionally, suggestions of positive and negative instruments were collected for specific CTD-ILD disease groups. Data was collected via a custom designed secure web-site. Participants typed their additions into a 'sparse' framework of 12 sample 'domains' with 12 sample 'instruments'. The steering committee initially participated in a series of individual exercises followed by a group effort to limit redundancy and identify the broadest spectrum of reasonable domains that would appropriately accommodate the diversity of 'instruments' or 'outcome measures' suggested by the participants.

Results: 98% of invited experts participated. 137 pulmonary, 102 rheumatology and 4 cardiology specialists participated from 32 countries representing 6 continents. 74% and 69% of participants considered 'ILD' and 'rheumatologic lung disease' respectively to be their primary fields of investigation. 133 domains were suggested and after review resulted in the 23 domains listed below. More than 6700 instruments were proposed and later reduced to 616.

Table 1. Final 23 Preliminary Domains From Tier 0 of the Delphi Process

Survival	Mental Health
Biomarkers	Sleep
Imaging	Global Assessment
Lung Physiology/Function	Health Related Quality of Life
Lung Parenchyma	Functionality
Lung Vascular	Participation
Cardiac Function	Employment
Composite Scores	Extra-Pulmonary/CTD Features
Gastroesophogeal Reflux	Medication
Cough	Co-Morbidities
Dyspnea	Barriers to Care
Fatigue	

Discussion: This is the first known multi-disciplinary effort to assess domains and instruments in the study of CTD ILD – which is essential in a field devoid of meaningful outcome measures and with many candidate therapies on the horizon. The high response rate of this comprehensive, multi-disciplinary, international effort reflects both the need for a systematic approach to ILD and the collective interest in establishing criteria for this group of diseases. The overall results are very promising and reflect the innate complexities of the spectrum of ILD, thus creating a robust platform for next phases of this consensus study.

1213

Development of a Limited Scleroderma Cutaneous Activity and Damage Index. Lorinda Chung[1], Daniel E. Furst[5], Paul Maranian[3], Kait Arefiev[2], Jeffrey Zwerner[2], Dinesh Khanna[4], Victoria P. Werth[6] and David Fiorentino[2]. [1]Stanford Univ Medical Center, Palo Alto, CA, [2]Stanford Univ Medical Center, [3]UCLA Medical School, [4]University of California Los Angeles, Los Angeles, CA, [5]University of California Los Angeles Medical School, Los Angeles, CA, [6]University of Pennsylvania, Philadelphia, PA

Purpose: Most clinical trials for skin disease in systemic sclerosis patients have excluded patients with the limited cutaneous subtype (lcSSc) due to the lack of a robust measure of cutaneous disease in these patients. We sought to develop and partially validate a novel cutaneous index for patients with lcSSc.

Methods: We developed the Limited Scleroderma Cutaneous Activity and Damage Index (L-SCADI) based on an extensive literature review and input from 11 SSc experts (6 rheumatologists and 5 dermatologists) providing face and content validity. Following a 30 minute training session, 6 physicians (2 rheumatologists and 4 dermatologists) used the L-SCADI to score the severity of skin disease in 12 lcSSc patients. To assess construct validity, physicians completed visual analogue scales (VAS) to score global assessment of cutaneous activity and damage (PGA-a and PGA-d), and patients completed a VAS global assessment of skin disease (PtGA), the Health Assessment Questionnaire Disability Index, the Dermatology Life Quality Index, and the Short-Form-36 (SF-36). Inter-rater reliability was assessed using intraclass correlation coefficient (ICC) in a 2-way random model. After scoring every patient once, each physician scored at least one patient a second time to assess intra-rater reliability.

Results: All 12 patients were female, 83% Caucasian, with mean disease duration from first non-Raynaud's symptom of 11.9 ± 9.6 years (5 with ≤ 6 years, 7 with > 6 years). Mean time to complete the L-SCADI was 6.9 ± 1.5 min. Mean activity (0–63), damage (0–53), and total (0–116) scores were 10.7 ± 6.3, 7.0 ± 5.2, and 17.7 ± 9.1, where 0=no disease. L-SCADI activity and damage scores were highly correlated with PGA-a and PGA-d (rho=0.77 (p=0.004) for activity, 0.8 (p=0.002) for damage). L-SCADI activity was moderately correlated with PtGA (rho=0.6, p=0.04), while L-SCADI damage was highly negatively correlated with the SF-36 Physical Component Summary score (rho=−0.92, p=0.0001). The inter-rater reliability for PGA-a and PGA-d was modest (ICC 0.34 and 0.43), while the consistency among raters for the L-SCADI activity, damage, and total scores was moderate (ICC 0.52, 0.58, 0.55). The ICC for L-SCADI total improved to 0.62 after excluding edema. Mean time between repeat assessments was 50.2 ± 34.7 min. Intra-rater reliability for PGA-a was not significant, but was excellent for PGA-d (ICC 0.89). Intra-rater reliability for L-SCADI activity was moderate (ICC 0.57), while the damage and total scores had much higher correlations (ICC 0.86 and 0.69).

Conclusions: The L-SCADI is easy to perform and has reasonable construct validity. Inter- and intra-rater reliability for the L-SCADI activity score is moderate, but better than the PGA-a, with much greater intra-rater agreement for the assessment of disease damage. The variability in physician assessments suggests that more extensive training prior to use of the L-SCADI is essential, and further development of the scale is necessary.

Effect of Selective and Dual Endothelin Receptor Antagonists (ERAs) on SSc and Control Endothelial Cells Apoptosis. Yongqing Wang, Omar R. Kahaly and Bashar Kahaleh. University of Toledo, Toledo, OH

Objectives: microvascular endothelial cells (MVEC) apoptosis is a critical event in the pathogenesis of SSc vascular disease. Endothelin 1 (ET) signaling in MVEC favors cell survival and antagonizes apoptotic signals. In this study we examined the effects of selective and non-selective ERAs on ET mediated resistance to apoptosis.

Methods: MVEC apoptosis was induced by oxidative stress or by growth factor withdrawal (GFW) and was assessed by flow cytometry, caspase-3 activity and cell viability. We tested the selective and non-selective ERAs: PD145065 a dual ERA, BQ 788 a selective B, and the selective type A ERAs FR139317 and Ambrisentan. We also investigated the effects of si-RNA knockdown of EDNRA, B or A&B mRNAs on MVEC apoptosis. Finally, a focused apoptosis gene expression microarray was utilized to investigate the effect of ET and ERAs on MVEC apoptotic gene expression profile.

Results: significant upregulation of both type A and B- ET receptors in SSc-MVEC was noted, particularly the A receptors. SSc- MVEC apoptotic responses to oxidation or GFW were significantly higher in SSc than in control cells. The addition of ET resulted in a significant, albeit incomplete, reversal of MVEC apoptosis, particularly in control cells. The addition of ERAs alone did not alter the level of apoptotic responses. Selective type A-ERAs maintained ET antiapoptotic effects, while selective type B-ERA and dual-ERAs completely blocked the antiapoptotic effect of ET. ET effects were also blocked when selective A-ERAs concentrations were increased beyond the concentrations associated with selectivity of the tested agent. To confirm the conclusion that signaling through type B receptor mediates ET protective effects, we performed si-RNA knock down experiments. Type A receptor mRNA knock down had no effect on ET protective effect, while type B receptor knock down and the combined A&B mRNAs knock down completely abolished ET antiapoptotic effects. Next, we performed focused apoptosis microarray gene expression profiling of MVEC after GFW and the effects of ET and ERAs on gene expression were examined. GFW induced an upregulation of the pro-apoptotic gene *BAX* expression and the addition of ET inhibited *BAX* expression. Selective type A-ERA maintained ET induced downregulation of *BAX* while the nonselective ERAs and selective type B-ERA prevented ET effect on *BAX* expression.

Conclusions: · Oxidation and growth factor withdrawal induced MVEC apoptosis is prevented by ET.

· ET antiapoptotic effects are mediated by inhibition of *BAX* gene expression.

· Selective A-ERAs preserve ET anti-apoptotic effects, while the dual and selective B-ERAs negate ET protective effect.

· Therapeutic strategies utilizing selective A-ERAs may be superior to the non-selective approaches from a vascular prospective.

Findings in Ocular Examination of Patients with Systemic Sclerosis. Niki Tsifetaki[3], Charalampos Papagoras[3], Contantinos A. Paschides[1] and Alexandros A. Drosos[2]. [1]Department of Ophthalmology, Medical School, University of Ioannina, Ioannina, Greece, [2]Ioannina Medical School, Ioannina, Greece, [3]Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece

Background: Systemic sclerosis (SSc) is characterized by vascular dysfunction (Raynaud's phenomenon, pulmonary hypertension), while patients often complain for dry symptoms. Eye examination provides information on both exocrine function and vascular integrity.

Objectives: To seek for evidence of vascular dysfunction and sicca syndrome in a cohort of SSc patients.

Methods: Patients with SSc, underwent ophthalmologic screening for dry eyes [Schirmer's test (ST), Break-up time (BUT), Rose Bengal stain (RBS)]. For comparison age and sex-matched healthy controls underwent similar testing. A patient or control was considered to have xerophthalmia, if at least 2 out of 3 tests were positive (ST$<$5 mm after 5 min, BUT $<$10 sec, RBS suggestive of dry keratopathy grade $>$3+). Patients were also surveyed for symptoms of xerostomia by means of a questionnaire and screened for antinuclear antibody (ANA) positivity and type. Those with strong evidence of Sjögren's syndrome (SS) underwent minor salivary gland biopsy. Finally, a random subset of patients underwent full ophthalmologic examination, including fundoscopy and fluorangiography.

Results: Seventy-two SSc patients (65 females, 7 males, mean age 53.4$\pm$14.8 years) and 72 matched controls were screened for dry eyes. Twenty-four SSc patients were positive for xerophthalmia (33.3%), compared to only 11 controls (15.3%) ($p<0.05$). Further, 38 (52.3%) SSc patients reported xerostomia, while 21 (29.2%) complained for both dry eyes and mouth. Only 31 (43%) of SSc patients were completely free of dry symptoms and signs. Among patients with xerophthalmia 87.5% reported dry mouth, 95.8% were ANA-positive, 45.8% had anti-Scl-70, 33.3% had anticentromere, 8.3% anti-U_1RNP, 25% anti-Ro and 12.5% anti-La antibodies. The corresponding values for SSc patients without dry eyes were 35.4% for dry mouth, 97.9% for ANA and 45.8, 18.8, 16.7, 35.4 and 2.1% for the ANA subtypes. Minor salivary gland biopsy was undertaken in 14 patients and was suggestive of SS in 9. Overall 9 (12.5%) patients had SS based on sicca symptoms, positive ophthalmologic tests and positive anti-Ro/La antibodies or biopsy, fulfilling the American-European consensus criteria for SS. Finally, 29 patients underwent anterior segment examination, fundoscopy and fluorangiography. Blepharitis was the most common clinical abnormality in 11 (37.9%) patients, followed by pinguecula in 6 (20.7%). In fundoscopy and fluorangiography retina was normal in 19 (65.5%) patients. The most common abnormality was maculopathy and pigmented epithelium impairment in 6 (20.7%) patients suggestive of vascular damage of the choroidal layer. Other findings were drusen in 3 (10.3%) patients, a peripheral aneurysm in one patient and a nevus in another. While all patients had Raynaud's phenomenon, no major retinal arterial abnormalities were detected.

Conclusion: Objective signs of xerophthalmia are encountered in 1/3 of SSc patients and are usually associated with symptoms of dry mouth. Full-blown SSj may be found in 1 every 8 SSc patients. There seems to be a sparing of retinal arteries in contrast to choroidal vessels in SSc.

Genetic and Clinical Correlates of Anti-Fibrillarin (U3-RNP) Auto-Antibodies in African Americans with Systemic Sclerosis. Roozbeh Sharif[2], Marvin J. Fritzler[4], John D. Reveille[3], Shervin Assassi[1], Maureen D. Mayes[5] and Frank C. Arnett[6]. [1]Univ of Texas Health Science, Houston, TX, [2]Univ of Texas Health Science Center at Houston, Houston, TX, [3]Univ Texas Health Sci Ctr, Houston, TX, [4]University of Calgary, Calgary, AB, Canada, [5]University of Texas-Houston, Houston, TX, [6]UT Medical School, Houston, TX

Background: Previous studies have suggested that anti-fibrillarin (U3-RNP) autoantibodies (AFA) are specific for systemic sclerosis (SSc) and occur more frequently in African Americans (AA) and men. A better prognosis in AAs with AFA also has been reported. The aim of this study was to investigate the associations of clinical features and human leukocyte antigen (HLA) class II alleles among AFA positive AAs with SSc and compare it with the AFA negative AA patients and unaffected AA controls.

Methods: Between 1990 and 2010, 74 AA patients were enrolled in the ongoing observational cohort studies of AA patients, at our institution. Genetic characteristics, autoantibody profile, and clinical manifestations were examined. AFAs were determined by immunoprecipitation of the full length radiolabeled recombinant protein. HLA class-II (DRB1, DQA1, and DQB1) alleles were oligotyped or sequenced in AA patients (n=74) and AA controls (n=263). We used chi-square, Fisher's exact test, and student's t-test for comparative studies. We compared allelic frequencies between AFA positive (n=30) and negative (n=44) AAs, and subsequently with unaffected AA normal controls.

Results: The mean age of AA patients with SSc was 47.7 ($\pm$13.4) years. Sixty one (61; 82.4%) were female and 52 (70.2%) had diffuse disease. There were no significant differences in gender and disease type (diffuse versus limited SSc). There were no significant differences in gastrointestinal, cardiac, and renal SSc between patients with and without AFA. Significant results are described in Table 1.

Conclusions: These findings imply a strong association between *HLA-DRB1*08, DRB1*0804, DRB1* 1302, DQB1*0301* and having two of three *DQB1* alleles HLA-*DQB1*0301, 0602,* and *0604* with AFA in AA patients with SSc. This subset of SSc patients had less musculoskeletal involvement and secondary Sjögren's disease.

Impact of Systemic Sclerosis on Occupational and Professional Activity with Attention to Patients with Digital Ulcers. Alice Berezne[3], Raphaele Seror[2], Sandrine Morell-Dubois[1], Christelle Nguyen[4], Eric Hachulla[1], Loic Guillevin[4] and Luc Mouthon[4]. [1]Service de Medecine Interne, Centre de Reference Pour la Sclerodermie Systemique, Hôpital Claude Huriez, Universite Lille 2, Lille, France, Metropolitan, [2]Université Paris Descartes, Faculté de Médicine, Pôle de Médecine Interne, Centre de Reference Pour les Vascularites Necrosantes et la Sclerodermie Systemique, Hôpital Cochin, Assistance Publique-Hopitau, [3]Universite Paris Descartes, Faculte de Medicine, Pôle de Medecine Interne, Centre de Reference Pour les Vascularites Necrosantes et la Sclerodermie Systemique, Hôpital Cochin, Assistance Publique-Hôpitaux de Paris, Paris, Fra, [4]Universite Paris Descartes, Faculte de Medicine, Pole de Medecine Interne, Centre de Reference Pour les Vascularites Necrosantes et la Sclerodermie Systemique, Hopital Cochin, Assistance Publique-Hopitaux de Paris (AP-HP), Paris, France, Metro

Objective: To evaluate the impact of systemic sclerosis (SSc) and digital ulcers (Dus) on daily living and professional activities.

Methods: We prospectively evaluated 189 SSc patients for employment status and handicap during meetings of the French patients association (n=86; 45.5%) or during hospitalisation (n=103; 54.5%).

Results: Seventy eight patients (43.6%) had diffuse SSc. The mean (±SD) age was 54±13 years and disease duration 9.3±8.4 years at the time of evaluation. Sixty patients (31.7%) had at least one DU. Global disability, hand disability and anxiety, respectively assessed using health assessment questionnaire (1.12±0.79 vs 1.39±0.84, P=0.001), Cochin hand function scale (20.2±18.3 vs 27.8±19.1, p<0.0001) and Hospital Anxiety Scale (9.9±5 vs 8.5±4,2, p=0.04) were significantly higher in patients with Dus than in others. Most patients reported a limitation in daily activities related to SSc, as assessed by a daily activity limitation scale (score 4.4±2.9) and an increased need for help in the home. Patients reported needing 4±13.5 hours per month of paid household help related to SSc and 1.5±10 hours per month related to Dus, with significant differences between patients with or without Dus (p=0.004). Among the 113 patients in the workforce, 67 (59.3%) were employed; 42 (37.2%) in were full-time employment, 36 (31.8%) received full disability pension, and 27 (23.9%) were on sick leave, with no difference between patients with or without Dus.

Conclusion: SSc has a significant impact on activities of daily living and work disability. Disability and the need for external home help are increased for those with Dus.

Is Surfactant D or CC-Chemokine Ligand 18 Biomarkers for Interstitial Lung Disease in Systemic Sclerosis? Shervin Assassi[2], Julio Charles[3], Frank C. Arnett[7], Roozbeh Sharif[2], Robert E. Lasky[3], Emilio B. Gonzalez[5], Hilda T. Draeger[4], Terry A. McNearney[1], Sandeep K. Agarwal[2], Ramana V. Gutala[3], Rosa M. Estrada-Y-Martin[3] and Maureen D. Mayes[6]. [1]Eli Lilly and Co, Indianapolis, IN, [2]Univ of Texas Health Science Center at Houston, TX, [3]Univ of Texas Health Science Center at Houston, [4]Univ of Texas Health Science Center at San Antonio, San Antonio, TX, [5]Univ of Texas Medical Branch Galveston, TX, [6]University of Texas-Houston, TX, [7]UT Medical School, Houston, TX

Objective: Previous studies have indicated that surfactant D (SP-D) levels correlate with the presence of interstitial lung disease (ILD) in patients with systemic sclerosis (SSc).

CC-chemokine ligand 18 (CCL18) is a chemokine produced by activated macrophages that upregulates collagen production in lung fibroblasts. Previous studies have suggested that CCL18 predicts the change in forced vital capacity (FVC) in patients with idiopathic pulmonary fibrosis.

Our goal was to investigate the predictive significance of SP-D and CCL18 for the decline rate in FVC over time in a large prospective cohort of SSc patients.

Methods: SP-D and CCL18 levels were determined in 266 SSc patients and 100 age, ethnicity and gender matched unaffected controls using commercially available ELISA kits. The SSc plasma samples were collected at the initial visit of the Genetics versus Environment in Scleroderma Outcome Study (GENISOS), an observational cohort of patients with early SSc. Pulmonary function tests (PFT) were obtained at the initial visit and annually thereafter. The primary outcome was FVC expressed as a percentage of predicted value. First, the protein levels between patients and controls were compared by t-test. Subsequently, the correlation of protein levels with the FVC at the enrollment visit was investigated by linear regression. Finally, a generalized linear mixed model with the sequentially obtained FVCs as the outcome variable was utilized for the longitudinal analysis. The predictive value of SP-D and CCL-18 for the decline rate in FVC was investigated by the interaction term between the protein levels and follow up time. The protein levels were examined as continuous variable as well as a dichotomized variable according to the 95th percentile level in controls.

Results: The average disease duration at enrollment was 2.5 years. 156 patients (59%) had diffuse cutaneous involvement. The mean follow up time in the study was 3.8 years. 926 FVC measurements belonging to 244 patients fulfilled the American Thoracic Society criteria and were included in the analysis.

SP-D levels were significantly higher in SSc patients than controls (p=0.001, mean difference= 643.9, CI= 256–1031.8). Furthermore, the SP-D level correlated with the FVC levels at enrollment (p=0.008, R^2=0.033). However, the SP-D did not predict the decline rate in FVC over time (p=0.649). Similarly, the dichotomized value of SP-D (based on 95th percentile in controls) did not predict the rate of decline in FVC (p=0.195).

CCL18 levels did not differ significantly between patients and controls (p=0.212, mean difference=7.4, CI= − 4.3– 19.1). The CCL18 did not correlate with the FVC at enrollment (p=0.21). Furthermore, CCL18 did not predict the decline rate in FVC over time as a continuous or dichotomized variable (p=0.439 and p=0.212, respectively).

A repeat analysis after adjustment for smoking status showed similar results for both proteins.

Conclusion: Although SP-D correlates with the concomitantly obtained FVC levels, it is not useful as a predictive biomarker for the decline rate in FVC. On the other hand, CCL18 correlates neither with the concomitantly obtained FVC nor with its progression over time in SSc.

Longitudinal Fatigue Severity Scale Scores Correlate with Modifiable Psychosocial Variables in Early Systemic Sclerosis. Astrud Lorraine Leyva[3], Shervin Assassi[1], Maureen D. Mayes[6], Deepthi K. Nair[1], Michael Fischbach[2], Roozbeh Sharif[1], John D. Reveille[5], Emilio B. Gonzalez[3] and Terry A. McNearney[4]. [1]Univ of Texas Health Science Center Houston, TX, [2]Univ of Texas Health Science Center San Antonio, TX, [3]Univ of Texas Medical Branch, Galveston, TX, [4]Univ of Texas Medical Branch; Currently at Eli Lilly and Co, Indianapolis, IN, [5]Univ Texas Health Sci Ctr, Houston, TX, [6]University of Texas-Houston, TX

Purpose: Fatigue is a major complication of Systemic Sclerosis (SSc). Longitudinal studies examining the baseline predictors of fatigue in SSc have not been reported previously. We analyzed the association of the baseline demographic, clinical and self-reported psychometric variables with longitudinally obtained Fatigue Severity Scale (FSS) scores to identify potentially modifiable factors to improve fatigue severity in SSc.

Methods: FSS scores in 266 patients enrolled in the Genetics versus Environment in Scleroderma Outcomes Study (GENISOS) were examined. GENISOS is a large multi-center, prospective observational cohort of patients with early SSc (disease duration $\leq$ 5 years at enrollment). The association of baseline variables with sequentially obtained FSS was investigated in a generalized linear mixed model. A comprehensive list of baseline variables including demographic characteristics, disease type, autoantibody status, pulmonary function test parameters and psychometric measures were examined. Initially a univariate analysis was conducted, followed by a multivariate analysis utilizing a hierarchical forward variable selection strategy. Internal consistency of the psychometric variables including the FSS was assessed and validated with Cronbach's alpha computation.

Results: The mean age was 48.6 years, 83% of patients were female and 47% of patients were Caucasian. Fifty-nine percent had diffuse cutaneous involvement. The mean follow up time was 3.8 years, ranging up to 11.4 years. The average baseline FSS score was 4.7 $\pm$ 0.96, comparable to scores reported in systemic lupus erythematosus and multiple sclerosis patients. A total of 1090 FSS measurements obtained during the enrollment time were studied for the longitudinal analysis. The FSS did not show a consistent trend for change over time ($p=0.221$). Although a number of baseline variables were associated with longitudinally obtained FSS, only coping skills as measured by the Illness Behavior Questionnaire ($p<0.001$), Short Form-36 physical component summary ($p<0.001$), shortness of breath-visual analogue scale ($p=0.011$) and Gastrointestinal Medsger Severity Index ($p=0.025$) were independent predictors of FSS in the multivariable model.

Conclusions: Longitudinal FSS scores were strongly associated with perceived physical functioning and coping patterns of illness behavior. Our results emphasize the importance of potentially modifiable psychosocial factors in treatment of fatigue. For example, an interventional strategy targeting coping mechanisms in SSc patients may directly improve fatigue severity. Consideration of specific psychosocial and behavioral support may have more impact in managing fatigue severity than currently available traditional or pharmacologic interventions.

Loss of Microvascular Response to Central Nervous Impulses to Finger Pulp in Systemic Sclerosis. Tone Kristin Bergersen[2], Anna-Maria Hoffmann-Vold[1], Oivind Midtvet[2], Jan Tore Gran[2], Cato Mork[2] and Karin Toska[3]. [1]Oslo University Hospital, Oslo, Nydalen, Norway, [2]Oslo University Hospital, Oslo, Norway, [3]University of Oslo, Blindern, Norway

Thickening and fibrosis of digital skin with recurrent digital ulcera are major problems in systemic sclerosis (SSc). Probably, digital ulcera are caused by damage of the microvascular bed (1). Typically, the fingers are more severely affected than the proximal parts of the palm. Blood flow in skin of hands is mainly controlled by the arteriovenous anastomoses (AVAs) located in the palm and nailbeds (2). The vasomotion of the AVAs is controlled by the CNS and is synchronous in all skin areas. We have studied the vasomotor activity in skin of fingers and thenar region in SSc.

Laser Doppler flux (Moor instruments, England) from finger pulp and thenar region were simultaneously recorded together with ipsilateral radial artery blood velocities (ultrasound Doppler, SD100, Vingmed, Norway) and mean arterial blood pressure (Finapres) in 11 patients and in 11 aged matched healthy subjects. The subjects were resting on a bench in thermoneutral condition for 30 min before a 15 min continuous recording was obtained.

The mean duration of SSc was 7.3 yrs (range 2–15 yrs), mean age 55 yrs (range 45–67 yrs). Eight of the patients had previous history of digital ulcera, but none had ongoing ulcera. All patients had Raynauds phenomenon and disturbed microvascular architecture visualized by nailfold capillaroscopy. The blood velocity in the radial artery in both groups showed the typical large fluctuations caused by synchronous opening and closing of the AVAs (2) (Fig. 1A). In the control group, fluctuations in thenar flux and finger pulp flux were closely correlated to the velocity fluctuations in the radial artery (Table 1). In the SSc group, there was also a close correlation between the thenar flux and the velocity fluctuations in the radial artery (Fig 1A and B, Table 1). However, the simultaneous finger pulp flux was statistically significantly less correlated to the velocity in radial artery than the thenar flux (Table 1). Furthermore, in some patients, a positive correlation was seen between finger pulp flux and short-time variability in MAP (Fig. 1 C and D).

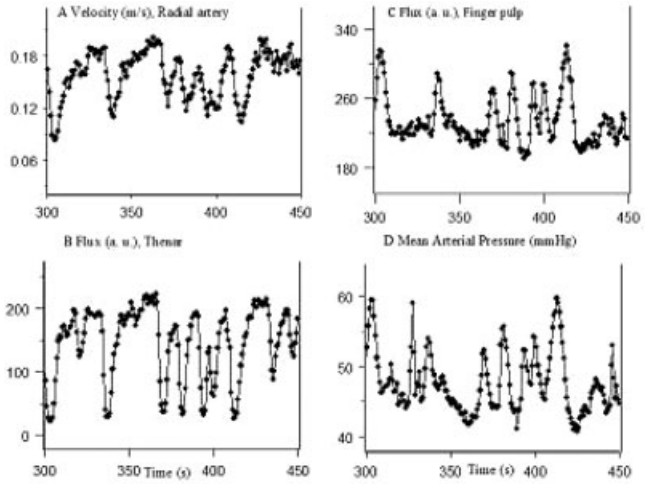

Figure 1. Simultaneous blood velocity, flux and MAP in a patient with SSc.

Table 1.

	SSc		Control group	
	median r	94% CI	median r	94% CI
finger pulp flux - radial artery	0.27	−0.15, 0.67	0.87	0.73, 0.96
thenar flux - radial artery	0.77	0.65, 0.86	0.90	0.87, 0.94
Wilcoxon sign test, p	0.016		0.81	

r= correlation coefficient, CI=Confidence Interval, significance level $p<0.05$

In conclusion, the pattern of bursts of efferent sympathetic impulses to skin AVAs is probably unchanged in SSc. However, the AVAs in the SSc finger do have an attenuated response to impulses from the CNS. A positive correlation between perfusion of finger tip and short-time variability in MAP suggest a passive vascular bed where blood flow variations is a result of variations in MAP.

1221

Lower Education as a Proxy for Socioeconomic Status Is?Not Associated with Poor Outcomes in Systemic Sclerosis (SSc): Data from a Large SSc Cohort (Canadian Scleroderma Research Group). Samah Mansour[4], Ashley Bonner[2], Murray Baron[1], Janet E. Pope[3] and The CSRG. [1]Jewish General Hospital, Montreal, QC, Canada, [2]McMaster University, [3]St Joseph Health Care London, London, ON, Canada, [4]University of Western Ontario

Background: In SLE, socioeconomic status (SES) has a large effect on outcomes such as renal failure. It is unknown what the effect of SES is on outcomes in SSc. SES is often measured by income and education. In SSc, in general, highest education would be attained often decades prior to disease onset whereas current income could be low due to SSc and thus would confound interpretation of effect of SES on SSc. SES can modify outcomes

by altering timing of access to care, access to medications, and adherence. Lower SES may be a surrogate for other health related behaviors that can impact outcome.

Methods: The Canadian Scleroderma Research Group (CSRG) collects detailed data annually on more than 1000 SSc patients including income, education level, antibodies, organ involvement, medications and survival. For measuring SES we used education: did not complete high school (<HS) or completed high school (HS). We could not use income for SES as poor outcome would be associated with lower income if it caused work disability. Linear regressions were used to assess the education effect on disease outcome as measured by severity score, global physician scores and survival (time from onset of scleroderma till death). Logistic regressions were done to detect any effect of education on mortality, presence of Class III pulmonary artery hypertension (PAH), interstitial lung disease (ILD) [total lung capacity (TLC) less or more than 70%], renal failure (serum creatinine level less or more than 150 umol/L). Data were subdivided into limited and diffuse cutaneous SSc and by disease duration.

Results: The study included 1145 patients. Eighty six percent of the patients were females (986 females) and 14 % were males (159 males). Their mean age was 55.4 years. About 27.6% of them did not complete high school while 72.4% completed high school. In table (1), linear regressions did not show any statistically significant association between education level and severity score, global physician severity score, global physician activity score, global physician damage score and survival (p = 0.94, 0.63, 0.89, 0.78, and 0.60 respectively). Moreover in table (2), logistic regressions did not show any statistically significant association between education level and ILD, PAH, renal failure and mortality. The odds ratio and its confidence interval were 0.87 (0.45, 1.72), 1.09 (0.72, 1.66), 0.66 (0.32, 1.36) and 0.61 (0.37, 1.02) respectively. Education was not predictive of worse outcomes of scleroderma containing usual risk factors (Gender, age, ESR, Hb, ANA and SCL70).

Conclusions: Unlike SLE which has younger onset, in SSc education is not associated with worse outcomes when adjusting for usual risk factors.

Open Label Trial of Oral Treprostinil in Patients with Systemic Sclerosis and History of Digital Ulcers: Multiple Dose Pharmacokinetics and Tolerability. Elena Schiopu[6], Laura K. Hummers[2], Ami A. Shah[2], Susan Walker[4], Kristine Phillips[6], James R. Seibold[5], Fredrick M. Wigley[1] and Kristan Rollins[3]. [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]United Therapeutics, RTP, NC, [4]United Therapeutics, [5]University of Conneticut, Farmington, CT, [6]University of Michigan, Ann Arbor, MI

Purpose: Fibrotic vasculopathy leading to endothelial dysfunction is the hallmark of scleroderma (SSc) and is the underlying cause of clinical complications including Raynaud's phenomenon, digital ulcers, pulmonary hypertension and renal crisis. Treprostinil diethanolamine (TDE) is an innovative salt form of the prostacyclin analog treprostinil for oral delivery as a sustained-release (SR) osmotic tablet for twice-daily dosing. Prior studies have demonstrated a therapeutic effect of IV prostacyclin analogs for ischemic DU, but oral prostacyclin analogs have had limited success. The lack of sustained plasma concentrations, particularly with immediate release oral prostacyclin analogs, may have limited the ability of prostanoids to produce sustained benefits in earlier studies. The objective of this study was to evaluate the disposition of TDE SR in patients with systemic sclerosis with peripheral vascular complications.

Methods: Patients with SSc and evidence of peripheral vaso-occlusive disease (defined as presence or history of an active digital ulcer within the past 6 months) participated in this study. Subjects with PAH were excluded. All subjects received oral treprostinil and the dose was titrated, based on tolerability, up to a target dose of 4 mg BID (or maximum dose tolerated by patients), in 0.25 mg increments approximately every 48 hours over eight weeks. Pharmacokinetic assessments were performed when subjects achieved a 2 mg and 4 mg BID (or maximally tolerated at end of study) dose. Eight blood samples were obtained over 12 hrs following dose administration and plasma concentrations of treprostinil quantified by liquid chromatography/mass spectrometry. Pharmacokinetic (PK) parameters were calculated using non-compartmental analysis.

Results: Twenty subjects (17 F/3 M), mean age of 47.9 yrs (SD 9.7) and mean scleroderma disease duration of 11.5 yrs were enrolled. Fifty-five percent of subjects had limited cutaneous scleroderma. Seventeen subjects reached a dose of 2 mg BID and twelve subjects completed the study at the target dose of 4 mg BID. Headache, gastrointestinal complaints (nausea, diarrhea, vomiting), body aches, and flushing were the most commonly reported adverse events. Manipulation of the study drug titration was a successful strategy for managing adverse events. Summary of pharmacokinetic parameters are shown as mean (CV%).

Parameter	2 mg (N=17)	4 mg (N=12)
AUC_{0-12hr} (hr*pg/mL)	7038 (45%)	12668 (43%)
Cmax (pg/mL)	1176 (44%)	2107 (46%)
Tmax (hr); median	4	4
$T_{1/2}$ (hr)	3.6	3.7

Conclusions: TDE SR is absorbed and provided sustained concentrations over the 12 hr dosing interval. Total plasma exposure and peak concentration appeared roughly proportional to dose at these two doses. There were no unexpected adverse effects following escalation up to a dose of 4 mg in SSc patients with occlusive vasculopathy. Selection of individual tolerable dosing regimens may be required in SSc patients, a finding also reported in previous clinical trials of prostacyclins in patients with PAH or Raynaud's phenomenon.

1223

Outcomes in a Newly Diagnosed Population of Connective Tissue Disease-Associated Pulmonary Arterial Hypertension Patients from the REVEAL Registry. Lorinda Chung[4], Lori Parsons[1], Paul M. Hassoun[2], Michael McGoon[3], David Badesch[6], Dave P. Miller[1], Mark R. Nicolls[5] and Roham T. Zamanian[5]. [1]ICON Clinical Research, [2]Johns Hopkins University, [3]Mayo Clinic, [4]Stanford Univ Medical Center, Palo Alto, CA, [5]Stanford University, [6]University of Colorado

Purpose: We previously examined a large cohort of prevalent and newly diagnosed cases of connective tissue disease-associated pulmonary arterial hypertension (CTD-APAH) patients from the REVEAL Registry. We found that patients with systemic sclerosis (SSc)- and mixed connective tissue disease (MCTD)-APAH had similar 1-year mortality rates, which were significantly higher than in patients with systemic lupus erythematosus (SLE)- and rheumatoid arthritis (RA)-APAH. The objective of this study was to examine outcomes in a newly diagnosed population of CTD-APAH patients followed for 3 years.

Methods: The Registry to Evaluate Early and Long Term PAH Management (REVEAL) is a prospective registry of >3,500 patients with WHO Group I pulmonary hypertension from 55 US centers. For this analysis, we included patients with CTD-APAH diagnosed by right heart catheterization (mean pulmonary artery pressure > 25mmHg and pulmonary capillary wedge pressure (PCWP) ≤ 15mmHg) within 90 days of enrollment into the registry. Patients with significant interstitial lung disease (chest imaging with severe fibrosis OR moderate fibrosis AND total lung capacity < 60% predicted) were excluded. SSc-APAH was used as the reference group. Comparisons of baseline characteristics were evaluated with Student's t-test and chi-square analyses. Kaplan-Meier curves were estimated for survival and freedom from hospitalization from the time of enrollment. Differences in outcomes between the groups were assessed by the log-rank test.

Results: Patients with SSc (N=166, 30 diffuse, 88 limited, 48 unclassified) were older than patients with MCTD (N=22) and SLE (N=30), with a mean age of 61±11 vs. 50±18 and 47±17 years (p<.001), but similar in age to patients with RA (N=17, age 59±18). The majority of patients were female and Caucasian in all groups, except there was a higher proportion of non-Caucasians in the SLE group. The SSc group did not differ from the other CTD groups with regards to functional class, hemodynamics, pulmonary function tests, echocardiographic findings, or brain natriuretic peptide (BNP) levels, except that SLE patients had a lower PCWP (8.4±3.4 vs. 9.1±3.5 mmHg, p=.04), higher FEV-1 (79±25 vs. 68±19 %predicted, p=.04), and lower BNP (255±369 vs. 676±999 pg/mL, p=.03) than patients with SSc. 6 minute walk distance was lowest in the SSc group (298±114 vs. 364±138 in MCTD (p<.001), 372±106 in SLE (p<.001), and 336±129 m in RA (p=.07)). PAH-specific therapies did not differ between the groups. Survival was poorest in the SSc and RA groups, with 1- and 3-year survival estimates of 78% and 54% in the SSc group, and 88% and 61% in the RA group (p=.4 vs. SSc), compared with 84% and 84% in the MCTD group (p=.1 vs. SSc), and 92% and 87% in the SLE group (p=.01 vs. SSc). Similarly, the SSc and

RA patients were less likely to remain free from hospitalization at 3-years (39% in SSc; 35% in RA (p=.98); 60% in MCTD (p=.38); 66% in SLE (p=.03)).

Conclusions: The poorer outcome of patients with SSc reinforces the need for compliance with recommendations for routine screening for PAH in these patients in order to permit early detection and treatment. Patients with RA also have poor outcomes after the initial diagnosis of PAH.

1224

Patients with Systemic Sclerosis and Anti-Centromere Antibodies Are Affected with Accelerated Atherosclerosis. Annica Nordin[2], Lena Björnådal[3], Kerstin Jensen-Urstad[1] and Elisabet Svenungsson[4]. [1]Dept. of Clinical Physiology, Södersjukhuset, Karolinska Institutet, Sweden, [2]Dept. of Medicine, Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [3]Dept. of Medicine, Rheumatology Unit, Karolinska Institutet, Sweden, Sweden, [4]Dept. of Medicine, Rheumatology Unit, Karolinska Institutet, Sweden

Purpose: If patients with Systemic Sclerosis (SSc) are affected with accelerated atherosclerosis is an unresolved question as previous studies report divergent results. We know that patients with Anti-centromere antibodies often have a limited disease and have a higher risk for vasculopathy such as pulmonary arterial hypertension (PAH), but we dont know if this subgroup of patients also have more atherosclerosis. We investigated surrogate measures of atherosclerosis in a cohort of well-characterized SSc patients and in populationbased matched controls.

Methods: 110 consecutive patients who fulfilled the American College of Rheumatology criteria for SSc and 105 controls matched for age, gender and region of living participated. All underwent a thorough medical examination. Traditional risk factors for cardiovascular disease (CVD), biomarkers of systemic inflammation and autoantibody patterns were investigated. As surrogate measures of atherosclerosis ankle-brachial index (ABI) and carotid ultrasound was performed.

Results: Mean age was 61.8 ± 12.4 years versus 61.4 ± 12.3 years among patients and controls respectively. There was no difference between patients and controls concerning carotid plaque occurence, intima media thickness (IMT) or ABI on a group level but Sedimentation Rate (p=0,007) and Triglycerides (p=0,03) were higher and BMI (p=0,03) lower in patients than controls. In the patient group, 35 (32%) were Anti-centromere Antibody positive (AcA+) and 75 (68%) were Anti-centromere antibody negative (ACA-). Of the 75 ACA- patients 23 (31%) had antibodies to Scl70, 22 (29%) to SSA and/or SSB, 22 (29%) had antinucleolar antibodies (ANA) of unknown specificities and 8 (11%) were ANA negative. Plaque occurred in 65.7% of the AcA+ patients and in 38.7% of the AcA- patients (p= 0.008). ABI was 1.09 ± 0.15 in the AcA+ patients and 1.13 ± 0.09 in the AcA- patients (p=0.05). IMT did not differ between the patient groups. After adjusting for age, Aca+, blood pressure and ever smoked still remained associated with plaque occurrence and Aca+, ever smoked and waist hip ratio remained associated with a low ABI. Waist hip ratio was lower in AcA + patients 0.80±0.07 vs. 0.85 ± 0.10 (p=0.008). Lipid levels, blood-pressure, blood glucose, ever smoked, Body Mass Index or markers of systemic inflammation did not differ between AcA+ and AcA- patients.

We included the variables, which remained associated after age adjustment in multivariable-adjusted logistic regression models. Independent predictors of plaque were age (p=0.0001),systolic blood pressure(p=0.02), ever smoked(p=0.02) and AcA+ (p=0.02)and for ABI age (p=0.02), ever smoked (p=0.008) and waist-hip ratio (p= 0.01)

Conclusion: Atherosclerosis was more prevalent in SSc patients with Anti-centromere antibodies than in SSc patients without these antibodies. AcA+ patients already has a higher risk for vasculopathy such as PAH and this subgroup of SSc patients also seems to have more atherosclerosis and may thus be at higher risk for CVD.

Physician Opinion of Variables That Differentiate Disease Activity and Damage in Systemic Sclerosis. Geneviève Gyger, Ernest Lo, Marie Hudson. Canadian Scleroderma Research Group and Murray Baron, McGill, Canada

Background: An important barrier to the study of systemic sclerosis (SSc) is difficulty in measuring disease activity and damage. We undertook this study to 1) identify the variables that physicians think indicate activity and damage, and 2) identify the variables that, according to physicians, best differentiate activity from damage in SSc.

Methods: We surveyed 18 rheumatologists with a specific interest in SSc. The participants were given a list of 148 variables that represent the spectrum of SSc manifestations. The participants rated the importance of each variable separately for activity and for damage, using a scale of 0 (not relevant) to 20 (absolutely important). The scores of each participant were used to rank the variables from 1 (highest importance) to 148 and the median rank for each variable across all raters was determined. We then compared the median damage rank versus median activity rank for each variable using a Mann-Whitney U test. We considered variables that **differentiated** between activity and damage to be those with the largest statistically significant difference between median ranks (P-values <0.05, after adjustment for multiple testing) AND were in the top 15% of the ranks for either activity or damage but not both.

Results: The variables with the highest median **ranks** for disease activity were: recent renal crisis, digital necrosis/gangrene, extent of change in DLCO in past year, presence of active myositis, and substantial increase in pulmonary systolic pressure in last year. The variables with the highest median **ranks** for damage were: uses home oxygen, needs total parenteral nutrition, worse New York Heart Association class, pulmonary arterial hypertension (PAH), and digital necrosis/gangrene. After excluding the variables that did not differentiate between activity and damage, the most important variables indicative of disease activity included extent decline in DLCO in the last year, active myositis, recent microangiopathy, active volar digital ulcers, and higher swollen joint count and the variables indicative of disease damage included uses home O_2, needs TPN, has PAH, pulmonary fibrosis on Xray or CT scan, and pacemaker (see Table).

Table. Variables that differentiate between activity and damage according to physician opinion with $p < 0.05$, are in top 15% of ranks AND are not in top 15% for both activity and damage

	Symptom	Median Damage Rank	Median Activity Rank	p-value: Damage vs. Activity Ranks
Variables more important for activity than damage	extent of change in past year of DLCO % predicted	52	21	0.03
	presence of active myositis	116.5	21.25	<0.001
	recent microangiopathy by your own assessment	85.5	24.75	0.02
	active volar digital ulcers	65	27.25	0.02
	higher joint count swollen joints	109	28.25	<0.001
	friction rubs anywhere	95.25	29	0.003
	CRP	115	31	<0.001
	pleurisy	90.5	32.75	0.02
	change in skin thickening last month	108.5	34.5	<0.001
	ESR	116.75	35.75	<0.001
Variables more important for damage than activity	uses home O2	16.25	76.25	<0.001
	needs TPN	17.5	64.5	<0.001
	has pulmonary arterial hypertension (PAH)	19.75	69.5	0.04
	degree of fibrosis on x-ray or CT scan	24	99.75	<0.001
	pacemaker	25.75	100.25	0.007
	malabsorption	30.5	67.5	0.003
	recently needed esophageal dilatation	32	54.75	0.02
	ECG conduction abnormalities or arthymias	32	94.5	0.02
	decreased LVEF	34.5	90.75	0.03

Conclusion: While experts felt that many variables were highly relevant to both disease activity and damage in SSc, a subset of variables that differentiates between the two states was identified. The results of this study will help to inform ongoing efforts aimed at developing measures of disease activity and damage in SSc.

Plasma Endogenous Met- and Leu-Enkephalin Levels Are Decreased and Associated with Clinical and Laboratory Parameters in Early Systemic Sclerosis. Terry A. McNearney[4], Kathleen A. Sluka[2], Chul W. Ahn[5], John D. Reveille[6], Michael Fischbach[1] and Maureen D. Mayes[3]. [1]Univ Texas Hlth Sci Ctr at San Antonio, San Antonio, TX, [2]University of Iowa Medical Center, Iowa City, IA, [3]University of Texas -Houston Health Sciences Center, Houston, TX, [4]University of Texas Medical Branch, Galveston, TX, [5]University of Texas Southwestern Medical Center, Dallas, TX, [6]University of Texas-Houston Health Sciences Center, Houston, TX

Objective: Met-and leu-enkephalins are endogenous opioid neuropeptides with potent analgesic, vasoactive, immunomodulatory and anti-apoptotic properties. Endogenous enkephalin levels demonstrate modest effects on vascular patency under normal physiologic conditions in the brain, but have appreciable influence under periods of traumatic or anoxic stress. We hypothesized that clinical or immunological variables of early systemic sclerosis (SSc) might be correlated to plasma enkephalin levels.

Methods: Plasma samples were collected at study entry of the Genetics versus Environment in Scleroderma Outcomes Study (GENISOS) cohort (early SSc, N=136). Plasma met-enkephalin and leu-enkephalin levels (ug/ml) were measured by high performance liquid chromatography (HPLC) and correlated to clinical and laboratory parameters in the GENISOS database. Statistical analyses were performed by nonparametric Wilcoxon rank sum tests and Pearson correlation coefficients.

Results: 1. SSc patient vs matched normal controls study: SSc patients had significantly lower plasma met-enkephalin levels (0.16±0.10 vs 0.28±0.14 mg/ml, p=0.05) and lower plasma leu-enkephalin levels (1.04±0.90 vs 2.45±0.10 mg/ml, respectively, p<0.03); 2. Significantly lower plasma met-enkephalin levels were associated with anti-topoisomerase-I seropositivity (6±8.3 vs 14.9±22.8 ug/ml, p=0.02). 3. Plasma leu-enkephalin levels were significantly higher in SSc patients with digital pulp loss (95.6±130 vs 64.9±101 ug/ml, p=0.03). Lower mean plasma met-enkephalin levels and inversely higher leu-enkephalin levels were noted in SSc patients with Raynaud's phenomena (p=NS). Plasma endogenous enkephalin levels were independent of seasonal temperatures, when analyzed by month or season (p=NS).

Conclusion: Lower plasma levels of endogenous enkephalins in small SSc vs matched control groups may reflect depressed synthesis or increased degradation related to ongoing neurogenic, vasogenic or fibrogenic processes. The associations of plasma enkephalin levels to immunologic or clinical pathologies in early SSc may underscore their vasogenic or fibrogenic significance and potential as therapeutic targets.

Predictors of Interstitial Lung Disease in Early Systemic Sclerosis: A Prospective Longitudinal Study. Shervin Assassi[2], Roozbeh Sharif[2], Robert E. Lasky[3], Terry A. McNearney[1], Rosa Estrada Y Martin[3], Hilda T. Draeger[4], Deepthi K. Nair[3], Marvin J. Fritzler[6], John D. Reveille[5], Frank C. Arnett[8] and Maureen D. Mayes[7]. [1]Eli Lilly and Co, Indianapolis, IN, [2]Univ of Texas Health Science Houston, TX, [3]Univ of Texas Health Science Houston, [4]Univ of Texas Health Science San Antonio, TX, [5]Univ Texas Health Sci Ctr, Houston, TX, [6]University of Calgary, AB, Canada, [7]University of Texas-Houston, TX, [8]UT Medical School, Houston, TX

Background: Pulmonary involvement is the primary systemic sclerosis (SSc) - related cause of death. Forced vital capacity (FVC, expressed as a percentage of predicted value) has been validated as an outcome measure of interstitial lung disease (ILD) in SSc. Large prospective observational studies examining progression of ILD and the predictive significance of clinical and demographic variables have not been reported. The purpose of this study was to examine the association of baseline demographic and clinical characteristics with sequentially obtained measurements of FVC and to identify predictors of decline rate in FVC over time.

Methods: At the time of analysis, 266 patients were enrolled in Genetics versus Environment in Scleroderma Outcome Study (GENISOS), a prospective, observational cohort of patients with early SSc. In addition to pulmonary function tests (PFT), clinical and laboratory data were obtained from each patient. PFTs were performed at the baseline visit and annually thereafter. The predicted PFT values were calculated according to consistent reference values. The association of baseline parameters with sequentially obtained FVC was investigated in a generalized linear mixed model. Using a similar model, the predictors of decline rate in FVC were examined by the interaction term between the baseline variable and follow up time.

Results: The cohort consisted of 125 white, 54 African American, and 77 Hispanic patients with average disease duration of 2.5 years at enrollment. The mean follow up time was 3.8 years, ranging up to 11.4 years; 59% of patients had diffuse cutaneous involvement. Only 22 patients (8.3%) had received cyclophosphamide before enrollment or during the follow up period. Upon review by a pulmonologist, 926 FVC measurements belonging to 244 patients fulfilled the American Thoracic Society criteria and were included in the analysis.

A number of baseline variables including African American ethnicity (p=0.002), diffuse disease type (p=0.012), baseline PFT values (p<0.001), modified Rodnan Skin Score (p=0.001), fibrosis on chest radiograph (p<0.001), subjective dyspnea (p<0.001), anti-topoisomerase antibodies (p<0.001), lung and skin subscores of Severity Index (p<0.001 and p=0.037, respectively) were associated with sequentially obtained FVC levels. Similar results were seen after adjustment for smoking status.

As expected, the follow up time in the study was associated with a decline in FVC (p<0.001). However, none of the baseline variables predicted the rate of decline in FVC over time. Specifically, ethnicity, disease type, baseline PFT values, Skin Score, chest radiographs, subjective dyspnea, autoantibody status, Medsger Severity Index subscores and smoking status did not predict the rate of decline in FVC. Moreover, an accelerated rate of decline in FVC was associated with poor survival (p=0.001).

Conclusion: Baseline clinical variables, associated with differential FVC levels did not predict the rate of decline in FVC. The association of faster decline in FVC with poor survival emphasizes the need for identification of predictive biomarkers by collection of genetic information and serial blood samples in cohort studies.

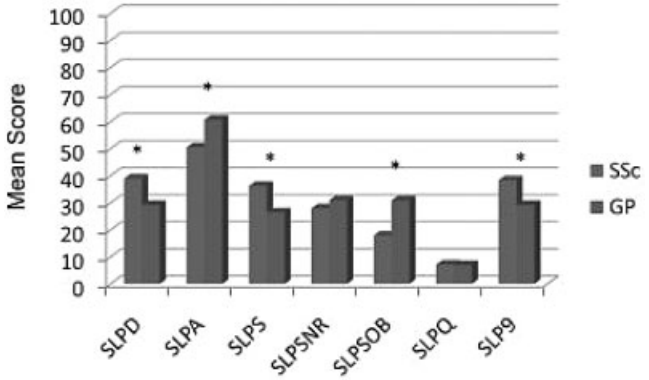
Prevalence and Correlates of Sleep Disturbance in Systemic Sclerosis — Results from the UCLA Scleroderma Quality of Life Study. Tracy M. Frech[1], Ron D. Hays[2], Paul Maranian[3], Philip J. Clements[6], Daniel E. Furst[5] and Dinesh Khanna[4]. [1]Department of Internal Medicine, University of Utah, Salt Lake City, UT, [2]Division of General Internal Medicine, David Geffen School of Medicine, Los Angeles, CA, [3]Division of Rheumatology, David Geffen School of Medicine, Los Angeles, CA, [4]University of California Los Angeles, Los Angeles, CA, [5]University of California Los Angeles Medical School, Los Angeles, CA, [6]University of California Los Angeles School of Medicine, Los Angeles, CA

Objective: Chronic arthritides are associated with sleep disturbances. This study examines the prevalence of sleep disorder and explores its correlates in patients with systemic sclerosis (SSc).

Methods: Participants are 180 SSc patients in the UCLA Scleroderma Quality of Life Study. At baseline, patients completed the Medical Outcomes Study Sleep measure (MOS-sleep scale). In addition, patients completed other patient-reported outcome (PRO) measures (SF-36, HAQ-DI, Functional assessment of Chronic Illness therapy-Fatigue (FACIT-Fatigue), Center for Epidemiologic Studies Depression scale (CESD), and University of California Los Angeles Scleroderma Clinical Trials Consortium Systemic Sclerosis Gastrointestinal Questionnaire (UCLA SCTC GIT 2.0). Descriptive statistics were assessed for 6 scales of MOS-Sleep and sleep problem index (SLP-9). We computed Spearman rank-order correlations between the MOS-sleep scale domains and the HAQ-DI, FACIT-Fatigue, CESD, SSc-GIT 2.0, and SF-36 scales. In addition, we regressed SLP-9 scores on sociodemographic variables, disease severity, and PRO measures outlined above.

Results: Patients SSc patients reported a mean (SD) of 7.1 (1.73) hours slept a night (range 0–11 hours). Patients reported worse scores on 4 of 6 scales (except for snoring and sleep quantity) compared to US General population. SLP9 had "moderate" correlations with the CESD and FACIT-Fatigue (rho's of 0.56 and 0.50) and "low" correlations with the HAQ-DI and UCLA SCTC 2.0 total score (rho's of 0.32 for both). In the multivariate regression model with sociodemographic variables, duration of SSc, patient assessment of disease severity, skin score, and PROs (HAQ-DI, FACIT-Fatigue, UCLA SCTC GIT 2.0 total score, and CESD), the CESD and GIT total scores had significant association with SLP9 index.



Legend: sleep disturbance (SLPD), sleep adequacy (SLPA), daytime somnolence (SLPS), snoring (SLPSNR), awakening short of breath or with headache (SLPSOB), quantity of sleep (SLPQ), sleep problems index (SLP9), scleroderma cohort (SSc), general population (GP), $p<0.05$ (*).

Conclusion: This the first study to evaluate sleep disturbances in SSc. Future studies should assess if successful interventions for GI involvement and depression may have a beneficial impact on sleep quality.

1229

Prevalence of Associated Autoimmune Diseases in a Spanish Population with Systemic Sclerosis. Esther Francisca Vicente[2], María Jesús García-Arias[2], Rosario García-Vicuña[2], Alicia Humbría[2], Juan Pedro López-Bote[2] and Santos Castañeda[1]. [1]Rheumatology Department, Hospital Universitario de La Princesa, IIS Princesa, Madrid, Spain, [2]Rheumatology Department, Hospital Universitario de La Princesa, IIS Princesa

Background: Systemic sclerosis (SSc) is a connective tissue disease that can occur in isolation or associated with other inflammatory diseases of autoimmune aetiology, modifying their phenotypic expression and/or prognosis. It has been suggested that subtypes of SSc may have an uneven trend towards those associations.

Aims: 1. To determine the prevalence of associated systemic autoimmune diseases in a Spanish population with SSc treated at our centre. 2. To evaluate the existence of differential patterns of association according to the subtype of SSc.

Methods: We performed a cross-sectional study that included a hospital in-patient and out-patient sample of all SSc patients who were assessed at our centre during 2009. Demographic, clinical and laboratory (antinuclear [ANA], anticentromere [ACA] and antitopoisomerase1 [Scl-70] antibodies) variables were collected. The definition of the associated autoimmune diseases (AAID) followed the international classification criteria. Statistical analysis: continuous variables are expressed as mean±SD and categorical variables as number of cases (%). The association between the presence of AAID and the manifestations and subtypes of SSc was analysed with the Student's t test for the continuous variables and the χ^2 test for the categorical ones. Statistical significance was set at $p<0.05$ (Stata v.10).

Results: Sixty one SSc patients were included (93.4% female), 45 (73.8%) with limited cutaneous subset (lcSSc) and 16 (26.2%) with diffuse cutaneous subtype (dcSSc). Mean age was 59.9±18.4 yrs and duration of disease was 9.7±9.5 yrs. The distribution of auto-antibodies was as follows: 91.5% were ANA positive (90.9% of lcSSc and 93.3% of dcSSc), 63.8% had ACA (only lcSSc) and 29.5% had Scl-70 (6.9% of lcSSc and 73.3% of dcSSc). At least one AAID was present in 29 (47.5%) patients: Sjögren's syndrome [SS] (36.1%), primary biliary cirrhosis [PBC] (9.8%), systemic lupus erythematosus [SLE] (3.3%), autoimmune hepatitis [AH] (3.3%), thyroiditis [AT] (3.3%), rheumatoid arthritis [RA] (1.6%) and polimyositis (1.6%). Seven (11.5%) patients combined 2 AAID, being SS and PBC the most frequent association (6.5%). Other combinations were SS and RA (1.6%), SS and SLE (1.6%) and AH and AT (1.6%). The prevalence of SS and AT was similar in both SSc subtypes: 37.8% and 2.2% for lcSSc and 31.2% and 6.2% for dcSSc, respectively. However, the rest of AAID were found only in lcSSc patients, although differences did not reach statistical significance, probably due to the small population size. Neither clinical nor laboratory manifestations of the disease showed significant association with the existence of AAID.

Conclusions: Nearly half of our SSc patients had AAID, being Sjögren's syndrome and primary biliary cirrhosis the most frequent associations. The prevalence of Sjögren's syndrome and autoimmune thyroiditis was similar in both subtypes of SSc. However, our results suggest that lcSSc could exhibit a higher tendency to be associated with other autoimmune diseases.

Serum Chemokine and Cytokine Levels as Indicators of Disease Activity in Patients with Systemic Sclerosis. Minoru Hasegawa, Manabu Fujimoto, Kazuhiko Takehara and Shinichi Sato, Kanazawa University

Background: There are no definitive serum markers to estimate the disease activity in the skin or the internal organs in systemic sclerosis (SSc). In most patients, severe organ involvement occurs within the first 3 years of disease onset and skin sclerosis seldom progresses after 5 or 6 years. Therefore, clarifying the disease activity is particularly important for SSc patients with a short disease duration.

Objective: In the present study, we sought to determine if serum chemokines and cytokines were associated with disease activity in SSc patients with a short disease duration.

Methods: Concentrations of 4 chemokines (interferon γ-inducible protein-10 (IP-10, CXCL10), monokine induced by interferon γ (MIG/CXCL9), monocyte chemoattractant protein-1 (MCP-1/CCL2), interelukin 8 (IL-8/CXCL8)) and 6 cytokines (IL-2, IL-4, IL-6, IL-10, tumor necrosis factor (TNF) −α, interferon (IFN) −γ) were measured using cytometric beads array kits in serum samples from 31 patients with active SSc and 20 normal controls. Clinical and laboratory data and serum chemokine and cytokine levels were assessed for each patient at their first visit and each subsequent year for 3 years.

Results: At their first visit, serum levels of IP-10, MIG and MCP-1 were significantly elevated in SSc patients compared with normal controls. In SSc patients, these levels declined, especially during the first year, probably due to the initiation of immunosuppressive treatment. Serum MCP-1 levels at the third year showed significant associations with variations of skin thickness scores during the 3 years. That is, patients with consistently high levels of MCP-1 tended to show intractable skin sclerosis. Unfortunately, serum makers that could estimate variations of skin sclerosis during the 3 years were not found at an earlier point in time (~2 years). When interstitial pneumonia progression was evaluated by variations of %VC, the variations of %VC during the 3 years were inversely associated with serum levels of IP-10 at the second and third years and MIG at the first to third years. That is, patients with increasing IP-10 or MIG levels showed a tendency for subsequent exacerbations of interstitial pneumonia.

Conclusions: These results suggest that MCP-1 is a serological indicator of the activity of skin sclerosis. Serum levels of type 1 helper T chemoattractants such as IP-10 and MIG may reflect interstitial pneumonia disease activity in SSc patients. However, a longer-term prospective study in a larger population will be needed to confirm their clinical utility as predictors of outcomes.

Severe Pulmonary Fibrosis Is Uncommon in Scleroderma Patients with RNA Polymerase 3 Antibody. Virginia D. Steen[1], Robyn T. Domsic[2] and Thomas Medsger[2]. [1]Georgetown University, Washington, DC, [2]University of Pittsburgh

Introduction: Patients with systemic sclerosis with diffuse scleroderma commonly have severe pulmonary interstitial fibrosis. However, although patients with RNA polymerase III (POL 3) have very severe diffuse cutaneous skin disease and a high frequency of renal crisis they seem to have less severe lung fibrosis. This study looks at the natural history of lung disease in patients with SSc and a positive POL 3.

Methods: We identified all patients with scleroderma and a positive POL 3 who had pulmonary function tests (PFTs) and compared the demographics, lung function and outcomes to SSc patients with diffuse cutaneous scleroderma without Pol 3 (DNoPol3) We compared the first and last PFTs in those with more than one set of PFTs. Survival and causes of death were determined.

Results: There were 372 patients with a POL 3 and 657 DNoPol3 pts who had PFTs. POL 3 patients were older at onset of disease and had a higher skin score, although they had a lower sedimentation rate and a lower symptom score for lung. Twenty-five percent had an episode of renal crisis (compared to 15% in the DNoPol3 pts, $p<0.001$). The disease duration at last follow up for both groups was more than 12 years. The first recorded forced vital capacity (FVC) in the POL 3 and DNoPol3 was 82% and 69% ($p<0.001$) and the smallest recorded values were 78% and 65% respectively ($p<0.001$). Only 11.3% of the POL 3 patients ever developed a FVC less than 60% predicted, a measure of severe fibrosis, compared to 24.8% in DNoPol3 pts ($p<0.001$). There were 102 POL 3 and 191 DNoPol3 pts who had more than onset of PFTs recorded. Table 1 shows the baseline and last FVC and diffusing capacity (DLCO) for these patients. Comparisons between 1st and last studies and between groups were all highly significant ($p<0.0001$). Only 29% of the POL 3 pts ever had some fibrosis on radiographic imaging compared to 51% in the DNoPol3 ($p<0.0001$). Only 6% of POL 3 pts were ever treated with cyclophosphamide for their lung disease compared to 18% of the DNoPol3 ($p<0.001$)

The 5 and 10 year survivals were 86% and 76% for the POL 3 and 83% and 69% for the DNoPol3 pts, ($p<0.0001$). Only 2% of the POL3 pts have died from pulmonary fibrosis compared to 13% of the DNoPol3 pts, ($p<0.001$). Fewer POL 3 pts died from scleroderma related causes (43% compared to 56% ($p<0.001$) and pulmonary fibrosis was the scleroderma related death in 15% of these patients compared to 25% ($p<0.05$) in the DNoPol3.

Conclusions: POL 3 antibodies are available commercially and are helpful progrostically. While POL 3 patients have severe cutaneous disease and a high frequency of renal crisis, they infrequently get severe lung disease. Premature treatment for pulmonary fibrosis in these patients who rarely get severe fibrosis should be used cautiously.

Antibody	1st FVC	Last FVC	Delta Time	1st DLCO	Last DLCO
POL 3	87%	83%	3.3	76%	79%
TOPO	73%	70%	3.5	61%	58%

Survival in Pulmonary Hypertension Associated with Scleroderma-Spectrum Disease: A Single Center Experience. Dinesh Khanna, Rajeev Saggar, Daniel Furst, Paul Maranian, Philip Clements and Rajan Saggar. UCLA

Introduction: SSc-PAH is leading case of mortality in SSc. The impact of SSc-ILD associated PH is not well characterized, however, portends a very poor prognosis. The objective of this study is to investigate the survival and characteristics among SSc-spectrum associated PH.

Methods: SSc patients with PH (defined as mPAP> 25 mmHg and FVC≥ 60%) or ILD associated PH (defined as mPAP> 25 mmHg and FVC< 60%) confirmed by right heart catheterization (performed at a tertiary center) were included in the study. Kaplan-Meier and Cox proportional hazard models were used to compare the survival between SSc-PAH and SSc-ILD associated PH and to identify predictors of survival.

Results: Ninety-three SSc patients (48 with isolated PH and 45 with ILD-PH) were identified. 1-, 2- and 3-year survival for the entire cohort was 80%, 76%, and 73%. Survival was similar for those with isolated SSc-PH and those with ILD associated SSc-PH (1-, 2-, 3-year survival rates 86%, 83%, 82% versus 71%, 65%, 59%), $p>0.05$.

In univariate analysis, gender, FVC%, DLco%, resting oxygen, cardiac output (CO) and pulmonary vascular resistance (PVR) were associated with increase mortality. Using multivariate cox-proportional hazard model, only PVR (HR 1.11) and CO (HR 0.39) were independent predictors of mortality in the overall cohort. Also, younger age had a greater risk of death (HR 0.95) in the CO model.

Baseline lung function and type of therapy did not predict mortality in our model.

Conclusions: Survival in SSc-spectrum associated PH remains poor, however, improved compared to historical cohorts. The prognosis of patients with SSc-ILD associated PH is similar compared to isolated SSc-PAH. This suggests PAH therapies, including parenteral prostanoids, are safe and efficacious in those individuals with significant ILD. Earlier diagnosis and potentially aggressive treatment may improve outcome as worse hemodynamic parameters (PVR) predict increased mortality.

Systemic Sclerosis Is an Independent Predictive Factor to Coronary Atherosclerosis. Mo Yin Mok, Chak Sing Lau, Sonny Chiu, Annette Tso, Ka Fung Mak, Woon Sing Wong, Pek Lan Khong and Karen S. L. Lam. The University of Hong Kong, Queen Mary Hospital, Hong Kong

Background: Endothelial dysfunction and inflammation are pathogenetic mechanisms shared by scleroderma (SSc) and atherosclerosis.

Objective: To examine coronary atherosclerosis by coronary calcium score and its relation to conventional cardiovascular and disease specific risk factors in SSc patients.

Methodology: Coronary calcium was measured by computed tomography and cardiovascular risk factors were examined in SSc patients compared with age-, sex- and glycaemic status- matched controls. Activity score, antiphospholipid antibodies, high-sensitivity C-reactive protein (hsCRP) and ESR were measured in SSc patients.

Results: 53 SSc (50 female and 3 male) patients and 106 controls were recruited. These patients were 53.1±12.8 years in age with median disease duration of 9 years. SSc patients were found to have significantly lower mean arterial pressure ($p<0.001$), cholesterol ($p=0.001$), LDL ($p=0.001$), HDL ($p=0.01$) levels, waist circumference and body mass index ($p<0.001$) and were more likely receiving vasodilators ($p<0.001$). There were more SSc patients who had absent, minimal to mild, moderate and severe coronary calcification compared to controls ($p=0.01$ linear by linear association). Multiple logistic regression analysis revealed 5.1-fold increased risk of coronary calcification in SSc [95% confidence interval (CI) 1.7–15.3] ($p=0.004$) and 31-fold for coronary calcium score >100 [95%CI 4.2–229.5,

p=0.001] after correction to conventional cardiovascular risk factors. SSc patients who had coronary calcification were older (<0.001), had higher mean arterial pressure (p<0.001), longer disease duration (p=0.006) compared to those with normal coronary arteries. Only age and disease duration were identified by logistic regression analysis as predictive factors for coronary calcification in SSc patients.

Conclusion: SSc was an independent predictive factor for coronary atherosclerosis.

The Psychological Impact of Systemic Sclerosis-Related Telangiectases. Holly Ennis[3], Helen L. Richards[1], Claire Cassidy[3] and Ariane L. Herrick[2]. [1]Mercy University Hospital, Cork, Co. Cork, Ireland, [2]Rheumatic Diseases Centre, Trust Salford, United Kingdom, [3]University of Manchester, Manchester, United Kingdom

Background: Systemic sclerosis (SSc)-related telangiectases commonly occur on the face and hands and, although often disfiguring, little is known about their psychological impact. Our objectives were to (a) determine the extent of body image dissatisfaction (BID) in patients with SSc-related telangiectases (b) identify disease-related correlates with telangiectases (c) examine the subjective experiences of patients with telangiectases through qualitative analysis.

Methods: 227 patients aged over 18 years with SSc were invited to participate in a questionnaire survey. Clinical and demographic data was obtained for all participants from a clinical database. Each participant completed the Adjusted Satisfaction with Appearance Scale (ASWAP), the Hospital Anxiety and Depression Scale (HADS) and an open-ended telangiectases questionnaire. Thematic analysis was utilised to describe the qualitative data.

Summary of Results: 141 patients (62%) with SSc responded to the survey (83% female, 70% limited cutaneous SSc, median age 62 years). Telangiectases was reported by 113 (80%). All ASWAP scores (Table 1) were higher in those reporting telangiectases, and this was significant for the 'dissatisfaction with appearance' subscore (p=0.02). Anxiety and depression scores were similar in those with and without telangiectases. Those reporting telangiectases were more likely to be anticentromere positive (40% versus 18%, p=0.02) and to have a history of severe digital ischaemia (38% versus 18%, p=0.04) than those not. Qualitative analysis revealed four themes: changes in behaviour as a result of telangiectases (e.g. social avoidance), public and private self-image (e.g. feeling self-conscious), negative emotional impact of telangiectases (e.g. feelings of sadness or anger) and gaining new perspectives on life (e.g. focusing on positives such as the ability to walk).

Conclusions: BID, as measured by the ASWAP, was higher in patients with telangiectases, especially within the 'dissatisfaction with appearance' subscale. Telangiectases were associated with anticentromere positivity and digital ischaemia, lending further support for telangiectases as a potential marker for vascular involvement. Qualitative analysis provided new insights into the thoughts and feelings of patients with telangiectases, highlighting concerns and also methods of coping with telangiectases. Our findings highlight the impact of telangiectases and the need to address and manage related concerns.

	All participants n=141	Telangiectases n=113	No Telangiectases n=28	p value (Mann-Whitney U)
ASWAP Social impact, median (IQR)*	14 (8–22)	14 (8–22)	12 (8–20)	p=0.67
ASWAAP Dissatisfaction with appearance, median (IQR)*	20 (14–26)	21 (15–27)	15 (12–23)	p=0.02
ASWAAP Total score median (IQR)*	30 (25–36)	37 (27–47)	26 (20–41)	p=0.09
HADS Anxiety, median (IQR)**	7 (4–10)	7 (4–10)	8 (5–12)	p=0.46
HADS Depression, median (IQR)**	6 (3–9)	6 (3–9)	6 (3–8)	p=0.52

* 125 subjects.
** 240 subjects.

The Use of Calcium-Channel Blockers May Prevent the Development of Scleroderma Renal Crisis. Gaia Montanelli, Lorenzo Beretta, Alessandro Santaniello and Raffaella Scorza. Referral Center for Systemic Autoimmune Diseases

Background: Scleroderma renal crisis (SRC) is one of the most severe complications of systemic sclerosis (SSc), with high mortality and morbidity rates. Past studies were conducted to determine which factors may precipitate or protect from the development of SRC. The use of corticosteroids, the diffuse cutaneous subset (dcSSc), the presence of friction tendon rubs, the presence of certain autoantibodies and an aggravating skin score were shown to be risk-factors for SRC. Apart from corticosteroids, which were associated with the onset of SRC, the role of other therapies, including vasodilators or Iloprost, in the progression of or in the protection from SRC is not clear.

Methods: A retrospective study was conducted in all the patients referred to our outpatient clinic between 1990 and 2010, with a disease duration < 5 years at referral. The development of SRC, defined as either hypertensive renal crisis or normotensive renal crisis, up to 5 years (20 trimesters) from referral was sought. Medical records were reviewed to determine whether the patients had been treated with calcium-channel blockers (CCB), Iloprost or steroids. The dose of steroids (expressed as the medium dose Prednisione/day/trimester) was also reviewed.

Univariate Cox regression analysis with or without time-dependent covariates was used to assess the individual risk for SRC for baseline demographic and clinical characteristics and for therapies. Meaningful variables were inserted in a multivariate Cox regression model.

Results: Two-hundred-ninety-one patients (females=89.7%; dcSSc=25.8%) with a disease duration of 13 months at referral (interquartile range [IQR]: 4 – 29), were considered. Fifteen SRC (5.2%; 12 hypertensive, 3 normotensive) were observed, the median time-to-onset of SRC was 6 months (IQR: 3 – 12 months). Overall, 165 patients were treated with steroids with a median maximum dose of 25 mg/day/trimester (IQR: 14 – 50 mg); 260 subjects (89.3%) received CCB and 100 (34.4%) Iloprost, prior or concurrently to corticosteroids. On univariate analysis, gender, disease subset and the use of steroids were associated with a positive risk of SRC, whilst FVC, disease duration prior to referral and the use of CCB were negatively associated with SRC. On multivariate analysis the use of CCB was negatively associated with SRC (HR=0.118, CI95=0.038–0.362, p<0.0001), whilst steroids (HR=1.014, CI95=1.002–1.026, p<0.035) and dcSSc (HR=6.75, CI95=1.988–22.195, p<0.003) increased the risk for SRC.

Discussion: SRC is a relatively rare event in Italian patients. We confirmed that the use of steroids increases the risk for SRC, albeit this risk is relatively low (1.4% for every milligram of Prednisone used in the trimester prior to SRC). Conversely, the use of CCB is highly protective against the development of SRC. In our centre, the vast majority of patients is prescribed first-second generation dihydropyridine agents (Nifedipine or Nicardipine), that acting on L-type calcium channels may favour afferent renal arterioles vasodilatation, and counteract angiotensin II vasoconstrictive effects thus increasing or stabilising the glomerular filtration rate and glomerular filtration fraction.

Time of Transition through Different Patterns of Nailfold Microangiopathy in Systemic Sclerosis. Alberto Sulli[1], Carmen Pizzorni[2], Francesca Ravera[2], Elisa Alessandri[2], Giuseppe Zampogna[2], Bruno Seriolo[2] and Maurizio Cutolo[1]. [1]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy, [2]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy

Background: Nailfold microangiopathy is an early aspect of systemic sclerosis (SSc), and its features may be detected by nailfold videocapillaroscopy (NVC). The evolution from "early", to "active", and to "late" patterns of microvascular damage was described by several studies.

Objectives: To investigate the time of transition through the different patterns of microangiopathy, in SSc patients with the "early" NVC pattern at baseline.

Methods: Thirty-eight SSc patients (mean age 48±12sd years; mean disease duration from Raynaud's phenomenon onset 10±10 years, from the onset of the first SSc symptom different from RP 1±1 year) with the "early"

pattern of nailfold microangiopathy at baseline were followed-up by NVC for a mean time of 90±18 months, every nine months by the same operator. The proper pattern of NVC microangiopathy ("early", "active", "late") was recorded at each visit, as previously reported(1,2). "Early" NVC pattern: few (<33%) giant capillaries, few capillary haemorrhages, relatively well-preserved capillary distribution, no evident loss of capillaries; "active" NVC pattern: frequent (>66%) giant capillaries, frequent capillary haemorrhages, moderate (<33%) loss of capillaries, mild (<33%) disorganisation of the capillary architecture, absent or mild ramified capillaries; "late" NVC pattern: irregular enlargement of the capillaries, few or absent giant capillaries and haemorrhages, severe (>66%) loss of capillaries with avascular areas, disorganisation of the normal capillary array, and ramified/bushy capillaries.

Results: At the end of the follow-up, 17 patients (43%) were still showing the "early" scleroderma-pattern, while the NVC pattern of microangiopathy was changed in 57% of the patients. The NVC pattern was found "active" in 14 patients (38%), "late" in 5 patients (14%), and normal in 2 patients (5%). The mean time of progression from the "early" to the "active" pattern was of 28±20 months, and from the "early" to the "late" pattern it was of 36±29 months. Interestingly, in the subgroup of patients whose microangiopathy progressed from the "early" to the "late" NVC pattern through the "active" pattern, the mean time of progression from the "early" to the "active" pattern was only 8±1 months, discovering a subset of SSc patients (14%) with fast progression of SSc microangiopathy.

Conclusions: The results of this longitudinal study confirm the transition of the SSc microvascular damage through different NVC patterns of microangiopathy. Fourteen % of SSc patients progressed quickly to "late" from "early" NVC pattern of microangiopathy. Patients showing a fast progression from the "early" to the "active" NVC pattern of microangiopathy should be strictly monitored as at risk of rapid progression to the "late" NVC pattern of microvascular damage, characterized by capillary desertification and disorganization.

Ultrasonographic Assessment of Hand Joint and Tendon Involvement in 30 Patients with Systemic Sclerosis. Emmanuel Chatelus, Hélène Chifflot, Viriginie Clavert, Christelle Sordet, Jacques-Eric Gottenberg and Jean Sibilia. Hospital of Hautepierre, Strasbourg, France

Objective: To evaluate joint and tendon involvement in the hands of patients with systemic sclerosis (SSc) using ultrasonography (US) and their correlation with clinical and X-ray examinations.

Methods: 30 patients with SSc according to ACR criteria (21 diffuse SSc and 9 limited SSc, median (25^{th}-75^{th}) age 55 (44–63) years, median (25^{th}-75^{th}) disease duration 5 (3–11) years, all negative for anti-CCP), were consecutively included in this study and underwent clinical, X-ray and US examinations. Synovial proliferation, joint effusion, bone erosion, tenosynovitis and the Power Doppler signal were evaluated using a Toshiba EUB-5500 with a 14 MHz linear-array transducer.

Results: US detected synovial proliferation in 11 patients (37%), and joint effusion in 10 (33%). US detected synovitis in 47% of patients, higher than that found by clinical examination (27%; p=0.01), which was not associated with the radiological presence of erosion and joint space narrowing. Synovial proliferation and joint effusion were more frequent in diffuse SSc (43% for both) than in limited SSc (22%, 11%, respectively). Lastly, tenosynovitis (24%), bone erosion and Power Doppler (19%) were observed only in diffuse SSc.

Conclusion: US provides relevant information on the hands of patients with SSc that complements that obtained by clinical and X-ray examination. Also, diffuse SSc is a subgroup at greater risk of tendon and joint involvement. US evaluation may therefore be particularly helpful in detecting synovitis and bone erosion early in patients with diffuse SSc, and designing therapy.

1238

Vaccination Against Influenza in Patients with Scleroderma. Irena Litinsky[3], Alexandra Balbir[2], Devy Zisman[4], Michal Mandelboim[1], Ella Mendelson[1], Marina Anouk[3], Ilana Kaufman[3], Daphna Paran[3] and Ori Elkayam[3]. [1]Central Virology Laboratory, Sheba Medical Center, [2]Department of Rheumatology, Rambam Health Care Campus Background, [3]Department of Rheumatology, Tel Aviv Medical Center, [4]Rheumatology Service, Carmel Medical Center

Purpose: To assess the efficacy and clinical safety of the influenza virus vaccine in patients with systemic sclerosis (SSc) in comparison with healthy controls.

Methods: The study population comprised 2 groups of patients. Group 1 included 26 SSc patients:12 (46.1%) with diffuse type,14 (53.9) with limited scleroderma, 22 (84.6%) women, 4(15.4%) men, mean age 51.7±12.9,disease duration 8.29±6.28 years, median 6.45years). Group 2 comprised 15 healthy controls: 13 women (81%),2 men (19%), mean age 44.5 ± 15.3.In group 1, 7 (26.9%) patients were on immunosuppressive therapy (2 prednisone, 2 cellcept, 2 methotrexate, 1 cuprimine) at the time of vaccination. All the participants were vaccinated with a trivalent influenza subunit vaccine including H1N1 A/Brisbane/59/2007(TGA 2008/81B) (H1N1, H3N2 A/Uruguay/716/2007 (A/Brisbane/10/2007-like, NIBSC 8/124) (H3N2) and B B/Brisbane/60/2008 (TGA 2009/82/B) (B).Disease activity was assessed by Rodnan score, number of ulcers, number of tender and swollen joints, changes of clinical signs (dyspnea, cough, dyspepsia and dysphagia), patient (PDAI) and physician (PHDAI) disease activity evaluation by VAS, ESR and CRP, on day of vaccination and 6 weeks after. The humoral response was tested by Hemagglutination inhibition (HI) antibodies against H1N1 and H3N2 by standard WHO procedure. Response was defined as ≥4-fold rise in antibodies 6 weeks after vaccination, or seroconversion in patients with non-protective baseline level of antibodies (<1/40). Geometric mean titers (GMT) were calculated to assess the immunity of the whole group

Results: At baseline, 62% of patients with scleroderma patients and 40 % of controls had protective levels against H1N1 while 15% of SSc patients versus 46% of controls had protective anti H3N2 antibodies. Six weeks after vaccination, in patients with SSc, the percentage of responders for H1N1 antigen achieved 78%. Surprisingly, the proportion of responders was significantly higher (p=0.0128) in SSc patients than in controls (33%). The proportion of responders against H2N3 was similar in the 2 groups (42% in group 1 vs 33% in group 2).SSc suffering from interstitial lung disease (ILD) demonstrated a significant lower response (p=0.02 for H1N1 AND P=0.03 for H3N1).(Table 1).

Table 1. Proportion of subjects with humoral response to H1N1 and H3N1

	SSc without ILD	SSc with ILD	P
H1N1	88.2	44.4	0.02
H3N1	58.8	11.1	0.03

Parameters of disease activity remained unchanged except for an increase in patient disease activity index (p=0.01)

Conclusions: Influenza virus vaccine generated a satisfactory humoral response in scleroderma patients. The presence of ILD seems to lower the humoral response. Influenza vaccine was found to be safe in this cohort of patients. Yearly, Influenza vaccination is recommended to patients with scleroderma

Wound Fluid of Skin Ulcers in Systemic Sclerosis: Cellular and Cytokines' Profile Helps To Define Healers Versus Non Healers Characteristics. Stefano Alivernini[1], Barbara Tolusso[2], Mariarita Gigante[2], Annunziata Capacci[2], Francesca Faustini[2], Silvia Laura Bosello[2], Maria De Santis[2] and Gianfranco Ferraccioli[1]. [1]Rheumatology Division, Catholic University of the Sacred Heart, Rome, Italy, [2]Rheumatology Division, Catholic University of the Sacred Heart, Rome, Italy

Background: Skin ulcers, being a common vascular complication in Systemic Sclerosis (SSc), have a relevant impact in the patients' daily life, causing pain, infection and loss of function. Studies on chronic diabetic (DM) skin ulcers showed that the wound fluid (WF) analysis could help to understand the nature of the lesions.

Objective: To evaluate cellular and soluble factors' profile of WF of SSc skin ulcers.

Patients and Methods: SSc patients with skin ulcers attending the Wound Care Outpatient Clinic of Rheumatology division of the Catholic University (Rome) were enrolled in the study. MMP-9, VEGF and IL-6 levels were detected through ELISA and MCP-1, IL-1β, IL-8 and TNFα levels through Flow CytoMix™ technology in plasma and WF, whereas the WF percentages of CD16, CD14, CD3 and CD19 were evaluated through Flow-cytometry at baseline. Each patient underwent skin lesion's evaluation, microbiological analysis and treatment with Suprasorb X® ± PHMB® or Suprasorb A® ± Ag® twice a week. WF collection was done through transparent dressing (Opsite, Smith & Nephew, UK).

Results: 11 SSc patients with skin ulcers (18% in fingertips) were enrolled in the study. A higher healing rate after 3 months of follow-up with the standard protocol was found in SSc compared to DM patients with chronic ulcers treated with the same protocol (8 patients (73%) vs 1/5(20%); $p<0.001$). Compared to healthy controls, SSc patients had higher plasma levels of IL-6 (2.4 ± 1.5 pg/ml vs 6.9±1.8 pg/ml, $p=0.01$), VEGF (17.2±15.4 pg/ml vs 43.11±36.03 pg/ml $p=0.01$), MCP-1 (255.5±59.2 pg/ml vs 528.35±270.78 pg/ml $p=0.001$) and IL-8 (1.66±3.62 pg/ml vs 3.55±3.59 pg/ml $p=0.02$). SSc patients with fingertip ulcers had lower levels of VEGF in WF compared to patients with major lesions (5157.3±3767.3 pg/ml/1g albumin vs 216632.0 ± 515864.0 pg/ml/1g albumin; $p=0.05$).

Direct correlations in WF were found between IL6 and MMP-9 ($r=0.64$, $p=0.04$), MMP-9 and IL-8 ($r=0.82$, $p=0.004$) and between percentages of CD3 and CD19 ($r=0.76$, $p=0.03$). Moreover there were direct correlations between the extension and border scores of ulcers and MCP1 ($r=0.62$; $p=0.05$ for extension and $r=0.63$;$p=0.03$ for border score) and TNFα ($r=0.65$;$p=0.03$ for extension and $r=0.65$;$p=0.02$ for border score) in WF of SSc patients.

SSc patients who healed after 3 months of follow-up had lower WF levels of MCP-1 (5012.9 ± 3600.1 pg/ml/1g albumin vs 505173.1± 576739.8 pg/ml/1g albumin, $p=0.03$), TNFα (248.1±372.8 pg/ml/1g albumin vs 36789.1±79499.5 pg/ml/1g albumin, $p=0.02$) and VEGF (2114.0±3825.7 pg/ml/1g albumin vs 111381.1± 212446.0 pg/ml/1g albumin, $p=0.03$) compared to non healers. All the inflammatory soluble factors (IL-6, IL-1β, TNFα and IL-8) were higher in WF compared to plasma in SSc patients ($p<0.05$).

Conclusions: A standard treatment seems to enhance healing rate in SSc skin ulcers. The plasma-WF polarization of factors such as IL-6, IL-1β, TNFα and IL-8 suggests that ulcers in SSc could be considered an acute phenomenon in a chronic inflammatory background. A stronger control of local inflammation should be looked for in the most inflamed lesions.

A Novel Role for the Jak-Stat Pathway in Rheumatoid Arthritis: Inhibition of TNF-Induced T Cell Attracting Chemokine Synthesis in Fibroblast-Like Synoviocytes (FLS) by Tasocitinib. Sanna Rosengren[2], Gary S. Firestein[2] and David L. Boyle[1]. [1]UCSD Schl of Medicine, La Jolla, CA, [2]UCSD School of Medicine, La Jolla, CA

Purpose: The pan-Janus kinase (Jak) inhibitor, tasocitinib (CP690,550) is currently in Phase III clinical trials for rheumatoid arthritis. Whereas the Jak-Stat signaling in lymphoid and myeloid lineage cells is well understood, less is known about its involvement in FLS signaling in the context of synovitis. Therefore, we measured the effect of tasocitinib on expression and secretion of inflammatory mediators by cytokine stimulated FLS.

Methods: Passage 3–8 RA FLS isolated from tissue obtained at the time of arthroplasty were serum-starved 48 h prior to stimulation. mRNA levels were determined by qPCR, and protein levels in supernatants determined by ELISA or multiplex bead assay. Phosphorylation of Stat proteins was determined by Western blot analysis.

Results: Stimulating FLS with IL-6, but not TNF, induced phosphorylation of Stat1 and Stat3, downstream indicators of Jak activation. Stat activation was inhibited by tasocitinib with IC50 values of approximately 21 and 72 nM, respectively. IL-6 also induced expression of MCP1 mRNA and protein secretion but not other markers of FLS activation such as MMP3. MCP-1 expression was also completely prevented by tasocitinib (200 nM-1 μM). Unexpectedly, tasocitinib also inhibited TNF-induced gene expression and production of several other pro-inflammatory proteins. Time-course studies showed induction of IP-10, RANTES, and MCP1 mRNA expression and protein secretion after 7h but no inhibition by tasocitinib. However, tasocitinib significantly decreased IP-10, RANTES, and MCP-1 mRNA expression after 16 hours of TNF stimulation (96%, 67%, and 55% inhibition, respectively; $p<0.001$ for all). TNF-induced secretion of RANTES and MCP-1 protein at 18h was inhibited by 53% and 38%, respectively ($p<0.005$ for both). A smaller effect was observed on TNF-induced IL-6 and MMP1 expression, whereas other TNF-induced genes like IL-8 and MMP3 were unaffected by tasocitinib. mRNA stability studies showed that the effect of the Jak inhibitor was independent of mRNA half life. However, blocking de novo protein synthesis with cycloheximide abolished the inhibitory effect of tasocitinib on TNF induced IP-10 and RANTES mRNA expression.

Conclusions: TNF induces FLS expression of several chemokines involved in T cell recruitment in a manner that indirectly depends on Jak-Stat activation. TNF-induced FLS expression of these chemokines requires de novo protein synthesis and could involve disrupting late autocrine cytokine networks mediated by Jak-Stat signaling. These findings illuminate a potential novel mechanism of tasocitinib in rheumatoid arthritis: not only does the compound directly inhibit cytokine signaling in T cells, but it also diminishes the production of chemokines by synovial fibroblasts and could limit recruitment of T cells and other infiltrating leukocytes to the synovium.

A Th17 Immune Response Can Be Amplified by Human Th9 Cells. Andreas Ramming[1], Hendrik Schulze-Koops[2] and Alla Skapenko[2]. [1]Division of Rheumatology, University of Munich, Munich, Bavaria, Germany, [2]Division of Rheumatology, University of Munich, Munich, Germany

Interleukin 9 (IL-9) is a pluripotent cytokine produced primarily by T cells in response to transforming growth factor (TGF)-β. Little is known about the role of IL-9 and of the IL-9-producing T cell subset. Herein, we investigated IL-9 production by different mature T helper (Th) cell subsets, and analyzed the effect of IL-9 on T cell differentiation.

CD4+ CD45RA+ naive and CD45RO+ memory, and CD4+CD25+ T cells were isolated from peripheral blood of healthy individuals, stimulated under different conditions, and analyzed for their cytokine profile by intracellular flow cytometry and Luminex.

TGF-β was identified as the master cytokine for the induction of human IL-9-producing T cells. CD45RA+ naive T cells required TGF-β together with IL-4 to convert into IL-9-producing cells. In CD45RO+ memory T cells, TGF-β alone was sufficient to induce IL-9 production. Mature T cell subsets, Th1, Th2, Th17 cells, and CD25+Foxp3+ regulatory T cells (Tregs) did not produce IL-9 together with the respective signature cytokine or transcription factor. Th9 cells itself demonstrated a highly specific cytokine secretion profile characterized by the exclusive production of IL-9. When the effect of IL-9 on T cells was investigated, IL-9 did not influence Th1 and Th2 cell differentiation, but significantly enhanced the differentiation of Th17 effector cells towards IL-17 single producers.

IL-9-producing Th9 cells represent a distinct T cell subset characterized by a highly specific cytokine secretion profile different from other effector cell subsets. Their signature cytokine, IL-9, enhances Th17 differentiation. Therefore, human Th9 cells are likely to exert a pro-inflammatory function.

Addition of Retinoic Acid and TGF-beta Accelerate the Maturation Naive CD8+ Cells into CD8+CD25+FOXP3+ Regulatory Cells. J. Dixon Gray[1], Stephanie Q. Pan[2] and David A. Horwitz[1]. [1]University of Southern California, Los Angeles, CA, [2]University of Southern California

Purpose: Regulatory T cells (Tregs) maintain immunologic homeostasis and prevent autoimmunity. Defects in the numbers and function of CD4+ Tregs in SLE and other immune-mediated rheumatic diseases are well described. Besides their well described cytotoxic activities, several populations of CD8+ regulatory cells (Treg) have been described that occur

naturally or can be induced ex-vivo and some of these subsets express Foxp3. The conditions required to induce mature functionally competent Foxp3+ Tregs are not well understood. We have reported that human naïve CD4+ cells polyclonally stimulated with IL-2, TGF-β and all-trans retinoic acid (atRA) rapidly become CD25+CD127- Foxp3+ cells with marked suppressive activity both *in vitro* and *in vivo*. Here the objective was to learn whether CD8+ cells could become Treg cells with a similar phenotype and function.

Methods: CD8+ CD28+ CD45RA+ CD127+ CD62L^{hi} CD25- cells from healthy subjects were stimulated with suboptimal numbers of anti-CD3/CD28 coated beads + IL-2 ± TGF-β or atRA for 5 to 7 days. Since all anti-CD3 activated CD8+ cells inhibit T cell proliferation *in vitro*, we investigated their ability to protect into immunodeficient NOD SCID IL-2R common gamma chain−/− (NOG) mice from a human anti-mouse GVHD.

Results: Activation of naïve CD8+ cells with TGF-β doubled Foxp3 expression and the cells became CD103+, but the cells retained a naïve phenotype and remained CD127+. With the addition of atRA to TGF-β, Foxp3 expression was consistently >50%. They remained predominantly CD62L^{hi}, but became CD45RO+ and CD127-, consistent with a regulatory phenotype. The transfer of 20×10^6 human CD25- PBMC to NOG mice results in the rapid demise of these animals. The addition of atRA/TGF-β CD8reg in a ratio of 1: reg to 4 PBMC doubled the survival of the mice. Studies with other epigenetic agents and comparing the effects of CD4 and CD8regs separately and together will be reported.

Conclusions: Although to date, attention has been focused on CD4reg, studies in both mouse and human SLE have documented an important, if not essential, role of CD8regs. The ability to rapidly generate both CD4+ and CD8+ Foxp3+ Tregs using convention cell separation techniques represents a novel, practical strategy to treat patients with SLE and other chronic inflammatory immune-mediated rheumatic diseases.

An Assessment of theThromboembolic Potential of CDP7657, a Monovalent Fab' PEG Anti-CD40L Antibody, in Rhesus Macaques. Ian Wakefield[2], Olivier Harari[2], David Hutto[1], Linda Burkly[1], Janine Ferrant[1], Fred Taylor[1], Martyn Robinson[2], Anthony Shock[2], Timothy Bourne[2] and Christopher Peters[2]. [1]Biogen Idec, [2]UCB

Background: CDP7657 is a novel monovalent Fab' PEG anti-CD40L antibody being developed for the treatment of Systemic Lupus Erythematosus (SLE) and currently in a phase I clinical study. Previously, an anti-human CD40L intact IgG_1 mAb, hu5c8 (Antova), has been associated with thromboembolic events in the clinic and subsequent investigations of hu5c8 in Rhesus macaques revealed extensive pulmonary thrombovasculopathy with intimal hyperplasia (IH). CDP7657 and other Fc function-deficient anti-CD40L antibody constructs were evaluated in Rhesus monkeys for their potential to induce thrombosis and vascular lesions as part of a non-clinical safety evaluation program.

Methods: Three studies were conducted in Rhesus monkeys. In the initial study, the hu5c8 mAb was administered *i.v.* weekly at 50mg/kg/week for 8 weeks. A second 8-week study investigated two PEGylated antibody fragments (the monovalent Fab' PEG CDP7657 and a bivalent di-Fab' PEG format using the same variable region) and two intact mAbs (hu5c8, and the Fc function-deficient aglycosyl hu5c8). These agents were administered *i.v.* weekly (50mg/kg) and compared with saline-injected control animals. In the third study, CDP7657 was administered *i.v.* weekly at doses of 20, 50, or 200 mg/kg (8/sex/group) for 12 weeks, while control animals (16/sex) received saline. Reversibility groups were assessed for 4 or 6 months. In all studies, there was extensive histopathology evaluation of the lungs (29 sections/animal).

Results: In the first study, hu5c8 produced widespread severe pulmonary vasculopathy in animals, consisting of intravascular thrombosis and IH. In the second study, hu5c8 also produced pulmonary intravascular thrombosis or IH in the lungs of 5 of 8 animals. Secondary changes were observed including recanalization of arterial thrombi, intra-alveolar hemorrhage, perivascular inflammation and fibrosis and coagulative necrosis of the lung parenchyma. By contrast, CDP7657 and other anti-CD40L antibody constructs lacking a functional Fc region were associated with an incidence of pulmonary changes comparable to that found in control animals. In the third study, CDP7657 showed no evidence of compound-related pulmonary or extra-pulmonary thrombovasculopathy after the treatment or reversibility periods and no other findings of toxicological significance at any dose level.

Conclusions: The pulmonary thrombovasculopathy observed with the hu5c8 mAb in Rhesus macaques is associated with the presence of a functional Fc region, and is not caused by CD40L blockade alone, or on the valency of the blockade, as seen by the absence of these pulmonary effects with the other antibody constructs. These data support the clinical testing of CDP7657 in humans for treatment of SLE and other immune-mediated diseases.

Blockade of CD40L with a Monovalent Fab' PEG Monoclonal Antibody Inhibits Disease in the Murine Collagen-Induced Arthritis Model. Alexander Vugler[2], Daniel Sutton[2], Diane Marshall[2], Stevan Shaw[2], Linda Burkly[1], Janine Ferrant[1], Ellen Garber[1] and Anthony Shock[2]. [1]Biogen Idec, [2]UCB

Background: Inhibition of CD40L is a potential approach for the treatment of autoimmune diseases. Whole IgG anti-CD40L mAb treatment was associated with thrombotic toxicity in man. A monovalent Fab' PEG antibody format is a promising approach to inhibit CD40L function without causing thrombotic complications. In this study the efficacy of an anti-mouse CD40L Fab' PEG antibody (MR1 Fab' PEG) was assessed in the collagen-induced arthritis model.

Methods: DBA/1 mice were dosed prophylactically with MR1 Fab' PEG (100mg/kg once a week) or PBS by subcutaneous route from 1 day prior to sensitisation. On Day 0, mice were sensitised intradermally with 100mg chick type II collagen (CII) emulsified in complete Freund's adjuvant. On Day 14, mice received a boost injection of 100mg CII in incomplete Freund's adjuvant. Mice were then monitored for signs of arthritis. The study was terminated on Day 48 post-sensitisation. Serum samples were taken to measure anti-CII antibody production and limbs were removed into formalin for histological analysis of joint structure.

Results: Administration of MR1 Fab' PEG resulted in an 81% ($p<0.01$) reduction in the area under the curve of the clinical score and suppressed anti-CII IgG1 and anti-CII IgG2a production by 61% ($p<0.05$) and 82% ($p<0.001$) respectively, as compared to PBS-treated control animals. Histological examination of the joints showed that MR1 Fab' PEG inhibited joint destruction by 86% ($p<0.001$).

Conclusion: These results demonstrate that a monovalent anti-CD40L Fab' PEG approach to blocking CD40L is efficacious in a pre-clinical model of rheumatoid arthritis and suggests that this approach may be beneficial in the treatment of chronic autoimmune diseases.

CDP7657, a Monovalent Fab′ PEG Anti-CD40L Antibody, Inhibits Immune Responses in Both HuSCID Mice and Non-Human Primates. Ian Wakefield[2], Christopher Peters[2], Linda Burkly[1], Ellen Garber[1], Janine Ferrant[1], Fred Taylor[1], Lihe Su[1], Yen-Ming Hsu[1], Martyn Robinson[2], Timothy Bourne[2], Roger Palframan[2], Lisa Berry[2], Olivier Harari[2] and Anthony Shock[2]. [1]Biogen Idec, [2]UCB

Background: CDP7657 is a novel monovalent Fab′ PEG anti-human CD40L antibody being developed for the treatment of Systemic Lupus Erythematosus (SLE) and is currently in a phase I clinical study. CD40L is a key regulator of T-cell dependent activation of accessory cells, particularly B cells and other antigen presenting cells. These studies were designed to evaluate the capacity of CDP7657, and other anti-CD40L antibody contructs, to block the humoral immune response to tetanus toxoid (TT) in both HuSCID mice and Cynomolgus macaques.

Methods: For the HuSCID study, CB17 SCID mice were dosed *s.c.* with CDP7657, hu5c8 (a humanized anti-human CD40L intact IgG_1 mAb) or an aglycosyl (Fc function-deficient) form of hu5c8. Human peripheral blood mononuclear cells (PBMC) and TT were then injected into the mice. The number of antibody forming cells generating human anti-TT IgG was determined on day 14 by ELISpot.

For the Cynomolgus macaque studies, different anti-CD40L mAb constructs were given as a single *i.v.* dose. In addition to CDP7657, hu5c8 and aglycosyl hu5c8, the variable regions of CDP7657 in bivalent di-Fab′ PEG and intact aglycosyl (human IgG_4) mAb formats were also tested. The effect

of these entities on the primary and secondary anti-TT responses was monitored.

Results: In the HuSCID model, CDP7657 demonstrated a dose-dependent inhibition of the anti-TT antibody response with equivalent efficacy to that of aglycosyl hu5c8. Although all three entities were able to completely block the anti-TT immune response, the IgG_1 version of hu5c8 was the most potent in this model system.

In the Cynomolgus macaque, all of the anti-CD40L molecules were capable of inhibiting the primary IgM and IgG anti-TT antibody responses, with a comparable degree of efficacy observed between CDP7657, the diFab′ PEG and the aglycosyl IgG antibody constructs. CDP7657 demonstrated a dose related effect on both primary and secondary (after re-challenge with TT) immune responses and also was able to effectively suppress secondary responses.

Conclusions: CDP7657 dose-dependently inhibited the immune response to TT in both HuSCID mice and Cynomolgus macaques. The inactive Fc formats tested had decreased efficacy in both models relative to hu5c8 which may reflect the potential depleting capacity of this active isotype. Demonstration of the effective inhibition of CD40L-dependent immune responses by CDP7657 supports the therapeutic potential of this molecule for the treatment of human immune-mediated diseases such as SLE.

Characterization of Human Follicular Helper T Cells. Sang Taek Kim[3], Jin-Young Choi[4], Begona Lainez[4], Leah DiPlacido[1], Vivian E. Vlamakis[2] and Joseph E. Craft[4]. [1]Department of Immunobiology, Yale University School of Medicine, New Haven, CT, [2]Division of Rheumatology, University of Washington School of Medicine, Bothell, WA, [3]Section of Rheumatology, Department of Internal Medicine, Yale University School of Medicine, Orange, CT, [4]Section of Rheumatology, Department of Internal Medicine, Yale University School of Medicine, New Haven, CT

Follicular helper T (T_{FH}) cells are specialized $CD4^+$ T cells that are localized in B cell follicles and help B cells produce antigen-specific antibodies via contact and secretion of IL-21 and IL-4. In mouse studies, a spontaneous increase in T_{FH} cells is associated with pathologic germinal center formation and autoantibody secretion, which leads to autoimmune diseases and end-organ damage. In mice, T_{FH} cells are characterized by high expression of CXCR5, PD-1, ICOS, and Bcl-6, and as we have found, low expression of P-selectin glycoprotein ligand-1 (PSGL-1); however, study of T_{FH} cells in human is more limited. Here we characterized T_{FH} cells in human tonsils using flow cytometry and immunofluorescence staining, and compared them using surface markers and cytokine production to traditional Th effector subsets. Samples were obtained from routine tonsilectomy at Yale New Haven Hospital. Both surface and intracellular staining were done with flow cytometry. T cells in human tonsil were sorted into populations of $CD4^+CD45RA^+$ cells (Naive T cells), $CD4^+CD45RA^-PSGL\text{-}1^{hi}PD\text{-}1^{hi}CXCR5^{hi}$ cells, $CD4^+CD45RA^-PSGL\text{-}1^{hi}PD\text{-}1^{lo}CXCR5^{lo}$ cells, $CD4^+CD45RA^-PSGL\text{-}1^{lo}PD\text{-}1^{hi}CXCR5^{hi}$ cells and $CD4^+CD45RA^-PSGL\text{-}1^{lo}PD\text{-}1^{lo}CXCR5^{lo}$ cells. Subsequently sorted populations were stimulated with PMA/Ionomycin for 6 hours. Stimulated cells were used for qPCR/intracellular staining and culture supernatants were used for ELISA. Tissue immunofluorescence staining was done using confocal microscopy to confirm the location of T_{FH} cells. We find that human T_{FH} cells are $ICOS^{hi}IL6\text{-}R^{hi}CD200^{hi}CD27^{hi}CXCR4^{hi}$ and $IL21\text{-}R^{lo}IL7\text{-}R^{lo}PSGL\text{-}1^{lo}CD62L^{lo}CCR7^{lo}$ and they produce both IL-4 and IL-21. Downregulation of PSGL-1 can be used as an additional surface marker for T_{FH} cells as well as an anatomical marker of the B cell follicle by microscopy.

Chronic Inflammatory Responses in Rheumatoid Arthritis: The Vicious Circle Might Be Related to Interaction of Th17 Cells with FLS or Mesenchymal Stem Cells. Assia Eljaafari[1], Marie-Laure Tartelin[1] and Pierre Miossec[2]. [1]HCL and UCBL, Lyon, France, [2]HCL and UCBL, France

Introduction: TH17 cells have been involved in the initiation and maintenance of several inflammatory and autoimmune diseases, such as Rheumatoid Arthritis (RA). More recently, they gained further interest, due to the demonstration of their involvement in anti-tumor responses.

Hypothesis: Here we postulated that if TH17 cells play a so preponderant role in inflammatory diseases, their development might be facilitated in this context. Therefore, using RA as a model of chronic inflammation, we hypothesized that interaction of T cells with mesenchymal cells, such as synoviocytes (FLS), or mesenchymal stem cells (MSC) could participate in the activation of the TH17 pathway, with the help of the inflammatory environment.

Methods: To investigate this possibility, mononuclear cells (MNC) from healthy blood donors were co-cultured with MSC from healthy controls, or FLS from either RA or osteoarthritic (OA) patients, and were activated with PHA or A/CD3+CD28 mABs, for 1 to 2 days. IL17A, TNFa, and or/IFNg were added or not to these co-cultures. Q-RT-PCR, ELISA,and cytoflurometry technics were used to assess for IL17-A production.

Results: We observed that the interaction of MNC with healthy MSC resulted in an extinction of TH1 and TH2 cell activation, but was sufficient by its own to induce a strong production of TH17 cells, as soon as 24 hours post-activation, as assessed by the increase of IL17A at the mRNA and protein levels and by Th17 staining.The levels of IL17A further increased at 48 hours, and/or in the presence of IL17A, TNFa, and or/IFNg. IL6, IL8, and IL1 mRNA levels increased as well. Interestingly, co-culture with FLS from either OA or RA patients, also resulted in a strong induction of IL17, but not in TH1 inhibition. Finally, TH17 production was partially inhibited in the presence of anti-IL6 mAbs, or CTLA4-Ig fusion molecules, demonstrating thus the roles of IL6 and costimulatory molecules in such a production.

In Conclusion: We show herein, that interaction of MSC,or FLS from RA or OA patients, with MNC results in enhancing the inflammatory response, through production of IL-17, IL6, IL-8 and IL-1 cytokines. Moreover, in the context of an inflammatory environment, i.e: presence of IL-17A, TNFa, and/or IFNg, such an interaction of T cells with MSC results in further amplifying the induction of TH17 cells, leading thus to a vicious circle, that may participate to the chronicity of inflammation.

Circulating FOXP3+ CTLA-4+ CD25+ Regulatory T Cells in Human Infants Counteract the Maturation and Homing Receptor Switch of CD4+ T Cells at 18 and 36 Months of Age. Hardis Rabe[2], Anna-Carin Lundell[2], Kerstin Andersson[2], Ingegerd Adlerberth[1], Agnes E. Wold[1] and Anna Rudin[3]. [1]Dept of Clinical Bacteriology, [2]Dept of Rheumatology and Inflammation Research, [3]Dept of Rheumatology and Inflammation Research, The Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden

Background: FOXP3+ CTLA-4+ CD25+ regulatory T cells are essential to prevent general overactivation of T cells and ensuing autoimmune and inflammatory disease as the lack of these cells leads to a lethal inflammatory syndrome. However, it is not known if the numbers of these cells in the circulation in early infancy of healthy children are associated with lower levels of activation and maturation of the T cells at later ages.

Methods: We followed a cohort of 66 children prospectively from birth to 3 years of age and analyzed T cells in blood samples phenotypically and quantitatively from ages 0 and 4 days, 1, 4 and 18 months and 3 years of age. The analysis of the CD4+ T cells was performed using flow cytometry to investigate the relation of the numbers of regulatory T cells in the circulation to the maturation and homing receptor switch of the CD4+ T cells at older ages. The relationship was analyzed using multivariate analysis by principal component analysis (PCA), orthogonal partial least squares modeling (OPLS) and thereafter univariate analyses as appropriate.

Results: We analyzed the numbers of regulatory T cells using both FOXP3 and CTLA-4 as markers together with CD25. We showed that the T cells expressing FOXP3 and CTLA-4, respectively, were associated in PCA and OPLS at 4, 18 and 36 months of age but not at earlier ages. The numbers of regulatory T cells av 4 and 18 month of age were positively associated with the proportion of immature unactivated CD45RA+ T cells as well as with gut-homing $\alpha4\beta7$+ CD4+ T cells at 18 and 36 months of age. Conversely, the numbers of regulatory T cells were negatively associated with the proportion of mature and previously activated CD45RO+ T cells as well as with CD4+ T cells expressing the extraintestinal homing marker CCR4.

Conclusion: We show for the first time that higher numbers of circulating FOXP3+ CTLA-4+ regulatory T cells in healthy infants are strongly related

to a lower proportion of mature previously activated CD4+ T cells at later ages. We conclude that the number of regulatory T cells in the circulation is important in the function of inhibition of immune activation, probably both to endgenous and exogenous antigens. Therefore, lower numbers of regulatory T cells in the circulation might preceed the onset of inflammatory disease.

Critical Role of IL-21 in Modulating Th17 Responses and Regulatory T Cells in Behçet Disease. Guillaume Geri[1], Benjamin Terrier[1], Michelle Rosenzwajg[1], Bertrand Wechsler[2], Du Le Boutin[1], Bahram Bodaghi[1], Tu-Ahn Tran[1], Nathalie Costedoat-Chalumeau[2], Lucile Musset[1], David Klatzman[1], Patrice Cacoub[1] and David Saadoun[1]. [1]Pitié-Salpetrière Hospital, Paris, France, [2]Pitie-Salpetriére Hospital, Paris, France

Background: Behçet disease (BD) is a systemic vasculitis of unknown origin. Infectious or environmental factors and Th1 cells producing IFN-γ have been involved in its pathogenesis, but these findings remain controversial.

Objective: To determine the implication of Th1, Th17 and regulatory T cells in the pathogenesis of BD.

Methods: Forty BD patients (20 active untreated [aBD] and 20 treated and inactive [iBD]) fulfilling the international diagnostic criteria and 20 healthy donors (HD) were included. Flow cytometric analysis of peripheral blood mononuclear cells and purified CD4+ T cells was performed for cell surface markers, intracellular production of cytokines and FoxP3 transcription factor. Measurements of cytokine levels in serum and culture supernatants were also performed.

Results: A marked enrichment in IL-17A-producing CD4+ CD45RO+CCR6+ T cells (Th17) was found in peripheral blood of aBD compared with iBD and HD (3.1 vs. 1.0 and 0.6 %, $P<0.0001$ for both), whereas IFN-γ producing CD4+ and CD8+ T cells did not differ between aBD and HD. Th17 expansion was more pronounced in cerebrospinal fluid of aBD with central nervous system involvement. CD4+CD25highCD127-FoxP3+ T cell subset was decreased in aBD compared to HD (1.78 vs. 3.2%, $P=0.02$). We found an increase in serum IL-21 in aBD compared with iBD and HD whereas no significant difference was noted for others cytokines promoting Th17 differentiation. Expansion of IL-21-producing CD4+ T cells was observed in aBD compared with iBD and HD (5.5 vs. 2.8 and 1.8 %, $P=0.002$ and $P<0.0001$, respectively), that correlated positively with Th17 expansion ($r^2=0.43$; $P<0.0001$) and negatively with activated Tregs ($r2=0.45$, $P=0.009$). Stimulation with anti-CD3/CD28 of purified CD4+ T cells, with human recombinant IL-21, significantly increased Th17 cells and decreased FoxP3 expression. The blockade of IL-21 using IL-21R/Fc chimera markedly decreased production of IL-17A and increased FoxP3 expression in sorted CD4+ T cells.

Conclusion: Taken together, these results are the first to demonstrate the implication of IL-21 in the pathogenesis of BD. IL-21 may exert a critical role in modulating Th17 responses and regulatory T cells in BD, and represent a potential target for novel therapy.

CXCL13 Signals through CXCR5 To Upregulate Nuclear CXCR5 and Bcl-6 and Promote the Development of Follicular T Helper Cells in Autoimmune BXD2 Mice. Yanna Ding[3], Hui-Chen Hsu[1] and John D. Mountz[2]. [1]Department of Medicine, The University of Alabama at Birmingham, [2]Department of Medicine, The University of Alabama at Birmingham; Birmingham VA Medical Center, [3]Department of Pathology, The Univerisity of Alabama at Birmingham

Background: Autoantibody production can be highly associated with B cells activation by Follicular T helper (T_{FH}) cells in germinal centers (GCs). Interaction of cell surface CXCR5 with its ligand, CXCL13, is critical to direct the trafficking of T_{FH} and B cells to GC light zone for their interaction. Bcl-6 is a critical transcription factor for T_{FH} cells while IL-21 is the major functional cytokine produced from T_{FH} cells. The purpose of this study is to determine how CXCL13-CXCR5 signaling is involved in the development of T_{FH} during the development of pathogenic GC response in BXD2 mouse model of autoimmune disease.

Methods: Frozen spleen sections were used for fluorescent confocal imaging analysis. Paraffin-embedded spleen sections were used for immunohistochemistry (IHC) staining. CD4 T cells or total spleen cells of BXD2 and normal B6 mice as well as Jurkat T cells were used for all in vitro experiments. Cells treated with either CXCL13 or neutralizing anti-CXCL13 were subjected to FACS staining with some cells cytospinned for fluorescent imaging analysis. Subcellular expression of CXCR5 in purified CD4 T cells and Jurkat cells was determined by western blot analysis. The expression of *Bcl6* and *Il21* at the mRNA were determined by RT-PCR.

Results: There was a 2.5- and 1.5-fold increased expression of $ICOS^+CXCR5^+$ and IL-21^+ $CD4^+$ T cells, respectively, in the spleens of BXD2 compared with those in B6 spleens. $ICOS^+CXCR5^+$ T_{FH} cells mainly clustered at GCs and were located adjacent to $CD21/CD35^+$ follicular dendritic cells. Surprisingly, CXCR5 exhibited the highest expression in the nucleus of CD4 T cells in the GC light zone. Western blot of cytoplasmic and nuclear fractions further confirmed that there was increased expression of CXCR5 in the nucleus of CD4 T cells from BXD2 mice compared with B6 CD4 T cells. CXCL13 stimulation of purified CD4 T cells from BXD2 mice or the human Jurkat T cell line led to a time-dependent increase of nuclear CXCR5 expression. $CXCR5^+CD4^+$ T cells from BXD2 mice also expressed higher levels of BrdU and lower levels of Fas, compared with those from B6 mice. *In vivo* nuclear expression of CXCR5 co-localized with $Ki67^+$ cells in situ. FACS analysis also showed that CXCL13 treatment promoted development of $CXCR5^+ICOS^+$ CD4 T_{FH} cells and upregulated Bcl-6 expression in this subset in BXD2 spleen cells and in Jurkat T cells. In contrast, anti-CXCL13 treatment decreased T_{FH} cells and downregulated Bcl-6 expression. The RT-PCR result supported the upregulation of *Bcl-6* by CXCL13.

Conclusions: Our study indicates that there was expansion of T_{FH} cells in BXD2 mice. CXCL13 binding to CXCR5 induced nuclear translocation and increased expression of CXCR5 in the nucleus of T_{FH} cells in autoimmune BXD2 mice. CXCL13 also upregulated Bcl-6 and promoted development and increased numbers of T_{FH} cells. Increased nuclear CXCR5 by CXCL13 may play an important role in survival of T_{FH} cells to facilitate autoreactive GC responses in BXD2 mice.

Decreasing Fli1 Levels in Lupus T Cells Has Effects on Serum Immunoglobulin Levels and T Cell Infiltration in the Kidney. Erin Morris[1], Maria I. Harrell[1], John Svenson[1], Laura Tonks[1], John Zhang[3] and Tamara K. Nowling[2]. [1]MUSC, [2]Ralph Johnson VAMC/MUSC, Charleston, SC, [3]Ralph Johnson VAMC/MUSC

Background: The Ets factor Fli1 is implicated as a key modulator of lupus disease expression. Over-expressing Fli1 in healthy mice, results in the development of an autoimmune kidney disease similar to that observed in lupus. Lowering the global levels of Fli1 in two lupus mouse models significantly improved disease and prolonged survival. Lowering the levels of Fli1 in hematopoietic cells only in MRL/lpr lupus mice resulted in significantly improved kidney disease. The cell type mediating this protective effect is unknown. Here we analyzed the effects of reducing Fli1 levels in MRL/lpr T cells on serum IgG and IgM levels, T cell infiltration in the kidneys and T cell proliferation.

Methods: T cells and B cells were isolated from spleens of lupus prone MRL//lpr Fli1+/+ and MRL/lpr Fli1 +/− mice. The cells were mixed in all possible Fli1+/+ and Fli1+/− T and B cell combinations in a 1:1 ratio and adoptively transferred into Rag-1-deficient mice, which do not produce mature T and B cells. Various markers of autoimmunity were measured in the serum of the recipient mice at 2 and 4 weeks after transfer by ELISA and T cell infiltration in kidneys was examined 4 weeks after transfer by immunofluorescence. Next, we measured the various T cell subsets infiltrating the kidneys of MRL/lpr Fli1+/+ and MRL/lpr Fli1+/− mice by flow cytometry. CFSE staining and Annexin V staining were used to measure proliferation and apoptosis, respectively of Fli1+/+ and Fli1+/− T cells following ex vivo stimulation.

Results: Our adoptive transfer results demonstrated that recipient mice that received Fli1+/− T and +/+ B cells or Fli1+/− T and +/− B cells averaged 50–75% lower levels of IgG and 60–70% lower levels of IgM compared to recipients that received Fli1+/+ T and +/+ B cells. The recipient mice that received Fli1+/− T and +/+ B cells also had approximately 30% fewer T cells (CD3+) present in their kidneys compared to recipients that received Fli1+/+ T and +/+ B cells. Analyses of kidneys from 14–16 week old MRL/lpr Fli1+/+ and MRL/lpr Fli1+/− mice demonstrated that the percent of CD4+ T cells

present was significantly decreased by 25% ($p<0.005$) and the percent of CD8+ T cells present was significantly increased by 57% ($p<0.01$) in the MRL/lpr Fli1+/− compared to MRL/lpr Fli1+/+. A 37% decrease in the number of total T cells and 42% increase in the percent of CD25+ T cells present in the kidney also was observed in the MRL/lpr Fli1+/− mice, but the differences did nto reach statistical significance. Furthermore, T cells isolated from spleen of Fli1+/+ and Fli1+/− mice demonstrated that reducing Fli1 results in a 10–12% increase in T cell proliferation.

Conclusions: The adoptive transfer results demonstrate that reducing Fli1 levels in T cells alone may have a positive therapeutic impact on the progression of lupus nephritis. This positive impact may be mediated by changes in the number and subtypes of T cells infiltrating the kidneys. Mechanistically, the effects of altered Fli1 levels in T cells has yet to be fully explored. Preliminarily, our results suggest that Fli1 may have an effect on proliferation.

Dendritic Cells and Continued Smoking in Rheumatoid Arthritis. Marina Kazantseva[3], John Highton[1], Lisa K. Stamp[4] and Paul A. Hessian[2]. [1]Univ of Otago Med Sch, Dunedin, New Zealand, [2]University of Otago, Dunedin, New Zealand, [3]University of Otago, Dundein, New Zealand, [4]University of Otago, Christchurch, New Zealand

Purpose: Tobacco smoking is the main environmental risk factor for the development of rheumatoid arthritis (RA). In established RA, smoking is associated with the increased production of rheumatoid factor (RF) and autoantibodies and with increased incidence of extra-articular manifestations that include the development of rheumatoid nodules. However, mechanisms linking smoking with the onset of RA, severity and/or progression of disease and that accommodate the genetic influence of the shared epitope are poorly understood. The aim of this study was to identify the pathogenic mechanism(s) within inflamed RA tissues which are triggered by smoking, with particular emphasis on the cells capable of responding via the aryl hydrocarbon receptor (AHR).

Method: Synovial membrane and subcutaneous nodule tissues were obtained at surgery from patients fulfilling ACR criteria for RA. Retrospective followup established whether patients were smoking at disease onset and/or continued to smoke at the time tissue was obtained, or had ceased smoking prior to tissue collection or had never smoked. All synovial samples were assessed using quantitative real-time PCR assays (Taqman; Applied Biosystems) to establish AHR expression and distinguish AHR activation, through CYP1A1 expression. Cryostat sections of synovial tissue were stained by double immuofluorescence using cell specific antibodies recognising lineage specific markers, in combination with biotinylated AHR- or CYP1A1-specific antibodies to identify cells responding to continued smoking. Genomic DNA was isolated from cryosections or from peripheral blood and genotyping for HLA-DR shared epitopes (SE) allotypes was performed using sequence specific-primer-PCR.

Results: The combination of AHR and CYP1A1 gene expression in synovial membrane distinguishes patients with RA who continue to smoke. CYP1A1 protein was observed in synovia obtained from smokers. Cell-specific markers confirmed both AHR and CYP1A1 were produced by CMRF56+ dendritic cells (DC) and CD3+ T lymphocytes in synovia from smokers. CD20+ B cells, CD14+ monocyte/macrophages CMRF44+ DCs, did not produce either AHR or CYP1A1 protein. No CYP1A1 protein expression was detected in synovial tissues from non-smokers. Synovia obtained from RA patients who smoked and carried a single or double copies of SE genes were largely positive for CYP1A1 gene expression. By comparison CYP1A1 was mainly expressed in nodule tissues from patients who were non-smokers but who carried double copies of SE genes.

Conclusions: Our results show that in rheumatoid synovial tissue, dendritic cells are armed and responsive to the components of cigarette smoke. A subset of T cells is also capable of responding. The response requires continued smoking as CYP1A1 expression, reflecting AHR activation, ceases within months of smoking cessation. The AHR-mediated response to smoking in synovial tissue is heightened in individuals who smoke requiring only a single copy of the HLD-DR shared epitope. This may reflect an increased sensitivity/activation of participating dendritic cells.

DNA Methylation Affects Gene Expression in CD4+CD28- T Cells through microRNAs. Dipak R. Patel, Anura Hewagama, Sushma Yarlagadda and Bruce C. Richardson, University of Michigan, Ann Arbor, MI

CD4+CD28- T cells are enriched in multiple autoimmune diseases such as rheumatoid arthritis. These cells are capable of enhanced cytotoxicity, and they are more resistant to apoptosis. Extra-articular disease manifestations and disease severity positively correlate with the relative abundance of these cells.

Compared to their CD28+ counterparts, CD28- CD4+ T cells over-express CD70 and other molecules that potentially contribute to their phenotype. Hypomethylation of the DNA in these genes' regulatory elements explains their aberrant expression. Recently, changes in DNA methylation have been shown to affect microRNA (miRNA) expression. MicroRNAs are small non-coding RNA molecules that block the translation of messenger RNAs (mRNAs). The role of miRNAs in regulating gene expression in CD4+CD28- T cells is unknown.

We investigated the role of miRNAs in CD4+CD28- T cell gene expression. CD28+ and CD28- CD4+ T cells were generated by chronic re-stimulation in vitro. Peripheral blood mononuclear cells were stimulated overnight with phytohemagglutinin. CD4+ T cells were then isolated by negative selection, and they were re-stimulated weekly with irradiated antigen presenting cells and IL-2. CD28+ and CD28- CD4+ T cells were separated by flow cytometry after 4–6 weeks of culture. Total RNA, including the miRNA fraction, was then isolated (Qiagen). Expression of miRNAs in each population was compared using a quantitative real-time PCR kit (Systems Biosciences).

In four sets of chronically re-stimulated cell cultures, we found five miRNAs that are over-expressed at least 1.5 fold in CD4+CD28- T cells, compared to their CD4+CD28+ counterparts. Another four miRNAs were over-expressed in all four cultures, though the 1.5 fold threshold was exceeded in only three of the four cultures. Online tools, including TargetScan and miRANDA, were used to predict potential interactions between these miRNAs and mRNAs. Two of the five miRNAs over-expressed in CD4+CD28- T cells did not have any predicted mRNA targets. The remaining three of five miRNAs over-expressed in CD4+CD28- T cells were predicted to interact with mRNAs encoding proteins that are required for DNA methylation and cytokine signaling.

Overall, these experiments identified several miRNAs that are over-expressed in CD4+CD28- T cells. These miRNAs potentially interact with genes encoding proteins required for DNA methylation. If miRNAs targeting DNA methylation are over-expressed, hypomethylation and over-expression of genes causing T cell activity could result. This could explain the increased disease severity seen when CD4+CD28- T cells are abundant in RA. The miRNAs we have identified could then be potential therapeutic targets.

Dys-Regulation of T-Cell Subsets and Cytokines Is Associated with the Development of Inflammatory Symptoms in ACPA-Positive Asymptomatic Individual. Richard J. Cuthbert[2], Rekha Parmar[2], Jackie Nam[2], Edith Villeneuve[2], Diane Corscadden[2], Karen Henshaw[2], Paul Emery[1] and Frederique Ponchel[2]. [1]Chapel Allerton Hospital, Leeds, United Kingdom, [2]University of Leeds, Leeds, UK

Background: We reported that T-cell subset dys-regulation can predict evolution towards rheumatoid arthritis (RA) from early symptoms, response to treatment in early disease as well as relapse in patients who achieved clinical remission. Naïve cells were the most informative circulating T-cells subset in early disease. Cytokine activated T-cells (IRC) were less informative as systemic inflammation is low in early disease. Asymptomatic ACPA-positive individual are at high risk of developing RA. The aim of the current study is to determine whether T-cell subset and cytokine analysis can predict future development of inflammatory symptoms in this group.

Methods: 35 asymptomatic ACPA+ individuals were enrolled; they were recruited if they had new onset musculoskeletal pain but no synovitis on clinical examination. 6 colour flowcytometry was performed using standard protocols. 36 healthy controls were used to build the age relationship with naïve cell frequency. ELISA were used to measure cytokines and chemokines.

Results: 35 individuals were recruited and followed for 12 months. There was clear difference at baseline between ACPA+ individuals and controls for

naïve (P<0.0001), CD25^{high}Foxp3+ Treg (P=0.020) and CD62L+Treg (P=0.001). IRC were not increased in asymptomatic individuals. During follow-up, 6 individuals were diagnosed with undifferentiated arthritis (UA), 6 with RA, 9 with non-inflammatory osteoarthritis or connective tissue disease and 16 remained with non-specific musculoskeletal symptoms or arthralgia. Analysis based on follow-up showed reduced naïve T-cell (P=0.007) and Treg (P=0.090) in arthralgia and CD62L+Treg frequency were increased (P<0.0001). In the group developing IA, naïve cells were reduced (P<0.0001) but Treg were not different from controls. CD62L+Treg in contrast were significantly reduced (P=0.025). All OA/CTD individuals were close to controls. Furthermore, OA/CTD patients compared to the age-naïve frequency relationship in controls were above normal, the arthralgia group was close to controls and IA patients below. Serum levels of IL-12 and IL-7 cytokines differed in arthralgia individuals compared to controls (P<0.0001) but MIP-1alpha levels were not raised. On follow-up reduced IL-12 (P=0.007) and IL-7 (P=0.019) were observed in the arthralgia group. In the group developing IA, IL-12 (P<0.0001) and IL-7 (P=0.006) were even more reduced and MIP-1alpha raised (P=0.018). In OA/CTD individuals, only IL-12 levels were reduced (P<0.001).

Conclusion: In ACPA+ asymptomatic individuals, the future development of inflammatory symptom appears clearly associated with abnormal immunological parameters at baseline. Furthermore, data suggest that Treg's involvement may be in the true pre-clinical phase and this battle is lost by the time symptoms develop. More work is needed to determine if loss of naïve cells is a cause or a consequence of this dys-regulation on T-cells, however, loss of CD62L+Treg suggests a role for the thymus.

Expression of $K_{2P}5.1$ Potassium Channels on CD4$^+$ T Lymphocytes Correlates with Disease Activity in Rheumatoid Arthritis Patients. Martin Feuchtenberger[2], Stefan Bittner[3], Nicole Bobak[3], Alexander M. Herrmann[3], Kerstin Goebel[3], Stefan Kleinert[3], Heinz Wiendl[1], Hans-Peter Tony[3] and Sven G. Meuth[3]. [1]University of Muenster, [2]University of Wuerzburg, Wuerzburg, Germany, [3]University of Wuerzburg

Background: CD4+ T cells express $K_{2P}5.1$ (TASK2; KCNK5), a member of the two-pore domain potassium channel family, which has been shown to influence T cell effector functions. Recently, it could be shown that $K_{2P}5.1$ is upregulated upon T cell stimulation. In addition, it has been shown that expression levels of this channel are strongly increased on CD8+ T lymphocytes from the peripheral blood from clinically active relapsing-remitting multiple sclerosis (MS) patients. The aim of this study was to analyze the expression of $K_{2P}5.1$ on T cells in patients with rheumatoid arthritis (RA).

Methods: Expression levels of $K_{2P}5.1$ were measured by RT-PCR in CD4+ and CD8+ T cells in the peripheral blood of 58 patients with RA and correlated with disease activity parameters (C-reactive protein levels, erythrocyte sedimentation rates, DAS28 scores). In a prospective study 20 patients were followed up for 6 months after changing DMARD therapy due to high disease activity. Additionally, synovial fluid was investigated for T lymphocytes expressing $K_{2P}5.1$.

Results: $K_{2P}5.1$ expression in contrast to MS is elevated in active RA only in CD4+ T cells in the periphery. Comparing synovial fluid and PBL $K_{2P}5.1$ expression levels of synovial fluid derived T cells are higher for both RNA level and protein level. In the cross sectional study $K_{2P}5.1$ expression levels in CD4+ T cells show a strong correlation to DAS-28 scores in RA patients (r=0.63). The correlation for serologic markers were r=0.39 for ESR, r=0.28 for CRP. In patients followed prospectively after a change of DMARD therapy for up to 6 months $K_{2P}5.1$ expression levels in CD4+ T cells follow nicely the individual clinical response.

Conclusion: Disease activity in RA patients correlates strongly with $K_{2P}5.1$ expression levels in CD4+ T lymphocytes in the peripheral blood in cross-sectional as well as in prospective, longitudinal observations. Further studies are needed to investigate the exact pathophysiological mechanisms and to evaluate the further use of $K_{2P}5.1$ as a potential biomarker for disease activity in RA.

Foxp3+ CD4+ Tregs Prevent Arthritis by Promoting Clonal Anergy Induction in Self Ag-Specific CD4+ T Cells. Ryan Martinez[2], Na Zhang[2], Sara Nandiwada[2], Stephanie Thomas[2], Bryce Binstadt[2] and Daniel L. Mueller[1]. [1]University of Minnesota Medical School, Minneapolis, MN, [2]University of Minnesota Medical School

Using a mouse model of self Ag recognition by naive CD4+ T cells, we have investigated the peripheral self tolerance mechanism that prevents the development of autoimmune arthritis in most individuals. As previously reported, an adoptive transfer of glucose 6-phosphate isomerase (GPI)-specific naive KRN TCR-transgenic CD4+ T cells into lymphopenic TCRalpha chain-deficient mice that naturally express GPI/I-A^{g7} complexes led to an intense clonal expansion, the production of anti-GPI IgG1 autoantibody, and the development of severe polyarticular arthritis. Recognition of GPI/I-A^{g7} in normal hosts, however, failed to elicit autoimmune disease, and instead was sufficient to stimulate only an abortive KRN CD4+ T cell clonal expansion and the induction of clonal anergy. Anergic KRN CD4+ T cells demonstrated a reduced proliferative responsiveness to Ag stimulation, the inhibition of IL-2, TNF-alpha, and IFN-gamma synthesis, and high-level expression of CD73 and Folate receptor 4 (FR4). Reconstitution of the T cell-deficient hosts with enriched CD25+ Foxp3+ CD4+ T cells was sufficient to promote the induction of KRN T cell clonal anergy and prevent the development of arthritis. More importantly, use of diphtheria toxin to selectively eliminate Foxp3-expressing cells from T cell-deficient hosts that had been reconstituted with polyclonal CD4+ T cells from Foxp3-GFP-diphtheria toxin receptor transgenic mice, prevented the development of clonal anergy in the transferred naive KRN CD4+ T cells, and led to their induction of autoimmune arthritis. These data suggest that during the initial encounter of naive CD4+ T cells with peripheral self Ag, CD25+ Foxp3+ T regulatory cells ensure that clonal anergy will be induced early during clonal expansion, and autoimmune arthritis can be avoided. Individuals deficient in Foxp3+ T regulatory cell activity or number are prone to autoimmune arthritis as a consequence of exuberant self Ag-specific CD4+ T cell clonal expansion and differentiation, and the provision of pathological helper activity that leads to a breakdown of self tolerance in the B cell compartment.

Gender and Sex Hormones Influence CD4+ Regulatory T Cells and Their Expression of FoxP3 in Healthy People and in SLE. Ravi K. Dinesh[1], Bevra H. Hahn[2] and Ram P. Singh[1]. [1]David Geffen Schl of Med/UCLA, Los Angeles, CA, [2]University of California Los Angeles School of Medicine, Los Angeles, CA

Purpose: The goal of the present study was to determine the role of gender and the effect of sex hormones on the regulation of Foxp3 gene in healthy individuals and in SLE patients.

Methods: Levels of sex hormones (17 b-estradiol, testosterone), cytokines, and chemokines were measured by ELISA in the serum/plasma of healthy donors and from the culture supernatant of peripheral blood mononuclear cells (PBMC) isolated from SLE patients and healthy controls. PBMC were immunophenotyped by flow cytometry, and mRNA gene expression studies were performed by real time PCR. Protein expression was analyzed by intracellular staining and by Western blot analysis. The *in vitro* effect of sex hormones 17 b-estradiol (60–100, 500pg/ml), and testosterone (100pg/ml) were studied by culturing sorted CD4$^+$CD25^{hi}CD127$_{lo}$ regulatory T cells for 24–72 hours followed by FACS/Western blot analyses.

Results: 1- The numbers of CD4$^+$ CD25^{hi} Foxp3+ and of CD8$^+$ FoxP3+ regulatory T cells are significantly decreased in healthy females compared to healthy males (p<0.01).

2- Both CD4+CD25+^{hi} and CD8+CD25+ subsets of healthy males had 3–4-fold higher Foxp3 mRNA compared to healthy females.

3- Plasma 17b-estradiol levels are significantly increased in female SLE patients compared to healthy females (p<0.01).

4- The addition of 17 b- estradiol (physiologic cycling luteal phase concentrations of 60 pg/ml) for 24 hours to cultured PBMC from healthy women (but not men) increased the total numbers of cells expressing CD4, CD25 and FoxP3. These effects were not seen in cells in women with SLE.

5- Incubation of CD4+ regulatory T cells with 100 pg/ml of 17b-estradiol maintained FoxP3 expression in SLE women, in contrast to the usual increase in CD4+ Treg that occurs in healthy women at this concentration.

6- Testosterone (100 pg/ml) significantly increased FoxP3 expression in CD4+CD25^{hi} cells from women with SLE. In fact, plasma concentrations of testosterone in those women correlated positively with the expression of FoxP3 in their CD4+CD25+ T cells ($p < 0.04$).

Conclusions: Women may be more susceptible than men to SLE and other autoimmune diseases in part because many healthy women have fewer regulatory T cells and less FoxP3 expression in those cells. In addition, women with SLE, compared to healthy women, seem to have less ability to generate CD4+ Treg in response to physiologic concentrations of 17 b-estradiol, whereas the testosterone metabolite increases the generation of Tregs. These data suggest that gender and sex hormones may influence susceptibility to SLE via their effects on regulatory T cells.

Identification of a Pathological TCR of Autoantibody-Inducing CD4$^+$ T Cell That Induces Autoantibodies and Lupus-Like Immune Tissue Injury. Kohsuke Yoshida[1], Ken Tsumiyama[2] and Shunichi Shiozawa[3]. [1]Department of Biophysics, Kobe University Graduate School of Health Sciences, Kobe, Hyogo, Japan, [2]Department of Biophysics, Kobe University Graduate School of Health Sciences, Kobe, Japan, [3]Department of Biophysics, Kobe University Graduate School of Health Sciences/Department of Medicine, Kobe University Graduate School of Medicine/The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan

Purpose: The purpose of this study was to identify the T cell receptor (TCR) of autoantibody-inducing CD4$^+$ T (*ai*CD4$^+$ T) cell that induces autoantibodies in naïve recipients with 100% efficiency when transfered. We have previously shown that overstimulation of CD4$^+$ T cell of the mice not prone to autoimmune diseases by repeated immunization with antigen results in *de novo* generation of *ai*CD4$^+$ T cell which had undergone TCR revision and was capable of inducing autoantibodies and lupus-like immune tissue injury (Tsumiyama K, *et al*. PLoS ONE 4(12):e8382, 2009). Here we tried to identify the TCR of *ai*CD4$^+$ T cell that induces autoantibodies, and identified the pathological TCR of *ai*CD4$^+$ T cell.

Methods: BALB/c mice were repeatedly injected i.p. with 25mg staphylococcus enterotoxin B (SEB) or PBS every 5 days and serum IgG-rheumatoid factor (RF) was measured using ELISA. Vβ8$^+$, a known SEB-reactive Vβ chain, and Vβ8$^-$CD4$^+$T cell were isolated from spleen using magnetic beads and cDNAs from these cells were subjected to RT-PCR amplification using Vβ1 to 18 and Vα1 to 20 specific primers. The cells were also transferred into naïve BALB/c mice *via* i.p. (1×10^7 cells/mouse) injection. The recipients received a single i.p. injection of 25mg SEB 24 h after cell transfer and sera was studied 2 weeks afterwards. Statistical analyses were performed using Student's *t* test and the correlation coefficient r was calculated.

Results: SEB-reactive Vβ8$^+$CD4$^+$T cell was significantly decreased in the mice immunized 12x with SEB as compared with PBS (17.4% vs. 21.2%, $P=0.001$), possibly due to clonal deletion because of anergy induction in the SEB-reactive T cell after 2x immunization with SEB. However, in these mice immunized 12x with SEB, the level of RF was positively correlated to the frequency of splenic Vβ8$^+$CD4$^+$T cell ($r=0.83$, $P<0.05$), indicating that once-anergized T cell re-proliferated and simultaneously produced RF. We then transferred either Vβ8$^+$CD4$^+$ T cell or Vβ8$^-$CD4$^+$ T cell from the mice immunized 12x with SEB into naïve mice. We found that Vβ8$^+$CD4$^+$ T cell, but not Vβ8$^-$CD4$^+$ T cell, induced RF ($P<0.001$), indicating that antigen-reactive CD4$^+$ T cell acquires the ability to induce autoantibodies. Further analyses showed that, among series of Va chains in the Vβ8$^+$CD4$^+$ T cell, a positive correlation existed between the selection of Vα13 chain and the level of RF ($r=0.87$, $P<0.05$), strongly suggesting that CD4$^+$ T cell with Vβ8$^+$Vα13$^+$ TCR induces RF.

Conclusion: We have tried to identify the TCR of *ai*CD4$^+$ T cell that induces autoantibodies in naïve recipients with 100% efficiency upon transfer, and identified that Vβ8$^+$Vα13$^+$ TCR is its candidate.

Disclosure: K. Yoshida: None; **K. Tsumiyama:** None; **S. Shiozawa:** None.

IL-23 Suppresses IL-22 Levels and AHR Expression in Human CCR6+ Memory T Cells. Ferry Cornelissen, Jan Piet van Hamburg, Nadine Davelaar, Patrick Asmawidjaja, Anne-Marie Mus and Erik Lubberts. Erasmus MC, University Medical Center

Background: Human CCR6+ T helper (Th) cells were shown to preferentially express the cytokines IL-17A and IL-22 (1). Recently, it became clear that within the CCR6+ Th cell population, cells are present which exclusively expressed IL-22 (2, 3). Although IL-23 and IL-1b are involved in the differentiation of naïve T cells towards effector CCR6+ Th cells (4), their role in the regulation of IL-17A and IL-22 expression by effector CCR6+ Th cells is unknown.

Objective: To investigate the role of IL-23 and IL-1b on the expression of Th17 specific cytokines by human memory CCR6+ Th cells.

Methods: CD4+CD45RO+CCR6+ T cells were FACS sorted from PBMC obtained from healthy individuals. These cells were cultured in the absence or presence of IL-23, IL-1b or the combination of IL-23+IL-1b. After culture, intracellular cytokine stainings for IL-17A, IL-22, and IFN-gamma were analyzed by flow cytometry. Cytokine levels of IL-17A, IL-22, and IFN-gamma were determined in the supernatant by enzyme-linked immunosorbant assay (ELISA). Semi-Quantitative RT-PCR was performed to analyse gene transcription of genes involved in Th differentiation and or function.

Results: IL-23 had no effect on the percentage of IL-17-positive and IFN-gamma-positive cells. However, IL-23 in contrast to IL-1beta significantly decreased the percentage of IL-22-positive CCR6+ memory T cells. This was mainly due to a significant reduction in the proportion of IL-22+IL-17A- and IL-22+IFN-gamma- T cells. In line with this, significantly lower IL-22 levels were found in the supernatant of CCR6+ T cells incubated with IL-23 and significantly lower expression of the transcription factor aryl-hydrocarbon receptor (AhR) in these cells. In contrast to IL-23, IL-1beta increased the percentage of both IL-17A-positive and IFN-gamma-positive CCR6+ T cells. However, the combination of IL-23/IL-1beta significantly and specifically increased the percentage of IL-17A+IL-22- and IL-17A+IFN-gamma- compared to IL-1beta alone, although the suppressive effect on IL-22-positive cells was not increased by this combination compared to IL-23 alone. Significant higher levels of IL-17A but also IFN-gamma were detected after incubation with IL-23/IL-1beta compared to IL-1beta alone. This latter may be due to an increase in IL-17A+IFN-gamma+ double positive CCR6+ memory T cells by IL-23/IL-1beta.

Conclusion: These data revealed that IL-23 specifically suppresses a Th22-like phenotype in CCR6+ memory T cells resulting in lower IL-22 levels and reduced AhR expression. Adding IL-1beta to IL-23 resulted in a specific increase of a Th17/IL-17A-like phenotype in CCR6+ memory T cells resulting in higher levels of IL-17A. However, the total IFN-gamma level was increased by IL-23/IL-1beta as well. These data suggest an important role for IL-23 in combination with IL-1beta in the regulation of human IL-17-positive and IL-22-positive memory T helper cells.

IL-23-Mediated RORγt Pathway Is Associated with Thymic Negative Selection of Autoreactive T Cells. Hao Li[2], Hui-Chen Hsu[2], Qi Wu[2], PingAr Yang[2], Jun Li[2] and John D. Mountz[1]. [1]Univ Alabama at Birmingham, AL, [2]Univ Alabama at Birmingham

Background: BXD2 mice develop erosive arthritis and high levels of autoantibodies. Spontaneously increased T_H-17 cells and IL-23 production by follicular dendritic cells have been found in the periphery of BXD2 mice. Since ROR gamma t (RORγt), the transcription factor downstream of IL-23, is expressed by CD4$^+$CD8$^+$ double positive (DP) thymocytes, we determined if IL-23 can regulate thymocyte selection via the RORγt pathway and if dysregulation of this pathway can be found in BXD2 thymus.

Methods: Thymii from B6, D^b/H-Y TCR transgenic (Tg), and BXD2 mice were analyzed. FACS analysis was carried out to determine the expression of IL-23R$^+$ and RORγt in subsets of thymocytes. TUNEL staining was carried out to determine apoptotic thymocytes. Subpopulations of different thymic cells were FACS sorted for qRT-PCR assay to determine the expression of *Il23, Il23r* and *Rorc*. *In vivo* overexpression of IL-23 was achieved by injection of mice with AdIL-23 using AdLacZ as the control (2×10^9 pfu/mouse, tail IV).

Results: D^b/H-Y Tg mice treated with an anti-IL-23 antibody exhibited a defect in thymic negative selection of H-Y specific T cells in male mice and

an increased proliferative response of self reactive spleen T cells to the H-Y antigen. AdIL-23 but not AdLacZ, injection to B6 mice lead to increased apoptosis (12.0±3.7% vs 1.4±0.3%) and a massive reduction of DP thymocytes ($18\pm3 \times10^7$ vs $4\pm1 \times10^7$) at day 5. This AdIL-23-induced thymocyte apoptosis response was partially prevented in RORγt$^{+/-}$ mice. Consistent with this, there was dramatically increased expression of IL-23R (24% vs 1%) and RORγt (15% vs 2%) in DP thymocytes of AdIL-23 vs AdLacZ injected mice at day 6. Autoimmune BXD2 mice exhibited upregulation of IL-23R on DP thymocytes and down-regulation of IL-23 production by thymic CD11C$^+$ dendritic cells compared with those in normal B6 mice. Consistent with this, there was lower IL-23 signaling *in vivo* indicated by a lower expression of RORγt in BXD2 thymocytes compared with B6 thymocytes at both the protein and the transcriptional levels. Administration of AdIL-23 resulted in upregulation of RORγt, leading to a 4-fold increase in apoptosis of DP thymocytes in BXD2 mice (20%) compared with that in B6 mice (5%) at day 3. Interestingly, CD4 single positive thmocytes in BXD2, but not B6 mice, failed to down-regulate IL-23R.

Conclusions: Our results reveal a novel function of IL-23 in that IL-23 can regulate thymocyte negative selection of autoreactive T cells via the RORγt pathway. The IL-23-mediated DP thymocyte apoptosis may be deficient in BXD2 mice, leading to the generation of autoreactive T cells. This is significant since it suggests that although IL-23 has a pro-autoimmune effect in the periphery, it has an opposite action in the thymus to prevent development of self-reactive T cells.

Immune Regulation by Peripheral Suppressor T Cells Induced upon Homotypic T Cell Interaction. Katja Thuemmler[1], Leipe Jan[1], Andreas Ramming[1], Hendrik Schulze-Koops[2] and Alla Skapenko[1]. [1]Division of Rheumatology, LMU Munich, Germany, [2]LMU Munich, Germany

The mechanisms by which regulatory T cells are generated in the periphery are incompletely understood. Interestingly, CD4 T cells up-regulate the expression of surface receptors specific for antigen-presenting cells during activation. The appropriate ligands of these receptors are physiologically expressed on resting CD4 T cells. Here, we tested the hypothesis, that activated T cells may interact with resting T cells and that this interaction results in the differentiation of the later.

CD4 memory T cells (responders) were cultured together with activated stimulator T cells. After five days of co-culture the phenotype and function of the T cells resulting from the responder cells was analyzed both in vitro and in vivo. The mechanisms underlying this homotypic T cell interaction were determined in co-cultures of activators and stimulators in the presence or absence of neutralizing antibodies to surface receptors.

Activated stimulator T cells induced proliferation and production of various cytokines in the responder T cells. Whereas Th1 stimulator T cells promoted the development of IL-10 and/or IFNγ producing cells, T cells cultured with Th2 cells produced IL-4. T cells induced upon homotypic T cell interaction expressed CD25 and reduced levels of CD127, and produced TGFβ. T-T cell communication is both, anchored and tuned through interaction of LFA-1 and its ligands ICAM-1, ICAM-2 and ICAM-3. Blocking of ICAM-1 diminished IFNγ production, whereas ICAM-3 was important for IL-4 secretion. Functionally, homotypic T cell interaction-induced T cells were anergic and inhibited the proliferation of CD25 negative T cells as potently as natural occurring CD25 Tregs in vitro. The inhibitory effect was partly contact dependent and partly dependent on IL-10 secreted after T cell interaction. Moreover, in vitro generated T-T cell induced T cells with a TCR specific for OVA prevented clonotypic expansion of OVA TCR transgenic T cells in BALB/c mice upon antigen challenge in vivo.

Together, the data suggest a negative feedback mechanism of specific immunity involving bystander-activated memory T cells.

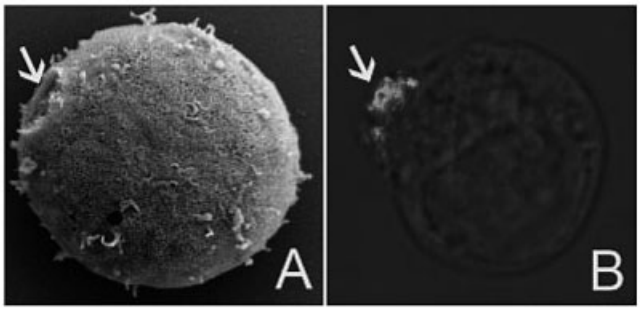
Late Complement Complex in T Cell Function and Cell Death. Anil Chauhan[1], John P. Atkinson[3] and Terry L. Moore[2]. [1]Saint Louis University, [2]St Louis University, St Louis, MO, [3]Washington University School of Medicine, St Louis, MO

Purpose: Recently, complement systems role in T cell modulation has been suggested. Excessive complement activation results in cell death due to the formation of membrnae attack complex (MAC). Lysis of nucleated cells by MAC is explained by the "multi hit hypothesis" that suggests formation of a large number of holes. We tested this hypothesis in human naïve CD4$^+$ T cells by in situ assembly of MAC using purified C5b-6, C7, C8 and C9. Scanning electron microscopy (SEM) and confocal imaging revealed formation of MAC on a single site. Thus, we hypothesize that due to strong affinity of C9 for membrane phopsholipids, sublytic MAC deposit resulted in reorganization of the T cell membrane. This resulted in the formation of a functional 'IS' synapse-like structure by lateral clustering of membrane rafts (MR). Thus, we explored the role of the structure formed by MAC in T cell physiology such as calcium channels, cell activation, proliferation and death.

Methods: MAC was assembled on human CD4$^+$T cells by treating with equimolar ratio of purified late complement proteins along with fifteen molar excess of Alexa 594 labeled C9 protein. These cells were then examined for alteration in membrane structures by confocal and SEM. MR in these cells were localized using cholera toxin B-FITC. Cell proliferation was studied with CFSC labeling and T cell activation by traditional methods. Calcium mobilization was examined using Fura-2 dye.

Results & Conclusions: Unlike present belief of multiple MAC generated holes in erythrocytes, in human T cells, MAC deposited on a single site. The SEM images showed a single hole surrounded by dense structures (A). These structures were also seen in confocal images (B).



The site of MAC was also the site of MR accumulation and formation of synapse-like structures. Signaling protein microclusters accumulated at this site and were phosphorylated. Such structures are also implicated in the function of NK cells. Sublytic doses of MAC trigger a number of events such as DNA synthesis, upregulation of cell cycle associated cyclins, CDK2, growth factors and proto-oncogenes such as NF-κB, c-jun, c-fos, jun-D, and protein kinase C. We have shown that in T cells these structures may participate in activation of the T cell receptor in the presence of immune complexes. However, in lytic doses of MAC, these structures that support cell function result in collapse of cell integrity, thus lysing the cell. Thus, we propose that ICs and MAC participate in the outcome of T cell differentiation by triggering and enhancing T cell activation. Complement activation and altered T signaling are observed in SLE. Here we link immune reactants observed in disease to the cells of adaptive immunity. Better understanding of these processes will allow us to delineate the disease process and design better therapeutic interventions.

Linking Power Doppler Ultrasound with Th17 Cells in the RA Joint. Nicola J. Gullick[1], Hayley G. Evans[2], Leigh Church[3], David Jayaraj[2], Andrew Filer[3], Bruce W. Kirkham[4] and Leonie S. Taams[2]. [1]CMCBI, King's College London, London, United Kingdom, [2]CMCBI, King's College London, [3]Rheumatology Research Group, University of Birmingham, [4]Rheumatology, Guy's & St Thomas' NHS Foundation Trust

Introduction: Power Doppler ultrasound (PDUS) is increasingly used to assess synovitis in Rheumatoid Arthritis (RA). Prior studies have shown correlations between PDUS scores and vessel counts, but relationships with immunopathology have not been described. This study investigated the presence of Th1, Th17 and TNFα producing CD4+ T cells in peripheral blood (PB), synovial fluid (SF) and synovial tissue (ST) from RA patients and related these data to PDUS scores of either single or multiple joints.

Methods: PB mononuclear cells were isolated from healthy controls or RA patients and stimulated with PMA and ionomycin for 3 hours in the

presence of Golgistop. Paired SF were analysed where available (n=21). ST was obtained at arthroscopic synovial biopsy from six RA patients. Synovial blood flow was evaluated by power Doppler (PD) signal at 10 metacarpophalangeal (MCP) joints, wrists and knee joints. PD signals were graded on a semi-quantitative scale from 0 to 3 (where 0 = no synovial flow; 1 < 25% signal within ST; 2 = 25–50% signal; 3 >50% signal). Intracellular expression of IL17, IFNγ, and TNFα was determined by multicolour flow cytometry. Serum, SF and fibroblast culture levels of vascular endothelial derived growth factor-A (VEGF-A) were assessed by ELISA.

Results: Th17 cells and dual IFNγ/IL-17-expressing cells but not Th1 cells are increased in PB of RA patients vs. healthy controls. These cells are further enriched in both SF and ST relative to PB. The percentage of PB Th17 cells did not correlate with systemic parameters of disease. The percentage of Th17 cells, but not Th1 cells, in SF positively correlated with CRP (r=0.51, p=0.03) and local PDUS-defined synovitis (r=0.62, p=0.003), suggesting a specific role for Th17 cells in active synovitis in RA. Patients with high levels of IL-17+ CD4+ T cells in SF display increased levels of vascular endothelial growth factor-A (VEGF-A) in SF; this was not observed for IFNγ+ T cells. The addition of IL-17 but not IFNγ increased VEGF-A production by RA synovial fibroblasts *in vitro*.

Conclusion: Our data demonstrate a link between the presence of highly inflammatory Th17 cells and RA disease activity assessed by PDUS scores, and offer a novel immunological explanation for the clinical observation that rapid joint damage progression occurs in patients with persistent positive PDUS signal. Furthermore, our findings highlight PDUS as a possible surrogate marker of Th17 cells, which may identify patients who would benefit from early, aggressive therapy, including IL-17 antagonists.

NKT Cell Is Required for the Break of T Cell Anergy, Inducing Autoantibody, and Generation of Autoantibody-Inducing CD4$^+$ T Cell That Causes Systemic Autoimmunity. Yuko Fujita[1], Ken Tsumiyama[2] and Shunichi Shiozawa[3]. [1]Depertment of Biophysics, Kobe University Graduate School of Health Science, Kobe, Japan, [2]Depertment of Biophysics, Kobe University Graduate School of Health Science, Kobe, Japan, [3]Depertment of Biophysics, Kobe University Graduate School of Health Science/Depertment of Medicine, Kobe University Graduate School of Medicine/The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan

Objective: With regards to how autoantibody-inducing CD4$^+$ T (*ai*CD4$^+$ T) cell is induced, which is the key as the cause of systemic autoimmunity including SLE, we consider the recovery from anergy as the essential step in generating *ai*CD4$^+$ T cell. Here, we studied the contribution of NKT cell to the break of anergy, induction of autoantibodies, and generation of *ai*CD4$^+$ T cell.

Methods: BALB/c mice were repeatedly immunized with staphylococcal enterotoxin B (SEB), staphylococcal enterotoxin A (SEA) and/or α-galactosylceramide (α-GC). SEB stimulates NKT cell and T cells, whereas SEA stimulates only T cells. Mice were also immunized 2x with SEB to induce T cell anergy, and then repeatedly immunized with α-GC. Further, spleen cells of naïve BALB/c mice were stimulated with α-GC *in vitro*, and supernatant from α-GC-activated NKT cells herein termed NKT-sup. This NKT-sup was repeatedly immunized in CD1d KO mice, following immunization 2x with SEB to induce T cell anergy. Spleen cells were stimulated *in vitro* with SEB, and IL-2 and mitotic events were measured. Autoantibodies, phoshorylation of ZAP70, LAT, Akt, the expression of Cbl-b and Ca^{2+} influx in T cell were examined.

Results: The T cells of the mice immunized 2x with SEB were rendered into anergy. However, after further immunization 8x with SEB, this once-anergized T cells were re-activated from anergy to resume IL-2 production and proliferation. This re-activation was accompanied by induction of RF and anti-Sm antibody in 100% of mice, and this property can be transferred by CD4$^+$ T cells into naïve recipients, thereby *ai*CD4$^+$ T cells are generated. Phosphorylation of ZAP70, LAT and Akt and Ca^{2+} influx were inhibited in anergic T cells of the mice immunized 2x with SEB as compared with PBS-immunized control. However, this inhibition was released after immunization 8x with SEB. Further, expression of Cbl-b, an anergy-inducible protein, was increased in the T cell of mice immunized 2x with SEB. The Cbl-b was subsequently down-regulated after further immunization 8x with SEB. As to the contribution of NKT cell to the break of T cell anergy and the generation of *ai*CD4$^+$ T cell, we found that spleen cells of mice immunized 8x with SEA neither induced RF nor secreted IL-2 because SEA did not activate NKT cell. When α-GC, a specific ligand for NKT cell, was co-immunized 8x with SEA, the once-anergized T cell was recovered from anergy and began to secrete IL-2 and RF and resume proliferation. Sole 2x immunization with SEB followed by 8x immunization with α-GC was also sufficient for the break of T cell anergy and induction of RF. Further, the once-anergized T cells of CD1d KO mice lacking NKT cells could be recovered from anergy after 2x immunization with SEB followed by 8x treatment with the NKT-sup, a supernatant of α-GC-activated NKT cells. These results indicate that the NKT cells and its effector molecule can break T cell anergy and induce autoantibodies, finally leading to the induction of *ai*CD4$^+$ T cells.

Conclusion: We show that the activation of NKT cell is indispensable for the re-activation of once-anergized T cell and the induction of autoantibodies, finally leading to the generation of *ai*CD4$^+$ T cell that causes systemic autoimmunity.

Peroxisome Proliferator-Activated Receptor α and γ Agonists Together with TGF-β Convert Human CD4$^+$CD25$^-$ T Cells into Functional Foxp3$^+$ Regulatory T Cells. Hitoshi Hasegawa[1], Jin Lei[2], Takuya Matsumoto[2] and Masaki Yasukawa[2]. [1]Ehime University Graduate School of Medicine, Toon, Ehime, Japan, [2]Ehime University Graduate School of Medicine

Background: Regulatory T cells (Treg) play a crucial role in the prevention of autoimmune diseases. Human peripheral CD4$^+$CD25$^-$ T cells can be induced to express Foxp3 after TCR activation in the presence of TGF-β, but the induced cells (iTreg) lack a regulatory phenotype. Human T cells require multiple stimulations to become a regulatory phenotype. Moreover, induction of functional human Treg cells would have therapeutic implications. Therefore, we screened molecules that would enhance the TGF-β-induced conversion of human CD4$^+$CD25$^-$ T cells into functional Treg cells.

Methods: We obtained three peroxisome proliferator-activated receptor (PPAR)α agonists (bezafibrate, GW7647, and 5,8,11,14-eicosatetraynoic acid) and two PPARγ agonists (ciglitazone and 15-deoxy-prostaglandin J_2) as molecules that increased Foxp3 expression in human iTreg cells from lipid and nuclear receptor ligand libraries. We analyzed the mechanism by which human CD4$^+$CD25$^-$ T cells are converted to functional Treg cells by PPARα and PPARγ agonists together with TGF-β.

Summary of the Results: These PPARα and PPARγ agonist-treated iTreg cells maintained a high level of Foxp3 expression and had suppressive properties. There were no significant differences in the suppressive properties of iTreg cells treated with the three PPARα and two PPARγ agonists, and all of the treated iTreg cells increased the demethylation levels of the Foxp3 promoter and intronic CNS3 regions significantly compared with the control iTreg cells. Furthermore, both PPARα and PPARγ agonists together with TGF-β inhibited more strongly the expression of all three DNA methyltransferases (DNMTs), DNMT1, DNMT3a, and DNMT3b, in activated CD4$^+$ T cells. These results demonstrate that PPARα and PPARγ agonists together with TGF-β elicit Foxp3 DNA demethylation through potent down-regulation of DNMTs and induce potent and stable Foxp3 expression, resulting in the generation of functional iTreg cells. In contrast, there are no differences of cytokine productions such as IL-10 and TGF-β between control and PPAR agonist-treated T cells. PPARγ produced retinoic acid (RA) in human blood monocyte-derived DCs. Addition of PPARγ agonist in the presence of TGF-β may generate antigen-specific Treg cells such as ANCA-associated vasculitis more efficiently upon coculture with antigen-pulsed DC through a RA-dependent mechanism and epigenetic regulation of the Foxp3 gene.

Conclusions: PPAR agonists converted human CD4$^+$CD25$^-$ T cells into functional Foxp3$^+$ regulatory T cells and may be benefical for the treatment of human autoimmune diseases.

Phenotype and Functional Stability of TGF-β-Induced CD4+Foxp3+ Regulatory T Cells in Steady and Inflammatory States. NIng Kong[3], Julie Wang[3], David Brand[4], Hejian Zou[1], Xuezhong Yu[2] and Song Guo Zheng[3]. [1]Fudan University Medical School, [2]H. Lee Moffitt Cancer Center and Research Institute, [3]USC Keck School of Medicine, [4]VA Medical Center, Memphis

Background: Although both natural CD4+Foxp3+ regulatory T cells (nTregs) and TGF-β-induced CD4+Foxp3+ regulatory T cells (iTregs) share many similar phenotypes and biological activities in the prevention of autoimmune diseases, recent studies from several groups observed that Foxp3 expression by iTregs is unstable and adoptive transfer of these cells had poorly therapeutic effect on acute GVHD model in animal although these cells prevented and even treated other autoimmune diseases in animal models. Here we try to determine the phenotype and functional characteristics of iTregs in the steady and inflammatory states.

Methods: iTregs were induced from naive CD4+ cells with IL-2, TGF-β and anti-CD3/CD28 beads or plate-bound anti-CD3 and soluble anti-CD28 antibodies. nTregs were isolated from splenocytes of foxp3-GFP knock in mice and expanded with IL-2 and anti-CD3/CD28 beads. 0.5×106 both Tregs were transferred to SCID mice. The mice were sacrificed in one and two months after adaptively transfer. 5×106 Tregs from DBA1/J mice labeled with CFSE were adaptively transferred to normal or established collagen induced arthritis (CIA) mice and the mice were sacrificed in one, three and six weeks for monitoring donor Treg fates.

Results: In SCID mice, both Tregs had the similar Foxp3 expression (near to 50%) in one and two months after cell transfer. In addition, both Treg subsets maintain the similar levels of Foxp3 expression (about 40%) in one month after transfer to naïve mice. Both nTregs and iTregs donor cells sorted from recipient mice in three weeks after transfer displayed the similar suppressive activities. We observed that suboptimal TCR stimulation was required for the maintenance of Foxp3 expression by iTregs. Of great interest, nTregs but not iTregs in the spleens, particularly in draining lymph nodes mostly lost Foxp3 expression only one week after cell transfer to established arthritis mice. Conversely, iTregs not only maintained Foxp3 expression but also induced more Foxp3+ cells in recipient mice compared to CIA mice received nTregs. We further observed that adoptive transfer of iTregs but not nTregs significantly suppressed the progression of the established arthritis.

Conclusions: iTregs are as stable as nTregs in immune deficient and normal states, and are more stable and functional than nTregs in an inflammatory milieu. We therefore conclude that manipulation of iTregs may have an advantage to treat the autoimmune diseases and inflammatory diseases.

Plasmacytoid Dendritic Cells Control Peripheral Treg Conversion to the RNA-Binding Nuclear Self Antigen La/SS-B. A. Darise Farris[1], Christina Lawrence[2] and Zi-jian Pan[2]. [1]Arthritis and Immunology Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK

Background: RNA-binding nuclear antigens are a major class of autoantigen targeted in systemic autoimmune diseases. Serologic tolerance to the RNA binding antigen human La/SS-B (hLa) is controlled primarily by $CD4^+$ T cells in transgenic (Tg) mice expressing hLa gene under its natural promoter. The goal of the present study was to uncover peripheral mechanisms of T cell tolerance to this RNA-binding nuclear antigen.

Methods: Genetically marked splenocytes of $TCR\alpha^{-/-}$ 3B5.8 T cell receptor transgenic (TCR Tg) mice, in which essentially all $CD4^+$ T cells are specific for an $I\text{-}E^k$-restricted, immunodominant T cell epitope of hLa (hLa 67–76) but do not recognize the mouse La antigen, were transferred into lymphocyte replete hLa Tg and non-Tg recipients and their phenotype assessed after retrieval from recipients. Impacts of recipient B lymphocytes, plasmacytoid dendritic cells (pDC), and Type I interferon receptor (IFNAR1) on donor T cell phenotype were assessed by administration of depleting or blocking monoclonal antibodies to recipient mice prior to and following transfers.

Results: Donor $CD4^+$ T cells of both $CD25^-Foxp3^+$ and $CD25^+Foxp3^+$ phenotypes were present in hLa Tg recipients on day 7 post-transfer and were absent in recipients that lacked expression of the hLa neo-self antigen. Donor cells retrieved from hLa Tg recipients were hyporoliferative and produced elevated levels of IL-10 following *in vitro* stimulation with irradiated splenocytes and hLa 61–84 peptide compared to donor cells retrieved from control recipients that lacked expression of hLa. Recipient pDC but not B cells directed the appearance of Foxp3-expressing donor T cells in hLa Tg recipients. Both conventional (c) DC and pDC purified from hLa Tg mice presented the hLa epitope constitutively as revealed by their capacity to stimulate IL-2 secretion from a hLa 67–76-specific T cell hybridoma. Treatment of hLa Tg recipients with an IFNAR1-blocking antibody resulted in significantly fewer $Foxp3^+$ donor T cells at day 7 compared to recipients treated with an isotype control antibody.

Conclusions: These studies suggest that peripheral differentiation of antigen-specific $Foxp3^+$ Treg is a mechanism of T cell tolerance to a representative RNA-binding nuclear antigen and that pDC play an important role in this process.

Protective Human CD4+CD25+FOXP3+ Regulatory T Cells Generated Ex-Vivo with IL-2, Retinoic Acid and TGF-bets Are Resistant to Pro-Inflammitory Cytokines. Xiaohui Zhou[1], Chin Lan[1], Juhua Wang[1], Song-guo Zheng[1] and David A. Horwitz[2]. [1]University of Southern California, [2]University of Southern California, Los Angeles, CA

Purpose: The stability of CD4+CD25+ Foxp3+ regulatory T cells (Tregs) under inflammatory conditions has been questioned. These Tregs may lose Foxp3 and acquire proinflammatory effector functions. Therefore, for Tregs to be used as a potential T cell therapy, they must not only be functionally competent, but also resistant to proinflammatory conversion. We have previously reported that CD4 Tregs induced with IL-2 and TGF-β (iTregs) are resistant to conversion and our objective has been to generate similar Tregs using human naïve CD4+ cells. We have previously reported that human iTregs generated with IL-2, TGF-β and retinoic acid become fully functional Tregs in one week. Here we compare the functional properties of iTregs with expanded endogenous CD4regs after treatment with proinflammatory cytokines

Methods: Naïve human CD4+ cells prepared by negative selection were suboptimally TCR activated for 6 days with anti-CD3/28 coated beads with IL-2, TGF-β1 and all-trans retinoic acid (atRA). Autologous CD4+CD25hi cells (nTregs) were also isolated and expanded with high dose IL-2 and rapamycin. Both iTregs and nTregs were then re-stimulated with with IL-1β and IL-6 and low IL-2 to bring out the inhibitory effects of these proinflammatory cytokines, the Treg subsets were examined for phenotype and function. To assess *in vivo* suppressive activity, sublethally irradiated NOD SCID IL-2R γ $chain^{-/-}$ (NOG) mice were injected IV with human CD25 depleted PBMC and various Treg subsets.

Results: After 6 to 10 days of TCR stimulation with IL-2 and TGF-β and atRA naïve CD4+ cells had become CD25+ CD127lo, CD45RA-/RO+, DR+, Foxp3+ cells that were anergic, produced low amounts of IL-2 and IFN-γ and exhibited strong in vitro suppressive activity. These cells protected NOG mice from a human xeno-GVHD as well as expanded nTregs. After restimulation of iTregs and nTregs with IL-1β and IL-6 nTregs Foxp3 and other Treg markers were down-regulated whereas these markers expressed by atRA/TGF-β induced iTregs were stable. While the protective effects of restimulated iTregs and nTregs was equivalent, the protective effects of nTregs treated with IL-1β and IL-6 decreased and was significantly less than iTregs.

Conclusion: These studies suggest that atRA TGF-β are not only important in the generation of iTregs, but also confer resistance when they are present in an inflammatory milieu.

RANKL Expression in Human T-Lymphocytes Requires Cooperative Signaling through the T-Cell Receptor and Adhesion Molecule CD2. Bohdan P. Harvey and Zehra Kaymakcalan. Abbott Laboratories, Worcester, MA

Purpose: T-lymphocytes contribute to osteolysis in rheumatic diseases through their production of the osteoclastogenic cytokine RANKL. Mitogenic stimulation of lymphocytes has been shown to induce expression of RANKL;

however, the extracellular events leading to its production have not been identified. We sought to determine whether cell-to-cell interactions through adhesion molecules such as lymphocyte function-associated antigen 2 (CD2) were necessary to promote RANKL secretion from T-cells following T-cell receptor (TCR/CD3) engagement.

Methods: Healthy donor PBMC was isolated by Ficoll gradient. Human CD4+ and CD8+ T cells were purified by negative magnetic bead selection method. PBMC samples from rheumatoid arthritis (RA) patients were obtained from Conversant Healthcare Systems. Cells were cultured in medium supplemented with 2% human serum, IL-2, IL-7, M-CSF and 1alpha,25-dihydroxyvitamin D3 in the presence of various combinations of bead bound anti-CD3, anti-CD2 and anti-CD28 (co-stimulatory receptor) antibodies for 4 days. Total RANKL was determined in culture supernatants by osteoprotegrin (OPG) capture sandwich ELISA, and remainder of supernatants were used in Meso Scale Discovery Multi-spot assay system to evaluate the levels of IFN-γ, TNF-α, IL-10, IL-4, IL-8 and IL-13. T-cell activation was determined by flow cytometry using CD69 and CD25 as markers.

Results: RANKL secretion by healthy donor PBMC was first detected after 72 hr incubation with anti-CD3/CD2/CD28 antibody coated beads with maximal secretion levels being reached following 96 hr. Anti-CD3/CD28 antibody coated beads failed to induce detectable levels of RANKL. When purified T-lymphocyte subsets were evaluated, both CD4+ and CD8+ T-cells produced RANKL only in response to the combined cross-linking of CD3 and CD2 whereas cross-linking of CD3 and CD28 was insufficient to promote RANKL expression even though the T-cells were activated based on the high levels of CD69 and CD25. Those conditions (anti-CD3/CD2) that led to increased RANKL secretion induced significantly lower levels of TNF-α, IL-4, IL-8 and IL-13 as compared to the combinations of anti-CD3/CD28 or anti-CD3/CD2/CD28 antibodies. The combination of anti-CD2 and anti-CD28 antibodies neither induced RANKL secretion nor led to the activation of T-cells. PBMC from RA patients also secreted RANKL in a CD3/CD2-dependent manner and at levels similar to PBMC from healthy donors.

Conclusions: Our results clearly demonstrate that T-lymphocytes (both CD4 and CD8 subsets) can generate RANKL following the co-ligation of the TCR/CD3 and the adhesion molecule CD2 in the absence of the co-stimulatory receptor CD28, suggesting that interactions between T-cells and non-traditional APCs, such as synovial fibroblasts, could lead to the production of osteoclastogenic cytokines without the need for other co-stimulatory signals. Interestingly, the cross-linking of CD3 and CD2 induced RANKL secretion with minimal impact on most of the inflammation-associated cytokines, indicating that RANKL expression is activated by a signaling cascade(s) separate from most other cytokines.

1270

Regulation of Human T Cell Activation and Effector Functions by Kv1.3 and KCa3.1 Channels. Gang Chen[1], Vaishali Patel[1], Rothschild Soto[2], Chen Shiow-Ling[2], Sandip Panicker[2], Philip A. Nunn[2] and Julie A. DeMartino[2]. [1]Inflammation Discovery, Hoffmann-La Roche, Inc., Nutley, NJ, [2]Inflammation Discovery, Hoffmann-La Roche, Inc.

Purpose: KCa3.1 and Kv1.3 are major potassium (K+) channels expressed in T cells that have been suggested to play essential roles in the activation and effector functions of central memory T cells (Tcm) and effector memory T cells (Tem), respectively. The goal of this study is to understand the relative contribution of these two K+ channels in human CD4+ T cell effector functions.

Methods: Selective small molecule inhibitors of KCa3.1 [TRAM-34, Icagen 17043 (Ica)], the Kv1.3-selective peptide inhibitor ShK(L5) and a CRAC channel inhibitor RO6712 were used in this study. The responsiveness of primary human T cells to K+ channel blockade was examined in the following manner: 1) Human mixed lymphocyte reaction: responder PBMC were co-cultured with Mitomycin C-treated stimulator PBMC for 4 days. Cell proliferation was measured by 3H-thymidine incorporation; 2) CFSE proliferation: Purified human CD4+ T cells or sorted Tem cells (CD45RA-CCR7-) were labeled with CFSE, pre-treated with the compounds and then stimulated with plate bound anti-CD3/CD28 for 3 days. 3) Cytokine secretion: compound-treated PBMC were stimulated with plate-bound anti-CD3/CD28. Then the levels of IL-2 and IFN-γ were measured in AlphaLISA assays. In a separate experiment, activated CD4+ T cells were re-stimulated with anti-CD2/CD3/CD28 coated beads for 20 hours. 4) For electrophysiological assays, purified human CD4+ T lymphocytes were stimulated for 48 hours using anti-CD3/CD28 coated beads in the presence of IL-2. Cells were then tested for the presence of KCa3.1 and K_V1.3 currents using the whole cell voltage clamp method on either the standard manual rig or an automated electrophysiological platform (QPatch).

Results: First, we found that neither resting Tem nor total CD4+ T cell proliferation could be fully blocked by TRAM-34, Ica or ShK(L5) alone. However, the combination of TRAM-34 or Ica with ShK(L5) could completely suppress resting T cell proliferation and cytokine production in the context of anti-TCR stimulation and MLR. In activated T cells, KCa3.1 blockade was able to suppress IL-2 production significantly. In addition, blockade of both Kv1.3 and KCa3.1 channels exerted similar extent of inhibition on T cell proliferation and cytokine production as CRAC channel blockade. Lastly, electrophysiological analysis showed that activated CD4+ T cells exhibited potassium currents consisting of varying contributions from both channels. Further analysis on the effect of K+ channel blockade on T cell calcium influx will be necessary.

Conclusion: We have demonstrated that in human CD4+ T cells, KCa3.1 and Kv1.3 function in concert in the regulation of the optimal activation and effector functions, possibly through maintaining a sustained CRAC current in these cells. Electrophysiological findings confirmed that human primary CD4+ T cells exhibit varying contributions of potassium flux from both Kv1.3 and KCa3.1 channels. Our data strongly suggest that in human inflammatory diseases driven by pathogenic T cells, targeting both KCa3.1 and Kv1.3 channels simultaneously could potentially provide therapeutic benefit to patients.

1271

Role for IL-23 in Differentiation of Human Th17 Cells. Hiroshi Kato[1], Laura Cooney[2], Judith Endres[2] and David A. Fox[3]. [1]University of Michigan, Northville, MI, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan Medical Center, Ann Arbor, MI

Purpose: Th17 cells, which are crucial in host defense, play significant roles in many autoimmune diseases, including RA. In mice, the combination of TGF-beta and IL-6 induces Th17 cells from naive CD4T cells. Whereas TGF-beta was shown to also be essential for human Th17 differentiation, it is unclear what additional pro-inflammatory cytokines are required to induce human Th17 cells. We proposed that IL-23 was dispensable for human Th17 cell differentiation given the expression of IL-23 receptor only after induction of ROR-gammat (master regulator gene of Th17 cells) in mice.

Method: Naive CD4T cells were isolated from peripheral blood mononuclear cells (PBMCs) from healthy adult donors by a naive CD4T cell enrichment kit, and were cultured in RPMI culture media with 10%FCS, 1% Penicillin/Streptomycin, and 2% L-glutamine, with beads coated with anti-CD3/CD28 antibodies, anti-IFN-gamma and IL-4 antibodies (5ug/ml), TGF-beta (0.1, 1 or 10ng/ml), IL-1 (5ng/ml), IL-6 (10ng/ml), and IL-23 (0, 1 or 10ng/ml). Cells were collected on day 5 and incubated for 6h with phorbol ester and ionomycin followed by GolgiPlug. After blocking Fc receptors, cells were fixed, permeabilized in PBS containing 0.5% Saponin, and stained with Phycoerythrin conjugated antibodies against IL-17A, IL-17F, IL-21, or IL-22. IL-17A in culture supernatants was measured by ELISA. On day 3, total cellular RNA was extracted to synthesize cDNA. Expression of ROR-c was assessed by RT-Q-PCR with GAPDH as a reference gene.

Results: Analysis of ELISA data from healthy subjects (n = 5) showed that IL-17A induction was more IL-23 dependent in lower TGF-beta: 0.1ng/ml; 162.8+/−70.2pg/ml (no IL-23), 233.9+/−133.0pg/ml (IL-23: 1ng/ml), 377.4+/−249.6pg/ml (IL-23: 10ng/ml) than in higher TGF-beta: 1ng/ml; 245.0 +/−115.4pg/ml (no IL-23), 338.1+/−168.0pg/ml (IL-23: 1ng/ml), 320.6+/−155.2pg/ml (IL-23: 10ng/ml). ROR-c expression was IL-23 dependent at TGF-beta concentrations of either 0.1ng/ml or 1ng/ml, but was IL-23 independent in 10ng/ml TGF-beta. These data indicate that the role of IL-23 in contributing to human Th17 differentiation varies depending on the concentration of TGF-beta. On flow cytometry, induction of IL-17A+ and IL-22+ cells was relatively independent of the concentration of IL-23. However, induction of IL-17F+ cells was more IL-23 dependent in lower TGF-beta: 0.1ng/ml whereas induction of IL-21+ cells was more IL-23 dependent in higher TGF-beta: 1ng/ml.

Conclusion: Contrary to initial predictions, our data suggest that IL-23 might promote human Th17 differentiation either through distinct mechanisms that are in part independent of TGF-beta or through contribution to low TGF-beta driven pathway. Furthermore, each Th17-derived cytokine may be differentially regulated by IL-23. The level of secretion of Th17 cytokines is not entirely predictable by enumeration of Th17 cells that contain a specific cytokine intracellularly.

Self-Organized Criticality Theory for the Cause of Autoimmunity. Ken Tsumiyama[1], Yumi Miyazaki[1] and Shunichi Shiozawa[2]. [1]Department of Biophysics, Kobe University Graduate School of Health Science, Kobe, Japan, [2]Department of Biophysics, Kobe University Graduate School of Health Science/Department of Medicine, Kobe University Graduate School of Medicine/The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan

Objective: Since 'clonal selection theory of immunity' of F. Macfarlane Burnet and subsequent molecular biological discoveries on V(D)J recombination and the diversity and individuality of immune response, how autoimmunity arises remains unclear. Apart from the term 'autoimmunity' which is now ready-made, in the present study, we tried to see the pathogenesis of autoimmunity from different angle and test the integrity of immune 'system'. The method we have chosen was to stimulate the system maximally by antigen to the levels far beyond its steady-state. In a perfectly reproducible experiments in which the mice not prone to autoimmune diseases were immunized repeatedly with antigen, we have discovered that overstimulation of immune system beyond its self-organized criticality inevitably leads to systemic autoimmunity akin to systemic lupus erythematosus (SLE). We now show that autoimmunity arises not from 'autoimmunity', but as a natural consequence of normal immune response when stimulated maximally beyond system's self-organized criticality.

Methods: BALB/c mice were repeatedly immunized with a conventional antigen such as ovalbumin (OVA), keyhole limpet hemocyanin (KLH) or staphylococcal enterotoxin B (SEB). Autoantibodies including rheumatoid factor (RF), anti-Sm and anti-dsDNA antibody and immune complex (IC) in sera were detected by using ELISA. Tissue injury was assessed by the detection of proteinuria and IC deposition in glomeruli, histopathological study and lupus band test. Splenocytes of mice repeatedly immunized with antigen were adoptively transferred into naïve mice, and the induction of autoantibodies and tissue injury in recipients were examined. Further, we also examined the T cell receptor (TCR) revision in spleen, maturation of $CD8^+$ T cell and antigen cross-presentation in dendritic cell (DC).

Results: Repeated immunization with antigen caused systemic autoimmunity in mice otherwise not prone to spontaneous autoimmune diseases. Overstimulation of $CD4^+$ T cells led to the development of a fully-matured autoantibody-inducing $CD4^+$ T cell type (*ai*$CD4^+$ T cell) which had undergone T cell receptor (TCR) revision and was capable of inducing autoantibodies. The *ai*$CD4^+$ T cell was induced by *de novo* TCR revision but not by cross-reaction to immunizing antigen, and subsequently overstimulated $CD8^+$ T cells, driving them to become MHC class I-restricted, antigen-specific cytotoxic T lymphocytes (CTL). These CTLs could be further matured by antigen cross-presentation, after which they caused autoimmune tissue injury. In fact, autoimmune tissue injury did not appear in $CD8^+$ T cell-deficient mice after repeated immunization with antigen. Further, inhibition of antigen cross-presentation by treating with chloroquine abrogated the generation of CTL and autoimmune tissue injury.

Conclusion: We show that systemic autoimmunity appears to be the inevitable consequence of over-stimulating the host's immune 'system' by repeated immunization with antigen, to the levels that surpass system's self-organized criticality. Thus, we propose here 'self-organized criticality theory' explaining the cause of autoimmunity.

SGN-70: Phase 1a Study of a Novel Humanized Antibody Targeting CD70 for the Treatment of Autoimmune Diseases. Jonathan G. Drachman[2], Julie A. McEarchern[2], Che-Leung Law[2], Luis Lopez-Lazaro[1], Gabriele Fabian[1] and Michael Seiberling[1]. [1]Covance Clinical Research Unit AG, Basel, Switzerland, [2]Seattle Genetics, Inc., Bothell, WA

Background: SGN-70 is a humanized IgG1 monoclonal antibody with high affinity for CD70 which can deplete CD70-positive cells via antibody effector mechanisms and can also block interaction of CD70 with its cognate receptor, CD27. CD70, a tumor necrosis factor family member, is expressed on activated T-cells, B-cells, and mature dendritic cells and co-stimulates immune responses. Based on these activities and preclinical studies, SGN-70 could reduce inflammation by targeting CD70+ immune cells while leaving the resting immune system intact.

Methods: A single-dose, dose-escalation, randomized, double-blind, placebo-controlled clinical trial was conducted in healthy volunteers (N=61) to evaluate safety, tolerability, PK, immunogenicity, and pharmacodynamic effects. Blood samples and clinical symptoms were collected for 50 days. Subsequently, a cohort of patients (N=8) with mild-moderate plaque psoriasis were evaluated at a single dose level. Upon randomization, 6 patients received SGN-70 (10 mg/kg) and 2 received placebo. This trial was conducted at a single site in Switzerland.

Results: SGN-70 was well tolerated over a wide dose range (0.0001 – 10 mg/kg) when administered without premedication as a single intravenous injection over 30 minutes (first 3 cohorts) or 60 minutes (higher dose levels). There were no serious adverse events or significant changes in laboratory values, vital signs, or ECGs, and a maximum tolerated dose was not established. Among healthy volunteers, the most frequent adverse events were URI symptoms, headache, and fatigue, which appeared to be balanced between treated and placebo subjects. Both Cmax and AUC appeared to increase linearly with dose level whereas terminal half-life increased at the highest dose levels. This resulted in a mean terminal half-life of 6–7 days for doses up to 1 mg/kg and 10 or 13 days at 3 mg/kg and 10 mg/kg, respectively. Low titer anti-therapeutic antibodies were detected in some subjects, but the effect of repeat dosing could not be assessed. In both the healthy volunteers and the psoriasis patients, a decrease in CD70+ B- and T-cells from peripheral blood could be demonstrated by qPCR or flow cytometry. Although the psoriasis patients had generally mild disease and were not eligible for more than 1 dose, preliminary evidence suggests that at least two of six patients experienced decreased skin thickness and cytokeratin 16 expression as well as modest improvement in PASI scores.

Conclusions: SGN-70 is well tolerated up to 10 mg/kg and has on-target pharmacodynamic activity when administered as a single dose. Based on the novel mechanism of action and ability to impact multiple arms of the activated immune system, this is a promising novel monoclonal antibody for rheumatologic and autoimmune diseases that warrants further evaluation in a multi-dose clinical trial.

1274

Vitamin D Suppresses the Pathogenic Behavior of Primary Th17 Cells from Patients with Early RA in Synovial Fibroblast Activation. Jan Piet van Hamburg[3], Patrick Asmawidjaja[3], Anne-Marie Mus[3], Mieke Hazes[2], Hans van Leeuwen[1], Edgar Colin[2] and Erik Lubberts[4]. [1]Department of Internal Medicine, Erasmus MC, University Medical Center Rotterdam, [2]Department of Rheumatology, Erasmus MC, University Medical Center Rotterdam, [3]Departments of Rheumatology and Immunology, Erasmus MC, University Medical Center Rotterdam, [4]Erasmus MC, Rotterdam, ZH, The Netherlands

Introduction: Vitamin D is a secosteroid hormone that is produced on the skin under the influence of sunlight or is obtained from the diet. In the liver, the inactive precursor vitamin D3 is converted to the hormonal precursor 25-hydroxyvitamin D3 (25(OH)D3). In the kidneys and extrarenal tissue, 25(OH)D3 is converted into its most active metabolite 1,25(OH)2D3. It has been shown that 1,25(OH)2D3 has immunomodulatory effects in many experimental autoimmune models. Recently, we showed that vitamin D modulated Th17 polarization and IL-22 expression by memory T cells from patients with early rheumatoid arthritis and stimulates IL-4 production by PBMC from early RA patients.

Objective: To identify the effect of vitamin D on the pathogenic behavior of primary Th17 cells on synovial fibroblast (RASF) activation both from patients with early RA.

Methods: From PBMC of patients with early RA, CCR6+ CD45RO+CD4+ Th17 cells were FACS sorted and co-cultured with early RA synovial fibroblasts (RASF) in the absence or presence of Vitamin D. Supernatant of these cultures were analyzed for the production of inflammatory cytokines and matrix metalloproteases (MMPs) with ELISA. Transcrip-

tion of genes involved in the differentiation and function of T cells or genes expressed by activated RASF were analyzed by quantitative RT-PCR analysis. In addition, TNF-alpha and IL-17A blocking experiments were performed in these co-cultures.

Results: Th17-RASF co-culture experiments revealed an increase of IL-6, IL-8, and MMP-1 and MMP-3. Vitamin D significantly suppressed the production of IL-6 and MMP-3 in these co cultures. Interestingly, the specific enhanced autocrine production of IL-17 due to this Th17-RASF interaction was significantly inhibited by vitamin D. In addition, markedly suppressed expression of RORgammat and significantly enhanced expression of GATA3 was noted in the presence of vitamin D. No effect of vitamin D was observed on T-bet and FoxP3 expression. In addition, lower IL-22 and enhanced IL-10 production was found in the presence of vitamin D. The regulatory effects of vitamin D on IL-17 production in the Th17-RASF co culture was comparable to neutralizing IL-17 and on IL-6 production comparable to neutralizing TNF or IL-17.

Conclusion: These data show that vitamin D modulates the pathogenic behavior of primary Th17 cells in their activation of synovial fibroblasts. In addition, vitamin D suppresses the pro-inflammatory IL-17 loop between Th17 and RASF cells. These data suggest that the activation of the vitamin D pathway may have therapeutic potential for the treatment or even prevention of persistent arthritis.

18F-Fluorodeoxyglucose Positron Emission Tomography Scanning (FDG-PET/CT) in Evaluation of Disease Activity in Takaysu Arteritis.

Øyvind Palm[3], Birgir Gudbrandsson[2], Torhild Garen[2], Kjersti Johnsrud[1] and Jan Tore Gran[2]. [1]Section for Nuclear Medicine, OUS, Rikshospitalet, [2]Section for Rheumatology, OUS, Rikshospitalet, [3]Section for Rheumatology, OUS, Rikshospitalet, Oslo, Norway

Purpose: To evaluate FDG-PET/CT findings and disease activity in patients with Takayasu arteritis (TA).

Background: The assessment of disease activity may be difficult in TA. Patients can have active and progressing disease in spite of normal levels of ESR and CRP. Unfortunately, specific markers of disease activity are still missing[1]. Edema-weighted MRI does not seem to correlate well with development of new vascular lesions[2] and angiographic methods will only reveal findings compatible with long-standing, irreparable disease.

Since the introduction of FDG-PET/CT, case reports and small studies have reported positive associations between pathological uptake in FDG-PET/CT and disease activity in TA[3]. However, a recent study failed to find such a correlation[4]. Obviously, further studies are needed to clarify the usefulness of FDG-PET/CT in assessing disease activity in patients with TA. In order to evaluate our experience, we retrospectively evaluated the results of FDG-PET/CT in our patients with TA.

Methods: Patients who fulfilled the ACR criteria for TA[5] and had been consecutively investigated with FDG-PET/CT between 2003 and 2009 were included. They were recruited from the Norwegian Registry of connective diseases and systemic vasculitides (n=36) and by a systematic search in our hospital register of diagnoses (n=11). The FDG-PET/CTs were evaluated by nuclear medicine physicians. Semi-quantitative measurements were used to aid the visual evaluation. The scans were performed 60–90 minutes after injection of 370 MBq FDG. Disease activity was assessed by ESR and CRP measured within 15 days of the FDG-PET/CT investigation, by clinical evaluation by a rheumatologist prior to the FDG-PET/CT and by applying the NHI criteria for disease activity[1].

Results: Totally, 45 female and 2 male patients were investigated. Their median age was 31 years (14–69). Disease duration was median 1 year (0–31). Among patients with pathological FDG-PET/CT uptake, the mean level of CRP (28 cases evaluated) were significantly higher compared to patients with normal FDG-PET/CT. Further, based on the clinician's evaluations, 79% of those with increased FDG-PET/CT uptake had active disease compared to 29% among those with negative FDG-PET/CT. However, neither the ESR levels, nor the fulfilments of the NHI criteria for disease activity did not show significant difference between the groups (Table 1).

Table 1. Pathological FDG-PET/CT (PET/CT+) and normal FDG-PET/CT (PET/CT−) by markers of disease activity in Takayasu arteritis

	PET/CT+	PET/CT−	p
n total	15	32	
ESR median (range)	62 (3–100)	26 (3–100)	<0.16^
CRP median (range)	48.5 (1–145)	9 (1–57)	<0.04^
	Active/Inactive	Active /Inactive	
Clinical evaluation*	11 (79%)/3 (21%)	8 (29%)/20 (71%)	0.003^^
Criteria for activity[1] fulfilled	11 (73%)/4 (27%)	15 (47%)/17 (53%)	0.13^^

* Totally, 5 cases could not be evaluated,
^ Man-Whitey-test, ^ ^ Fisher's exact test

Conclusions: We found a significant association between FDG-PET/CT results and disease activity measured by CRP and clinicians evaluation, but not by ESR or the NHI criteria.

1276

A Double-Blind Placebo Controlled Trial of Infliximab in Patients with Corticosteroid-Dependent Polymyalgia Rheumatica.

Victor M. Martinez-Taboada[11], Francisco Javier López-Longo[10], Rosario García de Vicuña[8], Jordi Gratacos[5], Georgina Espígol-Frigolé[2], Julio Medina[6], Javier Narváez[3], Rosa Roselló[7], Luis Carreño[9], Iñigo Rua-Figueroa[4] and María Cintia Cid[1] [1]Hospital Clinic, Barcelona, Spain, [2]Hospital Clinic, Spain, [3]Hospital de Bellvitge, Barcelona, Spain, [4]Hospital Doctor Negrín, Spain, [5]Hospital Parc Taulí, Barcelona, Spain, [6]Hospital Río Carrión, Palencia, Spain, [7]Hospital San Jorge de Huesca, Spain, [8]Hospital Universitario de la Princesa, Madrid, Spain, [9]Hospital Universitario Gregorio Maranón, Madrid, Spain, [10]Hospital Universitario Gregorio Maranón, Spain, [11]Hospital Universitario Marqués de Valdecilla, Santander, Spain

Background: Corticosteroids (CS) constitute the standard treatment of polymyalgia rheumatica (PMR). However, a significant proportion of patients remain CS-dependent. Open label studies have suggested that tumour necrosis factor (TNF) antagonists led to sustained improvement and CS sparing effect in patients with refractory PMR. To confirm these observations, we conducted a randomised, double-blind, placebo controlled trial with infliximab in CS-dependent patients with PMR.

Methods: We randomly assigned patients with CS-dependent PMR (defined as requiring ≥ 5 mg/day after at least 2 years of treatment to maintain remission or ≥ 7.5 mg/day after at least 6 months) to receive Infliximab (5 mg/kg i.v) at 0, 2, 6, 14 and 22 weeks (n = 11) or placebo (n = 11) together with CS that were reduced according to a predefined schedule. The primary outcome was the proportion of responder patients - defined as individuals with both complete clinical and analytical remission without receiving CS for at least three months- at 24 weeks. Secondary outcomes were cumulated CS doses and adverse events

Results: Baseline characteristics were similar in the two groups. The majority of patients were women (81.8% in infliximab versus 63.6% in placebo, $p=0.6$) with a mean age of 68.5±10.4 years in infliximab and 74.7±5.3 years in placebo group ($p=0.3$). PMR duration (median: 30.0 months and 36.0 months in infliximab and placebo groups, respectively; $p=0.8$) and CS dose at baseline (7.4±3.2 mg in infliximab versus 8.1±3.0 mg in placebo group; $p=0.5$) were also similar. At week 24, 17 patients continued in the trial (8 in infliximab and 9 in placebo group), and only 1 patient in the infliximab group and 2 in the placebo group fulfilled the definition of responder (p, NS). During the 24-week period, CS dose was increased according to physician judgment at least once in 36.4% of patients in the infliximab group compared with 72.72% in the placebo group ($p=0.2$). Patients in the infliximab group tended to have lower cumulated dose of prednisone during the first 24 weeks of treatment (533.7±366.8 mg versus 901.1±522.4 mg; $p=0.1$) and received lower CS dose at week 24 (1.1±1.4 mg versus 3.6±2.6 mg; $p=0.06$). There were 26 adverse events (24 mild/moderate) in patients treated with infliximab and 7 (all mild/moderate) in those patients treated with placebo.

Conclusion: The limited number of patients included in this trial does not allow definitive conclusions. The therapeutic role of infliximab in patients with CS-dependent PMR should be evaluated in trials enrolling larger patient cohorts.

The medication of the study (infliximab) was provided by Schering-Plough S.A.

1277

Adverse Outcomes of Glucocorticoid Therapy among Patients with Giant Cell Arteritis. Laura López Vives, Javier Narvaez, Paula Estrada, Carmen Gómez Vaquero and Joan Miquel Nolla. Department of Rheumatology, Hospital Universitario de Bellvitge, Barcelona, Spain

Background: Glucocorticoids (GC) are currently the only agents in giant cell arteritis (GCA) with proven efficacy. Two studies have demonstrated that GC therapy carries an important long-term morbidity, with an incidence of GC adverse events ranging from 58% to 86% of the patients[1,2].

Purpose. To evaluate the incidence and risks of adverse events associated with GC therapy in a series of patients with GCA diagnosed in an area of north-eastern Spain over a 23-year period.

Methods: Retrospective follow-up study of an unselected population of 140 patients with GCA diagnosed in 1 center between 1986 and 2008. Medical records of these patients were reviewed, and clinical variables, GC doses, and GC adverse events on each patient were recorded. Multivariate regression analysis were were used to identify variables associated with the development of adverse events.

Results: The series included 94 women and 46 men with a mean age at time of diagnosis of 75 ± 7 years (range, 56 to 92). TAB was positive in 112 (80 %) patients. For the total sample the mean duration of therapy after diagnosis was 41.6 months (range, 12.5 to 180) and the total median dose of prednisone was 10.2 gm.

Adverse events associated with GCs were recorded in 89 (63.6%) patients and 2 or more events occurred in 51 patients (36.4%). The main adverse events and their frequency are presented in the following table:

Major adverse events that occurred in 89 of 140 patients with GCA

Type of adverse event	Patients with the event, number (%)
Diabetes mellitus	22 (15.7%)
Hypertension	41 (29.2%)
Hypelipemia	49 (35%)
Total osteoporotic fractures	27 (19.3%)
Symptomatic vertebral fracture	15 (10.7%)
Hip fracture	7 (5%)
Colies' fracture	3 (2.1%)
Insufficiency fracture of the pelvis	2 (1.4%)
Osteonecrosis	2 (1.4%)
Posterior suboapsular cataract	30 (21.4%)
Glucocorticoid-induced myopathy	3 (2.1%)
Gastrointestinal bleeding	2 (1.4%)
Severe or opportunistic infections	25 (17.9%)

Among those patients experiencing and adverse event, the median duration of therapy was 48.7 months (range, 2 to 180), the total median dose of prednisone was 11.6 gm, and the average daily dose was 9.5 gm. The median time from initiation of therapy to the first adverse event was 8.5 months. In the multivariate analysis, only higher cumulative dose of prednisone (odds ratio = 1.17, 95% confidence interval: 1.05, 1.30) was associated with the development of adverse GC side effects

Conclusion: The incidence of GC adverse events in patients with GCA is high, occurring at least in 63.6% of cases; being this percentage close to that observed in other populations. Adverse events may occur even in low-dose therapy and appear to be dose and duration dependent. Osteoporotic bone fractures and infections were as frequent as cardiovascular adverse events.

Alemtuzumab (CAMPATH-1H) as Remission Induction Therapy in Behcet's Disease. Rona M. Smith[1], Yok W. Chow[2] and David R. W. Jayne[1]. [1]Addenbrooke's Hospital, Cambridge, United Kingdom, [2]Hospital Pantai Ayer Keroh Melaka, Malaysia

Introduction: Behcet's Disease is a chronic, relapsing inflammatory disorder, characterised by recurrent oral and genital ulceration, but the more severe, life threatening manifestations are neurological, gastrointestinal or vascular in nature. The precise aetiology and pathogenesis are unclear, but there is increasing evidence that T cells play a key role in the development of disease, and thus T cell depleting agents, such as the anti-CD52 humanised monoclonal antibody, alemtuzumab (CAMPATH-1H) are a potential therapeutic strategy.

Methods: We present a retrospective review of 20 patients treated with alemtuzumab since 1998 in Addenbrooke's Hospital, Cambridge, UK. Two dose schedules were used in this time period; a total dose of 134mg was administered prior to 2003, and 95mg in total in the latter years. Disease activity was measured using the Birmingham Vasculitis Activity Score (BVAS), and sequential evaluation of haematological and biochemical markers were performed.

Results:

Patient Characteristics

15/20 (75%) of patients were female, and the mean age at the time of alemtuzumab therapy was 36.2 years (range 18–59 years). All patients had oral and genital ulceration. 19 (95%) and 18 (90%) of patients had joint and skin involvement respectively. 11 (55%) had eye involvement, 13 (65%) gastrointestinal involvement and 9 (45%) central nervous system disease. Less common features included vascular manifestations (25%), peripheral nervous system involvement (10%) and lung disease (1 patient). Prior to alemtuzumab, the average disease duration was 59.8 months (range 1–203 months), and the mean duration of steroid exposure was 22.7 months (range 1–84 months). 17/20 (85%) of patients had received one or more immunosuppressive agents (including anti-TNF agents, cyclophosphamide, antimetabolites, calcineurin inhibitors and thalidomide) in addition to corticosteroids prior to receiving alemtuzumab The average duration of follow up was 85.47 months (range 20–134 months).

Outcomes

Six months after treatment, 74% of patients were in complete remission. Many of these remissions have been sustained over years, but in those that did relapse, re-treatment with alemtuzumab was effective. There were significant reductions in prednisolone dose and BVAS after treatment (Figure 1).

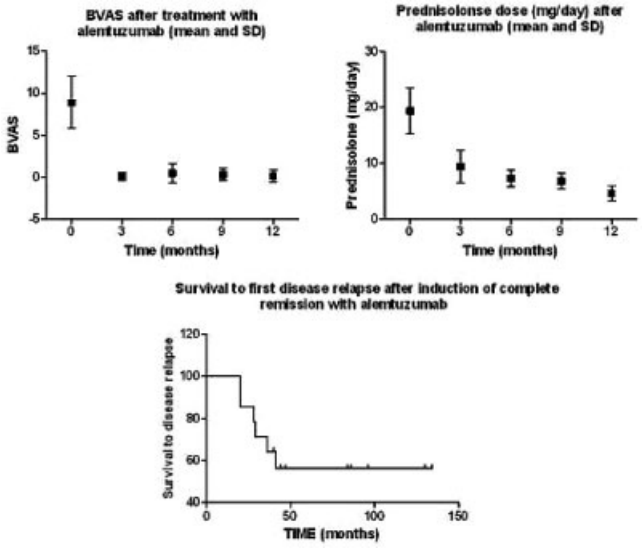

Figure 1. Prednisolone doses, BVAs, and relapse free survival post alemtuzumab.

Adverse events

Alemtuzumab was well tolerated. 25% of patients experienced infusion reactions, but in only one did the reaction necessitate termination of the treatment. There were no infectious complications directly attributable to alemtuzumab, but six patients developed new autoimmune thyroid dysfunction. Autoimmune diseases following alemtuzumab, including thyroid disease and ITP, have also been reported in multiple sclerosis.

Conclusions: Alemtuzumab is a safe and effective therapy for the treatment of Behcet's Disease, particularly in those cases which prove to be refractory or life threatening.

Ankylosing Spondylitis Associated with Takayasu Arteritis. Süleyman Yildirim, Gülen Hatemi, Sebahattin Yurdakul, Izzet Fresko and Huri Ozdogan. Istanbul University, Cerrahpasa Medical School, Rheumatology

Background: A number of case reports have been published on the association of Takayasu arteritis with ankylosing spondylitis. The aim of this study is to formally evaluate Takayasu patients for ankylosing spondylitis (AS).

Methods: All patients who were followed with a diagnosis of Takayasu arteritis in our clinic were evaluated. Apart from the 114 Takayasu patients who fulfill ACR criteria, 77 rheumatoid arthritis and 29 AS patients were included as controls. Patients were questionned for inflammatory back pain, arthritis and heel pain with a previously validated questionnaire for screening sero negative spondylarthropathies. Patients who gave an affirmative answer to at least one of the questions were further evaluated with physical examination and sacroiliac radiograms. Radiograms were evaluated twice on 2 seperate days by 3 rheumatologists blinded to each others observations and graded according to modified New York criteria. Patients who had bilateral grade 2 or unilateral grade 3 or 4 sacroiliitis on at least 3 of 6 observations were diagnosed as ankylosing spondylitis.

Results: Among the 114 patients with Takayasu arteritis 14 had died. Two of these patients had been diagnosed as AS, and one of them also as Crohn's disease before they died. Among the remaining 100 patients 4 already had a diagnosis of AS, one of them with accompanying Crohn's disease. We were able to reach 75 of the remaining 96 patients. 36 gave an affirmative answer to at least one of the questions. 29 of these 36 patients agreed to come to the clinic for further evaluation. Two of these 29 patients had scaroiliitis. One of them had a diagnosis of Crohn's disease. Among the controls 2/77 RA (3%) patients and 28/29 (97%) AS patients had sacroiliitis. Among the 114 patients with Takayasu arteritis a total of 8 (7%) patients had ankylosing spondylitis. Three of them were known to have Crohn's disease. None of the remaining 5 patients had symptoms related to Crohn's disease. The inter and intra-observer reliability of reading the sacroiliac radiograms was good. (kappa: inter-observer 0.89, 0.89, 0.69 and intra-observer 0.93, 0.69, 0.71)

Conclusion: The frequency of ankylosing spondylitis is increased in Takayasu arteritis. The association seems to include Crohn's disease in at least some of the patients. The HLA B27 status and other features of spondylarthropathy in these patients remains to be studied.

Association of *VEGF, NOS2, IL6, CCL2* and *IL1RN* Polymorphisms and Haplotypes with Susceptibility to Giant Cell Arteritis. A Simultaneous Study of 130 Potentially Functional SNPs in 14 Candiadte Genes. Anna Enjuanes[4], Yolanda Benavente[8], Jose Hernandez-Rodriguez[6], Carme Queralt[6], Jordi Yagüe[1], Pedro Jares[5], Silvia de Sanjose[7], Elias Campo[3] and Maria C. Cid[2]. [1]Department of Immunology, Barcelona, Spain, [2]Departmentof Systemic Autoimmune Diseases, Hospital Clinic, Barcelona, Spain, [3]Hematopathology Section, Department of Anatomic Pathology, Barcelona, Spain, [4]Hematopathology Section, Department of Anatomic Pathology, Hospital Clinic, Barcelona, Spain, [5]Hematopatholoy Section, Department of Anatomic Pathology, Barcelona, Spain, [6]Systemic Autoimmune Diseases, Barcelona, Spain, [7]Unit of Infection and Cancer, Cancer Epidemiology Research, Catalan Institute of Oncology, Barcelona, Spain, [8]Unit of Infection and Cancer. Cancer Epidemiology Research. Catalan Institute of Oncology

Background: Giant cell arteritis (GCA) is an immune-mediated vasculitis involving large and medium-sized arteries, especially the aorta and its cervico-cranial branches. GCA is probably a polygenic disease and it seems plausible that frequent genetic variants with modest effects may be related to GCA susceptibility. To date, existing studies assessing genetic risk for GCA have only analyzed limited number of candidate genes and restricted number of genetic variants.

Purpose: To investigate the genetic susceptibility to GCA, we performed a case-control study genotyping 130 SNPs in 82 biopsy-proven GCA patients and 166 healthy controls from the Spanish population. The study evaluates SNPs in potentially functional regions (coding and regulatory gene regions) and some tag SNPs in 14 candidate genes related to the inflammatory response (*CCL2*, *CCR7*, *IL10*, *IL12A*, *IL-1A*, *IL-1B*, *IL-1RN*, *IL6*, *IL8*, *INFG*, *LTA*, *NOS2*, *TNF* and *VEGF)*.

Methods: Genomic DNA was isolated from peripheral blood mononuclear cells and genotyping was carried out at the Spanish National Genotyping Centre (CeGen) using an Illumina Bead Array System. Hardy-Weinberg equilibrium (HWE) for each SNP was evaluated in control subjects. To test the hypothesis of association we used multivariate methods based on logistic regression analyses under four inheritance models (codominant, dominant, recessive and log-additive) and adjusted for age and sex.

Results: We found than 9 SNPs located in five genes had a significant statistical association with disease risk ($P < 0.05$) for any of the inheritance models. These SNPs were located in *NOS2* (rs2779251), *VEGF* (rs1885657, rs2010963, rs699946 and rs699947), *IL1RN* (rs17207494), *IL6* (rs7805828 and rs1546766), and *CCL2* (rs1860190) genes. The strongest associations were provided by rs2779251, rs1885657 and rs2010963 ($P = 2.3\ 10^{-5}$, $P = 0.0078$ and $P = 0.0097$, respectively). The association of rs2779251 and GCA risk was statistically significant after strong adjustment for multiple testing ($P\ corr = 0.0024$). The presence of the minor allele of *NOS2* variant rs2779251 had a protective effect for the risk of GCA (OR=0.27, 95% CI:0.14–0.52). Risk alleles for three of the four SNPs located in *VEGF* gene (rs2010963, rs699946 and rs699947), in homozygosis, showed an increase in the GCA risk (OR=4.22, 95% CI:1.38–12.87; OR=9.04, 95% CI:1.58–51.81; and OR=2.38, 95% CI:1.05–5.38; respectively). Minor allele for the other SNP in *VEGF* gene, the rs1885657, had a protective effect for GCA (OR=0.46, 95% CI:0.26–0.84). Moreover, we defined linkage disequilibrium blocks for each candidate gene included in this study and we explored the effect of haplotypes on disease risk. We found four haplotypes that showed significant association with susceptibility to GCA (*IL6,* OR=0.51, 95% CI:0.28–0.94; *VEGF,* OR=2.92, 95% CI:1.03–8.34; *VEGF,* OR=0.42, 95% CI:0.21–0.85; and *IL1B,* OR=2.94, 95% CI:1.29–6.67).

Conclusions: In summary, our results show that common genetic variants in *NOS2, VEGF*, *IL6*, *ILRN1* and *CCL2* genes are associated with risk for GCA, reinforcing a polygenic influence in susceptibility to this vasculitis.

Behcet's Disease and the Major Histocompatibility Complex: Looking beyond HLA-B51. Michael J. Ombrello[2], Yohei Kirino[2], Fulya Cosan[1], Ahmet Gul[1], Daniel L. Kastner[2] and Elaine F. Remmers[2]. [1]Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul University, Istanbul, Turkey, [2]Laboratory of Clinical Investigation, NIAMS, NIH, Bethesda, MD

Background: Behcet's Disease (BD) is a complex genetic disease of unknown etiology that is characterized by inflammatory lesions of the eyes, skin, and oro-genital mucosa. Family studies reveal a genetic contribution to BD, with estimates of the sibling recurrence-risk ratio from 11–52. Though the class I MHC molecule, HLA-B51 (B51), is reportedly the strongest known genetic risk factor for BD, the gene immediately centromeric to *HLA-B*, *MICA*, has also been implicated in BD. Because of strong linkage disequilibrium (LD) between *HLA-B* and *MICA*, their respective contributions to BD susceptibility have been debated.

Methods: In an effort to clarify the roles of B51, *MICA*, and other MHC locus genes in BD, we performed B51 typing with sequence specific oligonucleotide probes, and examined MHC locus SNP genotypes determined with Illumina Human CNV370 SNP chips in the largest single collection of BD patients ever assembled, 1190 Turkish BD patients and 1257 geographically matched, healthy Turkish subjects. Genotype association testing and regression analysis was performed using SNP Variation Suite 7. Haplotype analysis was performed using Haploview.

Results: We found that B51 was strongly associated with BD (allelic chi square p=5.47E-50, OR=3.49), occurring at allelic frequencies of 0.159 in healthy Turkish individuals and 0.352 in Turkish BD patients. We found 228 statistically significant BD-associated SNPs within the MHC locus (p<2.00E-5). The most strongly associated SNP (rs2848713, p=1.91E-45)

was located centromeric to *MICA*, and was contained within a cluster of 33 BD-associated SNPs within *HLA-B* and *MICA*. Analysis of LD and haplotype structure identified a BD-associated, B51-containing haplotype block (p=1.22E-46, OR 2.81) spanning the entire *HLA-B* and *MICA* genes. An otherwise identical B51-negative version of this haplotype also existed, although it occurred at identical frequencies, 0.04, in cases and controls. B51-containing haplotypes with recombinant events occurring between *HLA-B* and *MICA* continued to convey a risk of BD (OR=1.75, [95CI=1.15–2.58]). Taken together, these data indicate that B51 is essential to the causative nature of this BD-associated extended *HLA-B/MICA* haplotype, whereas *MICA* elements are dispensable. Finally, to identify B51-independent effects of MHC genes on BD susceptibility, we performed conditional analysis of all BD-associated MHC locus SNPs, specifying B51 as a covariate. We identified 23 B51-independent BD-associated SNPs, the strongest of which, rs9260997, was very near to *HLA-A* (p=5.49E-9, OR=1.84). Further analysis accounting for the effects of both B51 and rs9260997 identified additional regions of BD association in *PSORS1C1* (p=1.24E-5, OR=2.01), and *HLA-B* (p=1.18E-5, OR=1.46).

Conclusion: Our study demonstrates B51 to be the largest single contributor to BD susceptibility in Turkish individuals. We identify a common B51-containing BD-associated *HLA-B/MICA* haplotype. B51 was required on the haplotype for the conveyance of significant BD risk, whereas *MICA* variants were dispensable. Finally, we identified additional B51-independent BD associations in the *HLA-A, PSORS1C1*, and *HLA-B* regions.

Circulating Adipokine, Ghrelin and Acylated Ghrelin Levels in Patients with Takayasu's Arteritis. Hatice Yilmaz[1], Vedat Gerdan[3], Didem Kozaci[4], Servet Akar[3], Gercek Can[3], Aytac Gulcu[2], Volkan Cakir[2], Yigit Goktay[2], Merih Birlik[3], Nurullah Akkoc[3] and Fatos Onen[3]. [1]Internal Medicine, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey, [2]Radiology, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey, [3]Rheumatology, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey, [4]Science, Technology Research and Aplication Center, Aydin, Turkey

Objective: The follow-up of the disease activity is of great importance as it requires intense treatment in active period of Takayasu's arteritis (TA) of which etiology is unknown. Today, clinic and laboratory activity criteria alone are not quite enough in follow-up. This study aims to investigate serum leptin, adinopectin and plasma ghrelin and acylated ghrelin levels and the relationship of these parameters with the disease activity

Material and Method: 31 TA patients and 32 healthy controls were included in the study. In TA patients, the disease activity was evaluated based on the NIH activation criteria, DEI.TAK scoring, "DEI.TAK-physician's global opinion (PGO)" and radiological investigations (B-mode and Doppler USG and MR angiography). Serum leptin, adinopectin and plasma ghrelin and acylated ghrelin levels were measured by ELISA in all patients and controls. Mann-Whitney U test and Pearson's correlation analysis was used in the comparison of the groups and testing the inter-variety correlations, respectively.

Results: Of the 31 TA patients, 29 were female and 3 were male and the mean age was 44.2± 11.3 years. Distributions of age, sex, waist and hip circumferences and BMI in TA and healthy controls were similar.

Twenty% of TA patients were active based on NIH activation criteria; 19.4% were active, 22.6% were persistent and 58% were inactive based on "DEI.TAK- PGO" and 33% were active based on the radiological findings. There was a positive correlation between NIH activation criteria and DEI-.TAK scoring "DEI.TAK-PGO" and also radiological activity (r=0.566, p=0.001; r=0.603, p=0.001; r=0.409, p=0.031, respectively). Serum ESH, WBC and % neutrophil levels were higher in TA patients than controls (p=0.017, p=0.002 and p<0.001, respectively).

Ghrelin (319.3±202.6 pg/ml) and acylated ghrelin (120,5±94,4 pg/ml) levels in TA patients were significantly lower than controls (623,2±270 pg/ml and 180,9±128,7 pg/ml respectively), (p<0.001 and p=0.031, respectively). They were negatively correlated with serum WBC and % neutrophil levels. Ghrelin levels were significantly lower in active patients than inactive patients according to NIH activation criteria and "DEI.TAK-PGO" (p=0.041 and p=0.016 respectively).

No difference was found between leptin and adinopectin levels in TA patients and healthy controls. However, a significant negative correlation was found between leptin levels and ghrelin and acylated ghrelin levels in TA patients (r=0.344, p=0.006 and r=0.389, p=0.002, respectively). Leptin and adinopectin levels were significantly lower in patients with coronary involvement (p=0.027, p=0.016 respectively). There was a significant positive correlation between mean carotid intima-media thickness (IMT) measurements and adinopectin levels in TA patients (p=0.001 and p=0.004, respectively).

Conclusion: Ghrelin levels were considered to be useful in monitoring the disease activity and adjusting the treatment plan in TA. DEI.TAK scoring, "DEI.TAK- PGO" and radiological activity indicators which are in accordance with NIH activation criteria can also be used for disease follow-up.

Circulating Endothelial Cells and Endothelial Progenitor Cells in Takayasu Arteritis. Serkan Dogan[2], Dilek Solmaz[4], Ozden Piskin[1], Servet Akar[4], Aytac Gulcu[3], Faize Yuksel[1], Volkan Cakir[3], Gercek Can[4], Yigit Goktay[3], Merih Birlik[4], Nurullah Akkoc[4] and Fatos Onen[4]. [1]Hematology, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey, [2]Internal Medicine, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey, [3]Radiology, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey, [4]Rheumatology, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey

Objective: In Takayasu arteritis (TA) with unknown etiology, it is very important to monitor the disease activity because intensive treatment is needed during active periods. Today's clinical and laboratory activity criteria alone are not very satisfactory for follow-up. This study aims to investigate the numbers of circulating endothelial cells (CEC) and endothelial precursor cells (CEPC) and also the correlation of these parameters with disease activity in patients with TA.

Patients and Methods: 32 patients with TA, 25 with systemic lupus erythematosus (SLE) (patient control group) and 30 healthy subjects were included in this study. Detailed medical history was obtained and full physical examination was done in all patients. The NIH activation criteria, DEI.TAK scoring and ''DEI.TAK-physician's global opinion (PGO)" and also radiological investigations (B-mode and doppler USG and MR angiography) were used to evaluate disease activity in TA patients. The numbers of CEC and CEPC were measured by flow cytometry in patient and control groups.

For comparison of the groups, Krusskall-Wallis analysis or chi square tests were used. When significance were determined between the groups, they were recompared in pairs by way of Mann-Whitney U test. For the purpose of testing the correlations between the variables, Spearman's correlation analysis was applied.

Results: There were 29 female and 3 male patients with TA (mean age: 43.5 years). Mean disease duration was 5.4 years.

According to NIH activation criteria in TA patients, 18.8% of patients were active; according to "DEI.TAK-physician global opinion", 18.8% active, 28.1% persistent and 53.1% inactive and; according to the radiological findings, 31% active. A significant correlation was determined between the NIH activation criteria and DEI.TAK scoring, "DEI.TAK-PGO" and also radiological activity (r=0.529, p=0.002; r=0.540, p=0.002; and r=0.361, p=0.046 respectively).

Serum CRP levels in TA patients (p=0,018) and SLE patients (p=0,009) were significantly higher than in healthy control group. The numbers of CEC were higher in patients with TA (7,02 ± 2,78 n/μl) and patients with SLE (7,24 ± 2,06 n/μl) in comparison to healthy control group (4,90 ± 1,82 n/μl), (p=0,001 and p<0,001, respectively). CEC numbers were correlated positively with serum CRP levels (r=0.228, p=0.34). CEPC numbers were not different between the groups.

Carotid intima-media thickness (IMT) has been found to be significantly higher in TA patients (1,06 ± 0,60 mm) in comparison to SLE patients (0,56 ± 0,11 mm) and healthy controls (0,55 ± 0,11 mm) (p<0.001). The frequency of carotid atherom plaque did not show any statistical difference between the groups

Conclusion: The results of this study suggests that the changes in numbers of CEC might be useful in monitoring the disease activity and planning the treatment in TA patients. The DEI.TAK scoring, "DEI.TAK-PGO" and radiological activity indexes which work parallel to NIH activation criteria may also be used for the purpose of monitoring the disease activity and deciding on the treatment.

Clinical Characteristics, Treatment and Ethnic/Racial Differences in the Manifestations of 518 Behcet's Syndrome Patients in the United States. Yusuf Yazici, Maria T. Filopoulos, Elizabeth Schimmel, Andy McCraken and Christopher Swearingen. NYU Hospital for Joint Diseases

Background: Behcet's syndrome (BS) is a systemic vasculitis is rare in northern Europe and the US. Previous reports have suggested that there may be ethnic and racial differences in disease presentation and possible clustering of manifestations. We started a dedicated Behcet's clinic in 2004 and now report on the disease characteristics of the first 518 patients.

Methods: All patients seen at the center have completed a MDHAQ, and a questionnaire about past medical history, medication use, Behcet's specific history, ethnic and demographic information. These data are prospectively collected and updated each visit. About 2/3 of patients live within driving distance of New York City while patients from over 45 states have been seen. Patients were analyzed as the whole cohort and then also separated into to 2 groups: Group A= with ethnic background in northern Europe and North America and/or self declared Caucasians without background around the Mediterranean and/or the Far East; Group B= Patients with an ethnic background in the Mediterranean, Middle East, North Africa, and Far East. These groups were compared for disease manifestations, demographic information and medication use.

Results: 518 patients (398 (77%) female, mean (SD) disease duration 4(6.5) years, age 35 (13.6), 324 (60%) fulfilled International Behcet's classification criteria) were analyzed. Disease characteristics of the whole cohort and those fulfilling criteria are given in Table 1. When divided by ethnic background, Group A had statistically more significant GI disease (47% vs. 28%, $p<0.001$) and more females compared to Group B (83% vs. 71%, $p=0.005$) for those meeting criteria. For the whole cohort, less eye disease and vascular involvement than other centers was reported. There was only one blind eye.

	Total cohort (%)	Meeting criteria (%)	Not meeting criteria (%)
N	518	313	205
Oral ulcers	481 (90%)	313 (100%)	151 (74%)
Genital ulcers	376 (73%)	285 (91%)	91 (44%)
Skin	342 (66%)	287 (92%)	55 (27%)
Arthritis	268 (52%)	199 (64%)	69 (34%)
GI	179 (35%)	121 (39%)	58 (29%)
Eye	144 (28%)	127 (41%)	17 (8%)
CNS	81 (16%)	59 (19%)	22 (11%)
DVT	20 (4%)	17 (5%)	3 (1%)
Pathergy	41 (8%)	37 (12%)	4 (2%)
HLA B51	58 (11%)	37 (12%)	21 (10%)

Most commonly used medication at baseline was low dose prednisone (62%), followed by colchicine (46%), TNF inhibitors (21%) azathioprine (19%) and methotrexate (10%).

Conclusions: In this cohort of 518 Behcet's patients, largest cohort to be reported in the US. demographic and clinical differences were noted between patients with different ethnic backgrounds. There were significantly more female patients in the non-ethnic groups. The frequency of GI disease was also significantly more in this group. Eye disease prevalence for the whole cohort was far less than reported from other centers. These finding point to considerable heterogeneity in disease expression in BS at different geographic areas.

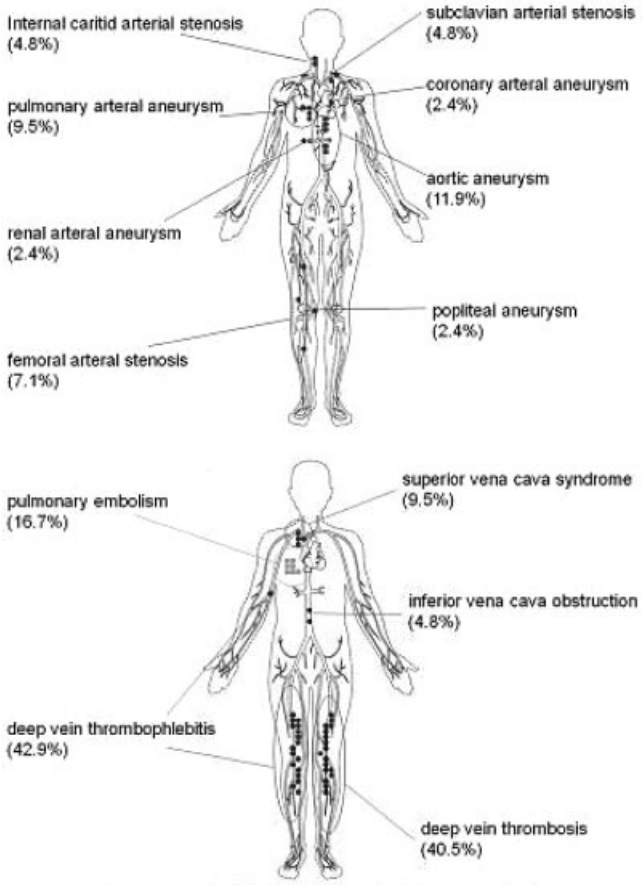
Clinical Features of Behçet's Disease with Vascular Involvement. Hirotoshi Kikuchi[2], Kurumi Asako[1], Maki Takayama[1], Hajime Kono[1], Shunsei Hirohata[4] and Yasuo Ono[3]. [1]Department of Internal Medicine, Teikyo University School of Medicine, [2]Department of Microbiology and Immunology, Teikyo University School of Medicine, Itabashi-ku, Tokyo, Japan, [3]Department of Microbiology and Immunology, Teikyo University School of Medicine, [4]Department of Rheumatology and Infectious Disease, Kitasato University School of Medicine, Kanagawa, Japan

Background: Behçet's disease (BD) is characterized by recurrent oral aphthous stomatitis, ocular involvement, genital ulcer, and skin lesions. Although one of the serious manifestations of BD is vascular involvement (VBD), its pathogenesis remains unclear. The current studies were therefore undertaken to delineate the clinical characteristics of VBD and to explore its pathological features.

Patients and Methods: The clinical records of 277 patients who satisfied the 1990 international criteria for Behçet's disease and were hospitalized in Department of Internal Medicine, Teikyo University School of Medicine, from January 1989 to December 2009 were reviewed.

Results: Forty two patients (25 males and 17 females) had been diagnosed with VBD. The mean age of BD onset was 35.6±11.8 years (mean±SD), and the mean delay for the development of VBD was 5.8 years. The frequency of HLA-B51, HLA-A26, pathergy test and complete type was 34.4%, 13.3%, 42.9% and 38.1%, respectively. The vessels involved were as follows: the most frequent venous lesion was deep vein thrombophlebitis (42.9%), followed by deep vein thrombosis (40.5%), superior vena cava syndrome (9.5%), and inferior vena cava obstruction (4.8%) and frequent arterial lesions were aortic aneurysm (11.9%), pulmonary aneurysm (9.5%), femoral artery stenosis (7.1%), and subclavian arterial stenosis (4.8%).



Seven patients suffered from both venous and arterial lesions.

Seven patients suffered from both venous and arterial lesions. Two patients died because of hemoptysis from pulmonary arterial aneurysms. One of 7 patients who were complicated with pulmonary embolism died.

Conclusion: These results indicate that the frequency of vascular manifestations tended to be higher for venous lesions (81.0%) compared with arterial lesions (28.6%). In particular, the main complication associated with death was pulmonary vessel involvement.

1286

Clinical Spectrum, Angiographic Findings and Outcome in Takayasu Arteritis, Using the Disease Extent Index for Takayasu Arteritis (DEI.TAK). Sivakumar M. Rajappa. Cerebrovascular and Vasculitis Research Foundation, Chennai, Tamilnadu, India

Background: Takayasu's arteritis (TA) is a chronic, inflammatory large vessel vasculitis affecting the aorta and its major branches, pulmonary and

coronary arteries. Although more common in Asia, the disease has been found worldwide, with different vascular involvement patterns, clinical manifestations and outcome usually affecting young women. The disease involves all the three layers of the vessel walls and results in luminal abnormalities like intima medial thickening, stenosis, occlusion, and aneurysm formation. The Disease Extent Index for Takayasu Arteritis (DEI.Tak), is a validated instrument for assessment of the clinical involvement in Takayasu Arteritis (TA), without need for imaging. The index is also useful to study damage and outcome in TA.

Objective: To analyze data in TA, regarding demographics, race, clinical manifestations, angiographic findings by CT/MR/Digital Subtraction Angiograms, outcome of vascular interventions and mortality over a period of 20 years, using the DEI.Tak.

Methods: This is a prospective cross sectional study 222 TA patients who fulfilled the ACR diagnostic criteria for TA, seen at Chennai, India between January 1988 and March 2010. The clinical findings were entered into a database using the DEI.Tak. All the relevant laboratory parameters like ESR, CRP and imaging modalities like Carotid and Vertebral Duplex Ultrasound and Intima-Media Thickness(IMT), CT/MR/Invasive Angiograms and PET CT scans were performed to classify TA according to Nummano's angiographic classification. The survival of grafts and interventional procedures like Carotid, Subclavian, Renal and Aortic angioplasty and stenting done on TA patients were analyzed. The outcome with treatment and surgery/interventional procedures and mortality over a 22 year period is reported.

Results: A total number of 222 TA patients (151 women and 71 men) were seen with a mean age of 34.62 ± 14.8 years. The systems scored commonly were: Systemic-93(42.66%), Renal-84(38.33%) and Cardiovascular system(CVS)-134(61.46%)[Bruit: 32(14.67%),Pulse Inequality: 42(19.19%),Pulse loss:6429.35%), Claudication:36(16.51%),Aortic incompetence:18(8.25%),Angina:19(8.71%), CCF:21(9.63%).Systems rarely involved were skin, mucous membrane and abdomen. The mean Common Carotid Artery IMT was 0.845 cm. The long term survival of stents with effective immunosuppressive treatment pre and post stenting were 92%, 83% and 72% at the end of 5, 10 years and 15 yeras respectively. The 5 Angiographic distribution of involvement of the aortic arch and its branches were: Type I: 19, IIa: 26, IIb: 37, III: 43,I V: 33 and V: 64. During the follow up of over 20 years, 41 patients expired.

Conclusions: This study involving a large cohort of TA cases, followed up for more than two decades provides a comprehensive assessment of the extent and severity of TA using the DEI.Tak. CVS is the most important system affected and the presence of new pulse loss was a good indicator of active disease. With effective immunosuppressive therapy, there is good long term patency of stents in the Indian subjects with improved morbidity and mortality.

Disclosure: S. M. Rajappa: None.

Cluster Analysis of Vascular Involvement in Takayasu Arteritis: Extension of the Lesions Is Contiguous in the Aorta and Symmetric in Paired Arterial Beds. Laurent Arnaud[1], Julien Haroche[1], Dan Toledano[2], Patrice Cacoub[1], Nathalie Costedoat-Chalumeau[1], Du Le Thi Huong-Boutin[1], Philippe Cluzel[2] and Zahir Amoura[1]. [1]Department of Internal Medicine, Groupe Hospitalier Pitié-Salpêtriere, UPMC Univ Paris 6, AP-HP, 47–83 bd de l'Hôpital, Paris, France, [2]Department of Radiology, Groupe Hospitalier Pitié-Salpêtrière, UPMC Univ Paris 6, AP-HP, 47–83 bd de l'Hôpital, 75013, Paris, France.

Background: The determinants of vessel targeting are largely unknown in vasculitides. The aim of this study was to identify patterns of vascular involvement in Takayasu's arteritis (TA), using cluster analysis.

Methods: Peripheral vascular Doppler, CT angiography and angio-MRI data of 82 patients with TA (ACR criteria) were studied between Jan. 1995 and May 2006. Cross-involvement between 24 main arteries were assessed using the Phi correlation coefficient. Patterns of vascular involvement were identified using hierarchical cluster analysis.

Results: Data were obtained from 68 women (82.9%) and 14 men (17.1%). The median duration of follow-up was 5.1 years (range: 1 month to 30 years).

For 16 (80%) of 20 paired arteries, the highest correlation of involvement was observed with the contralateral artery ($r=0.31$ to 0.66). Conversely, the involvement of the abdominal aorta best correlated with that of the thoracic descending aorta ($r=0.38$, $p=0.0005$), and this latter best correlated with the aortic arch ($r=0.44$, $p<0.0001$). This suggests contiguous extension in the aorta.

Cluster analysis visually confirmed that all paired arterial beds, but the internal and external carotid arteries, clustered with their contralateral counterpart, and that the aortic arch, the descending thoracic aorta and the abdominal aorta clustered together.

Conclusion: Our study reveals that TA lesions mostly develop in a symmetric manner in paired vascular territories and that disease extension is contiguous in the aorta. This may prove useful for improving the radiological follow-up of patients with TA, and for providing a pattern for further investigations focusing on the mechanisms of vessel-specificity in vasculitides.

1288

Colchicine Does Not Decrease the Need for Immunosuppressive Use at Long Term in Behçet's Syndrome. Vedat Hamuryudan[3], Gülen Hatemi[3], Sebahattin Yurdakul[3], Cem Mat[1], Koray Tascilar[3], Yilmaz Ozyazgan[2], Emire Seyahi[3], Serdal Ugurlu[3] and Hasan Yazici[3]. [1]Istanbul University, Cerrahpasa Medical School, Dermatology, [2]Istanbul University, Cerrahpasa Medical School, Ophthalmology, [3]Istanbul University, Cerrahpasa Medical School, Rheumatology

Background: A recent survey looking at the long term outcome of patients who had entered a controlled trial of thalidomide showed a trend for less immunosupressive use among those who had previously used colchicine (1). This time we looked at the long term outcome of patients who took part in a 2 year, randomized, placebo controlled trial of colchicine.

Methods: 116 BS patients (60 men, 56 women) with only mucocutaneous and joint involvement were re-evaluated 16.6 ± 1.1 years after the trial ended. The main outcome measure was the need for immunosuppressive use during follow-up.

Results: Outcome information was achieved in 90/116 (78%) patients. Of these, 51 were men and 39 were women (mean age 27.1 ± 5.3, disease duration 8.4 ± 8.1 months at randomization). The group distribution of patients who could not be reached was similar. During follow-up, 18/51 (36%) men and 8/39 (20%) women had received immunosuppressives (Table). There was no difference in immunosuppressive use between patients who had been randomized to colchicine or placebo arms (men: 11/25 colchicine vs 7/26 placebo and women 3/18 colchicine vs 5/21 placebo).

	Men (n=51)		Women (n=39)	
	Colchicine (n=25)	Placebo (n=26)	Colchicine (n=18)	Placebo (n=21)
Eye Involvement	1	–	1	1
DVT	2	2	1	–
Pulmonary artery aneurysm	–	1	–	–
Neurologic involvement	2	1	–	–
Gastrointestinal	1	–	–	1
Arthritis	2	3	1	3
Mucocutaneous involvement	3	–	–	–

Conclusion: Initial use of colchicine does not seem to decrease the need for immunosuppressive use, hence the development of major organ involvement of BS patients at long term.

Diagnostic Value of Pathergy Phenomenon in Behcet's Disease. Fereydoun Davatchi, Cheyda Chams-Davatchi, Farhad Shahram, Bahar Sadeghi Abdollahi, Abdolhadi Nadji, Massoomeh Akhlaghi, Tahereh Faezi and Roghieh Larimi. Rheumatology Research Center, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran

Background: Pathergy phenomenon (PP) is used for the diagnosis of Behcet's Disease (BD). It is an important criterion of many classification/diagnosis criteria. The sensitivity of PP was 83% in Russia, 77% in Morocco, 71% in Iraq, 62% in China and Egypt, 61.5% in Iran, 55% in Germany, 44%

in Japan, and 18% in Saudi Arabia. The sensitivity of PP is changing over the time. It has changed in Iran from 71.8% for the first 1000 patients to 33.9% for patients 5000 to 6000. The aim of this study was to look for the diagnostic value of PP in the present time, and its change over the past 35 years.

Patients and Methods: The Behcet's Disease registry, has the data of 6607 BD and 4292 Control patients from the past 35 years. Patients were divided in 4 groups of 1650 BD and 1073 controls. Sensitivity, Specificity, Positive and Negative Predictive Value (PPV & NPV), Positive and Negative Likelihood Ratio (PLR & NLR), Diagnostic Odds Ratio (DOR), and Youden's Index (YI) were calculated. The first and the 4th quartiles were compared.

Results: Positive PP changed from 64.2% to 35.8% (1st and 4th quartiles) in BD and from 13.4% to 1.6% in control patients (Table 1). Sensitivity, specificity, PPV, NPV, PLR, NLR, DOR, and YI are shown in Table 2.

Table 1. Details of Behcet's Disease and control patients

Patients	First Group	Second Group	Third Group	Fourth Group
BD Patients	1–1650	1651–3300	3301–4950	4951–6607
PP Done	1580	1639	1622	1643
Positive PP	1014	971	820	588
% Positive	64.2	59.2	50.6	35.8
95% CI	61.8–66.5	56.8–61.5	48.2–53.1	33.5–38.1
Control Patients	1–1073	1074–2146	2147–3219	3220–4292
PP Done	1069	1069	980	1061
Positive PP	143	96	10	17
% Positive	13.4	9.0	1.0	1.6
95% CI	11.5–15.6	7.4–10.9	0.5–1.9	1.0–2.6

Table 2. Performance and Diagnostic value of Pathergy Test

Patients and Controls	First Group	Second Group	Third Group	Fourth Group
Sensitivity	64.2	59.2	50.6	35.8
Specificity	86.6	91.0	99.0	98.4
Positive Predictive Value[a]	82.7	86.8	98.1	95.7
Positive Predictive Value[b] 33%	70.2	76.4	96.1	91.7
Positive Predictive Value[c] 0.08%	0.38	0.52	3.89	1.76
Negative Predictive Value[a]	82.7	69.0	66.7	60.5
Negative Predictive Value[b] 33%	83.1	81.9	80.3	75.7
Negative Predictive Value[c] 0.08	99.97	99.96	99.96	99.95
Positive Likelihood Ratio	4.8	6.6	50.6	22.4
Negative Likelihood Ratio	0.41	0.45	0.5	0.65
Diagnostic Odds Ratio	11.6	14.7	101.4	34.3
Youden's Index	0.5	0.5	0.5	0.34

a: Predictive Value of PP without taking in account the prevalence of Behcet's disease
b: Predictive Value calculated for the Behcet's Disease clinic at RRC (prevalence of BD: 33%)
c: Predictive Value calculated for the population of tran (prevalence of BD: 0.08%)

Discussion: The sensitivity of PP decreased while the specificity increased. The difference was statistically significant (Table 2).

PPV shows the probability that the positive test is true positive. PPV is influenced by the prevalence of the disease in the tested population. The prevalence of BD in Iran is 0.08%. In BD clinic, 1/3rd of new patients have BD. PPV improved from 0.38% to 1.76 (population) and from 70.2% to 91.7% in BD Unit (between 1st and 4th quartile). Although the sensitivity of PP has decreased over the time, its value as a diagnostic test, when positive, has improved. NPV shows the probability that a negative test is truly negative. NPV lost a little in the BD Clinic, going from 83.1% to 75.7% (Table 2).

PLR shows the odds of having the disease. PLR improved from 4.8 to 22.4 (1st to 4th quartile), meaning the risk of having BD with positive PP is 22.4 times. The NLR deteriorated from 0.41 to 0.65, meaning the error rate of not having BD increased from 41 to 65%.

The diagnostic odds ratio (DOR) combines the results of PLR and NLR, A value of 1 means no discrimination between patients and controls. Higher values mean better discrimination. DOR improved from 11.6 to 34.3 (from 1st to 4th quartile).

Youden's Index (YI) shows the accuracy of PP. Zero is the worse and one the best. The YI decreased from 0.5 to 0.34, showing a deterioration of precision rate over the time.

Conclusion: PP improved its diagnostic value.

Disease Activity Assessment in Large Vessel Vasculitis. Luca Magnani[1], Annibale Versari[1], Diana Salvo[1], Massimiliano Casali[1], Giuseppe Germanò[1], Riccardo Meliconi[3], Lia Pulsatelli[2], Debora Formisano[1], Gianluigi Bajocchi[1], Nicolò Pipitone[1], Luigi Boiardi[1] and Carlo Salvarani[1]. [1]Arcispedale S Maria Nuova, Reggio Emilia, Italy, [2]Istituti Ortopedici Rizzoli, Bologna, Italy, [3]University of Bologna, Italy

Purpose: Assessment of disease activity in patients with large vessel vasculitis (LVV) is challenging because clinical, biologic and radiologic data do not always correlate. ^{18}F-fluorodeoxyglucose-positron emission tomography (FDG-PET) and serum interleukin-6 (IL-6) may be useful for the assessment of disease activity, however data on their usefulness are not well defined.

The aims of this study were to compare National Institute of Health (NIH) criteria and Indian Takayasu's arteritis activity score (ITAS) with FDG-PET scan results, as well as with erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and serum IL-6 values for the assessment of disease activity in a group of patients with LVV.

Methods: Fifty-eight patients with LVV (24 with Takayasu's arteritis, 31 with giant cell arteritis according to the ACR criteria, and 3 with chronic periaortitis) underwent a total of 99 PET scans. Images were reviewed by a nuclear medicine physician (AV) who was unaware of the clinical diagnosis and assessed images for pattern and intensity of vascular uptake. LVV activity data, including laboratory tests, were obtained within 14 days of the PET scans.

Results: PET scanning revealed abnormal vascular uptake ($\geq$ 2 on a 0–3 scale in at least 1 of the 7 vascular regions analyzed) in 57.6% of the 99 examinations. According to the NIH criteria, 27 patients had active and 72 inactive disease. Thirty-three patients had ITAS $\geq$ 1 and 66 equal to 0. ESR, CRP and IL-6 levels were stratified into 4 groups according to distribution quartiles. 12.5% of patients (9/72) with inactive disease according to NIH criteria had ITAS $\geq$ 1, while 11.1% of patients (3/27) with active disease according to NIH criteria had ITAS = 0. The agreement between ITAS and NIH criteria was 87.9% (87/99) (kappa value: 0.71). Abnormal FDG vascular uptake was present in 52.8% of patients (38/72) with inactive disease according to NIH criteria, while 30.8% of patients (8/26) with active disease according to NIH criteria had normal FDG vascular uptake. The total agreement between FDG vascular uptake and NIH criteria was 53.1%. Abnormal FDG vascular uptake was present in 53.0% of patients (35/66) with ITAS = 0, while 33.3% of patients (11/33) with ITAS $\geq$ 1 had normal FDG vascular uptake. The agreement between FDG vascular uptake and ITAS criteria was 53.5%. ESR and CRP levels were significantly associated with disease activity according to the NIH criteria and ITAS ($p = 0.0001$). In contrast, there was no association between IL-6 serum levels and disease activity according to NIH criteria and ITAS.

Conclusion: The agreement between NIH criteria and ITAS for disease activity assessment in LVV is excellent. ESR and CRP values are associated with disease activity as assessed by the NIH criteria and ITAS, while FDG vascular uptake and IL-6 serum values are not.

1291

Disease Assessment in Takayasu's Arteritis: Data from a Literature Search and a Survey of Expert Opinion. Haner Direskeneli[3], Sibel Z. Aydin[3], Peter A. Merkel[2] and Turkish Takayasu Study Group[1]. [1]Istanbul, Turkey, [2]Boston University School of Medicine, West Newton, MA, [3]Marmara University, School of Medicine, Istanbul, Turkey

Purpose: To study approaches to disease assessment in Takayasu's arteritis (TAK) by summarizing published clinical studies and surveying current expert opinion in Turkey.

Methods: A literature search was conducted in "PubMed" with keywords "Takayasu's arteritis", "assessment", "activity", "remission", and "relapse" for studies published in English between 1994–2010 (case reports and reviews excluded). Informed by the literature review, Turkish rheumatologists (n=34, 20 specialists/academicians and 14 rheumatology fellows) and two foreign experts completed a questionnaire on disease assessment in TAK.

Results: Of the 4004 articles with the key-word "Takayasu's arteritis", items associated with disease assessment and activity were present in 62 studies. Among these, 45% (n=28) focused on clinical issues (case series, treatment, outcome), 32% (n=20) on biomarkers/pathogenesis, and 22% (n=14) on vascular imaging. An NIH study *(Kerr et al, 1994*) was most commonly cited for a definition of active disease (48%, n=30). Acute-phase response (ESR/CRP) was part of an "active" disease definition in 84% (n=52), constitutional features in 73% (n=45), clinical features of vascular ischemia in 53% (n=33), and angiographic involvement in 58% (n=36). A composite index of activity was used in three studies (BVAS=2, ITAS=1) and a patient-derived outcome tool (SF-36) in two studies.

After a presentation of the results of the literature search, experts were asked to define a "gold-standard" of disease activity in TAK. New vessel/organ involvement determined clinically or by imaging was chosen by 84%, physician global assessment by 13%; no expert named patient global assessment. The most commonly chosen items for a disease-assessment tool were new bruits or arterial imaging changes (both 100%), new extremity claudication (97%), acute-phase reactants (97%), arterial tenderness (94%), fever (88%), and constitutional symptoms (84%). Although experts felt that a dichotomous assessment (active vs. inactive) was not suitable (63%), they also agreed that damage vs. activity (83%) and grumbling vs. highly active disease (80%) cannot be reliably differentiated in TAK. Some organ manifestations present in BVAS and DEI.Tak (a recently-developed TAK-specific tool) were found suitable for TAK (cardiovascular-100%, CNS-93%, renal-87%, abdominal-83%, ocular-83%, musculoskeletal-72%) whereas others were felt to have a limited value (respiratory-50%, cutaneous-47%, ENT-24%, genitourinary-19%). The majority of experts (62%) agreed that an outcome measure could be developed for large-vessel vasculitis for use in research of giant-cell arteritis and TAK that incorporated manifestations of both diseases.

Conclusion: Outcome measures used in research for TAK vary considerably in content and do not consistently include clinical manifestations that experts give a high value to regarding disease assessment, including vascular imaging and biomarkers. These data are helpful in guiding the process of creating an internationally-accepted core set of outcome measures in large vessel vasculitis.

1292

Effect of Glucocorticoids on Gelatinase (MMP-2 and MMP-9) Expression in Giant-Cell Arteritis (GCA) Using an *Ex-Vivo* Temporal Artery Culture Model. Marc Corbera-Bellalta, Ana García-Martínez, Ester Planas-Rigol, Ester Lozano, Marta Segarra, Georgina Espígol-Frigolé, José Hernández-Rodríguez, Itziar Tavera and Maria C. Cid. Department of Systemic Autoimmune Diseases. Hospital Clínic. University of Barcelona, IDIBAPS, Barcelona, Spain

Background: GCA is the most frequent systemic vasculitis in the elderly. Increased gelatinase expression and proteolytic activity have been demonstrated in GCA lesions. Gelatinases may play an important role in the progression of inflammatory lesions given their proinflammatory functions and elastinolytic activity and may also participate in vascular remodelling in response to injury. Glucocorticoids (GC) are the cornerstone of GCA treatment but it is not know how GC treatment influences gelatinase expression.

Purposes: To explore the effects of GC on gelatinase expression in GCA lesions using an *ex-vivo* arterial culture system.

Methods: Fresh temporal artery sections obtained from 19 GCA patients and 10 controls were embedded in the reconstituted basement membrane Matrigel™ and cultured for 5 days as described (Arthritis Rheum 2008 (suppl) 58:9; S929–S929). Cultured sections were treated with medium alone or with medium supplemented with 0.5mg/ml of dexamethasone. MMP-2 and MMP-9 mRNA was measured in recovered sections by quantitative real-time PCR (Applied Biosystems). Both gelatinases were also measured in the supernatant fluid by immunoassay (R&D Systems).

Results: MMP-9 mRNA was significantly more abundant in cultured sections from patients compared to controls (1283±1353 vs 304±222 relative units, p=0,039). Contrarily, no differences were observed in MMP-2 mRNA between normal and GCA cultured sections (2097±918 vs 3450±2800 relative units, p=0,758). MMP-9 and MMP-2 protein concentrations were higher in the supernatant from GCA sections compared to controls (48,9±30,3 vs 7,83±7,02 ng/ml, p=0,006 for MMP-9) although differences were not significant for MMP-2 (39,1±31,5 vs 15,3±16,6 ng/ml, p=0,192). Dexamethasone treatment for 5 days highly reduced MMP-9 expression both at the mRNA (861,2±1054 vs 88±110 p=0,018) and at the protein level (48,9±30,4 vs 8,6±5,4 ng/ml, p=0,003) whereas no effect was apparent on MMP-2 expression.

Conclusion: The pattern of gelatinase expression in cultured temporal artery sections parallels what has been observed in fresh biopsies (Ann Rheum Dis. 2007 Nov; 66(11):1429–35). In the present model, dexamethasone treatment dramatically reduced MMP9 expression with a much lesser effect on MMP-2 expression. These findings reinforce a pro-inflammatory role for MMP9 during active disease and suggest a role for MMP2 in vascular remodelling before and after treatment. Supported by SAF 05/06250 and MTV3 06/0710.

1293

Efficacy of Cerebrospinal Fluid Testing and Magnetic Resonance Imaging for Diagnosis of Neuro-Behcet's Disease: A Multicenter Retrospective Analysis. Shunsei Hirohata[3], Hirotoshi Kikuchi[5], Tetsuji Sawada[6], Hiroko Nagafuchi[4], Masataka Kuwana[2], Mitsuhiro Takeno[1] and Yoshiaki Ishigatsubo[7]. [1]Department of Internal Medicine and Clinical Immunology, Yokohama City University Graduate School of Medicine, [2]Keio University School of Med, Tokyo, Japan, [3]Kitasato Univ School of Med, Kanagawa, Japan, [4]St Marianna University School of Med, [5]Teikyo Univ School of Med, [6]Tokyo Medical University, Shinjuku Tokyo, Japan, [7]Yokohama City Grad Sch of Med, Yokohama, Japan

Objective: Central nervous system (CNS) involvement in Behcet's disease (BD) is one of its most serious complications (neuro-Behcet's disease [NBD]). Since there are factors causing neurological manifestations other than BD (non-NBD), the diagnosis of NBD is often difficult. The present study was therefore designed to delineate the clinical characteristics of NBD and to determine the reliable diagnostic parameters. Special attention was paid to cerebrospinal fluid (CSF) cell counts and interleukin-6 (IL-6) as well as magnetic resonance imaging (MRI) findings.

Methods: A multicenter retrospective survey was performed on BD patients who fulfilled the diagnostic criteria of the international study group and presented neurological manifestations between 1987 and 2008. The diagnosis of either NBD or non-NBD was confirmed by retrospective review of the clinical records. NBD was further classified into acute NBD and chronic progressive NBD according to the clinical courses.

Results: A total of 144 BD patients were studied, including 76 with acute NBD, 35 with chronic progressive NBD, and 33 with non-NBD. Smoking and HLA-B51 were correlated with chronic progressive NBD (p=0.0024 and p=0.0106, respectively). CSF cell counts were most prominently elevated in acute NBD, but were within normal limits in approximately 15% of chronic progressive NBD. ROC curve analysis revealed that the sensitivity and specificity of CSF cell counts for diagnosis of acute NBD were 97.3 % and 96.7%, respectively, at the cut-off value of 6.5/mm^3. Whereas CSF IL-6 was elevated in both acute NBD and chronic progressive NB, it was decreased only in acute NBD after treatment. Moreover, the sensitivity and specificity of CSF IL-6 for differential diagnosis of chronic progressive NBD from

recovery phase of acute NBD were 86.7 % and 94.7%, respectively, at the cut-off value of 16.55 pg/ml. High intensity lesions on MRI T2-weightened images were found in 60.5% of acute NBD, 54.2% of chronic progressive NBD, and 42.4% of non-NBD, whereas brainstem atrophy was observed in 7.5% of acute NBD, 71.4% of chronic progressive NBD, and 9.0% of non-NBD.

Conclusion: The results indicate that CSF cell count is a useful marker for diagnosis of acute NBD, whereas determination of persistent elevation of CSF IL-6 along with brainstem atrophy on MRI is pivotal for diagnosis of chronic progressive NBD. The data have also disclosed that T2 high intensity lesions on MRI are neither sensitive nor specific for diagnosis of NBD.

1294

Endothelin-1 (ET-1) Induces Collagen Type I and Type III Production by Temporal Artery-Derived Myointimal Cells. A Mechanism Potentially Leading to Intimal Hyperplasia in Giant-Cell Arteritis (GCA). Ester Planas-Rigol, Marc Corbera-Bellalta, Ester Lozano, Montserrat Butjosa, Sergio Prieto-González, José Hernández-Rodríguez, Marta Segarra and Maria C. Cid. Department of Systemic Autoimmune Diseases. Hospital Clínic. University of Barcelona, IDIBAPS, Barcelona, Spain

Background: GCA is a granulomatous vasculitis involving large and medium-sized arteries. The inflammatory process leads to intimal hyperplasia and vascular occlusion with the ensuing ischemia of supplied tissues. Intimal hyperplasia results from proliferation and matrix production by myointimal cells. Recent studies demonstrate up-regulation of the ET system in GCA lesions and increased ET-1 concentrations in plasma from patients with cranial ischemic complications (Ann Rheum Dis. 2010 Feb; 69(2):434–42). ET-1 is one of the most potent vasoconstrictor agents and may create a microenvironment prone to the development of vasospasm, contributing to ischemic events.

Purpose: To investigate whether ET-1 may additionally contribute to vascular occlusion by inducing pro-fibrotic responses in cultured human temporal artery-derived myointimal cells (HTAMC) potentially participating in the development of intimal hyperplasia.

Methods: HTAMC were obtained from cultured temporal artery sections from patients with GCA as described (Ann Rheum Dis. 2008 Nov; 67(11): 1581–8). Transforming growth factor b (TGFb), collagen type I (COL1) and type III (COL3) expression was assessed by quantitative real-time PCR (Taqman^{R} Gene Expression Assay) from Applied Biosystems.

Results: ET-1 up-regulated TGFb and COL1 expression by HTAMC in a dose-dependent manner. A delayed increase in COL3 expression was also observed which was partially mediated by TGFb. Study of underlying mechanisms is in progress.

Conclusions: ET-1 may contribute to intimal hyperplasia directly by inducing collagen type I and indirectly by inducing the synthesis of the fibrogenic cytokine TGFb by human temporal artery-derived myointimal cells. These preliminary results suggest that ET receptor antagonists may prevent vascular occlusion in GCA.

1295

Expansion of Peripheral Blood Plasma Blasts Reflects Disturbances of B Cell Homeostasis in Patients with Takayasu Arteritis and Success of B Cell Depletion Therapy. Bimba F. Hoyer[3], Imtiaz M. Mumtaz[3], Udo Schneider[2], Rolf Keitzer[1], Gerd-Rüdiger Burmester[2], Andreas Radbruch[5] and Falk Hiepe[4]. [1]Dep. Pediatric Rheumatology, Charité Universityhospital Berlin, [2]Dep. Rheumatology and Clin. Immunology, Charité Universityhospital Berlin, [3]Dep. Rheumatology and Clin. Immunology, Charité Universityhospital Berlin and German Rheumatism Reserach Center Berlin, Berlin, Germany, [4]Dep. Rheumatology and Clin. Immunology, Charité Universityhospital Berlin and German Rheumatism Reserach Center Berlin, [5]German Rheumatism Reserach Center Berlin

Purpose: Takayasu arteritis (TA) is a rare form of chronic large vessel vasculitis mainly affecting the aorta and its branches.

The etiology of TA is yet unknown but highly suggestive of T cell-mediated autoimmunity. The presence of autoantibodies against endothelial cells (AECA) however indicates that autoreactive B cells and plasma cells may be involved in the pathogenesis.

Therefore, we comprehensively analysed the peripheral blood B cell subpopulations from TA patients.

Methods: 14 patients suffering from TA (7 active, 7 inactive) were analysed. As controls, 10 patients with active SLE and 9 healthy donors were investigated.

PBMCs were surface stained for expression of CD27, CD19, CD20 and MHCII and analysed by flowcytometry. Plasmablasts were characterized as being $CD19^{+}CD20^{-}CD27^{+++}$ and $MHCII^{++}$. All $CD27^{+++}$ $CD20^{-}CD19^{+}$ cells represent both newly generated plasmablasts and plasma cells. Sera of patients were tested for the presence of Anti-Endothelial-Cell-Antibodies (AECA).

Data was analysed using Flowjo-Software. Statistical analysis was done with SPSS.

Results: Patients with active TA revealed significantly more peripheral blood plasmablasts compared to patients with inactive disease as well as healthy persons. Absolute numbers of plasmablasts in patients with active TA (mean 0,0068/nl, SD 0,0049/nl) were comparable to active SLE patients (mean 0,01908/nl, SD 0.02/nl) whereas inactive patients (mean 0,001629/nl SD 0.0016/nl) show numbers comparable to healthy persons (median 0,001057/nl, SD 0.0005/nl). The same is true for the frequency of plasma cells within the B cells.

In addition a significant correlation between the frequencies of $CD27^{+++}CD20^{-}CD19^{+}$ cells in the B cell population and Crp-level could be observed as well ($r=0{,}731$ $p=0{,}0029$, Pearson-Test).

No correlation could be found with the presence of AECA.

Based on these results we successfully treated three patients refractory to conventional immunosuppressive drugs and TNF blockers with B cell depletion.

Conclusion: For the first time disturbances in the B cell homeostasis in TA that might be crucial in the pathogenesis are described. Therefore B cells and plasma cells should be considered as a target for therapeutic approaches as successful treatment of three patients by B cell depletion underlines.

Analysis of peripheral blood plasmablasts seem to emerge as biomarker, which characterizes disease activity in TA and can be helpful for therapeutic decisions.

1296

Expression and Function of Toll Like Receptors in Peripheral Blood Mononuclear Cells of Patients with Polymyalgia Rheumatica and Giant Cell Arteritis. Lorena Alvarez-Rodriguez[4], Marcos Lopez-Hoyos[4], Cristina Mata[1], Ana Fontalba[4], Jaime Calvo-Alen[1], Maria Jose Marin[4], Jose Luis Fernandez-Luna[4], Jesus Agüero-Balbin[4], Maitane Aranzamendi-Zaldunbide[4], Ricardo Blanco[4], Ignacio Villa[2], Orlando Pompei[4], Marien Peiro[4], Teresa Ruiz[1] and Victor M. Martinez-Taboada[3], [1]Hospital de Sierrallana, Spain, [2]Hospital de Sierrallana, Spain [3]Hospital Universitario Marques de Valdecilla, Santander, Spain, [4]Hospital Universitario Marques de Valdecilla

Objective: To investigate the expression and function of the TLR family in PBMCs of patients with polymyalgia rheumatica (PMR) and giant cell arteritis (GCA).

Methods: We analyzed 70 patients with PMR, 20 with GCA and 24 healthy controls (HC). TLR expression was assessed by flow cytometry. TLR function was studied by stimulating PBMCs with specific ligands.

Results: A significant increased expression of TLR7 in PBMCs of patients with active disease compared with HC was found. Despite an increased expression of TLR7, circulating monocytes from patients showed a significant lower *in vitro* response to TLR7 agonists. No amino acid substitutions predicted to be functionally damaging were found in TLR7. A normal response to specific TLR7 agonists in patients in complete remission eliminated a genetic defect. The expression profile on PBMCs from HC induced by plasma from PMR and GCA were marked by up-regulation of type I IFN-response transcripts, suggesting that the diminished response to TLR7 agonists in active disease was secondary to receptor saturation with natural ligands. We attempted to identify the presence of a set of respiratory virus in plasma from patients without conclusive results.

Conclusion: These data suggest the activation of TLR7 by a natural(s) ligand(s) in patients with PMR and GCA that is followed by a selective desensitization of the receptor. Despite the failure to identify a responsible virus in plasma from patients, the up-regulation of type I IFN-response genes

after stimulation with patients' plasma suggests a possible viral etiology in these two syndromes.

Extracellular HMGB1 Is Increased in Patients with Behcet's Disease with Intestinal Involvement. Joong Kyong Ahn[2], You Sun Lee[3], Eun-Jung Park[4], Ji-Won Hwang[4], Ji-Min Oh[4], Jaejoon Lee[4], Chan-Hong Jeon[1], Eun-Mi Koh[4] and Hoon-Suk Cha[4], [1]Bucheon Hospital, Soonchunhyang University College of Medicine, [2]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, [3]Masan Samsung Hospital, Sungkyunkwan University School of Medicine, [4]Samsung Medical Center, Sungkyunkwan University School of Medicine

Objective: Behcet's disease (BD) is a chronic multisystemic inflammatory disorder of unknown etiology consisting of orogenital ulceration, ocular inflammation, and skin lesions. HMGB1 (High-Mobility Group Box 1 protein) has been demonstrated to play an important role in chronic inflammatory diseases including rheumatoid arthritis, systemic lupus erythematosus, and inflammatory myositis. HMGB1 is a crucial cytokine that mediates the response to infection, injury and inflammation. HMGB1 activates macrophages and monocytes to release proinflammatory cytokines, upregulates endothelial adhesion molecules, and stimulates epithelial cell barrier failure. We performed this study to investigate the association between extracellular HMGB1 expression and disease activity and clinical features of Behcet's disease.

Method: Extracellular HMGB1 expression from the sera of 42 BD patients and age- and sex-matched 22 healthy controls (HC) was measured using ELISA.

Results: According to the activity criteria based on clinical manifestation at the time of study, 42 patients with BD comprised 25 active and 15 inactive patients with mean age of 47 years (range 22–65 years). The HMGB1 concentration was significantly increased in BD patients compared to HC (78.70±20.22 vs. 10.79±1.90 ng/ml, p=0.002). In addition, HMGB1 concentration was significantly elevated in patients with intestinal involvement compared to those without (179.61±67.95 vs. 61.89±19.81, p=0.04). Patients with vascular involvement showed decreased trend of serum HMGB1 expression compared to those without vascular involvement (36.79±12.63 vs. 95.47±27.41 ng/ml, p=0.059). There was no significant association between HMGB1 concentration and clinical manifestation, including genital ulcer, erythema nodosum, ocular involvement or musculoskeletal symptoms. No significant difference in the serum HMGB1 level was found between inactive and active BD patients (58.78±18.46 vs. 92.26±31.63 ng/ml, p=0.367). No significant correlation was found between HMGB1 concentration and leukocyte counts, ESR, or CRP.

Conclusion: This is the first study to evaluate the expression of HMGB1 in Behcet's disease. An important finding in our study is that extracellular HMGB1 concentrations are significantly increased in BD patients compared to HC, and are significantly increased in the sera of BD patients with intestinal involvement compared to those without intestinal involvement. These results suggest that extracellular HMGB1 may play an important role in the pathogenesis of BD.

Eye Involvement in Behcet's Syndrome Patients in a North American Cohort. Johannes Nowatzky[3], Maria T. Filopoulos[4], Christopher Swearingen[1] and Yusuf Yazici[2]. [1]Biostatistics UAMS Pediatrics, [2]Hospital for Joint Diseases, Hastings on Hudson, NY, [3]NYU Hospital for Joint Diseases, Brooklyn, NY, [4]NYU Hospital for Joint Diseases

Background: Ocular disease has been reported in up to 75 % of patients with Behcet's Syndrome (BS) in endemic regions where permanent visual loss is common. The prevalence of eye disease in North American BS patients is unknown, but felt to be lower than in endemic regions. More prevalent and severe eye disease is expected in North American populations with an ethnic background in those regions.

Methods: A BS center was established in New York City in 2004. Patients at the center completed an MDHAQ, BSAS (Behcet Syndrome Activity Score), questionnaires about past medical history, medication use, Behcet's specific history, ethnic and demographic information. These data were prospectively collected over 5 years and updated on each visit. Patients fulfilling the International Behcet's Classification Criteria were analyzed as one cohort and then in 2 groups: Group A= with ethnic background in northern/central Europe and North America and/or self declared Caucasians without Mediterranean, Middle Eastern and/or Far Eastern background; Group B= Patients with Mediterranean, Middle Eastern, North African, or Far Eastern ethnic background. These groups were compared for their prevalence, type and outcome of ocular disease.

Results: 471 patients were seen for suspected BS. 296 (62.8%) fulfilled the International Behcet's Classification Criteria and were included in the present study. Of those, 121 (40.9%) patients had eye disease, which included 56 (18.9%) with uveitis, 8 (2.7%) with retinitis, 11 (3.7%) with episcleritis, and 42 (14.2%) with other eye disease. There was no statistically significant difference between Groups A (n=163) and B (n=133) regarding the prevalence of eye disease (41.1% vs. 40.6%, p<0.93), types of involvement: uveitis (19.6% vs. 18.0%, p<0.729), retinitis (1.8% vs. 3.8%, p<0.311), episcleritis (3.1% vs. 4.5%, p<0.514), baseline disease activity and use of immunosuppressive medications. None of the patients presented with or developed blindness during the study period.

Conclusions: Eye involvement was less prevalent and seemed to have better outcomes in this North American cohort of BS patients than in cohorts studied in high-incidence/endemic BS regions. Contrary to our expectations, there was no significant difference in prevalence or outcome of Behcet's eye disease between North Americans of non-Mediterranean European ancestry compared to individuals of Mediterranean, Middle- or Far Eastern descent living in the US. These findings could suggest a role of environmental factors in the phenotypic expression of BS in general, and in the pathogenesis of Behcet's eye disease in particular.

Glucocorticoid Therapy in Giant Cell Arteritis: Duration and Predictors for Long-Lasting Remission. Paula Estrada, Javier Narvaez, Laura Lopez Vives, Carmen Gomez Vaquero and Joan Miquel Nolla. Department of Rheumatology, Hospital Universitario de Bellvitge, Barcelona, Spain

Purpose: To analyze the clinical course and duration of glucocorticoid (GC) therapy in a series of patients with giant cell arteritis (GCA), identifying those predictors for the achievement of a long-lasting remission.

Methods: Retrospective follow-up study of an unselected population of 140 patients with GCA diagnosed in 1 center between 1986 and 2008. The end-point of patient follow-up was the date of the last clinic visit or the date of death. Long-lasting remission was recorded as the date of permanent discontinuation of treatment without recurrence of symptoms for at least 1 year.

Possible correlations between the duration of therapy and demographic, clinical, laboratory and treatment variables were explored. Multivariate regression analysis were used to identify variables associated with the achievement of long-lasting remission.

Results: The series included 94 women and 46 men with a mean age at time of diagnosis of 75 ± 7 years (range, 56 to 92). TAB was positive in 112 (80 %) patients. The median follow-up duration after diagnosis was 36.6 months (range, 12.5 to 180).

All patients were treated with GCs and responded rapidly (mean initial dosage of prednisone: 50.1 ± 13.7 mg/day). The dosage was later reduced according to the treating physicians' judgment. The median duration required to achieve a maintenance dose of less than 10 mg prednisone/day was 8.5 months. Relapses or recurrences occurred in 82 (52.6%) patients, with a mean of 2.7 ± 1.7 relapses per patient.

In 60 (42.8%) patients, GCs were discontinued and permanent remission achieved after a median of 26.7 months of treatment, with a range of 13 to 90 months. The median cumulative dose of prednisone taken by these patients was 8.51 gm. Only in 33.3% (20/60) of these patients GCs could be withdrawn within the first 2 years of treatment. This percentage increased to 73% (33/60) at 3 years, 81.6% (49/69) at 4 years, and 88.3% (53/60) at 5 years, with only 11.6% (7/60) of the patients requiring therapy for more than 5 years.

At the time of last follow-up, 80 (57.2%) of the 140 patients were still taking GCs with a median treatment duration of 36 months; in 50% of these patients the duration of treatment was longer than 3 years.

A significant correlation was found between the duration of therapy and ***(1)*** diagnostic delay (r=0.240; p=0.004), ***(2)*** age at disease onset (r = −0.237; p = 0.004), ***(3)*** the value of pre-treatment erythrocyte sedimentation rate (r=0.154; p=0.047), and ***(4)*** total dose of prednisone (r=0.824; p=<0.0001). In the multivariate analysis, the only variables associated with the achievement of long-lasting remission were the age at disease onset

(OR=0.93, 95% CI: 0.87, 1.00) and the cumulative dose of prednisone (OR=0.85, 95% CI: 0.77, 0.95)

Conclusion: Results of the currtent study show that it is rare to stop steroid therapy before at least 2 years of treatment (only achieved in 14% of the patients). In the majority of cases the disease follows a protracted course requiring long-term treatment with GCs, with a subset of patients who need low dose prednisone indefinitely. Some baseline parameters can help to identify those patients at high risk for prolonged steroid use.

Infliximab Therapy Is Beneficial for Intestinal Behcet's Disease in Japan. Reikou Watanabe, Mitsuhiro Takeno and Yoshiaki Ishigatsubo. Department of Internal Medicine and Clinical Immunology, Yokohama City Graduate School of Medicine

Objects: Intestinal involvement is one of the most serious manifestations in patients with Behcet's disease. The therapy is not established. Although there are a few English written reports concerning clinical efficacy of infliximab (IFX) for intestinal Behcet's disease, the therapy is not uncommon in Japan. We conducted a nationwide survey of clinical efficacy and safety issues in IFX therapy for patients with intestinal Behcet's disease in Japan.

Methods: We retrospectively collected clinical data of 121 patients who had received infliximab therapy more than once for intestinal Behcet's disease from 38 institutes in Japan by using questionnaires. Of them, 89 patients (male 45, female 42, 43.3 + 14.3 y.o) who met the Japanese criteria revised in 1987 were included in the study.

Results: The major clinical features in the patients were abdominal pain (88%), diarrhea (55%), and gastrointestinal bleeding (51%). The lesions were mainly distributed in ileum (84%), cecum (45%), and ascending colon (34%). Before starting the IFX, the patients had received corticosteroids (83%), mesalazine (69%), colchicine (55%), and any immuosuppressants such as cyclosporine, azathioprine, and methotrexate (70%). Surgical operation was conducted in 31 patients (35%). IFX (3 to 5 mg/kg) was give one to 48 times. Nineteen patients received IFX more than 20 times over three years. Subjective improvement was noted in 81% of patients. Endoscopic improvement and/or steroid sparing effect were confirmed in 52%. Favorable responses were found in patients having ocular lesions and arthritis, latter of which was proven as an independant factor by multivariate logistic regression analysis. On the other hand, patients having concurrent esophageal lesions showed a poor response to the therapy. Eleven adverse events including 8 infections were noted. The therapy was discontinued in 24 patients (27%) because of remission (5 patients), adverse events (10 patients) and exacerbation or insufficient efficacy (9 patients).

Conclusions: IFX therapy showed favorable clinical outcomes even in Behcet's disease patients who had refractory intestinal lesions to conventional therapies.

Influence of CD40 rs1883832 Polymorphism in the Susceptibility to and Clinical Manifestations of Biopsy-Proven Giant Cell Arteritis. Luis Rodríguez-Rodríguez[8], Santos Castañeda[4], Tomás R. Vazquez-Rodriguez[7], Inmaculada C. Morado[3], Beatriz Marí-Alfonso[1], Carmen Gómez-Vaquero[5], Jose A. Miranda-Filloy[7], Javier Narvaez[5], Norberto Ortego-Centeno[2], Ricardo Blanco[6], Benjamín Fernández-Gutiérrez[3], Javier Martín[9] and Miguel A. Gonzalez-Gay[6]. [1]Department of Internal Medicine, Corporació Sanitaria Parc Taulí, Instituto Universitario Parc Taulí, UAB, Sabadell, Barcelona, Spain, [2]Department of Internal Medicine, Hospital Clínico San Cecílio, Granada, Spain, [3]Department of Rheumatology, Hospital Clinico San Carlos, Madrid, Spain, [4]Department of Rheumatology, Hospital de la Princesa, Madrid, Spain, [5]Department of Rheumatology, Hospital Universitario de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, Spain, [6]Department of Rheumatology, Hospital Universitario Marqués de Valdecilla, IFIMAB, Santander, Spain, [7]Department of Rheumatology, Hospital Xeral-Calde, Lugo, Spain, [8]Instituto de Parasitología y Biomedicina López-Neyra, C.S.I.C., Granada, and Department of Rheumatology, Hospital Clinico San Carlos, Madrid, Spain, [9]Instituto de Parasitología y Biomedicina López-Neyra, C.S.I.C., Granada, Spain

Objective: The purpose of this study was to assess the potential association between CD40 rs1883832 polymorphism and biopsy-proven GCA. We also studied whether this polymorphism might influence the phenotypic expression of this vasculitis, in particular the development of visual ischemic manifestations.

Methods: 305 Spanish patients with biopsy-proven GCA and 788 matched controls were assessed. DNA from patients and controls was obtained from peripheral blood. Samples were genotyped for the CD40 rs1883832 C/T polymorphism using a predesigned TaqMan allele discrimination assay and by polymerase chain reaction amplification.

Results: Biopsy-proven GCA patients showed a trend towards a higher frequency of the minor allele homozygote of rs1883832 (TT) compared to healthy controls (12.1% vs. 8.3%, respectively; p= 0.05, odds ratio-OR: 1.54 [95% confidence interval-CI: 0.98–2.40]). Also, a marginally significant increased frequency of the minor allele T was observed in GCA patients with visual ischemic manifestations (36.9%) compared to those without visual ischemic manifestations (27.7%); OR: 1.53 [95% CI: 0.99–2.34], p=0.04). In this regard, biopsy-proven GCA patients carrying the minor allele T (either TT or TC) experienced visual ischemic manifestations more commonly than those carrying the CC genotype (58.5% versus 44.2%, OR 1.78 [95% CI: 0.99–3.22], p=0.04).

Conclusions: Our results suggest a potential implication of the CD40 rs1883832 C/T polymorphism in the susceptibility to visual ischemic manifestations in individuals with biopsy-proven GCA.

Large-Vessel Involvement in Newly-Diagnosed Giant Cell Arteritis: A Case-Control Study Using Color-Doppler Sonography. Alessandra Ghinoi[1], Luigi Boiardi[1], Nicolò Pipitone[1], Giovanna Restuccia[1], Alberto Nicolini[1], Mauro Silingardi[1], Giuseppe Germanò[1], Gianluigi Bajocchi[1], Ilaria Chiarolanza[1], Luca Magnani[2], Pierluigi Macchioni[1], Andrea Caruso[1] and Carlo Salvarani[1]. [1]Arcispedale S Maria Nuova, Reggio Emilia, Italy, [2]Arcispedale S Maria Nuova, Reggia Emilia, Italy

Purpose: The prevalence of large-vessel vasculitis (LVV) in newly diagnosed giant cell arteritis (GCA) is still poorly documented. Two studies have estimated such prevalence at 30**%** and 83% using Color-doppler sonograhy (CDS) (1) and ^{18F}-FDG PET (fluoroxedoxyglucose positron emission tomography) (2), respectively. CDS allows to visualize the temporal, axillary, and subclavian arteries, as well as the aortic arch, abdominal aorta and supra-aortic vessels. The presence of a hypoechoic halo around the arterial walls is considered quite specific for GCA.

The aim of this study was to investigate the prevalence of LVV in newly diagnosed GCA using CDS and to compare the clinical findings of GCA patients with and without LVV.

Methods: Sixty-two consecutive patients with a diagnosis of new-onset GCA according to the American College of Rheumatology criteria who had a CDS performed were analyzed. The identified patients with LVV were randomly matched to an equal number of GCA patients without LVV.

Results: In 19 out of 62 patients (30.6%), CDS showed the characteristic halo sign in at least one vessel examined. Comparing patients with and without LVV, no significant difference was found for any of the following parameters: gender (male:female 0.0/100% versus 21.1%/78.9%), positivity of the temporal artery biopsy (82.4% versus 88.2%), presence of a transmural infiltrate (78.6% versus 86.7%) or periadventitial infiltrate (21.4% versus 13.3%), temporal arteries' abnormalities on inspection (85.7% versus 92.3%), cranial (77.8% versus 94.1%) and constitutional (66.7% versus 35.3%) manifestations. Similarly, the ESR was similar in both groups (91±30 versus 72±25 mm/1st hour).

Conclusion: LVV evidenced by CDS occurred in 30.6% pts with newly diagnosed GCA. This prevalence is very similar to that found in a previous study with a similar design. Constitutional manifestations were more frequent and cranial manifestations were less frequent in our GCA patients with LVV, although the difference did not reach significance. Early diagnosis of LVV in GCA can help tailor treatment accordingly and may prevent vascular complications.

New Disease Activity Indices in the Management of Behcet's Disease: A Comparative Study of Patients from Turkey and the USA. Gonca Mumcu, Yusuf Yazici, Nevsun Inanc, Tulin Ergun, Maria Filopoulos and Haner Direskeneli. Faculty of Health Sciences, Department of Health Informatics and Technologies, Marmara School of Medicine

Purpose: The aim of this study was to evaluate and compare oral ulcer activity by Composite index (CI) and general disease activity by Behcet Syndrome Activity Score (BSAS) in patients from Turkey (TR) and the USA with Behcet's disease (BD).

Methods: In this cross-sectional study, age- matched 30 Caucasian active female patients from TR (mean age: 41.10 ±11.04 years) and 30 Caucasian active female patients from USA (mean age: 41.40± 11.56 years) with BD were included. Patients from TR were examined in Marmara University Hospital, Department of Rheumatology whereas patients from USA were examined in NYU, Hospital for Joint Disease in the same time span. Composite index (CI) was previously validated (1) for oral ulcer activity. It evaluates both pain scored by visual analogue scale (VAS) and functional status. Behcet Syndrome Activity Score (BSAS) (2) is a general disease activity index and evaluates clinical activities according to organ involvement in BD. CI and BSAS were filled by both patients from Turkey (TR) and USA. Scores could be between 0 and 10 in CI and 0 –100 in BSAS, (0=inactive disease). Oral health related quality of life was evaluated by oral health impact profile-14 (OHIP-14) in both groups. Better oral health-related quality of life was indicated with lower scores in OHIP-14 (range 0–56).

Results: No significant difference was found in OHIP-14 scores between patients from TR (21.4±13.7) and USA (21.9±12.7) ($p=0.886$). Although the number of oral ulcers was higher in patients from TR than patients from USA (4.3±2.5 and 3.3±2.8, respectively), this was not statistically significant ($p=0.161$). Yet, CI index score and pain score evaluated by VAS as its subscale score, were higher in patients from TR (7.8±1.6, 52.7±22.1) compared to the US patients (4.2±1.5, 35.9±27.8) ($p<0.001$ and $p=0.013$, respectively). CI score was correlated with BSAS score in patients from TR ($r=0.36$ $p=0.04$) and USA ($r=0.44$ $p=0.02$).

BSAS score was higher in patients from USA (44.5±18.5) compared to patients from TR (23.4±15.4)($p<0.0001$). In accordance with these results, majority of patients from USA (76.7 %) were treated with immunosuppressive medications compared to patients from TR (6.7 %) ($p<0.0001$).

Conclusions: CI and BSAS, two patient derived disease activity measures, showed moderate correlation with the manifestations of BD and moderate correlation with one another in these two different patient populations They may be suitable tools for use both in routine clinical care and clinical studies in BD patients.

Normal Sedimentation Rate and C-Reactive Protein at Diagnosis in Biopsy-Proven Giant Cell Arteritis. Tanaz A. Kermani, Cynthia S. Crowson, Steven R. Ytterberg, Gene G. Hunder and Kenneth J. Warrington, Mayo Clinic, Rochester, MN

Purpose: 1) To determine the frequency of normal erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) at diagnosis in biopsy-proven giant cell arteritis (GCA) and 2) to evaluate clinical factors associated with discordant or normal ESR/CRP.

Methods: In this retrospective cross-sectional study, medical records of all patients with biopsy-proven GCA evaluated between January 1, 2000 and December 31, 2008 were reviewed. Only subjects with ESR and CRP available at the time of diagnosis were included. Clinical information was abstracted. Subjects with both ESR and CRP normal and those with discordant ESR/CRP were identified. We used our laboratory cut-off values for elevated ESR (>22 mm/hour for men and >29 mm/hour for women) and CRP (>8 mg/L). Fisher's exact test was used to compare categorical variables between patients with discordant results to those with concordant ESR/CRP, and GCA patients with normal ESR/CRP to those with elevated ESR/CRP. Rank sum tests were used to compare continuous variables between the above two groups.

Results: Two-hundred and forty patients were diagnosed with biopsy-proven GCA at a single institution during the study period. Of these, 160 subjects (78%) had ESR and CRP available prior to GCA diagnosis. The final study population included 119 women (74.4%) and 41 men (25.6%); mean age at diagnosis 74.3 years (±7.59). Nine patients (5.6%) had discordant ESR and CRP of whom 7 had elevated CRP but normal ESR. Mean age at diagnosis of GCA, mean duration of symptoms, clinical symptoms and laboratory findings at GCA diagnosis were similar in patients with discordant ESR/CRP compared to patients with concordant results ($p>0.05$).

Both ESR and CRP were normal in 18 patients (11.3%), 11 of whom were on prednisone and were excluded from the analysis. However, 7 patients (4%) had normal ESR and CRP at diagnosis in the absence of prednisone use. Table 1 compares the clinical manifestations and laboratory findings of these 7 patients to those with elevated ESR or CRP. A greater proportion of patients with normal ESR and CRP had polymyalgia rheumatica (PMR) symptoms compared to patients with elevated ESR or CRP ($p=0.02$). Furthermore, fewer patients with normal ESR and CRP had anemia ($p<0.001$) and there was a trend toward less thrombocytosis ($p=0.09$) compared to subjects with elevated ESR or CRP.

Table 1. Clinical manifestations of GCA patients with normal ESR and CRP to those with elevated ESR and/or CRP

Clinical Variable	ESR, CRP elevated, No (%) N=126	ESR and CRP normal, No (%) N=7	p-value
Female gender	92 (73)	6 (85.7)	0.68
Mean age at diagnosis, years	74.3 (±7.88)	70 (±5.87)	0.12
Median duration symptoms, days	53	113	0.32
Mean duration from laboratory testing to biopsy, days	6.1 (±8.34)	8.7 (±9.07)	0.52
New headache	79 (62.7)	4 (57.1)	1.00
Jaw claudication	61 (48.4)	2 (28.6)	0.45
Scalp tenderness	43 (34.1)	2 (28.6)	1.00
Permanent vision loss	11 (8.7)	1 (14.3)	0.49
Fever	31 (24.6)	0 (0)	0.20
Anorexia	16 (12.7)	0 (0)	0.60
Weight loss	42 (33.3)	1 (14.3)	0.43
Polymyalgis rheumatica	33 (26.2)	5 (71.4)	0.02
NSAID use	61 (49.6)	2 (28.6)	0.44
Anemia	89 (70.6%)	0 (0)	<0.001
Thrombocytosis	43 (36.4)	0 (0)	0.09

Conclusions: CRP is considered a more sensitive marker in GCA. This is the largest, single center study to date evaluating the prevalence of normal CRP in biopsy-proven GCA. While ESR and CRP were concordantly elevated in most patients, discordant results were noted in 5.6%. More significantly, 4% of patients in this study had both normal ESR and CRP at diagnosis. They were more likely to present with PMR symptoms. Absence of a systemic inflammatory response does not exclude GCA and biopsy should be pursued in patients with high clinical suspicion of GCA, especially if PMR symptoms are present.

Meyer Institut Florence, Florence, Italy, [11]Pediatric Rheumatology, Bicêtre University Hospital, Le Kremlin-Bicêtre, France, [12]Pediatric Rheumatology, Robert Debré University Hospital, Paris, France, [13]Pediatric Rheumatology, Toulouse University Hospital, Toulouse, France, [14]Pediatric Rheumatology, Vaudois University Hospital, Lausanne, Switzerland, [15]Rheumatology Research Center, Shariati Hospital, Tehran, Islamic Republic of Iran, [16]Rhumatology, Childrens Hospital, University of Tuebingen, Tübingen, Germany

Aim of the Study: To set up an algorithm for definition of pediatric Behçet's disease (PED-BD) based on international cohort of children suspected with BD

Patients and Methods: An international expert committee has defined the inclusion criteria as follows: Recurrent oral aphthosis (ROA) associated with at least one of following: genital ulceration (GU), erythema nodosum, folliculitis, pustulous/acneiform lesions, positive pathergy test, uveitis, venous/arterial thrombosis, family history of BD. Onset of disease is before the 16th birthday, disease duration is ≤ 3 years, minimum future follow up duration is 4 years and to obtain informed consent. Clinical data are updated every year. Accordingly, the included patients are classified by the expert committee into 3 groups: definite PED-BD, probable PED-BD and no PED-BD. Statistical analysis are performed at the end to compare the 3 groups of patients. Centers specializing in PED-BD have been called to collaborate and document their patients into a single database, (available online).

Results: In January 2010, 110 patients (56M/54F) from 16 centres of 11 countries have been included. Mean age at first symptom: 8.1 y (median 8.2,). Mean age at BD suspicion: 11.8 y, (median 14.4y). At inclusion 38 % of them had only 1 symptom associated with ROA, 31% had 2 and 31% had at least 3. 106 first evaluations have been done. Chronology of symptoms at presentation: 59 patients with 1 symptom (ROA: 45, and fever:5 being the most frequent)), 26 with 2 symptoms (OA + GU: 6), 14 with 3 and 3 with 4.

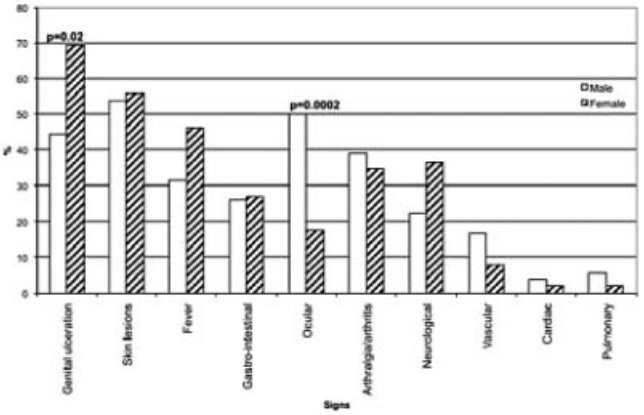

Figure 1. Clinical signs (percentages) at first visit, according to their gender, in 106 PED-BD patients.

93% were receiving treatment: colchicine 59%, steroids 58%, and azathioprine 14%. Fifty-seven patients underwent the first year evaluation and 36 had no new symptom, 12 had one, and 9 had 2. The expert committee has examined 48 files and classified 30 as definite and 18 as probable. Among our patients classified as definite, 26 (87%) fulfilled the ISG criteria. 17/18 classified as probable did not meet the international criteria ($p < 0.001$)].

Table. List of symptoms in addition to oral aphthosis in patients classified as definite and probable by the committee of experts.

	Confirmed n=30	Probable n=18
Genital ulceration*	21	7
Skin lesions**	22	3
Uveitis	16	6
Arthralgia/arthritis	11	7
Gastro-intestinal	12	6
Neurological***	12	3
Vascular	7	1
Urological	1	0
Fever	13	6
Pulmonary	3	0
Cardiac	3	0
Family history	3	4

Significant values: *p=0.03; **p=0.0001; ***p=0.09

Conclusion: The expert committee has classified the majority of patients in the BD group although they presented with few symptoms independently from BD classification criteria.

Plasma Fibrinogen Is More Specific Than Either ESR or CRP for Confirmation of Response to Treatment in Patients with Active Polymyalgia Rheumatica. Eoghan M. McCarthy[2], Paul A. MacMullan[4], Shibeb Al-Mudhaffer[4], Anne Madigan[4], Suzanne Donnelly[4], Conor J. McCarthy[3], Eamonn S. Molloy[5] and Geraldine M. McCarthy[1]. [1]Mater Misericordiae Univ. Hosp, Dublin, Ireland, [2]Mater Misericordiae University Hospital, Dublin, Ireland, [3]Mater Misericordiae University Hospital, Dublin, Ireland, [4]Mater Misericordiae University Hospital, [5]St Vincent's University Hospital, Dublin, Ireland

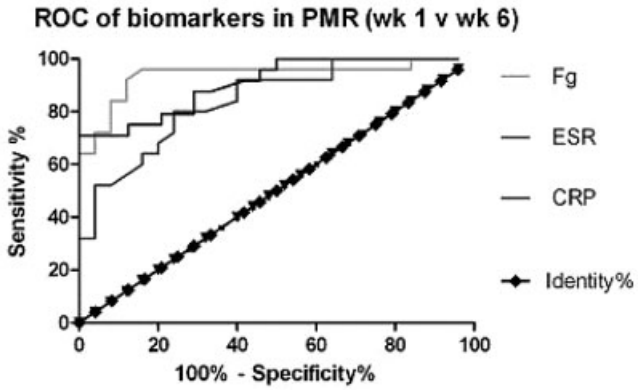
Purpose: To evaluate fibrinogen as a marker of disease activity in polymyalgia rheumatica (PMR).

Background: Measurement of disease activity in PMR is challenging due to the subjective nature of symptoms and absence of consistent physical signs in an elderly population. ESR and CRP are used in clinical practice to guide therapeutic decisions. Both are non specific markers of inflammation. Disease activity in PMR has been shown to correlate with interleukin 6(IL6) levels. IL6 also regulates fibrinogen production. We sought to prospectively evaluate plasma fibrinogen as a biomarker of active inflammation in patients with PMR.

Methods: 60 patients with PMR (as per Jones Hazleman criteria) were divided into Active disease (group 1, n=25) or Inactive disease(group 2,n=35), based on symptoms, physician assessment and standard biomarkers ESR and CRP. Plasma fibrinogen was also assayed. Both groups underwent clinical and laboratory assessment at baseline and 6 weeks. The following disease activity data was collected: Duration of morning stiffness(mins), Visual Analogue Scale(VAS) for pain(Vaspain) and VAS for patient assessment of disease activity(VasDA). Demographic data and categorical variables were assessed using Fischers Exact Test. Between group disease activity data were assessed using Wilcoxon Signed Rank Test. Receiver operator curves (ROC), predictive values, and likelihood ratios were calculated for all biomarkers measured.

Results: Demographic data was similar in all groups. Median steroid dose was 15mg (range 10 –60mg) in the active group and 5mg (range 0–15mg) in the inactive group. There were significant differences in steroid dose between the two groups($p<.001$).Mean scores for Vas pain (7.44 versus 2.8), Vas disease activity (7.38 vs 2.77) and duration of morning stiffness(72mins vs 9mins) improved significantly in the Active group between week 1 and week 6 ($p<0.001$).Mean fibrinogen reduced from 5.2g/L to 3.5g/L (normal<4g/L) between weeks 1 and 6. ESR and CRP reduced from 59.6 mm/hr to 24.3 mm/hr (normal <20mm/hr) and 45.9mg/L to 12.66mg/L(normal<5mg/L). There was no significant difference between the mean disease scores at week 6 in the Active group and the Inactive group at either week 1 or 6

ROC curve analysis revealed fibrinogen to be more specific than either ESR or CRP for the detection of response to treatment in patients with active PMR (Fig 1).



Values above the upper limit of normal for fibrinogen, CRP and ESR were associated with likelihood ratios for active disease of 20.53, 2.9 and 2.8 respectively ($p<0.001$).

Conclusion: Plasma fibrinogen was more specific for the confirmation of both active PMR and response to treatment than either ESR or CRP. While validation by other studies is required, this data suggests that measurement of fibrinogen as an adjunct to ESR and CRP in patients with suspected active PMR may enhance accuracy of diagnosis and guide therapeutic decisions.

Prevalence of Behçet's Disease in Southern Sweden. Aladdin Mohammad[1], Thomas Mandl[3], Gunnar K. Sturfelt[2] and Mårten Segelmark[2], [1]Helsingborg Hospital, Helsingborg, Sweden, [2]Skåne University Hospital, Lund, Sweden, [3]Skåne University Hospital, Malmö, Sweden

Background: Behçet's Disease (BD) is a chronic inflammatory disease of unknown etiology characterized by recurrent oral and genital ulcerations and a variety of systemic manifestations, most of which are believed to be due to vasculitis. BD has a distinct geographic distribution with highest prevalence in the countries of East Asia, the Middle East and the Mediterranean (the old Silk Route).The epidemiology of BD in Sweden is largely unknown. Studies from other European countries have shown significantly higher prevalences among immigrants in comparison to populations with European ancestry.

Objectives: To estimate the prevalence of Behçet's Disease (BD) in a well defined multiethnic population in southern Sweden.

Method: The study area is two health care districts in the southern part of Skåne, the southernmost county in Sweden. The study population (adult $\geq$ 15 years) at the date of prevalence estimate was 582347 inhabitants (51 % females). The majority of the population was Scandinavian but about 23 % were of non-Scandinavian ancestry. Patients with BD living within the study area were identified by search in clinical registries at the departments of Rheumatology, Nephrology and Ophthalmology at the 3 hospitals within the study area. The search period was between 1997 and the end of 2009. All case records were reviewed to ascertain the diagnosis. Only patients fulfilling the criteria for diagnosis of BD according to the International Study Group for Behçet's Disease were included. The date of point prevalence was January, 1st, 2010.

Results: A total of 21 patients (five women) fulfilling the diagnosis criteria for BD were included in the study. The main clinical and demographic features of all patients are summarized in Table 1. Eighty one percent of patients (17 of 21) were of non-Scandinavian ancestry, mostly from the Middle East, Iraq and Turkey. The prevalence of BD was 36.1/million adults, and was significantly higher among subjects of non-Scandinavian ancestry in comparison to subjects of Scandinavian ancestry (125.8 *vs.* 8.9/million adults, $p<0.001$). For the entire study population, the gender-specific prevalence rate of BD was significantly higher among men than women; 55.9/million *vs.* 16.9/million ($p=0.013$).

Table 1. Clinical and demographic characteristics of patients with Behçet's Disease In southern Sweden

	All patients (n=21)	Men (n=16)	Women (n=5)	P[1]
Prevalence/million adult (95% CI)				
All patients, n=21 (5 women)	36.1 (20.6–51.5)	55.9 (28.5–83.3)	16.9 (2.1–31.7)	0.013
Scandinavian, n=4 (3 women)	8.9 (0.2–17.7)	4.6 (0–13.5)	13.2 (0–28.1)	0.336
Non-Scandinavian, n=17 (2 women)	125.8 (66.0–185.5)	223.9 (110.6–337.1)	29.3 (0–70.0)	0.001
Diagnosis delay[2], months, median (range)	42 (4–96)	48 (10–96)	36 (4–72)	0.618
Age at diagnosis, yrs, median (range)	30 (15–42)	31 (15–42)	24 (19–38)	0.380
Age at point prevalence, yrs, median (range)	41 (27–66)	42 (27–66)	40 (31–54)	0.809
Clinical features[3], N (%)				
Oral ulceration	21 (100)	16 (100)	5 (100)	
Genital ulceration	17 (81)	13 (81)	4 (80)	0.819
Skin lesions	17 (81)	12 (75)	5 (100)	0.072
Eye lesions	13 (62)	10 (63)	3 (60)	0.920
Arthritis/arthralgia	5 (24)	4 (25)	1 (20)	0.819
Venous thrombosis	4 (19)	4 (25)	0 (0)	0.214

[1] men vs. women, [2]time from first symptom to diagnosis, [3]occurring anytime throughout the disease course

Conclusions: The prevalence of BD in our area was significantly higher among subjects of non-Scandinavian ancestry in comparison to subjects of Scandinavian ancestry. These findings are consistent with previous epidemiologic reports from other European countries.

Safe, Rapid-Onset, and Sustained Biological Activity of IL-1β Regulating Antibody XOMA 052 in Resistant Uveitis of Behçet's Disease: Results of a Pilot Trial. Ahmet Gül[2], Bahar Artim-Esen[2], Alan M. Solinger[4], Linda Giustino[4], Charles Dinarello[3] and Ilknur M. Tugal-Tutkun[1], [1]Istanbul, Turkey, [2]Istanbul University, Istanbul, Turkey, [3]University of Colorado, Aurora, CO, [4]XOMA (US) LLC, Berkeley, CA

Introduction: Behçet's disease (BD) is a vasculitic multi-system inflammatory disorder of unknown etiology. Increased expression of proinflammatory cytokines, including IL-1β has been considered to play a critical role in the pathogenesis of BD. Uveitis is a major manifestation of BD, and recurrent attacks can cause permanent vision loss in patients resistant to immunosuppressive drugs. XOMA 052 is a recombinant humanized monoclonal antibody. It binds and regulates IL-1β activity, and its administration may produce rapid and sustained reductions in symptoms in IL-1β-mediated systemic inflammatory diseases.

Aim: To evaluate the safety and PK of XOMA 052 in BD uveitis. Additional assessments were planned as exploratory measures of biologic and clinical activity, particularly of uveitis.

Methods: This pilot open-label study enrolled BD patients who developed a posterior/panuveitis or retinal vasculitis attack despite cyclosporine and/or azathioprine treatment. XOMA 052 was administered as a single 0.3 mg/kg intravenous infusion. Subjects suspended their immunosuppressive treatments and maintained prednisolone at $\leq$10 mg/day (6 patients) or 20mg/day (one patient) without any increase.

Results: Seven patients enrolled in and completed the study period of 98 days. No adverse events related to XOMA 052 were observed. Preliminary PK analysis of the first 6 patients showed a clearance of 2.6 mL/day/kg, a beta half-life 26.7 days and a volume of distribution for the central compartment of 54 mL/kg. Intraocular inflammation started to resolve in all patients on Day 1, and complete resolution of retinal findings and vitreous haze was achieved in 4 to 21 days. Five patients were in remission on Day 28, and one was still in remission at Day 98 with a single infusion. One of the patients received increased doses of prednisolone for new retinitis attack in the contralateral eye on Day 25, and other received intravitreal methyl pred-

nisolone for cystoid macular edema (CME) on Day 22 as rescue. After a protocol amendment, five patients received a second infusion for new retinal infiltrates between Day 49 and Day 95, and one patient for CME in the contralateral eye on Day 29. All patients responded to the repeat infusions. Five patients, who had recurrent oral ulcers and folliculitis before the trial, experienced recurrences of those manifestations despite resolution of intraocular inflammation.

Conclusions: Findings of this pilot trial suggest that IL-1β plays a major role in BD uveitis. Administration of XOMA 052 appears safe, and regulation of IL-1β using XOMA 052 shows a rapid-onset effect for the treatment of intraocular inflammatory attack. This favorable effect of XOMA 052 was observed despite discontinuation of immunosuppressives as of infusion day and without any increase in corticosteroids. Results of this pilot trial warrant additional studies. Responses of non-ocular disease manifestations to XOMA 052 need also be studied further.

Serum Hepcidin Is Elevated in Patients with Giant Cell Arteritis and Is Inversely Associated with Serum Iron Levels. Curry L. Koening[2], Jose Hernandez-Rodriguez[1], Marc Corbera-Bellalta[1], Maria C. Cid[1], Bradley Katz[3] and Ivana De Domenico[3]. [1]University of Barcelona, [2]University of Utah, Salt Lake City, UT, [3]University of Utah

Background: Giant cell arteritis (GCA) is a systemic inflammatory blood vessel disease characterized by an elevated sedimentation rate and anemia of chronic disease (ACD). ACD is primarily mediated through hepcidin, a peptide hormone that causes iron retention in macrophages when expressed at high levels. Iron retention in macrophages leads to serum hypoferremia and decreased red blood cell production. Hepcidin is expressed primarily by hepatocytes and mononuclear cells and is upregulated by proinflammatory cytokines such as interleukin 6 (IL-6) and IL-1. Both IL-1 and IL-6 play a role in the pathogenesis of GCA. We hypothesized patients with GCA would have higher serum hepcidin levels than that of controls and that these values would be inversely proportional to serum iron levels.

Methods: The serum of 20 patients with biopsy-proven, untreated GCA was analyzed for hepcidin using a competitive assay. Serum levels of iron and IL-6 were also analyzed. Results were compared to 41 healthy control patients with similar age and gender. Continuous variables were compared using the Student's t test. Categorical variables were compared using Chi square test. Pearson's correlation test was used to test the association between two variables. P values <0.05 were considered significant.

Results: The average age of patients with GCA and controls did not differ (79.1; SD 6.6 vs 81.4; SD 5.0; P=0.19). Females were more predominant in the control group (80%) than in patients with GCA (60%). Differences in gender were not statistically significant between the two groups (P=0.09). The mean serum hemoglobin value for patients with GCA was 11.1 (SD 1.3) g/dl. Serum hepcidin levels in patients with GCA were 361.2 (SD 124.1) ng/ml compared to 82.9 (SD 6.3) ng/ml in controls (P<0.05). Patients with GCA were significantly more hypoferremic than controls. Serum iron levels in patients with GCA were 80.1 ug/dl (SD 22.9) compared to 213.8 ug/dl (SD 215.7) in controls (P=<0.05). Serum hepcidin levels were directly proportional to serum IL-6 values (CC 0.75; P<0.05) and inversely proportional to serum iron values (CC −0.32; P<0.05). For patients with GCA, no significant correlation was seen between the serum hemoglobin and hepcidin values (CC 0.43; P=0.06).

Conclusions: Patients with active GCA have higher levels of serum hepcidin than controls. These values were inversely correlated with serum iron but directly proportional to serum IL-6 values. Serum hepcidin values did not correlate with hemoglobin values since circulating red blood cells are not affected by hepcidin. Furthermore, the effect of hepcidin on red blood cell production may not be immediate. For patients with GCA, increased expression of hepcidin is associated with lower serum iron values, which may reduce red blood cell production. Hepcidin appears to be involved in the development of ACD in patients with GCA.

Severe and Opportunistic Infections during Giant Cell Arteritis Course: A Case-Control Study. Javier Narvaez[1], Laura López Vives[1], Paula Estrada[2], Nuria del Castillo[1], Montserrat Robustillo[1] and Joan Miquel Nolla[1]. [1]Department of Rheumatology, Hospital Universitario de Bellvitge, Barcelona, Spain, [2]Department of Rheumatology, Barcelona, Spain

Purpose: To assess the incidence of severe and opportunistic infections in GCA patients as compared to age- and sex-matched, population based randomly selected controls.

Methods: Case-control study including 140 cases with GCA diagnosed in 1 center from 1986 to 2008. Patients were diagnosed with GCA if they had a positive temporal artery biopsy (TAB) or, in cases with negative biopsy or no biopsy, if they fulfilled the 1990 ACR criteria for the classification of GCA and had a prompt and persistent response to glucocorticoid (GC) treatment. The end-point of patient follow-up was the date of the last clinic visit or the date of death. For each GCA patient, 2 subjects without GCA of the same sex and similar age an time of follow-up were randomly selected from the population of patients attended in our outpatient clinic due to osteoporosis, osteoarthritis or gout. Severe infection was recorded as any bacterial infection leading to hospitalization.

Results: The series included 94 women and 46 men with a mean age at time of diagnosis of 75 ± 7 years (range, 56 to 92). TAB was positive in 112 (80 %) patients. The median duration of follow-up after diagnosis was 36.6 months (range, 12.5 to 180).

All patients were treated with GCs and responded rapidly (mean initial dosage of prednisone: 50.1 ± 13.7 mg/day). The dosage was later reduced according to the treating physicians' judgment.

During follow-up, severe and/or opportunistic infections were recorded in 17.9% (25/140) of GCA patients compared to 3.5% (10/280) in the control group (odds ratio (OR) = 5.87, 95% confidence interval (CI): 2.73, 12.61).

Among GCA patients, opportunistic infections occurred in 5.7% (8/140) of the patients (including 1 case of tuberculosis, 6 cases of herpes zoster and 2 cases of candidiasis) compared to 1.4% (4/280) in the control group (OR = 4.18, 95% CI: 1.23, 14.14). Several bacterial infections occurred in 13.6% (19/140) of the cases compared to 2.14% (6/280) in the non-GCA subjects (OR = 7.17; 95% CI: 1.79, 18.4).

Interestingly, the incidence of tuberculosis (TB) in our GCA patients, in whom prophylaxis with isoniazid was not regularly administered, was 181/100,000 patient-years (1 case in 550 patient-years of follow-up). During the same period (1990–2008) the pooled annual incidence of TB infection in the general population of Spain ranged from 23 to 30 cases/100,000 individuals. This data reflects that the incidence of TB in GCA patients receiving GC is at least 6 times higher than in the general population.

Only one of the GCA patients died due to pulmonary TB complicated with upper gastrointestinal bleeding. The overall mortality was similar in cases and controls (p>0.05).

Logistic regression models identified the cumulative dose of prednisone (OR=6.19, 95% CI: 1.61, 23.71; p=0.007) and the presence of large-artery complication (aortic involvement and/or large-artery stenosis) (OR=11.35, 95% CI: 2.24, 57.33; p=0.003) as significant predictors of severe/opportunistic infections.

Conclusion: The incidence of severe and opportunistic infections is increased in GCA. This increased risk is mostly influenced by GC therapy. We found a 6-fold increased risk of TB infection in patients diagnosed with GCA.

Significance of "Healed Arteritis" (HA) on Temporal Artery Biopsy. Rahul Sehgal, Elise Belilos, Matthew Geller, Lorna Ogden, Steven E. Carsons and George K. Turi, Winthrop University Hospital, Mineola, NY

Purpose: Although temporal artery biopsy (TAB) is the gold standard for the diagnosis of Giant Cell Arteritis (GCA), the presence of skip lesions, and atypical biopsy features limit its utility. In particular, the pathologic diagnosis of HA is controversial. Many changes described for HA may be seen in aging and atherosclerosis alone. We attempted to determine the significance of HA by comparing pathologic features, clinical and laboratory manifestations, and corticosteroid (CS) requirements of HA patients to those displaying classical GCA on TAB.

Methods: We performed a retrospective cohort study, comparing the clinical presentation, laboratory data and CS requirements of 8 cases having a

pathology report indicating HA to 12 cases of classical GCA. To validate the pathologic impression of HA for our cases, a literature review was performed to identify the pathologic features most commonly reported in HA. These were found to include intimal thickening, medial fibrosis, scarring and calcification and internal elastic lamina (IEL) fragmentation. If present, inflammatory cells must be focal or scant. All slides (~25 sections/patient) were reviewed by 3 pathologists to 1) quantitate the features of HA and GCA and 2) to ensure that any cases with inflammatory infiltrates graded more than scant or focal (0–1 on a scale of 0–4) were excluded from the HA group. Clinically, all 20 patients were treated for GCA. CS exposure prior to TAB was also recorded.

Results: Other than the presence of significant medial and/or adventitial inflammation in GCA, there were no significant differences in the pathologic features previously identified to be associated with HA when slides from HA and GCA were compared. Although there was slightly more medial fibrosis, scarring and calcification in the HA group, this was not significant. The proportion of headache, jaw claudication, visual symptoms, fever, weight loss and scalp tenderness did not significantly differ between groups. No difference was noted in ESR. A trend towards higher alkaline phosphatase levels in GCA vs. HA (36% vs. 0%; p=0.11) was seen. Only the presence of PMR was significantly associated with HA (86% vs. 8.3%; p=0.002). Although the mean CS dose at Day 1 was significantly higher for GCA (150mg GCA vs. 45 mg HA; p=0.045), no significant differences in subsequent CS dosing at days 30, 60 or 90 was seen. Importantly, cumulative pre-biopsy CS exposure was nearly identical (357 GCA vs. 366 mg HA; p=0.857).

Conclusion: The presence of only scant or focal inflammation on TAB and a significant association with PMR symptoms were the only pathologic or clinical features that distinguished HA from GCA. CS courses were similar as well. Pre-biopsy CS exposure is not responsible for this phenotype, thus, use of the term "healed arteritis" should be reexamined. "Mild arteritis" may be appropriate for biopsies demonstrating scant or focal inflammation. Intimal thickening, medial fibrosis, scarring and calcification in the absence of any inflammation appear indistinguishable from changes due to aging and atherosclerosis.

1312

Some Manifestations Disappear Earlier Than Others in Behcet's Syndrome (BS). Sevgi F. Sacli[2], Emire Seyahi[4], Yilmaz Ozyazgan[3], Cem Mat[1] and Hasan Yazici[4]. [1]Cerrahpasa Medical Faculty, Dermatology Department, Turkey, [2]Cerrahpasa Medical Faculty, Internal Medicine Department, Turkey, [3]Cerrahpasa Medical Faculty, Ophthalmology Department, Turkey, [4]Cerrahpasa Medical Faculty, Rheumatology Department, Turkey

In a 20 year outcome study, we had observed that the frequency of all mucocutaneous lesions and arthritis decreased in frequency with the passage of time (1). In this study we investigated whether some manifestations disappeared before others.

Patients and Methods: We studied consecutive BS patients who were seen in the rheumatology outpatient clinic at Cerrahpasa Medical Faculty in Istanbul between February 2009 and April 2010. Only BS patients whose disease duration and follow-up were 10 years or longer were included in the study. With the help of a questionnaire, patients were asked whether skin mucosa lesions, arthritis and uveitis attacks occurred for the preceding one year. If not, they were asked about the date when the manifestation occurred for the last time. Information given by the patients was confirmed with the patient charts whenever it was possible. Also a pathergy test was done to those who volunteered.

Results: We studied 115 (60 M, 55 F) patients. The mean age of the patients was 48 ± 8 and the mean disease duration 20 ± 6 years. 63 patients had eye, 20 vascular and 6 neurological disease. Vascular and neurological attacks were not evaluated due to rarity. The frequency of those with any BS manifestation during the preceding one year including pathergy positivity was decreased significantly at the final visit compared to that found at the beginning.

Table. Frequency of BS manifestations

Frequency n (%)	Initial visit	Final visit	P
Oral ulcers	115 (100)	84 (73)	<0.001
Genital ulcers	105 (115)	13 (11)	<0.001
Papulopustular lesions	104 (90)	61 (53)	<0.001
Erythema nodosum	72 (63)	23 (20)	<0.001
Arthritis	39 (34)	8 (7)	<0.001
Pathergy positivity	85/109 (78)	6/39 (15)	<0.001

As seen in the Kaplan-Meier curve, eye attacks were the first to cease followed by arthritis, genital ulcers and skin lesions.

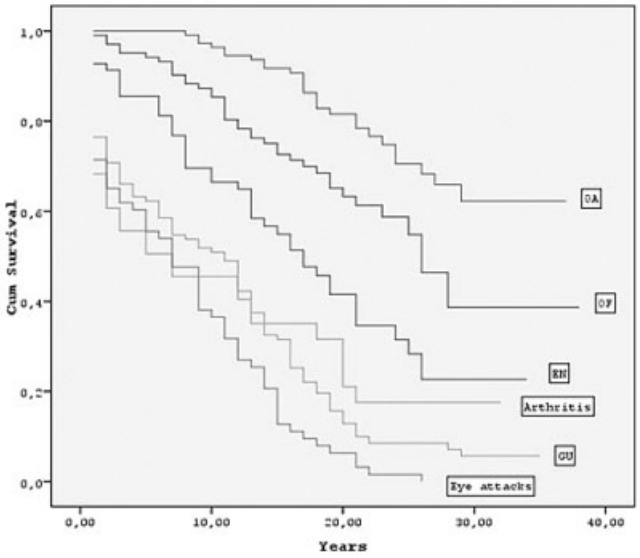

Figure. Kaplan Meier survival plot for duration of BS manifestations.

This was most prominent among females. Oral ulcer was the most frequent lesion after 30 years of disease course.

Conclusions: In BS some disease manifestations disappear earlier than others. These findings may have important pathogenetic and clinical implications. Since our survey was cross-sectional to retrospective caution is required in interpretation.

Takayasu's Arteritis Is Associated with HLA-B*52, but Not with B*51, in Turkey. Turkish Takayasu Study Group. Turkey

Aim: HLA-B*51 and B*52 are two close HLA alleles with minor amino acid differences. However, they are associated with two different vasculitides (B*51 with Behcet's disease and B*52 with Takayasu's arteritis-TAK) with major clinical and immunological differences. This study aimed to screen a large cohort of TAK patients from Turkey for the presence of HLA-B*51 and B*52 alleles as susceptibility factors.

Material and Methods: TAK patients (n=305) followed by 15 centers were included in the study. The mean age of the patients was 37,8 years and 86% (n=264) were female. DNA samples of the patients and healthy controls (n=210) were isolated by salting-out technique. HLA-B*51 and B*52 were investigated by using polymerase chain reaction (PCR) with sequence specific primers (SSP). The presence of the alleles were compared by chi-square method.

Results: B*52 has shown a significant association with TAK (67/305 (22,3%) vs. 14/210 (6,6%), p<0.0001, OR: 4,07, CI: 2,19-7,36). However, the distribution of B*51 did not differ between TAK and control groups (24.6% (75/305) vs. 24.8% (52/210), OR: 0.99). Trends towards an association of B*52 presence with limited aortic involvement (Type I: OR: 0.4, p=0.05), medically refractory disease (OR: 1.8, p=0.14) and late-onset (OR: 0.25, p=0.009) were observed. No significant association of B*52 was present with surgical procedures.

Conclusion: In this study, the previously reported association of TAK with B*52 in Japanese and other populations was confirmed in patients from Turkey, whereas no association with B*51 was observed. This association might have implications about the functional relevance of B*52 in TAK pathogenesis, which has to be further explored.

Disclosure: Turkish Takayasu Study Group: None.

Treatment with Angiotensin Converting Enzyme Inhibitors (ACEI) or Angiotensin II Receptor Antagonists (ARA) Is Associated with Higher Frequency of Ischemic Complications but Better Response to Therapy in Patients with Giant-Cell Arteritis (GCA). Marco A. Alba[3], Ana Garcia-Martinez[1], Georgina Espigol-Frigole[3], Itziar Tavera[2], Montserrat Butjosa[3], Sergio Prieto-Gonzalez[5], Jose Hernandez-Rodriguez[4] and Maria C. Cid[2]. [1]Emergency Department, Hospital Clinic, Barcelona, Spain, [2]Systemic Autoimmune Diseases, Hospital Clinic, Barcelona, Spain, [3]Systemic Autoimmune Diseases. Hospital Clinic, Barcelona, Spain, [4]Systemic Autoimmune Diseases. Hospital Clininc, Barcelona, Spain, [5]Systemic Autoimmune Diseases.Hospital Clinic, Barcelona, Spain

Background: GCA is a chronic inflammatory disease involving large and medium-sized arteries. Involvement of cranial arteries is particularly symptomatic. About 15–20% of patients develop cranial ischemic events derived from occlusion of involved vessels. Previous studies have shown that angiotensin receptor 1 is expressed in vascular lesions from patients with GCA (Ophthalmology 2009; 116: 990–6). Angiotensin II is an important mediator of angiogenesis and vascular remodelling.

Purpose: To investigate whether ACEI or ARB therapy is related to vascular complications or response to glucocorticoid therapy in patients with GCA.

Methods: Between 1995 and 2005, 160 patients were diagnosed with biopsy proven GCA at our institution. Among them patients with the following criteria were selected: prospective treatment and follow-up by the authors according to uniform criteria, prospective recording of GCA-related complications, relapses and glucocorticosteroid doses, and a follow-up duration of at least 3 years. Eighty-four patients fulfilled the selection criteria and were eligible for this study. Although retrospective in design, the study was performed on a prospectively followed cohort. Fisher exact test and Kaplan-Meyer survival analysis/log-rank test were used for statistical comparison.

Results: Eighteen patients (21%) were receiving ACEI (12 patients) or ARB (6 patients) at the time of diagnosis. GCA-related complications (amaurosis fugax, diplopia, anterior ischemic optic neuritis, transient ischemic attack or stroke) occurred in 18 (21%) of patients at disease presentation. Ischemic complications occurred in 5 (27.8%) of patients receiving ACEI or ARB compared to 5 (7.6%) of those not receiving these therapies ($p = 0.033$). The proportion of patients who relapsed at least once was lower among those receiving ACEI or ARB (54% vs 75%, $p = 0.06$). Patients with multiple relapses were significantly less frequent among the ACEI/ARB treated group ($p = 0.03$). Patients receiving ACEI/ARB tended to achieve a maintenance prednisone dose < 10 mg/day earlier than patients not receiving these therapies (71 vs 82 weeks, $p = 0.07$).

Conclusions: Previous ACEI/ARB use is associated with higher frequency of ischemic complications at the time of GCA diagnosis but is associated with better response to glucocorticoid treatment. These preliminary data suggest that ACEI/ARB effects on angiogenesis or vascular remodelling nay be relevant to patients with GCA.

Use of Peri-Operative Glucocorticoids and Post-Operative Complications in Patients with Takayasu's Arteritis Undergoing Vascular Surgical Procedures. Bijal A. Jayakar[1], Gary S. Hoffman[3] and Carol A. Langford[2]. [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic Foundation, Cleveland, OH, [3]Cleveland Clinic Foundation, Pepper Pike, OH

Purpose: The risks and benefits of peri-operative glucocorticoids (POGC) in patients with Takayasu's arteritis (TAK) undergoing vascular surgery have been unclear. We studied the relationship between POGC and disease activity in TAK patients who received vascular surgery to determine if these factors influenced the risk of infection, vascular events, and other complications.

Methods: Retrospective chart review of TAK patients undergoing vascular surgery at the Cleveland Clinic from 1979–2008. Standardized definitions were used for the diagnosis of TAK, disease activity, and POGC. POGC was defined as prednisone use within 1 month prior to or after surgery and analyzed as 0mg, $<$ 20mg, and $\geq$20mg. Variables including POGC, other immunosuppression, disease activity, age at diagnosis, age at surgery, disease duration at surgery and sex were examined by univariate and multivariate analysis using SAS 9.2.

Results: In this study we identified 40 TAK patients who underwent 56 vascular surgical procedures. Mean age at diagnosis was 33.5 years and at surgery was 40 years. Mean duration of disease at surgery was 6.2 years (0–28.3). Mean time between surgery and last follow-up was 2.1 years (0–8.7). Active disease was present in 24/56 procedures (43%). Histology was obtained in 42/56 (75%) procedures with 8/42 (19%) being histologically active. Discordance between clinical and histological activity was seen in 17/42 (40%). Erythrocyte sedimentation rate (ESR) was increased in 18/44 (41%) measurements including 12/20 (60%) with active disease and 6/24 (25%) with inactive disease. POGC doses were prednisone=0 in 21/56 (37%), <20mg in 10/56 (18%), ≥20mg in 25/56 (45%). 28/56 (56%) were on other immunosuppressives. 42 complications occurred in 30 patients, consisting of 11 infections, 12 vascular events, and 19 other complications. Relapses occurred in 25/56 (45%) with 6 (11%) being within 3 months of surgery. There were 5 deaths, 2 from strokes in the immediate post-operative period. POGC were not associated with a higher frequency of infections ($p = 0.84$). For inactive TAK, total complications were no lower in those who did not receive POGC ($p=0.11$). This lack of association remained present for each subgroup: infection ($p=0.90$), vascular ($p=0.22$), and other complications ($p=0.37$). In active TAK, there was no difference in the occurrence of total complications between those on and not on POGC ($p=0.67$). Although this lack of association was present for other complications ($p=0.74$), subset analyses were not possible for infection or vascular complications because of absence of an event.

Conclusions: The absence of an increased risk of infection in this study support that POGC can be used in TAK patients felt to have active disease at the time of vascular surgery. These results did not support that POGC should be routinely used in all patients with TAK undergoing surgical procedures as the risk of complications was no different in patients who received this. Performance of surgery is not associated with a high rate of immediate relapse, although relapses are common over time in TAK. ESR and clinical definitions remain imperfect measures of disease activity and underscore the need for better biomarkers in TAK.

Application of the Generalizability Theory for Determining Inter-Rater and Inter-Trial Reliability of Spine Curvature Measures in Postmenopausal Women with Osteoporosis of the Spine Using the Flexicurve Ruler and the Digital Inclinometer. Norma J. MacIntyre[1], Lisa Bennett[2], Alison Bonnyman[2] and Paul W. Stratford[2]. [1]McMaster University, Hamilton, ON, Canada, [2]McMaster University

Purpose: Spine curvatures are often measured in physical therapy practice using a flexicurve ruler to calculate kyphotic index (KI) and lordotic index (LI) or a digital inclinometer to quantify the angle at the cervicothoracic (CT), thoracolumbar (TL) and lumbosacral (LS) junctions. Generalizability theory (G-Theory) provides tools that characterize the sources of variation, or facets, in a measurement procedure and permit identification of a protocol that provides optimal reliability. The purpose of this study was to use the tools of G-Theory to investigate the inter-rater and inter-trial reliability of these spine curvature measures and to establish an optimal measurement protocol.

Methods: Nine postmenopausal women over the age of 60 years with established osteoporosis of the spine were recruited for this cross-sectional observational study. Two raters completed triplicate measures of spine curvatures using both the flexicurve ruler and the digital inclinometer according to a standardized protocol. G-Theory was applied through a Generalizability Study to estimate G-coefficients (analogous to the reliability coefficient in the Classical Test Theory). The facets included were participants (P), raters (R) and trials (T). Three-way ANOVAs were used to generate variance components for the following terms: P, R, T, PxR, PxT, RxT and error. G-coefficients were calculated as the proportion of the overall variance that can be attributed to the facets and interactions and the proportions of variance attributed to rater and trial. Follow-up Decision Studies were performed to identify a measurement protocol that minimized error and optimized reliability. G-coefficients ≥ 0.8 were considered desirable and 0.70 to 0.79 were considered acceptable.

Results: Inter-rater reliability is excellent for KI, LI, TL and LS (G-

coefficient = 0.97, 0.91, 0.85 and 0.80, respectively) and acceptable for CT (G-coefficient = 0.74) using our protocol for measuring spine curvatures. Three raters are required to achieve excellent inter-rater reliability for CT (0.81). A single trial would result in excellent reliability for all measures (G-coefficient ≥ 0.94 for all except LI where G-coefficient = 0.84). Triplicate trials improve inter-trial reliability (G-coefficient ≥ 0.98 for all except LI where G-coefficient = 0.94). Little gains are achieved by increasing trials beyond three; eight trials are needed to raise the inter-trial reliability of LI measures to 0.98.

Conclusions: This study demonstrates the application of G-Theory to identify a protocol for measuring spine curvatures in osteoporotic women which optimizes reliability by testing the gains achieved by increasing the number of raters or the number of trials. If more than one rater is involved in assessing spine curvatures, triplicate measures acquired using the flexicurve ruler will be most reliable. For a given rater, inter-trial reliability is optimized by measuring in triplicate whether using the flexicurve ruler or the digital inclinometer.

Baseline Serum Interleukin-6 (IL-6), Tumor Necrosis Factor-α (TNF-α) and C-Reactive Protein (CRP) Do Not Predict Subsequent Hip Bone Loss in Men or Women: The Framingham Osteoporosis Study. Robert R. McLean[3], Xiaochun Zhang[4], Joao D. T. Fontes[2], James B. Meigs[7], L. Adrienne Cupples[1], Douglas P. Kiel[5] and Marian T. Hannan[6]. [1]Boston University School of Public Health, [2]Framingham Heart Study and Boston University, [3]Hebrew Senior Life, Boston, MA, [4]Hebrew SeniorLife, [5]Hebrew SeniorLife and Harvard Medical School, [6]Hebrew SL & Harvard Med Sch, Boston, MA, [7]Massachusetts General Hospital

In vitro studies suggest that several pro-inflammatory cytokines increase bone resorption and that their activity is amplified following estrogen withdrawal. Yet there is little epidemiologic evidence that circulating concentrations of inflammatory markers predict bone loss in men and women, or that estrogen status may influence this relation. We therefore examined the associations of serum concentrations of the cytokines IL-6 and TNF-α, and CRP, a marker of systemic inflammation, with bone loss among men and women in the Framingham Offspring Study. We hypothesized that increased baseline concentrations of inflammatory markers would be associated with greater bone loss, and that this association would be strongest among postmenopausal women not using hormone replacement therapy (HRT). Baseline fasting blood samples were obtained (1998–2001) from 501 men, 106 premenopausal women, 206 postmenopausal using HRT at baseline, and 334 postmenopausal not using HRT. Serum IL-6 (pg/mL) and TNF-α (pg/mL) were measured using ELISAs and CRP (mg/L) using a high-sensitivity assay. Total femur bone mineral density (BMD; g/cm^2) was measured at baseline with a Lunar DPX-L (1996–2001) and at follow-up using a Lunar Prodigy (2002-05), accounting for equipment change. Bone loss was calculated as percent BMD change per year. Within each of the 4 groups defined by sex, menopause status and HRT use, participants were categorized into tertiles of inflammatory markers. We used analysis of covariance to compare mean bone loss in each of the upper 2 tertiles to the lowest tertile and test for a linear trend across tertiles, adjusting for baseline age (y), BMI (kg/m^2), height (in), physical activity, and current smoking (y/n). Mean age at baseline was 61 y (range 29–85 y), and mean follow-up time was 4.6 y (range 1.5–7.9 y).

Least squares-adjusted mean annual % change (SE) in total femur BMD for tertiles of inflammatory biomarkers in Framingham Offspring men and women.

	T1 (Low)	T2	T3 (High)	P trend
Men				
IL-6	−0.01 (0.08)	0.12 (0.07)	−0.03 (0.08)	0.90
TNF-α	0.08 (0.09)	−0.04 (0.09)	−0.05 (0.09)	0.34
CRP	0.04 (0.08)	−0.03 (0.07)	0.07 (0.08)	0.79
Premenopausal women				
IL-6	−0.46 (0.16)	−0.15 (0.16)	−0.02 (0.18)	0.07
TNF-α	−0.08 (0.18)	−0.29 (0.18)	0.05 (0.18)	0.62
CRP	−0.44 (0.17)	−0.13 (0.16)	−0.07 (0.19)	0.16
Postmenopausal women				
HRT users				
IL-6	0.17 (0.12)	0.22 (0.12)	−0.13 (0.13)	0.12
TNF-α	0.31 (0.13)	−0.05 (0.14)	0.11 (0.14)	0.29
CRP	0.09 (0.13)	−0.02 (0.12)	0.19 (0.13)	0.60
HRT non-users				
IL-6	−0.23 (0.12)	−0.20 (0.11)	−0.29 (0.11)	0.72
TNF-α	−0.19 (0.13)	−0.23 (0.12)	−0.47 (0.12)	0.12
CRP	−0.37 (0.12)	−0.23 (0.11)	−0.13 (0.12)	0.18

There were no statistically significant associations between inflammatory markers and total hip bone loss in any of the sex/menopause/HRT groups (Table). Our findings suggest that circulating biomarkers of inflammation are not associated with hip bone loss in men or groups of women categorized by menopause status and HRT use. Future investigations of inflammation and BMD should address limitations of our study by including longitudinal measures of inflammatory markers, more precise measures of estrogen status (e.g. sex hormones), and larger samples that could detect the small bone loss effects suggested by our results.

Development of a Motivational Interviewing Protocol for Clinical Application in Osteoporosis. Maura D. Iversen[3], Laura Rekedal[1] and Daniel Hal Solomon[2]. [1]Boston, MA, [2]Brigham and Womens Hospital, Boston, MA, [3]Northeastern University, Boston, MA

Background: While many effective therapies exist for osteoporosis (OP), most people do not adhere to such treatments long-term. Few proven interventions exist to improve OP medication adherence. Motivational interviewing (MI) is a counseling technique that may improve adherence. We report on methods used to develop MI skills among 5 health educators to promote patient adherence to OP medications.

Methods: Five health educators (HE) participated in an initial 2 day educational session led by a rheumatologist, a behavioral scientist and a certified MI trainer which detailed information on MI techniques and OP. Reinforcement of MI was provided via semi-monthly calls with the study team over one year. Two additional telephonic MI training sessions were provided at the trial midpoint based on two 20–30-minute audio taped client conversations. A second certified MI trainer listened to tapes, coded the MI performance using the Motivational Interviewing Treatment Integrity code (MITI) and then provided feedback using examples from the tapes. The MITI contains 5 domains: evocation, autonomy, collaboration, direction and empathy and MI global spirit. Scores range from 0 (low) to 5 (high). Conversations with clients were also coded based on the ratio of total reflections to questions used. This information was then used to individually tailor feedback about the use of MI techniques for each health educator.

Results: All HEs were female. Mean age was 42 years and range of experience was 7 to 15 years. One health educator was a registered nurse, one a dietician, and one a social worker. At baseline, only one of the five health educators had any experience using MI; two were familiar with MI concepts but had not received training and one was not familiar with MI. Scores across the five MITI domains suggested the HE performance was strongest in the areas of providing direction (all received scores of 3.5 or better) and empathy (average range 2.5–4.5).

Table: MITI Performance Scores for Each Health Educator For MITI Domains During Two Separate Audiotaped Conversations

Global Domains		001	002	003	004	002	005
Evocation	*Tape 1*	3	2	3	3	4	3
	Tape 2	2	3	3	2	4	2
	Average	2.5	2.5	3	2.5	4	2.5
Collaboration	*Tape 1*	2.5	2	3	3	3	3
	Tape 2	2	3	3	2	3	2
	Average	2.25	2.5	4	2.5	3	2.5
Autonomy/Support	*Tape 1*	3	3	3	4	3	3
	Tape 2	3	3	4	4	3	2
	Average	3	3	3.5	4	3	2.5
Direction	*Tape 1*	5	3	5	4	5	5
	Tape 2	5	4	5	4	5	5
	Average	5	3.5	5	4	5	5
Empathy	*Tape 1*	3	2	5	4	4	4
	Tape 2	4	3.5	4	3	4	3
	Average	3.5	2.75	4.5	3.5	4	3.5
Global Spirit Score	*Tape 1*	2.8	2.3	3.0	3.3	3.3	3.0
	Tape 2	2.5	3.0	3.3	2.6	3.3	2.0
		2.65	2.65	3.15	2.95	3.3	2.5

The areas which needed improvement were the domains of evocation, collaboration and autonomy/support. With respect to total reflection to

question ratios, on average the ratio across HEs was 1.3 suggesting the need for the HEs to allow more time for client reflection during conversations.

Discussion: Among a group of health educators who did not use MI skills in their routine counseling activities, a multi-faceted training program in MI over the course of one year led to improvements in the health educators ability to apply MI skills to patient counseling. The strategies which required the most focus were evocation, collaboration and autonomy/support. Both group and individually tailored education sessions were used to promote the use of MI in patient counseling and resulted in competent performance of MI techniques over the course of the clinical trial.

Type of Activity Pacing Instruction Affects Physical Activity Variability in Adults with Symptomatic Knee or Hip Osteoarthritis. Susan L. Murphy[2], Dylan M. Smith[1] and Angela K. Lyden. [1]StonyBrook University, [2]University of Michigan, Ann Arbor, MI

Objective: In a recent trial, we examined the effect of two different activity pacing interventions, general versus tailored, on symptom management for people with knee or hip osteoarthritis and found that fatigue was improved after the tailored compared to the general intervention. The current study was done to examine the secondary effect of activity pacing instruction on objective physical activity patterns (using ambulatory monitoring).

Methods: Thirty two adults with knee or hip osteoarthritis, who were randomly stratified by age and gender, received either tailored or general activity pacing instruction. Both interventions involved two sessions with an occupational therapist. All participants wore an accelerometer for five days that measured physical activity and allowed for repeated symptom assessment at baseline (which was used for tailored activity pacing instruction) and at the 10 week follow-up period. Activity patterns were assessed by examining: physical activity variability, measured using the standard deviation of 5-day average activity counts per minute, and average activity level, the 5-day average activity counts per minute.

Results: Physical activity variability decreased in the tailored group and increased in the general group. Participants in the tailored and general groups did not have significant changes in their average physical activity from baseline to 10 week follow-up.

Conclusion: The type of activity pacing instruction affected the objective physical activity of adults with symptomatic knee or hip OA. Tailored activity pacing was more effective at reducing high and low activity bouts corresponding to the message of keeping a steady pace to reduce symptoms.

A Prospective, Longitudinal Cohort Study Evaluating Psychosocial Risk and Protective Factors for Post Lyme Disease Syndrome. Afton L. Hassett[6], Terry Shlimbaum[2], Diane C. Radvanski[4], David J. Herman[1], Ronald Nahass[1], Steven Buyske[3] and Leonard H. Sigal[5]. [1]ID CARE, [2]Phillips-Barber Family Health Center, [3]Rutgers University, [4]UMDNJ-Robert Wood Johnson Medical School, Union City, NJ, [5]UMDNJ-Robert Wood Johnson Medical School, [6]University of Michigan Medical School, Ann Arbor, MI

Background: Rarely do patients manifest objective evidence of ongoing infection with *B. burgdorferi* after antibiotic treatment and yet it has been estimated that at least one third of treated Lyme disease patients report chronic pain, fatigue, and cognitive problems. The condition referred to as Post Lyme Disease Syndrome, may be more appropriately thought of as fibromyalgia triggered by an infectious disease. There is evidence that illness factors at baseline, such as symptom severity and functional status are associated with symptom persistence and functional status after treatment; however, little is known about psychosocial risk and protective factors.

Methods: In a multicenter longitudinal study, 99 patients newly diagnosed with Lyme disease underwent comprehensive psychometric and medical/laboratory assessments at baseline. All patients received antibiotic treatment and at one year after diagnosis completed the Fibromyalgia Impact Questionnaire revised for Lyme disease (FIQ-LD) to evaluate the presence of chronic symptoms and functional status. Psychosocial factors assessed at baseline included: functional status (FIQ-LD), symptoms checklist, depression (PRIME-MD PHQ), catastrophizing (Coping Strategies Questionnaire-Catastrophizing subscale), negative affect and positive affect (Positive and Negative Affect Scale). At one year, patients with persistent symptoms ascribed to Lyme disease were compared to patients with resolved symptoms.

Results: Of the 74 patients who completed the 1-year assessment, 24 (32.4%) reported chronic symptoms – predominantly pain (VAS mean PLDS: 3.38±2.63 vs. Recovered: 0.43±0.85) and fatigue (VAS mean PLDS: 5.98±1.83 vs. Recovered: 1.56±1.96). Compared with patients who reported no chronic symptoms at one year, only functional status (45.00±18.23 vs. 31.90±21.19, $p<0.01$) and positive affect (31.57±6.63 vs. 35.92±4.96, $p<.003$) at baseline differed between groups. After correcting for multiple comparisons, positive affect alone remained significant. Logistic regression showed that group membership (PLDS vs. recovered from Lyme disease) was predicted by positive affect ($p=0.003$, Somers' Dxy rank correlation of 0.40) and baseline functional status ($p=0.01$, Somers' Dxy rank correlation of 0.35). No other variables were predictive of group status at one year. At baseline, positive affect and functional status were not correlated ($r=0.06$).

Conclusion: Almost one third of Lyme disease patients will manifest chronic symptoms post antibiotic treatment. Consistent with others, we found worse functional status at baseline to be predictive of PLDS. Further, we found that a resilience factor, positive affect, was the most valuable factor for predicting outcome in this population. Patients with higher levels of positive affect were more likely to fully recover from Lyme disease after treatment. Typically, psychological batteries only measure negative factors, but these data are consistent with emerging data in other fields that suggest that positive factors at baseline may better predict outcomes than negative factors.

Changing Shoes: Metaphorical Descriptions of Rheumatoid Arthritis and Identity. Catherine L. Backman[1], Anne Townsend[2] and Linda C. Li[1]. [1]University of British Columbia, Vancouver, BC, Canada, [2]W. Maurice Young Centre for Applied Ethics, University of British Columbia

Background: People lead storied lives and narrative inquiry makes sense of human experience through analyzing stories told. Personal accounts of episodes and events include narrative/rhetorical devices, like metaphors, which help us understand how individuals interpret and apply meaning to their experiences. These interpretations are central to their sense of self and may influence how people engage in future activities and collaborate with health care providers. This study explored how descriptions of emotional and physical adjustments to living with rheumatoid arthritis (RA) serve as metaphors for the impact of RA on identity.

Method: A secondary analysis of two qualitative studies was undertaken using a narrative approach. Study one explored the impact of RA on the role of mother in 12 women; study two explored the help-seeking process in 37 women diagnosed with RA in the year prior to recruitment. During the original data analysis for both studies, narrative devices were observed in descriptions of daily life experiences that had been disrupted by RA, and this prompted the present analysis. All 49 transcripts were reviewed and metaphorical descriptions of how RA experiences shaped sense of self or identity were extracted. Representative metaphors were then written by research team members, supported by verbatim passages from transcripts, and revised until consensus was achieved by the team as a whole.

Results: A number of metaphors illustrate the process of adapting to RA, characterized by adjustments to daily routines from the most basic of self care to participation in valued life roles. A powerful example is "changing shoes" or "no more shoes." This metaphor arises from descriptions of actual events where women could no longer wear the shoes that reflected their style, preference, or life roles. Underlying the seemingly superficial loss of favored shoes was a loss of self – a professional self, a country-club self, a stylish self. "Changing shoes" then becomes a metaphor for a shift in identity from a healthy person to one living with chronic illness and the new work that entails. The things women did to accommodate arthritis, either on their own or on the advice of a health professional, are shown through narrative analysis to represent emotional and physical adaptation to everyday activities that are meaningful to each individual. Metaphors were also observed to exemplify

key concepts specific to identity in current occupational therapy and rehabilitation theories that are intended to inform practice and clinical reasoning.

Conclusion: Metaphor was used to interpret stories of women living with RA. In the example presented here, changing shoes represents not only a physical adjustment to accommodate pain and apply joint protection principles, but also part of an internal process of reshaping identity. Appreciating how small changes carry greater meaning with regard to one's identity may foster more effective patient-provider communication and client-centered practice.

Emotional Response to Serial Doppler Echocardiography Examinations as a Screening Method To Detect Developing Congenital Heart Block in SSA/Ro Positive Pregnancy. Joanna Tingström[2], Mia Barimani[1], Sven-Erik Sonesson[1], Marie Wahren-Herlenius[2] and Elisabet M. B. Welin Henriksson[3]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Karolinska Institutet CMM, Stockholm, Sweden, [3]Karolinska Institutet Rheum, Stockholm, Sweden

Objective: Congenital heart block may develop in the fetus during pregnancy in SSA/Ro52 autoantibody positive women. The aim of this study was to investigate how women with SSA/Ro52 autoantibodies experience their pregnancy focusing on the period between gestational weeks 18–24 when serial Ultrasound/Doppler examinations were performed to detect early signs of congenital heart block. The implementation of a new screening method has the benefit of detecting heart block early and allowing treatment at the stage when it is most effective, but may also cause negative side effects such as increased stress for the women.

Methods: Data were collected through individual semi-structured interviews with Swedish SSA/Ro52 positive women post pregnancy (n=14). None of the women gave birth to a child with congenital heart block. The interviews were audio taped, transcribed verbatim and analyzed by qualitative content analysis.

Results: Three categories emerged from the responses; information, emotional response and support. The information received prior to and during early pregnancy was focused on the need for attending a specialized antenatal clinic, and information on the risk for congenital heart block was scarce or missing. During gestational week 18–24 when the ultrasound/Doppler examinations were performed all women described increased stress in some way. However, nobody wanted to renounce the examinations and the interaction with the caregivers made the women feel more safe and secure. Several women described that they did not emotionally acknowledge the pregnancy and could not fully take in that they were pregnant until after gestational week 24. None had been offered psychological support.

Conclusions: There is a need for structured information and organized programs for surveillance of SSA/Ro52 positive pregnancy. Despite the increased stress the women described in connection with the ultrasound examinations, all women felt that the advantages outweighed the disadvantages of the procedure. Further, offering psychological support to the women and their families to give them tools to handle the stress and to facilitate the early attachment to the child should be considered.

Psychological Factors but Not Clinical Markers of Disease Activity Predict Adherence among Rheumatoid Arthritis (RA) Patients Receiving DMARDs and Adalimumab (ADA): Results from the British Society for Rheumatology Biologics Register (BSRBR). C. Morgan[1], J. McBeth[2], L. Cordingley[2], K. D. Watson[2], BSRBR Control Centre Consortium, K. L. Hyrich[2], D. P. M. Symmons[2], I. N. Bruce[2] and on Behalf of the BSR Biologics Register. [1]The University of Manchester, Manchester, United Kingdom, [2]The University of Manchester

Background: Drug adherence rates amongst RA patients are reported to be between 30–78%. Psychological factors such as illness perceptions and coping mechanisms are important predictors of adherence. The aim of this study was to establish the relative contributions of demographic, physical and psychological factors to adherence.

Methods: The analysis included 610 patients recruited between 01/05/07–30/04/09 to the BSRBR, a UK national observational cohort study monitoring the long term safety of biologic agents in RA patients receiving anti-TNF therapy. Two patient groups were identified for this analysis: (i) those taking ADA as a monotherapy or in combination with a DMARD and (ii) those taking a DMARD-only based regime as mono or combination therapy. At baseline, demographic data, DAS28, physical function (HAQ), quality of life (SF36) and psychological data including illness perception, coping strategies and belief about medication use were collected. Adherence was assessed indirectly using the validated 19-item patient self-complete Compliance Questionnaire Rheumatology (CQR) at baseline. The CQR yields a total score between 0–100, with higher scores indicating higher levels of adherence. Linear regression (adjusted for age, gender and disease duration) was used to investigate the relationships between baseline factors and CQR scores.

Results: A total of 358 ADA and 252 DMARD patients were available for analysis of which 75% were female. Compared to the DMARD group, ADA patients had a younger age at disease onset (median 44 v 51 years, $p<0.001$), longer disease duration (median 9 v 5 years, $p<0.001$) and higher disease activity (mean DAS28, SD: 6.5, 0.9 v 5.4, 0.9, $p<0.001$). 287 (80.2%) of the ADA group were also taking a DMARD, and in the DMARD-only group, 101 (40.1%) were taking ≥ 2 DMARDs at time of study. The median CQR score for the DMARD and ADA patients were 71.9 (IQR 64.9–78.9) and 75.4 (IQR 64.9–82.5), respectively. The DAS28 and HAQ did not predict CQR score in either group. In both treatment groups a lower CQR score was predicted by poor physical health (physical component summary (PCS) SF36). Perceiving RA to be a chronic illness, that medication was a necessity, and adopting positive coping mechanisms were all associated with higher CQR scores while increasing concern over medication use was associated with lower scores in both groups. Perceived control over treatment also predicted higher CQR scores in the ADA group alone.

Regression results* for significant associations with total CQR score

	DMARD group (n=252)		ADA group (n=358)	
Factor	β co-efficient	95% CI	β co-efficient	95% CI
Poor physical function (PCS, SF36)	−0.2	−0.3, −0.08	−0.1	−0.2, −0.006
Perception of illness being chronic	0.7	0.3, 1.2	0.6	0.3, 0.96
Necessity of medication	1.8	1.5, 2.2	1.6	1.2, 1.9
Positive coping mechanisms	1.5	0.8, 2.3	1.1	0.3, 1.9
Medication concerns	−0.3	−0.7, 0.06	−0.5	−0.8, −0.3
Perceived control over treatment	−0.1	−0.7, 0.4	0.8	0.4, 1.2

* adjusted for age, gender and disease duration

Conclusion: Wider recognition of the role of beliefs about medication adherence would have substantial clinical benefits in RA. In the biologics era, it may also have important health economic benefits. This study has identified modifiable psychological factors that are putative targets for strategies to improve adherence.

Spousal Social Support and Well-Being among Persons with Rheumatoid Arthritis: Is Support in the Eye of the Beholder? Allen J. Lehman[1], Anita DeLongis[3], Daniel D. Pratt[3], John B. Collins[3] and John M. Esdaile[2]. [1]Arthritis Research Centre of Canada; Simon Fraser University, Vancouver, BC, Canada, [2]Arthritis Research Centre of Canada; University of British Columbia, Vancouver, BC, Canada, [3]University of British Columbia, Canada

Background: Much evidence suggests that social support is beneficial to persons with RA, both in terms of disease course and quality of life. It is essential that research identify the pathways through which support is beneficial. Several recent studies of people undergoing relatively chronic, but ultimately time-limited stress, suggest that spousal support is most health protective when it is "invisible" (the beneficiary of support is unaware that it has been provided). The stress associated with living with RA, however, is not time-limited. Whether extant findings on invisible support can be extended to couples in which one spouse has RA is unclear. Our study objective was to determine if invisible support for the person with RA is associated with significantly better well-being for the recipient than when both spouses agree that support was provided.

Methods: English speaking adults with RA ≥ 6 months and their spouses (N=222 couples) independently completed standardized questionnaires that assessed the perceptions of each regarding social support received by the person with RA and support provided by the spouse, as well as relationship satisfaction, positive affect, and depression. A dummy-coded 2×2 table summarized spousal congruence or divergence on perceptions of support for the person with RA (present, absent). Couple congruence on support present for the person with RA served as the reference category. Separate hierarchical regression models tested the effects of spousal support congruence or divergence on persons with RA's relationship satisfaction, positive affect, and depression, after adjusting for gender, RA severity, and spouse depression.

Results: Questionnaire response rate for couples was 82%. Of the persons with RA, 73% were female, the mean RA duration was 12 yrs, with mean relationship duration 31 yrs. Spousal congruence or divergence on perceptions of support for the person with RA include congruence on support present (65%) or absent (16%), and "invisible support" (13%). Even after statistically adjusting for the effects of RA, gender, and spouse depression on well-being among persons with RA, couple congruence or divergence on perceptions of support explained additional variability in relationship satisfaction ($R^2 = 0.492$, $p<0.001$), positive affect ($R^2 = 0.099$, $p<0.001$), and depression ($R^2 = 0.084$, $p<0.001$). Invisible support from the spouse showed a significant negative association with well-being in the person with RA, including poorer relationship satisfaction ($\beta=-0.503$, $p < 0.001$), less positive affect ($\beta=-0.269$, $p < 0.001$), and higher depression levels ($\beta=0.168$, $p < 0.01$).

Conclusion: Perceptions of social support from the spouse were significantly associated with positive well-being among persons with RA, regardless of whether the spouse reported having provided support. Contrary to findings of previous studies in non-RA samples, invisible support was associated with poorer well-being. Our findings suggest that what is most important is the recipient's perception of support received from the spouse. Such findings will be useful in designing evidence-based family and couple clinical interventions for those with RA and their families.

Sustained Reduction in Fatigue Impact in Rheumatoid Arthritis: RCT of Cognitive Behavioural Therapy. Sarah E. Hewlett[5], Nicholas Ambler[2], Bev Knops[2], Alena Cliss[1], Celia Almeida[6], Denise Pope[3], Alison Hammond[4], Annette Swinkels[6], Karen Kitchen[3] and Jon Pollock[6]. [1]Frenchay Hospital, Bristol UK, [2]Frenchay Hospital, Bristol, UK, [3]University Hospitals Bristol, UK, [4]University of Salford, Matlock Derbyshire, United Kingdom, [5]University of the West of England, Bristol, United Kingdom, [6]University of the West of England, Bristol UK

Aim: Up to 90% of RA patients experience distressing, unmanageable fatigue that impacts profoundly on life. In other long-term conditions, fatigue self-management programmes of cognitive behavioural techniques (CBT) show benefit. This randomized controlled trial tested CBT for RA fatigue.

Methods: CBT was delivered by a clinical psychologist and specialist occupational therapist in 6 × 2hr weekly group sessions (1hr booster at wk 14), addressing thoughts, feelings and behaviours, underpinned by goal-setting. Included were activity pacing, self-monitoring diaries for energy management, achieving balance (prioritizing), stress, communication, assertiveness, sleep, and managing setbacks. The information-only control arm comprised a 1hr group session based on the Arthritis Research UK fatigue leaflet. Entry criteria were fatigue VAS ≥6/10 and no change in major medication in previous 16 wks (steroids 6 wks). Assessments: VAS 0–10 for fatigue impact, severity and coping, Multi-dimensional Assessment of Fatigue (MAF 0–50), quality of life (RAQoL 0–30), sleep (good/poor), anxiety and depression (HADS 0–21), helplessness (AHI 5–35).

Results: Of 168 patients randomized, 41 withdrew before entry, 51 did not complete all datasets, 76 completed to wk 18 (no significant baseline differences for age, gender, disease duration). At baseline, the 76 patients (38 CBT, 38 Control) comprised 55F, 21M, mean age 60.4 yrs (95% CI 57.8–62.9), disease duration 11 yrs (10–15). All data were tested for normality and outcomes transformed where necessary. Analysis was adjusted for group and for baseline scores. At baseline, CBT and Control patients only differed by better RAQoL in CBT arm: 13.7 (11.8–15.6) vs 17.3 (14.8–19.9).

At the end of the programme (6 wks) the CBT group had significantly better scores than the Control group for every fatigue and every well-being outcome, which were maintained at 18 wks, except for RAQoL (see Table). More CBT than Control patients reported better sleep quality (6 wks 22/38 vs 19/38, p=0.024; 18 wks 30/38 vs 20/38, p=0.012).

	Week 6		Week 18	
	CBT n=38 mean (95% CI)	Control n=38 mean (95% CI)	CBT n=38 mean (95% CI)	Control n=38 mean (95% CI)
Fatigue:				
Impact	4.2 (3.4–5.1)	6.0 (5.1–6.9)	4.2 (3.3–5.1)	6.0 (5.1–6.9)
Severity	4.7 (3.8–5.5)	6.3 (5.5–7.1)	4.8 (4.0–5.6)	6.2 (5.2–7.1)
Coping (high good)	7.3 (6.6–8.0)	5.3 (4.4–6.1)	7.2 (6.6–7.9)	5.8 (4.9–6.6)
MAF	24.7 (21.3–28.0)	30.7 (27.2–34.4)	24.0 (20.2–27.7)	28.8 (24.9–32.7)
Well-being:				
RAQoL	10.8 (8.7–12.8)	16.8 (14.1–19.5)	10.9 (8.8–13.1)	14.8 (11.5–18.2)*
Anxiety	5.7 (4.3–7.1)	8.6 (6.8–10.4)	5.2 (3.6–6.7)	7.8 (6.2–9.4)
Depression	4.7 (3.7–5.8)	7.5 (6.0–9.0)	4.75 (3.5–6.0)	7.2 (6.2–9.3)
Helplessness	13.4 (11.9–14.9)	18.7 (17.0–20.3)	13.6 (12.3–15.0)	18.0 (16.3–19.8)

High scores are worse, except for Coping
All p=0.001 to 0.045
* p=0.480

Interim assessment at 10 wks showed the CBT group was still significantly better than the Control group in all except 3 outcomes that just failed to reach statistical significance (Anxiety p=0.057, Fatigue Coping p=0.066, Fatigue Severity p=0.064). The planned booster session was delivered at 14 wks. At 18 wks these outcomes were all significantly different again (Table).

Conclusion: CBT for fatigue self-management in RA significantly improves fatigue and well-being, maintained at 3 months. The loss of significance in three variables before the booster session and subsequent improvement afterwards may indicate the value of 'top-up' sessions in clinical practice. As clinical psychology provision is often limited, the efficacy and cost of a lower-intensity CBT approach provided by the clinical team (with training and support) should be explored.

The Effect of Social Support from Physicians and Partners on the Health-Related Quality of Life of Vasculitis Patients in Relapse and Remission. Delesha M. Carpenter[2], Jessica A. Kadis[2], Robert F. DeVellis[2], Susan L. Hogan[3] and Joanne M. Jordan[1]. [1]Chapel Hill, NC, [2]UNC, Chapel Hill, NC, [3]UNC

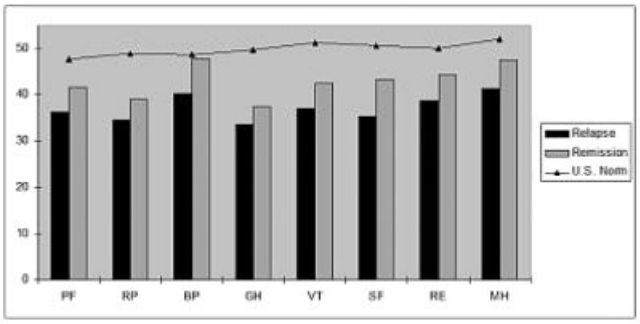
Background: Although social support has been shown to positively impact the physical and mental health of chronic disease patients, few studies have explored whether the benefits of support vary by level of disease activity.

Objective: Our goal was to determine whether the disease status (relapse vs. remission) of vasculitis patients moderated the effect of physicians' and partners' social support on patients' health-related quality of life (HRQOL).

Methods: Vasculitis patients (n=228) completed two online surveys. The baseline survey assessed demographic information, self-reported disease status (relapse vs. remission), and social support from physicians and partners. The 3-month follow-up survey measured 8 dimensions of HRQOL (SF-36): physical functioning (PF), physical role limitations (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), emotional role limitations (RE), and mental health (MH). Higher scores indicate better HRQOL. We compared the HRQOL of patients in relapse and remission. We also determined whether disease status moderated the effect of physician support and partner support on patient HRQOL; Wilks' Λ indicated whether the physician support-by-disease-status and partner support-by-disease-status interaction terms were significant.

Results: Relapsing patients reported significantly worse health when compared with non-relapsing patients for 7 of 8 HRQOL dimensions: physical functioning, bodily pain, general health, vitality, social functioning, emotional role limitations, and mental health (Figure 1). Disease status did not moderate the effect of physician (Wilks' Λ=0.49, p=.86) or partner social support (Wilks' Λ=1.49, p=.16) on HRQOL. However, social support from

both physicians and partners was associated with better HRQOL. Specifically, physician support predicted better HRQOL for 6 of 8 dimensions (all except for except bodily pain and vitality). Partner support predicted fewer physical and emotional role limitations and better social functioning.



Conclusion: Vasculitis patients experience compromised HRQOL when compared with U.S. population norms, but the magnitude of the compromise is greater for patients experiencing a relapse. Social support from physicians and partners is beneficial for patient HRQOL regardless of where the patient is in the relapse/remission cycle.

Foot Pain in Relation to the Foot Biomechanical Measures of Plantar Peak Pressures and Pressure Time Intergral. Virginia A. Casey[3], Andrew M. Galica[3], Alyssa B. Dufour[1], Robert R. McLean[1] and Marian T. Hannan[2]. [1]Hebrew Senior Life, Boston, MA, [2]Hebrew SL & Harvard Med Sch, Boston, MA, [3]IFAR Hebrew SeniorLife, Boston, MA

Introduction: Foot pain is a major cause of mobility limitation, however, the mechanisms that lead to foot pain are not completely understood. Small laboratory studies have shown that uneven distribution of the forces applies to the foot during normal walking result in areas of high pressure, which are associated with foot pain. Yet, these relations between plantar peak pressures and pressure-time integrals have not yet been investigated in a large, population-based sample. Thus, we examined the associations between generalized foot pain and peak pressure (PP) and pressure time integral (PTI) in men and women of the population-based Framingham Foot Study. We hypothesized that individuals reporting foot pain would exhibit higher peak pressure in specified foot areas compared to those reporting no foot pain.

Methods: Foot pressure data were obtained from 200 men and 262 women enrolled in the Framingham Foot Study. Between 2002 and 2005, plantar pressure values were collected using a Tekscan Matscan pedobarographic system (resolution of 1.4 sensels/cm^2) while participants walked at a comfortable pace barefoot across the mat. Novel software was used to calculate PP and PTI from 12 segments of the right foot (toes, submetatarsal heads 1–5, medial arch and heel, lateral arch and heel). Self-reported foot pain was determined by the response to the question: "On most days, do you have pain, aching or stiffness in either foot?" Two-tailed Student's T-tests assessed differences in PP and PTI between those with and without foot pain, separately for men and women.

Results: Study participants were 66% female with mean age of 65 years, and mean BMI of 28. In women who reported foot pain, there was significantly greater PP at the 2nd and 3rd metatarsal heads ($p<0.0001$) compared to those who did not report foot pain. In men, significant differences in PP were only seen at the 5th metatarsal head ($p<0.001$). There were no significant findings for foot pain and PTI measures in either men or women.

	Peak Pressure, N/cm^2			Pressure Time Integral, (N/cm^2βsec		
Foot Region	No Foot Pain	Foot Pain	P Value*	No Foot Pain	Foot Pain	P Value*
Female	n=187	n=75		n=184	n=75	
Submetatarsal head 1	17.8 ± 6.1	16.9 ± 5.8	0.32	8.3 ± 3.9	8.4 ± 4.1	0.77
Submetatarsal head 2	22.6 ± 4.7	21.0 ± 5.1	0.01	10.8 ± 3.3	10.6 ± 5.0	0.73
Submetatarsal head 3	22.1 ± 4.7	20.4 ± 5.0	0.01	10.5 ± 3.2	10.4 ± 4.6	0.81
Submetatarsal head 4	17.3 ± 5.4	16.5 ± 4.8	0.28	7.8 ± 2.9	7.6 ± 2.6	0.65
Submetatarsal head 5	14.2 ± 6.1	13.9 ± 5.8	0.69	5.9 ± 3.2	6.0 ± 3.3	0.80
Male	n=164	n=36		n=164	n=36	
Submetatarsal head 1	18.9 ± 6.3	19.5 ± 6.1	0.61	9.1 ± 5.1	9.5 ± 4.7	0.61
Submetatarsal head 2	22.9 ± 4.1	23.4 ± 4.5	0.53	11.0 ± 4.4	11.6 ± 3.9	0.45
Submetatarsal head 3	22.8 ± 4.1	23.5 ± 4.5	0.34	11.0 ± 4.8	11.5 ± 3.5	0.46
Submetatarsal head 4	18.9 ± 4.7	20.3 ± 5.2	0.13	8.6 ± 3.6	9.2 ± 2.6	0.21
Submetatarsal head 5	15.4 ± 6.2	17.8 ± 5.0	0.03	6.9 ± 4.8	7.7 ± 2.9	0.18

* Two-Tailed Students T-Test

Discussion: In a large population-based sample, general foot pain was associated with higher PP under several of the metatarsal heads, albeit differently in men and women. Significant findings were not observed for the pressure-time integral measures. It may be that the accumulation of pressure loading over time does not cross a pain threshold as easily as peak pressure. We are unaware of differences in gait between men and women, or other reasons for different PP and reports of foot pain. Future work should investigate specific foot pain location in relation to areas of plantar pressure loading to elaborate on potential mechanisms.

Hallux Valgus and Foot Bimechanics: Relation between Structure and Function. Andrew M. Galica[5], Alyssa B. Dufour[1], Marian T. Hannan[2], Virginia A. Casey[5], Jocelyn C. Frey[4], Mark W. Lenhoff[4] and Howard J. Hillstrom[3]. [1]Hebrew Senior Life, Boston, MA, [2]Hebrew SL & Harvard Med Sch, Boston, MA, [3]Hospital Special Surgery, New York, NY, [4]Hospital Special Surgery, New York, NY, [5]Institute for Aging Research

Background: While there are many clinical and case reported studies of hallux valgus (HV), the etiology and biomechanics of the pathology remain poorly understood. Although previous studies have noted differences in peak pressures in various regions of the foot between individuals with and without HV, results are inconsistent and have not been confirmed in larger studies. The purpose of this research is to describe peak plantar pressures and pressure-time integrals in an epidemiological population-based study and to investigate whether these measures differ between those with and without HV as defined by standardized foot examinations. We hypothesize that it is possible to distinguish individuals with and without HV based on differences in peak pressure and pressure-time integral measures.

Methods: Data were obtained from a subset of participants enrolled in the Framingham Heart Study (N = 464; 57% female; mean age, 65 years; mean BMI, 28). Between 2002 and 2005, plantar pressure values were collected using a Tekscan Matscan system (model 3150, resolution of 1.4 sensels/cm^2) while participants walked at a comfortable pace barefoot across the mat. Data was imported into Novel software and masked into 12 segments (toes, submetatarsal heads 1–5, medial arch and heel, lateral arch and heel). Peak pressure and pressure time integral values were then calculated. Two-tailed Students T-tests assessed differences between those with and without HV.

Results:

Foot Region	Peak Pressure, N/cm²			Pressure Time Integral, (N/cm²)×sec		
	No Hallux Valgus	Hallux Valgus	P Value	No Hallux Valgus	Hallux Valgus	P Value
FEMALE	n=172	n=87		n=171	n=87	
Hallux	18.5 ± 6.1	18.4 ± 6.1	0.84	7.9 ± 3.9	8.0 ± 4.6	0.90
Submetatarsal head 1	17.7 ± 5.8	17.1 ± 5.8	0.46	8.4 ± 3.7	8.0 ± 4.2	0.50
Submetatarsal head 2	22.2 ± 4.8	21.9 ± 5.1	0.67	10.7 ± 3.1	10.9 ± 5.1	0.72
MALE	n=155	n=45		n=155	n=45	
Hallux	19.3 ± 7.0	18.0 ± 7.3	0.27	7.7 ± 4.5	8.2 ± 5.8	0.61
Submetatarsal head 1	18.9 ± 5.9	19.3 ± 7.6	0.8	8.7 ± 3.7	10.5 ± 7.9	0.15
Submetatarsal head 2	23.0 ± 3.9	22.8 ± 5.2	0.82	10.9 ± 3.1	11.9 ± 7.0	0.38

Preliminary analysis revealed significant sex differences in plantar pressures. Therefore, subsequent analyses were stratified by gender. Since the right foot is considered more dominant, only these results are reported. Tables 1 and 2 present a subset of the 12 analyzed foot areas. Female subjects with HV exhibited greater peak pressure values under the lateral arch than those without HV ($p = 0.046$). No significant differences were found in pressure-time integrals for females with and without HV, regardless of foot area. Male subjects with HV exhibited greater peak pressure ($p=0.007$) and pressure-time integral ($p=0.015$) values than those without HV under groupings of the 3rd, 4th, and 5th toes.

Conclusions: Significant gender differences in peak pressures and pressure time integrals were noted. The data did not support our hypothesis as analyses did not distinguish between those with and without HV based on pressure-related measures. It is possible that the accuracy and resolution of Tekscan, in comparison to other foot mat systems, may have affected our results. It is also possible, since both groups contained concomitant pathologies, the plantar loading effects for HV washed out. Future work may investigate whether consideration of additional foot disorders or deformities may better use the plantar pressure measures to distinguish foot pathologies.

Hallux Valgus and Pes Cavus Are Highly Heritable in Older Men and Women: The Framingham Foot Study. Marian T. Hannan[4], Yi-Hsiang Hsu[3], L. Adrienne Cupples[2] and Joanne M. Jordan[1]. [1]Chapel Hill, NC, [2]BUSPH, Boston, MA, [3]Hebrew SeniorLife, HSPH and Harvard Medical School, Boston, MA, [4]Hebrew SL & Harvard Med Sch, Boston, MA

Foot disorders are common among adults, affecting 20–60% of adults and often linked to mobility limitations. Although genetics are commonly suspected in foot disorders, only one family aggregation study has been done, reporting that 90% of 350 participants with hallux valgus had a family history, and inheritance may be an autosomal dominant transmission. To our knowledge, no other studies have examined the association between foot disorders and genetics in humans. We have the unique opportunity to link data that we have collected on specific foot disorders to a wealth of genetic data in the community-based Framingham Study. Our aim was to evaluate the possible heritability of two common foot disorders, using the pedigree structure in the Framingham Study.

The Framingham Foot Study (n=2179) was designed to examine common foot disorders and functional limitations. A trained examiner used a validated foot exam to assess 20 foot disorders in 2179 participants between 2002–2005. Of participants, 959 men and 1220 women had been genotyped. We estimated overall, sex-specific and age (< 60, 60+y) heritability of hallux valgus and pes cavus (our most common and least common foot disorders) in the Framingham participants. Hallux valgus (present/absent) was defined as the angular deviation of the hallux with respect to the first metatarsal toward the lesser toes at >=15°. Pes cavus was defined using a digital recording of foot pressure while walking (MatScan pedobarographic device, Tekscan, Inc. Boston MA), that allowed calculation of the ratio of arch width (medial to lateral, to nearest 0.01 cm) to heel width. Pes cavus was defined as either foot as having a weight-bearing arch width=0, regardless of heel width. We estimated heritability of hallux valgus and pes cavus by the threshold model of a standard quantitative genetic variance-components model implemented in the Sequential Oligogenic Linkage Analysis Routines (SOLAR) package.

Mean age was 66y (range 39–99y); 57% were female. The prevalence of hallux valgus (HV) was 31% (675 hallux valgus cases with available pedigree structure). The overall HV heritability was 0.39 for women and 0.38 for men. For persons aged < 60y, the HV heritability was 0.89. The prevalence of pes cavus (PC) was only 7% (154 cases with available pedigree structure have pes cavus). The PC heritability was 0.68 for women and 0.20 for men. For individuals < 60y of age, the PC heritability was 0.99 for women and 0.63 for men. Thus, hallux valgus and pes cavus are highly heritable, especially for younger adults.

This study breaks new ground in an area that has received very little attention, yet is critically important to public health. Our study documented for the first time, the high heritability (strongly suspected by many) of two specific foot disorders phenotypes. Foot disorders are common and it is important to identify persons at high risk, as effective interventions exist and may also be targeted to individuals to lessen the impact of foot disorders or prevent development. Genome-wide association analyses are planned to identify potential genetic determinants for these common foot disorders.

Racial Differences in Foot Disorders: The Johnston County Osteoarthritis Project. Yvonne M. Golightly[2], Marian T. Hannan[1], Alyssa B. Dufour[1] and Joanne M. Jordan[2]. [1]Institute for Aging Research, Hebrew Senior Life, [2]University of North Carolina at Chapel Hill

Background: Clinical impressions are that African Americans have pes planus (flat feet) and hallux valgus (bunions) more frequently than Caucasians, but few population-based studies exist. This cross-sectional analysis describes racial/ethnic differences in the prevalence of physical disorders of the foot in a large, bi-racial cohort of individuals 45 years of age or older.

Methods: Of the1,540 Johnston County Osteoarthritis Project participants clinically evaluated in 2006–2010, four with lower extremity amputation were excluded, leaving 1,536 available for analyses (mean age 69 years, mean body mass index [BMI] 31.5 kg/m2, 68.4% female, 30.3% African American). Presence of specific foot conditions (coded as present or absent) were evaluated using the Foot Assessment Clinical Tool, a validated clinical examination with specific criteria to assess 10 foot disorders (Table). The most common foot disorders were identified (prevalence of ≥ 10%), and logistic regression was used to compare each foot problem by race, controlling for age, BMI, and gender, as these factors may affect foot disorders. Effect modification between race (African American versus Caucasian) and age, BMI (categorized as >30 or ≤30 kg/m2), or gender were examined ($p<0.10$ for interaction was considered statistically significant).

Results: In 1536 participants, the 5 most common foot conditions were hallux valgus (62.8%), hammer toes (35.6%), overlapping toes (31.8%), pes planus (22.5%), and corns (20.5%). In adjusted models, African Americans were almost 3 times as likely as Caucasians to have pes planus and corns (Table). Non-obese (BMI ≤30 kg/m2) African Americans were almost twice as likely as non-obese Caucasians to have hallux valgus (aHR=1.90, 95% CI= 1.29–2.78) and over twice as likely to have hammer toes (aHR=2.30, 95% CI=1.62–3.27). These conditions did not differ significantly by race among the obese (BMI >30 kg/m2). There were no other interactions by age or gender. African Americans were 70–80% less likely than Caucasians to have Tailor's bunion and pes cavus (Table).

Table. Prevalence of Foot Disorders by Race.

Foot Disorder	African American N=466 (%)	Caucasian N=1,070 (%)	Adjusted* Odds Ratio (95% Confidence Interval)
Hallux Valgus	40.3	28.4	Non-obese: 1.90 (1.29–2.78)
	27.9	32.0	Obese: 1.28 (0.94–1.74)
Hammer Toes	22.1	16.6	Non-obese: 2.30 (1.62–3.27)
	19.1	16.6	Obese: 1.10 (0.80–1.50)
Claw Toes	3.7	2.8	1.56 (0.85–2.89)
Overlapping Toes	33.5	31.1	1.16 (0.91–1.47)
Corns	32.0	15.5	2.89 (2.20–3.79)
Tailors Bunion	1.5	6.7	0.21 (0.10–0.47)
Morton's Neuroma	8.8	7.9	1.11 (0.74–1.65)
Plantar Fasciitis	5.6	4.6	1.10 (0.67–1.82)
Pes Cavus	1.5	5.6	0.28 (0.12–0.61)
Pes Planus	37.6	16.0	2.89 (2.24–3.73)

* Adjusted for age, body mass index, and gender.

Conclusions: Foot disorders are common among adults 45 years of age or older, and these conditions tend to be more prevalent among African Americans than Caucasians. The racial differences in the prevalence of hallux valgus and hammer toes are most evident among those who are not obese, suggesting that obesity equalizes the odds of having these conditions, regardless of race.

1331

Risk Factors for Hallux Valgus (HV) in a Population-Based Study of Older Adults: The Framingham Foot Study. Alyssa B. Dufour[4], Virginia A. Casey[5], Andrew M. Galica[5], David R. Gagnon[1], Howard J. Hillstrom[3] and Marian T. Hannan[2]. [1]Boston University School of Public Health, Boston, MA, [2]Hebrew SL & Harvard Med Sch, Boston, MA, [3]Hospital Special Surgery, New York, NY, [4]Institute for Aging Research, Hebrew SeniorLife & Boston University School of Public Health, Boston, MA, [5]Institute for Aging Research, Hebrew SeniorLife, Boston, MA

HV is common in older adults, but its risk factors and relation with foot pain are understudied. The few studies of risk factors have reported conflicting results and had small samples, with limited age ranges. Our purpose was to determine if HV is associated with foot pain and potential risk factors in large numbers of community-dwelling older men and women.

This cross-sectional study included 3415 ambulatory adults from the population-based Framingham Study. We used a validated foot exam done by trained examiners with criteria to assess H valgus, foot pain, pes planus, and current and past high heel use. HV was present if the angle of the hallux toward the lesser toes was observed to be >15°. Pes planus was defined using a weight-bearing ratio of arch width to rear-foot width on a computerized pressure mat (y/n if ratio>.75 on either foot). Foot pain (y/n) was queried: "on most days, do you have pain, aching or stiffness in either foot?" High heel use in women was determined by the subject choosing high heels/pumps from a list of 13 shoe types as the shoe most typically worn currently and in their past. Past high heel use was categorized into 3 groups: main shoe between ages 20–64y; main shoe at some ages between 20–64y; not worn between 20–64y. Age, sex, and body mass index (BMI, grouped <25, 25–30, >30 kg/m^2) were also collected. Sex-specific multivariate logistic regression models were performed to examine the effect of the above risk factors on HV.

1498 men & 1917 women had mean age of 67 ± 10.6 y (range 40–100 y). 20% of men and 41% of women had HV. Current high heel use was not associated with HV in women and thus excluded. Table shows risk factors for HV by sex. Foot pain and older age increased the odds of having HV in both women and men (all p<0.03), even after adjusting for other factors. In women only, having pes planus increased the odds of HV by 70% (p=0.01); BMI>30 was protective, decreasing the odds by 35% (p=.0007); and wearing high heels as main shoe during ages 20–64y increased the odds of HV by 22% (p=0.01), after adjusting for the other factors. To extend the BMI findings, we examined a biomechanical measure (1st met-head peak pressure) in a subset (n=573) and found no interaction with BMI (p<0.56). Adding peak pressure to the model did not change the effects of BMI (ORs~0.99).

Risk Factors for Hallux Valgus (adjusted for all other risk factors)

	Male		Female	
	Prevalence (%)	OR (95% CI)	Prevalence (%)	OR (95% CI)
Age (10 year increment)		1.15 (1.01, 1.31)		1.20 (1.09, 1.31)
BMI <25 (referent)	18.2	1.00	33.5	1.00
BMI 25–30	45.0	0.95 (0.67, 1.36)	35.1	0.96 (0.76, 1.21)
BMI >30	36.9	0.72 (0.49, 1.06)	31.4	0.65 (0.51, 0.83)
Foot pain (yes/no)	18.8	1.81 (1.33, 2.47)	28.5	1.36 (1.10, 1.69)
Pos Planus (yes/no)	8.8	1.45 (0.84, 2.25)	6.4	1.68 (1.13, 2.60)
Past high heel use (never, referent)	–	–	43.2	1.0
Past high heel use (some)	–	–	38.9	1.45 (1.09, 1.93)
Past high heel use (always)	–	–	18.0	1.22 (0.99, 1.51)

We saw strong relations between HV and foot pain and increased age in both men and women. While current high heel use was not linked to HV, several other factors were associated with this structural foot disorder in women. Results for BMI>30 are in agreement with ≥1 previous study showing a protective effect. Perhaps this is due to differing weight distributions and thus different foot biomechanics in obese women versus those with BMI<25. Future studies should include additional risk factors such as occupational weight bearing load, pregnancies and toe box structure of shoewear.

A Model of Quality Patient-Health Care Provider Communication. Elizabeth Salt[1] and Graham Rowles[2]. [1]University of Kentucky, Lexington, KY, [2]University of Kentucky

Background: Quality treatment of rheumatoid arthritis (RA) includes effective communication between patients and health care providers (Lempp, Scott, & Kingsley, 2006). Effective patient-health care provider communication may have a positive effect on health outcomes, medication adherence, and a trusting patient-health care provider relationship, and a negative effect on the number of complaints to medical regulatory authorities (Berrios-Rivera et al., 2006; Tamblyn et al., 2007; Viller et al., 1999; Wolfe, 1995). The purpose of this study is to develop a model of the patient's perception of quality patient-health care provider communication.

Methods: Following Medical Institutional Review Board approval, a sample of 15 English-speaking patients with RA were recruited from a university rheumatology clinic to participate in two focus groups sessions (n = 6) and individual interviews (n = 9). Verified transcripts from the audio-recorded interviews were analyzed using constant comparative analysis (Straus & Corbin, 1990). The resulting codes were collapsed into themes which were organized into a model of the patient's perception of quality patient-health care provider communication.

Findings: The model of the patient's perception of quality patient-health care provider communication involves dynamic interactions between the patient and health care provider. Participants described entering the encounter with past experiences and outside influences. They explained their symptoms and concerns and asked their health care provider questions. Participants felt that their health care provider should both listen to them and believe the information reported. Participants reported that the health care provider, who can come to the encounter with assumptions, should disseminate information, ask questions, and make recommendations. The participants in this study felt that providers should be personable, empathetic, respectful, un-hurried and caring during this interaction. They also felt that health care providers should be honest, straightforward, positive, and decisive when providing accurate information using face-to-face conversation or visual aids.

Conclusion: A model of the patient's perception of quality patient-health care provider communication has been developed. This model, if substantiated, can further our understanding of patient-health care provider communication and provide direction for future research.

Comparison of Physician- and Nurse Prescriber-Led Dose Adjustment of DMARD Therapy in RA. Grainne Murphy, Mary Daly, John Ryan, Fergus Shanahan, Sinead Harney and Molloy Michael. Cork University Hospital

The advent of nurse prescribing has greatly enhanced the role of the specialist nurse in the care of the rheumatology patient. Patient education and monitoring of patients receiving disease-modifying (DMARD) therapies has been a pivotal part of the rheumatology nurse specialists (RNS) scope of practice. The importance of frequent review and DMARD dose adjustment in early RA has been repeatedly highlighted. Improved clinical responses in those seen on a monthly basis in comparison to those seen every 3 months were observed in patients treated with methotrexate (MTX). The ability of the advanced nurse practitioner (ANP) to review patients in this timely manner may be more feasible than that of physician directed clinics.

Objective: To assess the effectiveness of the ANP in the appropriate escalation of MTX and dose reduction of prednisone and to assess the patient response to such interventions.

Methods: We included all patients who attended the ANP-led clinic in a

12 month period who underwent a dose adjustment in either MTX or prednisone. Treatment records were retrospectively reviewed and the frequency and magnitude of dose escalation (MTX) or reduction (prednisone) were assessed. Patients were asked to complete a retrospective questionnaire to assess the effectiveness of the consultation. Consecutive patients attending a physician led clinic were used as a control group. The ANP prescriptions were audited for appropriateness and safety.

Results: We identified 33 consultations for adjustment of MTX and 74 consultations for prednisone. Of 1282 attendances at the ANP clinic 107 included a consultation in which a medication dose adjustment occurred. The mean increase in MTX was 2.63mg/month (+/− 0.25mg) for the ANPs clinic in comparison with 0.87mg/month (+/− 0.09) for the physician - led clinic, p=0.000. In relation to prednisone, the ANP achieved a 2.57mg/month dose reduction. All patients attending the ANPs clinic felt adequately informed about their treatment and, by recall, were educated in relation to the nature, administration and side-effects of their medication. Patients demonstrated high levels of confidence in the ANP; 83.3% would be as likely to adhere to the ANP decision as the physician led approach and only 11.1% felt that they would have more confidence in a physician-prescribed adjustment. Interestingly, 61.1% felt they would have received less information in the physician led clinic. No episode of inappropriate or unsafe treatment alteration was identified.

Conclusion: We demonstrated that ANPs can effectively and safely escalated DMARDs with the added benefit of steroid dose reduction. This is in contrast with the sub-optimal dose escalation previously demonstrated in physician-led clinics. This study supports the expanded role of ANPs in delivering optimal care or RA patients.

Developing an Interactive Health Communication Application within Rheumatology: What Do Patients Want? Rosalie van der Vaart[2], Constance H. C. Drossaert[2], Erik Taal[1] and Mart A. F. J. van de Laar[2]. [1]Arthritis Centre Twente, Institute for Behavioural Research, University of Twente & Medisch Spectrum Twente, Enschede, The Netherlands, [2]Arthritis Centre Twente, Institute for Behavioural Research, University of Twente & Medisch Spectrum Twente

Background: The potential of Interactive Health Communication Applications (IHCA's) to improve health care has been acknowledged and the development of online health applications is quickly evolving, for various chronic conditions. For rheumatic patients, however, no IHCA's exist yet and research on online applications within rheumatism is scarce. In this project we aim to develop a hospital based rheumatology IHCA. To ensure acceptation and future use of it, a needs assessment among patients was conducted.

Objectives: To examine patients' current disease related internet use and their intentions to use various online support tools on a rheumatology IHCA. Furthermore, we examined which variables are associated with the intention to use these support tools.

Methods: We conducted a survey among a random sample of patients of a large teaching hospital's rheumatology clinic (N=484). Inclusion criteria were: having visited a rheumatologist in the past 6 months and an age below 70 years. Questions included demographics and health related variables as well as patients' current disease related internet use and their intention to use seven different support tools: (1) disease and treatment information, (2) care and support information, (3) peer communication, (4) patient-provider communication, (5) symptom monitoring, (6) self-management support and (7) an online personal health record.

Results: The response rate was 47% (N=227). Current disease related internet use was mainly limited to searching information. Nevertheless, many patients reported they intended to use six of seven possible support tools when offered in a hospital rheumatology IHCA (49% - 68%). An exception was peer communication; only 11% of patients intended to use this tool. Of all support tools the personal health record was mostly preferred, followed by information provision. Although we found some small significant correlations between this reported intention and participants characteristics, these were all small (below 0.21) and showed no clear predictors.

Conclusion: Our results reveal a discrepancy between the low current health related internet use and the high interest to use online support tools offered by the hospital. Patients are especially positive about the option of an online personal health record. Demographics and health related variables showed no clear relation to intention to use.

Disclosure: R. van der Vaart: None; **C. H. C. Drossaert:** None; **E. Taal:** None; **M. A. F. J. van de Laar:** None.

Does an RA Peer Support Program Impact Disease Outcomes? Melanie Zibit[3], Jing Cui[4], Christine K. Iannaccone[2], Nancy A. Shadick[1], Michael E. Weinblatt[1], Meghan Courtney[3], Margo Hanlan[3], Husen Tsao[3] and Anne Fossel[3]. [1]Brigham & Womens Hospital, Boston, MA, [2]Brigham and Woemens Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham and Womens Hospital, Boston, MA

Purpose: A diagnosis of RA can lead to loss of function, increased pain, depression, and complex medical care. Peer support, used effectively in other illnesses, may provide support that can lead to improvement in RA disease outcomes. This pilot study evaluates whether a peer support program for RA patients can improve fatigue, pain, functional status, self-efficacy, emotional health, and medication adherence.

Methods: RA patients at a hospital arthritis clinic seeking peer support enrolled in a peer support program. Patients wishing to provide support to others (mentors) were trained by a social worker to learn how to help other patients with concerns, coping strategies and medical decision-making. Mentors and mentees were partnered based on age, disease duration, comorbidities, lifestyle, physical activity, and employment status. Mentors contacted mentees by phone once a week for 6 weeks, with some email or a face-to-face meetings. To evaluate the efficacy of the program, mentees seeking support were compared with controls from an RA registry at baseline and at 6 month follow up. Both groups filled out questionnaires concerning fatigue and pain (VAS), flares, self-efficacy(Arthritis Self-Efficacy), emotional health and functional status (SF12 Health Status Survey), and medical adherence (ASK20). Univariate analyses were done to compare both groups at baseline and a linear regression model was used to compare differences after 6 months.

Results: 10 mentees and 6 controls, to date, have completed baseline and 6 month questionnaires. There were no differences in disease duration (p=0.98) and gender (P=0.89), but age distribution differed (p=0.02) between mentees and controls. Analysis at 6 months, using linear regression analyses, showed that mentees had a significant improvement in self-efficacy compared to the controls (p=0.05) (see Table 1). Subjects completing the program to date showed a trend toward less fatigue (p=0.11) and improvements in medical adherence (p=0.12).

Conclusions: This pilot study suggests that RA patients who have active disease and receive peer support show improvement in self-efficacy. Peer support programs may be effective in enhancing patients' coping skills. Further analyses are needed to demonstrate the impact of the program on patient self-reported outcomes of fatigue and medical adherence.

Table 1. Linear Regression Analysis Mentees (N=10) compared to Controls (N=6)

Age		
20–45	3 (30%)	0

Educational Needs Assessment among Patients with Rheumatic Diseases in Kenya. Ines Colmegna[1], Susan J. Bartlett[1], Sharon Kodhek[2], Omondi G. Oyoo[3] and International League of Associations for Rheumatology East Africa Initiative. [1]McGill University, Montreal, QC, Canada, [2]Nairobi SLE Support Group, Nairobi, Kenya, [3]University of Nairobi, Nairobi, Kenya

Background: In Africa, access to comprehensive musculoskeletal (MSK) health care is very limited. Patient education and self-management have been shown to reduce inequities and improve functional status, pain, psychological wellbeing, employment, and even disease activity. Educational interventions need to be tailored and contextualized to meet individuals' specific needs.

Objective: To assess educational needs among patients with rheumatic conditions in Africa as a first step in developing interventions to reduce the gap in health service provision.

Methods: English-speaking patients who attended community lectures sponsored by ILAR in Nairobi on rheumatic diseases completed a questionnaire about demographics, diagnosis, pain and disability. Topics also queried included overall interest in learning about arthritis, specific needs, preferred learning modalities as well as internet access.

Results: The sample consisted of 61 patients, mostly female (87%) with a mean ± SD age of 41.4 ± 13.5 yrs and education of 14.6 ± 3.7 yrs. Most reported working full (76%) or part time (10%) and lived with family or others with only 14% living alone. Diagnoses reported included SLE (37%), RA (30%), other (19%), "RA+SLE" (9%) and gout (5%). Nearly half (48%) reported having pain every day. The highest MHAQ scores were associated with RA (0.7 ± 0.7), "RA + SLE" (0.6 ± 0.6), and SLE (0.4 ± 0.5).

Across conditions, disease knowledge was suboptimal; only 33% reported having "enough" to a "great deal" of knowledge and almost all (95%) wanted to learn more about their condition. Most reported it to be "very" to "extremely important" to learn more about pain (100%), medications (98%), fatigue (98%), exercise (96%), expectations about disease (96%), use of heat and cold (94%), and coping with emotions (90%). One fourth expressed interest in learning about diet and reproductive issues. Preferred learning modalities included groups (43%) and videos (26%) at hospitals (54%) or online (15%). Most (77%) reported having Internet access. Half (50%) reported current or previous participation in support groups. Support group participation was not associated with demographics, disease characteristics or specific interests or educational needs.

Conclusions: There is a clear need for rheumatic disease education among patients in Kenya. Participation in support groups does not appear to lessen interest or select for specific educational needs, a finding that is consistent with other studies showing that "experienced" patients are still eager to learn about their illness and treatment. Leaders in Rheumatology from developed countries have unique opportunities to empower patients in developing parts of the world using internet-based technologies.

1337

Phone Administration Compared to Self-Administration on Paper of the Main Instruments Used To Evaluate Ankylosing Spondylitis Patients. Rafael Ariza-Ariza, Blanca Hernández-Cruz, Victoria Navarro-Compán and Federico Navarro-Sarabia, Hospital Virgen Macarena, Sevilla, Spain

Background: BASDAI, BASFI, and other instruments used to evaluate Ankylosing Spondylitis (AS) patients are usually self-administered on paper. However, it limits their use in daily clinical practice because paper forms are resource demanding regarding the time spending for filling them. A phone administration previously to the medical visit it would facilitate the use of these tools.

Objective: to assess the performance of the instruments used to evaluate AS patients when administered by phone in comparison with the traditional self-administration on paper.

Methods: Design: a test-retest study. Patients with AS (modified NY criteria) consecutively selected in a tertiary care center were included. Patient global assessment on numerical rating scale (NRS), patient global pain assessment on a NRS, patient night pain assessment on a NRS, BASDAI, BASFI, and ASQoL were administered by phone. 48 later the same instruments were self-administered on paper at the hospital. Descriptive statistics were done. Agreement between the two tests was assessed by the intraclass correlation coefficient. Spearman correlation coefficient was also calculated.

Results: 51 patients, 76% males, with age 47.7±13 years were included. The time between phone administration and self-administration on paper was 1.5±1.0 days. Mean±SD values of the instruments obtained by phone administration and self-administration on paper, intraclass correlation coefficients (ICC) and Spearman correlation coefficients (rho) were as follows: patient global assessment on a NRS: 3.8±2.8, and 3.8±2.4, ICC: 0.80*, and rho: 0.80*; patient global pain assessment on a NRS: 3.9±2.9, and 3.7±3.0, ICC: 0.89*, and rho 0.82*; patient night pain assessment on a NRS: 3.6±3.0, and 3.4±3.0, ICC: 0.90*, and rho: 0.87*; BASDAI: 3.9±2.6, and 3.5±2.5, ICC: 0.91*, and rho: 0.92*; BASFI: 3.6±2.7, and 3.5±2.7, ICC: 0.91*, and rho: 0.92*; and ASQoL: 6.2±5.3, and 6.1±4.9, ICC: 0.93*, and rho: 0.87*, respectively. *p<0.001.

Conclusions: the phone administration of these instruments is comparable to their self-administration on paper. It can facilitate their use in daily clinical practice.

Rheumatology Health Professionals' Care: Current and Future Tasks and Education. Emalie J. Hurkmans[3], Rinie Geenen[1], John Verhoef[4] and Thea P. M. Vliet Vlieland[2]. [1]Clinical and Health Psychology, Utrecht University & University Medical Center, Utrecht, The Netherlands, [2]Department of Rheumatology and Orthopaedics, Leiden University Medical Center, Leiden, The Netherlands, [3]Department of Rheumatology, Leiden University Medical Center, Leiden, The Netherlands, [4]Faculty of Health, University of Applied Sciences, Leiden, The Netherlands

Background: In the Netherlands, as in many other countries, advanced arthritis training for HPs (clinical nurse specialists, physical therapists, occupational therapists, social workers and psychologists) is organized separately for each discipline. A study of their actual and preferred tasks and education may lead to recommendations for improvement of education and, eventually, care provided by HPs.

Objectives: To examine which tasks currently are performed and preferred by Dutch HPs involved in the care of patients with rheumatic diseases, and to what extent the required knowledge and skills are and should be covered in advanced arthritis training.

Methods: For this cross-sectional study a questionnaire was developed, based on a comparable project of the UK Arthritis Research Campaign and interviews with experts from the various disciplines involved. The first part pertained to the current en preferred performance of 19 diagnostic and 27 therapeutic tasks (yes/no). The second part included 13 "knowledge" and 22 "skills" items. It was asked whether the items were not, globally or in detail covered in their advanced arthritis training. Part 1 was administered to all members of the Dutch Allied Health Professionals in Rheumatology (NHPR) (n = 416) whereas part 2 was sent to all NHPR members, rheumatologists (n=263), and 200 patients with rheumatic diseases.

Results: The response rates were 44% for the HPs, 38% for the rheumatologists and 80% of the patients, respectively. On average clinical nurse specialists and physical therapists each perform 23 of the 46 included tasks, occupational therapists 21, social workers 17 and psychologists 12. Of the 46 included tasks, 35 were performed by >50% of two or more groups of HPs. The least provided tasks were medical tasks, such as ordering and judging X-rays and prescribing medication. The majority (>50%) of 4/5 groups of HPs indicated a wish to apply (more) measurement instruments and to provide (more) education. The majority of all knowledge and skills items (27/35) was not sufficiently covered in the advanced training according to >50% of 2 or more HP groups. According to >50% of the HPs and rheumatologists medical tasks should not or only globally be covered in the advanced arthritis training for HPs. In contrast, >50% of the patients thought that all tasks (including medical tasks) should be covered in the advanced arthritis training.

Conclusion: There is considerable overlap in the tasks performed by Dutch HPs in rheumatology. HPs did not express a need to expand their daily tasks with medical tasks. A large number of knowledge and skills items were found not sufficiently covered in the current advanced arthritis training. These findings suggest that there is room for the improvement of the current advanced arthritis training for Dutch HPs. Given the overlap in current tasks and preferences with respect to education, the development of common educational modules appears to be a good option.

*And the Project Steering Group: Prof. dr. JWJ Bijlsma, drs. H Bloo, drs. JE Voorneveld-Nieuwenhuis, L Wassenberg, drs. G Geven, dr. M Veehof, drs. C Veldhuizen.

Accuracy of the Early Detection of Juvenile Idiopathic Arthritis Questionnaire—A Multicenter Study. Claudio A. Len[7], Luciana T. P. Paulo[7], Maria Teresa R. A. Terreri[7], Silvana B. Sacchetti[3], Virginia P. L. Ferriani[5], Clovis A. A. Silva[4], Cássia M. P. Barbosa[1], Simone Lotufo[2] and Roberto Marini[6]. [1]Hospital Darcy Vargas, São Paulo, Brazil, [2]Hospital Menino Jesus, São Paulo, Brazil, [3]Santa Casa de São Paulo, São Paulo, Brazil, [4]Universidade de São Paulo, São Paulo, Brazil, [5]Universidade de São Paulo, Ribeirão Preto, São Paulo, Brazil, [6]Universidade Estadual de Campinas, São Paulo, Brazil, [7]Universidade Federal de São Paulo, São Paulo, Brazil

Background: Many factors are associated to the delay in the diagnosis of juvenile idiopathic arthritis (JIA), some of them related to the disease and other to the difficulty in referring patients to specialists. The Early Detection of Arthritis Questionnaire (EDA-12) was designed to be used as an auxiliary tool for screening of suspect cases in general practice. However, its reliability was tested only in a small number of subjects.

Objective: To assess the reliability of EDA-12 in the detection of suspect cases referred to outpatient pediatric rheumatology reference clinics in 3 large urban areas.

Methods: EDA-12 (score range 0–12) was applied to parents of children (0 –18 y) who sought spontaneously or were referred for evaluation in 7 outpatient pediatric rheumatology clinics. Diagnostic suspicion was recorded in the first consultation (initial diagnosis), and definitive diagnosis was recorded after, at least, 6-month period of follow-up.

Results: Six hundred and sixty patients (57% girls) were included, with age (mean) of 9 years-old. JIA initial diagnosis was performed in 12% of the consultations, being also observed in the definitive diagnosis (12% of the consultations), with a high agreement between the first suspicion and the diagnostic confirmation (kappa coefficient = 87.2%). A ROC curve was used in the assessment of a score able to distinguish JIA children from non-JIA children, being obtained a value of 5 (five) in the first consultation, with sensibility of 93% and specificity of 76%.

Conclusion: The EDA-12 has demonstrated reliability for discrimination of suspect cases of JIA and reinforces its relevance as an auxiliary tool in the first medical consultation.

Engaging Youth in a Web Based Transition Intervention: Usability and Feasibility of Rheumtogrow.org. Peter Scal, Ann Garwick and Keith Horvath. University of Minnesota

Purpose: This pilot study tests the usability and feasibility of a theoretically grounded, internet based intervention for youth with Juvenile Arthritis (JA)

Method: We developed Rheumtogrow.org for youth with JA based on Self-Determination Theory (SDT) through a user centered and participatory process. This intervention seeks to increase the likelihood that youth will engage in behaviors that reduce the impact that arthritis has on their lives across multiple domains including the transition from child to adult focused care. We enrolled 32 youth (age 14–18) and provided them with access to the site for six weeks. We collected self-reported assessment measures pre and post intervention via an internet based questionnaire and measured actual intervention site use.

Results: Of the 32 enrolled youth, 1 (3.1%) did not complete pre-test and 2 (6.3%) completed the pretest but did not login to the intervention site during the trial. Pre and post test questionnaires were completed by 29 (90.6%). Most users agreed or strongly agreed that the intervention site was be easy to understand (82.7%) and easy to use (72.4%) that it was contained creditable information (96.5%), was sensitive to teen issues (89.7%) and relevant to their life (71.4%). Most would use the site again (88.9%) and recommend it to a friend (88.9%). Open ended responses indicated that users most liked the ability to learn from the experiences of other teens and that they site would be more appealing if there were an opportunity to connect with other teens through a message board, chat or instant messaging. Site use varied considerably between users in the total time (range 2 minutes to 6 hours 33 minutes, median 42 minutes) and the number and content of the pages viewed. Youth report of a stronger belief that a website is a good way to learn more about arthritis and that others think it should be used were significant predictors (linear regression, $p \leq .05$) of site use (greater number of page views). Fewer page views were predicted by the belief that a website would be a way to connect and share with other teens with arthritis suggesting that the discrepancy between youth expectations and intervention approach is problematic.

Conclusions: We found youth eager to participate in this pilot of an internet based program for JA. Participants found the intervention site to be relevant and engaging, especially the opportunity to learn from the experiences of other teens. Users had a strongly stated preference for improving the youth-to-youth interactivity on the site which is consistent with their current patterns of use and expectations of technology. Interest in learning more about JA and the influence of others was associated with greater site use while expectations that the site would have real-time youth-to-youth interaction (when it did not) was associated with lower use. Youth engagement in a web-based intervention for JA is influenced by individual and social characteristics and the nature of the technology. Rheumtogrow.org offers a promising foundation on which to refine and test intervention for youth with JA.

1341

FEAR (False ELISA Associated Rheumatic) Syndrome in Children. Donald P. Goldsmith[1], Carolann Martucci[3] and Svetlana Lvovich[2]. [1]St Christopher Hosp Children/Drexel University College of Medicine, Philadelphia, PA, [2]St Christopher's Hosp Children/Drexel University College of Medicine, Philadelphia, PA, [3]St Christopher's Hospital for Children, Philadelphia, PA

Introduction: Non specific arthralgias associated with a positive ANA remain a common referral source to the pediatric rheumatologist. Multiple studies have documented the unlikely progression to a recognizable inflammatory disorder and allow the pediatric rheumatologist to effectively alleviate parent and patient anxiety. There is now increased use of ANA reflex panels which use solid phase ELISA assays rather than indirect immunofluorescence. If positive, even without a reported quantitative titer, these panels automatically cascade (with increased cost) to additional antibody tests. Children are now being referred for isolated positive ELISA tests such as anti centromere, anti SS-A/B, anti SCL-70, anti Sm/RNP, and anti dsDNA antibodies.

Purpose: To characterize and bring to attention increasing numbers of children with a positive ANA screen without a quantitative titer and one or more positive additional specific antibody tests.

Methods: A retrospective outpatient chart review from 06/01/2008 to 01/01/2010)

Results: Of 415 new patient assessments seen over this 18 month period we identified 20 (5%) children with a positive ANA screen and one or more additional positive antibody tests. All children had non specific complaints, primarily arthralgias, myalgias, and/or transient cutaneous eruption. These tests had been obtained prior to consultative assessment. There were 19 F, 1M; 16 White, 3 African-American, and 1 Hispanic. Mean age 11.4 y (range 6–17). Within this group of children there were 6 positive tests for anti SS-A, 4 anti SS-B, 4 anti SCL-70, 3 anti centromere, 3 anti RNP, 2 anti Smith, and 2 anti dsDNA. Four children had more than 1 antibody present. The average duration of symptoms prior to laboratory assessment was 18 months (range 4–48). Prior to assessment 15(75%) of the parents had seriously web researched those disorders associated with each of these antibodies. None of these children have thus far developed a characteristic pediatric rheumatic disorder.

Conclusions: Although these children require careful follow-up observation, in view of the extended duration and non specific nature of symptoms prior to the recognition of each positive antibody as well as the lack of corroborative physical findings we predict it's unlikely that significant morbidity will develop. As 5% of our recent new patient assessments/year, this represents a significant number of children. Parent/patient fear and anxiety is considerable and in our opinion lead to subtle variants of the vulnerable child syndrome. To minimize the creation of FEAR syndrome we need to better inform our referring physician base about the most suitable, if any, ANA tests to order. Commercial laboratories should fully disclose the nature of each panel and not solely offer cascading tests on pre-printed forms.

Physiotherapy Management of Children with Hypermobility: A Review of an Out-Patient Self Management Exercise Programme. Susan M. Maillard[1], David Adkins[2], Elaine Haggart[2] and Swati Bhagat[2]. [1]Great Ormond Street Hospital, London, Maidenhead, United Kingdom, [2]Great Ormond Street Hospital, London, United Kingdom

Background: The recognition of hypermobility in the paediatric population has increased and common complaints associated with this are pain and fatigue. Great Ormond Street Hospital, UK has implemented a self management exercise programme, which is specific and progressive to key muscle groups. It utilises open chain exercises with high repetitions (30) and low weights (0.5–2.5kg), in order to manage these patients from an outpatient-based clinic.

Objectives: To establish whether this specific muscle training programme can be effectively used in the paediatric hypermobile population, to increase muscle strength, decrease pain and improve overall function.

Method: A retrospective case note review of children who had attended the hypermobility out-patient service between Nov 2009 and March 2010 was completed (comparing initial assessment and follow up). Assessments of muscle strength, school attendance, Childhood Health Assessment Questionnaire (CHAQ), parental visual analogue scale (VAS) of general well being and pain VAS were collected on the children. All children were provided with an exercise programme at the initial assessment, based on 4–5 key exercises, focusing on increasing repetitions and weights. An excel database was used to compile findings.

Results: Data from 20 children (10 males:10 females) who had already been diagnosed with hypermobility (Beighton score of >4/9), was collected. The mean age was 11 years (range 5–16 years). The primary complaints within the cohort were of pain and fatigue longer than 6 months in duration. School attendance for all but one patient was 100%.

On initial assessment the mean muscle strength score was 3.5/5 (oxford manual muscle score) in hip abductors, hip extensors and inner range quadriceps (range 2.5–5) and 7.25/10 repetitions for plantar flexors (range 2–10). At 8–12 week follow up, all children were completing 30 repetitions and using an average weight of 1.5kg (range 0.5–2.5kg). There was an average increase in muscle strength of hip abductors (60%), hip extensors (70%), inner range quadriceps (55%) and plantar flexors (40%).

The average score of the CHAQ on assessment was 1.15/3, pain VAS was 4.6/10cm and parental VAS of general well being 3.9/10cm (10=most unwell).There was a 60% decrease in the score of CHAQ between visits. Pain and parental VAS diminished by 55% and 45% respectively and all parents reported an improvement in fatigue.

Conclusion: The use of a specific progressive resisted muscle strengthening programme using open chain exercise, with high reps and low weights has been shown to increase muscle strength, improve overall function and decrease pain in children with hypermobility. This can therefore considered to be an effective method of managing hypermobile children within an outpatient clinic.

Stress in Adolescents with Idiopathic Musculoskeletal Pain. Juliana Molina[2], Flavia H. Santos[1], Maria Sylvia Vitalle[2], Maria Odete E. Hilário[2], Maria Teresa R. A. Terreri[2], Simone G. L. Silva[2] and Claudio A. Len[2]. [1]Universidade Estadual de São Paulo, Assis, São Paulo, Brazil, [2]Universidade Federal de São Paulo, São Paulo, Brazil

Background: Musculoskeletal pain syndromes are raising complaints at pediatrics practice, affecting mainly children and adolescents from 5 to 14 years. Adjacently to the pain, reports of emotional and cognitive difficulties are also common.

Objective: To investigate the presence of stress in the attended population in a Pediatric Rheumatology outpatient clinic.

Method: Nineteen adolescents from 14 to 16 years with idiopathic musculoskeletal pain (IMP) were assessed regarding to stress symptoms through Lipp's Inventory of Stress Symptom for Adults, and compared to a control group of 20 matched healthy adolescents.

Results: IMP adolescents had significantly higher stress scores comparing to the control group. Thus, 79% of IMP adolescents had complaints related to stress, while the same scores were observed in only 35% of the control group. The differences between groups (t-test) were notable in the intermediate stage of stress, known as resistance phase (p=0.009), followed by exhaustion phase (p=0.023), final stage of stress where the organism becomes vulnerable to diseases. Also, regarding to complaints, the differences were pointed out either for physical (p=0.013) or emotional (p=0.030) aspect.

Conclusion: Adolescents with chronic pain have physical, social, emotional, and behavioral aspects in their lives affected by a chronic process of pain. In our sample we have demonstrated that the complaints presented by adolescents and their parents also show a stress response in a worsening process.

To Explore the Use of the PedsQL Subjective Questionnaire To Assess Levels of Fatigue in Children with Juvenile Dermatomyositis. Susan M. Maillard[1], Amy Todd[2], Kiran Nistala[3], Clarissa Pilkington[2] and Abdul Hassan[2]. [1]Great Ormond Street Hospital, London, Maidenhead, United Kingdom, [2]Great Ormond Street Hospital, London, [3]Institute of Child Health, London

Background: Fatigue is one of the regularly reported clinical features of Juvenile Dermatomyositis (JDM), however there is no standardised method of assessing the degree of fatigue. The PedsQL Fatigue score (FS) is a self reported questionnaire and a Visual Analogue Scale (FVAS) which has been developed to measure fatigue in children with paediatric inflammatory diseases. Great Ormond Street Hospital has a specialist service for children with JDM and the FS and FVAS were used to assess whether they were an effective measure of disease related fatigue.

Objectives: To establish if the PedsQL FS measures fatigue in children with JDM compared to clinical outcome measures of active JDM including muscle strength and function.

Methods: All children attending the JDM clinic were routinely assessed using the Childhood Myositis Assessment Score (CMAS), manual muscle testing score (MMT8), parental VAS score of general wellbeing (PaVAS), physicians VAS of disease activity (PVAS), 6 minute walk test (6MWT) and Childhood Health Assessment Questionnaire (CHAQ). The PedsQL questionnaire was given out separately to both parents and children and includes a fatigue VAS (FVAS), a pain VAS as well as specific questions about cognitive fatigue, physical activity and sleep. The data was analysed using SPSS v16.0.

Results: The patient cohort comprised of 52 children (39 F: 13 M). The mean age was 11.92 years (range 3–19). The mean disease duration was 9.42 years (range 0.2–13yrs)

The PedsQL FS (both parent and child) showed statistical significance with pain VAS, Pa VAS and CHAQ however did not show significance with the objective markers- MMT8 and CMAS. The child and parent FVAS shows statistically significant results with the pain VAS, MMT8 and the CHAQ. Additionally, the child FVAS statistically shows a correlation with the CMAS. Neither the PedsQL FS or FVAS showed any statistical correlation with the 6MWT or the PVAS.

Spearman's Correlation		Pain VAS	CMAS	MMT8	PaVAS	PVAS	6MWT	CHAQ
Parent FS	Correlation	−.632**	.222	.286	−.427**	−.029	.129	−.406**
	Sig (2-tailed)	.000	.162	.060	.006	.868	.490	.008
Child FS	Correlation	−.648**	.087	.144	−.445**	.029	.137	−.411**
	Sig (2-tailed)	.000	.577	.363	.005	.876	.478	.009
Parent FVAS	Correlation	.550**	−.303	−.313*	.280	.110	−.280	.417**
	Sig (2-tailed)	.000	.057	.041	.085	.537	.134	.007
Child FVAS	Correlation	.535**	−.304*	−.415**	.311	.004	−.324	.545**
	Sig (2-tailed)	.000	.044	.006	.054	.984	.086	.000

Conclusions: It appears that the PedsQL FS does not fully objectively measure fatigue but combined with the FVAS may be a reasonable tool for assessing fatigue in JDM. However it is also recognised that psychological and psychosocial factors also play a role in patient self reported fatigue and further research is required into this area.

Disclosure: S. M. Maillard: None; **A. Todd:** None; **K. Nistala:** None; **C. Pilkington:** None; **A. Hassan:** None.

Utilizing Social Media To Reach Young Arthritis Patients. Jane S. Brandenstein[1], Emily Cope[3], Allison J. Kerr[2], Ashley M. Boynes[2], Carol D. Popp[2] and Lori Knapp[2]. [1]Freedom, PA, [2]W Pa Arthritis Foundation, Pittsburgh, PA, [3]WPa Arthritis Foundation, Pittsburgh, PA

Background: Many people in their teens through thirties affected by Arthritis can feel like they are the only one with this disease. Young people often have difficulty finding age appropriate resources and peers with similar chronic diagnoses. School, work schedules and family commitments make traditional arthritis exercise classes and self management programs challenging to access for this population. This isolation and lack of information can be very stressful and harmful to arthritis patients mental well being.

Objective: To create an online community and informative online resources for young people with arthritis.

Summary: Social media was used to connect to the target audience of young people affected with arthritis. To do this the organization created and regularly maintains accounts on Twitter, facebook, and YouTube. Since the online community's creation it has gained 1,634 followers on Twitter, 164 fans on facebook and uploaded 12 videos to YouTube.

The organization also created *Rheum for Wellness*, a blog, which serves as an outlet for all arthritis-related topics. The blog has featured posts on cooking, rare forms of arthritis, personal stories of hope, physical activity and much more. Another hugely popular feature of the blog is a series entitled *The Journey to Wellness.* In this series a young woman blogs about her personal battle with several inflammatory diseases and her quest to remain positive and reach out to others with similar issues. *Rheum for Wellness* has sparked online conversations and connected readers from all over the world. This blog has had 99 posts, 493 comments, and 73,775 views. There has been overwhelming feedback in support of the blog. Readers constantly comment that it makes them feel understood and not alone and that they have a voice. Mariah posted, "I want to say Thank You for writing this! I also 'live' with autoimmune disease, as well as other things. It is such a great feeling to know that someone out there knows how I truly feel everyday." Elizabeth said, "Thank You! Someone needed to express what we are all feeling, and you did it so eloquently."

Arthritis Radio, a podcast, was established showcase the many voices of arthritis. The podcast features interviews with health professionals, community leaders, physical therapists and many others. The goal of the show is to make knowledgeable experts accessible to all of those affected with arthritis. *Arthritis Radio* has had 16 episodes, 9,558 channel visits and 732 subscribes. Listeners have described this podcast as "a wonderful learning tool you have provided people who have arthritis" and state that the interviews on cutting edge research give them hope for the future.

Conclusion: Social media can be successfully utilized to provide information, resources and support to young arthritis patients. This target population benefits from supplementing traditional forms of communication with online communities and social networks.

Frequency and Impact of Symptoms Experienced by Patients with Systemic Sclerosis: Results from a Canadian National Survey. Marielle Bassel[1], Marie Hudson[3], Suzanne S. Taillefer[4], Orit Schieir[1], Murray Baron[1] and Brett D. Thombs[2]. [1]Jewish General Hospital, Montreal, QC, Canada, [2]McGill University, Montreal, QC, Canada, [3]McGill University and Jewish General Hospital, [4]SMBD Jewish General Hospital, Montreal, QC, Canada

Background: Patients with systemic sclerosis (SSc) report a number of problems that have been linked to disability and reduced quality of life. Due to the rarity and heterogeneity of SSc, not enough is known about the range of problems faced by individuals living with SSc. Several studies have assessed problems faced by patients with SSc, however, knowledge about the relative importance of these different problems is limited by the small number of studies that have been conducted, the relatively narrow scope of potential problems assessed in existing studies, and the small sample sizes in these studies. The objective of the present study was to identify, in a large SSc sample, symptoms of SSc that patients rated as frequent and that highly impacted their ability to carry out daily activities.

Methods: Patients with SSc were recruited to complete the anonymous Canadian Scleroderma Patient Survey of Health Concerns and Research Priorities through patient advocacy group websites, Canadian magazines, scleroderma-related newsletters, and support groups across Canada. The survey included questions regarding the frequency and impact of 69 SSc symptoms, which were generated from a panel of Canadian Scleroderma Research Group and Scleroderma Society of Canada members using existing questionnaires, symptom checklists and research articles. Descriptive analyses were performed dichotomizing symptom frequencies into *never* or *rarely* versus *sometimes*, *most of the time* or *always* and symptom impact on daily activities into *no or minimal impact* versus *moderate* to *severe* impact. In addition, for each item, among patients with symptom frequency of at least *sometimes*, the percentage of patients with at least *moderate* impact on daily activities was calculated.

Results: Our study included 464 Canadian persons with SSc. The 5 highest-rated symptoms in terms of frequency were fatigue (89%), Raynaud's phenomenon (86%), hand stiffness (81%), joint pain (81%) and difficulty sleeping (76%). The same 5 symptoms were the highest-rated in terms of having a moderate to severe impact on daily activities, in the order of fatigue (72%), Raynaud's phenomenon (67%), joint pain (64%), hand stiffness (59%), and difficulty sleeping (59%). In addition to these symptoms, items related to decreased hand function (difficulty making a fist; difficulty holding objects; difficulty opening hand; difficulty faucet) were frequently endorsed by more than 400 patients and of these patients, at least 67% endorsed a moderate to severe impact on daily activities.

Conclusion: The results of this study confirmed the importance of core symptoms of SSc with respect to quality of life, such as fatigue. Limitations in hand function, another area identified by patients as being significant, is common and contributes to overall disability levels. However, little literature exists testing the effectiveness of rehabilitation techniques to improve hand function among patients with SSc. Other areas with very little research that appear to play important roles in daily functioning include sleeping problems and male sexual functioning. A patient- researcher consensus is suggested in order to focus future SSc research.

1347

Sociodemographic and Disease Correlates of Body Image in Systemic Sclerosis (SSc). Lisa R. Jewett[2], Marie Hudson[3], Murray Baron[1], Brett D. Thombs[2] and Canadian Scleroderma Research Group (CSRG), [1]Jewish General Hospital, Montreal, QC, Canada, [2]McGill University, Montreal, QC, Canada, [3]McGill University and Jewish General Hospital

Background/Objective: Systemic sclerosis (SSc) is a chronic disease that results in significant disfigurement to socially relevant body parts, including the face and hands. There is very little research, however, on body image concerns in SSc. The objective of this study was to identify socioedemographic and disease-related correlates of dissatisfaction with appearance and social discomfort among patients with SSc. Furthermore, the study aimed to identify disfigured areas of the body most closely related to body image dissatisfaction and social discomfort.

Methods: The sample of SSc patients came from the 15-center Canadian Scleroderma Research Group Registry. Sociodemographic information was based on self-report, and patients' medical histories and disease characteristics were obtained via clinical histories and examinations by study physicians. The Brief-SWAP was used to assess social discomfort and dissatisfaction with appearance. Structural equation models were conducted with MPlus to determine the relationship of the dissatisfaction with appearance and social discomfort factors of the Brief-SWAP with age, sex, marital status, total body skin involvement, disease duration, and telangiectasias. A secondary model assessed relationships between each factor and skin involvement scores from specific body areas, including face, hands/fingers, arms, chest/abdomen, thighs, and lower legs.

Results: A total of 788 SSc patients (94 men and 694 women) were included. Subjective dissatisfaction with appearance was significantly associated with greater skin involvement (standardized regression coefficient $=.26$, $p<.01$) and longer disease duration (.08, $p=.04$). Social discomfort was significantly associated with greater skin involvement (0.24, $p<.01$), presence of telangiectasias (0.06, $p<0.01$), longer disease duration (.09, $p=.03$), younger age (-0.17, $p<.01$), and being unmarried ($-.08$, $p=.04$). Model fit was good, ($\chi 2(14)=38$, CFI=0.99, TLI=0.99, RMSEA=0.05). Secondary

analysis found that skin involvement of the face, hands/fingers, and chest/abdomen were significantly related to both social discomfort and subjective dissatisfaction with appearance. Model fit was again good, ($\chi 2(18)=42$, CFI=0.99, TLI=0.99, RMSEA=0.04).

Conclusion: This study found that appraisal of appearance (dissatisfaction with appearance) was related to SSc disease factors, most prominently skin involvement. Social discomfort, in addition to being associated with disease characteristics, was also linked to younger age and being unmarried, which is highly relevant for social interactions, particularly in the context of establishing intimate relationships. The prominent association of disfigurement to the face and hands/fingers with body image concerns is not surprising. Chest/abdomen disfigurement, which is much less common, may be a proxy for overall severity of disfigurement. In sum, the results of this study underline the need to attend to both disease and social contexts in understanding the impact of disfigurement on body image distress among patients with SSc.

Development and Validation of the Brief-Satisfaction with Appearance Scale (Brief-SWAP) for Measuring Body Image in Systemic Sclerosis (SSc). Lisa R. Jewett[4], Marie Hudson[5], Jennifer A. Haythornthwaite[3], Leslie Heinberg[1], Fredrick M. Wigley[3], Murray Baron[2], Brett D. Thombs[4] and Canadian Scleroderma Research Group (CSRG), [1]Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, [2]Jewish General Hospital, Montreal, QC, Canada, [3]Johns Hopkins University School of Medicine, [4]McGill University, Montreal, QC, Canada, [5]McGill University and Jewish General Hospital

Background: Systemic sclerosis (SSc) often results in disfiguring physical changes that commonly occur in visible and socially relevant areas of the body, including the face, mouth, and hands. The few studies that have investigated body image in SSc have found that patients with more severe SSc reported higher levels of body image dissatisfaction and low appearance self-esteem. These studies, however, used general measures of body image distress developed for use in eating disorders and not validated among patients with acquired disfigurement from disease or injury. Recently, a measure of body image originally developed for patients with burn injury, the Satisfaction with Appearance Scale (SWAP), was validated for use in SSc. The 14-item SWAP, however, which measures social discomfort and dissatisfaction with specific body parts, includes numerous items that are highly redundant and some that are less relevant for patients with SSc. The objective of this study was to develop and cross-validate a brief 6-item version of the SWAP in order to increase SSc-relevancy, reduce item redundancy, and improve feasibility of body image assessment in SSc.

Methods: Female SSc patients in a developmental sample (Johns Hopkins Scleroderma Center) and a validation sample (Canadian Scleroderma Research Group Registry) completed the 14-item SWAP. Items for the 6-item Brief-SWAP were selected based on theoretical considerations and psychometric data from the developmental sample. In both samples, internal consistency reliability, convergent validity (depressive symptoms, physical and mental health function, pain), and the hypothesized two-factor structure (Perceived Social Impact and Subjective Dissatisfaction) were compared between the Brief-SWAP and SWAP. Confirmatory factor analysis models were conducted with MPlus.

Results: 217 women from the developmental sample and 654 women from the validation sample completed the SWAP. Cronbach's alpha for the Brief-SWAP was 0.82 in both samples compared to 0.90 and 0.91 for the full SWAP. Correlations between the Brief-SWAP and SWAP were 0.94 and 0.95 in the developmental and validation samples. All correlations of the Brief-SWAP and SWAP with measures of convergent validity were substantively equal with no statistically significant differences in either sample. Based on confirmatory factor analysis, model fit for the Brief-SWAP was good in the developmental ($\chi 2(4)=9.0$, CFI=0.99, TLI=0.99, RMSEA=0.07) and validation samples ($\chi 2(4)=19.5$, CFI=0.99, TLI=0.99, RMSEA=0.08) and better than for the SWAP in both samples.

Conclusion: The Brief-SWAP is a reliable and valid measure of body image dissatisfaction and social discomfort related to disfigurement in SSc. Compared to the full 14-item SWAP, the 6-item Brief-SWAP reduced item redundancy, increased relevance to the experience of SSc patients, and demonstrated good psychometric properties including reliability and validity, thus providing a less burdensome and more feasibly administered scale. The results from the current study constitute a significant step towards the improvement of measurement of important body image constructs for individuals with SSc.

Work as a Daily Challenge: Working with Scleroderma. Cindy F. Mendelson[2], Janet L. Poole[3] and Saralynn H. Allaire[1]. [1]Boston Univ School of Medicine, Boston, MA, [2]Univ of New Mexico, Albuquerque, NM, [3]University of New Mexico, Albuquerque, NM

Background: Systemic sclerosis (SSc) may severely limit one's ability to participate in paid employment, which may threaten an individual's economic, social, physical, or mental well being. This study identified challenges in the work environment and adaptations made by persons with SSc.

Study Sample: 32 persons were recruited from the Scleroderma Foundation website. The participants mean age was 47.3 years, mean disease duration was 9.6 years and mean education level was 17.1 years. The majority of participants were in professional or managerial jobs and had been at their current jobs for mean of 9.8 years. 56.2% had diffuse scleroderma, 59.4%were married, and 71.9%worked 35 hours or more a week.

Methods: Each participant engaged in a single structured interview. Questions were posed about challenges getting to/from work, the work environment, managing the physical/mental demands of the job, working with others, performing essential job functions, balancing work/home activities, changes to work hours or job type, and adaptations made to keep working. Interviews were audio taped and transcribed. Interviews were coded using the interview guide questions as an initial framework. Content analysis were used to determine the key content of the code and a summary statement generated for each code. Working from the summary statements the data was aggregated into four themes and a single overarching theme.

Results: Employees with SSc experience *work as a daily challenge*. This overarching theme described the work experience for most participants, who, on a daily basis, dealt with the details of work, such as getting to work in the cold knowing that their Raynauds will be triggered or shuffling paper with limited hand mobility. Four subthemes describe their experiences. Their *work environment presented options, opportunities and challenges.* Participants discussed work options such as home offices, part-time or flex time schedules, and problems within the work environment such as the temperature or inaccessible buildings. Successful employees were skillful at *managing the present while looking forward*. Most planned to either stay at their current job or occupation. However, they also were mindful of future opportunities and potential problems and planned by watching for opportunities to move into less physically demanding positions. Participants remained hopeful about the future and the possibility to work until retirement. *Managing the tasks of work* described how participants performed their daily jobs. For most participants this was the least problematic part of their work, as they found ways to modify the job, use adaptations, found help, or left positions that were a poor fit. Employees had a network that included *family, friends, colleagues and their employer,* who contributed to their success by lessening the load at home, providing a supportive emotional network, helping with tasks at work, and providing accommodations at work.

Conclusions: It is in the best interest of all of us that those who can work continue to work. We found that our participants wanted to continue to work, and were anxious to find win-win scenarios that allowed them to work and that benefited their employer.

Suppression of Collagen-Induced Arthritis in Mice by Anti-CD19 Antibody That Co-Engages BCR and Inhibitory Receptor FcγRIIb: Efficacy Does Not Require B Cell Depletion. Saso Cemerski[1], Seung Y. Chu[2], Erik Pong[2], Holly M. Horton[2], John R. Desjarlais[2] and David E. Szymkowski[1]. [1]Xencor, Inc., Monrovia, CA, [2]Xencor, Inc.

Background: The B cell is a clinically validated target in autoimmune disease, yet current therapeutic approaches that involve B cell depletion (such as anti-CD20 antibodies rituximab and ocrelizumab) are associated with increased infection risks, including viral reactivation leading to PML. On the other hand, approaches that target individual B cell survival factors including BLyS and APRIL (such as belimumab and atacicept) are reportedly safer but less efficacious, possibly due to redundant activities of other survival factors. We have therefore developed a new therapeutic antibody that globally suppresses B cell functions without promoting B cell depletion. This biologic exploits the natural ability of immune complex to suppress humoral immunity by coengaging B cell receptor with the inhibitory receptor FcγRIIb.

Methods: XmAb5871, an anti-human CD19 antibody with >400-fold increased FcγRIIb affinity relative to native IgG1 Fc, was produced as described (Chu et al. Mol. Immunol. 2008; 45:3926). For use in mouse models, we generated surrogate antibodies against mouse CD19 and CD20 including XENP8206 (with identical Fc domain to XmAb5871), XENP8243 (a surrogate for rituximab), and their Fc and isotype controls. For humanized SCID mice, 3×10^7 human PBMCs were engrafted prior to immunization and treatment with therapeutic antibodies. For collagen-induced arthritis models, C57BL/6 mice transgenic for human FcγRIIb were obtained from J. Ravetch (Rockefeller). CIA was induced in transgenic mice and littermate controls using chicken collagen as described in Inglis et al. (Arth. Res. Therap. 2007; 9:R113). Suppression of B cell activation was assayed by calcium flux, as described in Chu et al. (2008).

Results: Antibodies coengaging CD19 and FcγRIIb suppressed humoral immunity to foreign antigens in both human PBMC-engrafted SCID mice and huFcγRIIb-transgenic mice. XENP8206, but not control anti-CD19 antibodies with native IgG1 or Fcγ receptor knockout Fc domains, suppressed BCR-mediated activation of splenic B cells from transgenic mice. XENP8206 also suppressed joint inflammation in CIA induced in huFcγRIIb-transgenic C57BL/6 mice, an arthritis model known to possess a strong T cell-mediated disease phenotype. Notably, therapeutic efficacy of XENP8206 occurred without depletion of peripheral B cells in mice, in contrast to XENP8243 (mouse surrogate for rituximab), which potently depleted such B cells.

Conclusions: We show that a recombinant antibody engineered for enhanced binding to FcγRIIb via its Fc domain is a potent suppressor of B cell activation that inhibits humoral immune responses and arthritis in humanized mouse models. In contrast to other B cell-targeted therapeutic approaches, this antibody suppresses activated B cells without depletion, thus mimicking the natural function of immune complex. Our results demonstrate the critical role of FcγRIIb in regulating human and murine humoral immunity, and suggest that replication of immune complex-mediated immunosuppression by XmAb5871 has potential as a novel therapy for rheumatoid arthritis and other autoimmune diseases.

Micro RNA 155 Deficiency Protects from the Development of Inflammatory Arthritis. Stephan Blüml[1], Michael Bonelli[2], Birgit Niederreiter[1], Antonia Puchner[1], Georg Mayr[1], Marije Koenders[3], Smolen Josef[1] and Redlich Kurt[1]. [1]Medical University Vienna, Austria, [2]Medical University Vienna, Austria [3]Radboud University Nijmegen Medical Center, Nijmegen, The Netherlands

Objective: Micro RNAs are a new class of regulatory elements in various biological processes. Altered expression of certain micro RNAs has been demonstrated in rheumatoid arthritis. However, the pathogenic role of micro RNAs is not known in the development of this disease. The aim of this study was to assess the role of microRNA 155 in the development of murine inflammatory arthritis.

Methods: Collagen-induced arthritis (CIA) as well as K/BxN serum transfer arthritis was in induced in wild-type (wt) and microRNA 155 knock out ($miR155^{-/-}$) mice. Clinical scoring was performed on a weekly basis. Histological analysis of synovial inflammation as well as local bone destruction was performed. Cytokine production was measured in serum as well as from supernatants of cultured lymph node cells after immunization after induction of CIA. The humoral as well as T cell response to collagen as well as T cell polarization was assessed in serum, spleen and lymph node, respectively. The cellular composition of the draining LN in CIA was analyzed by flow cytometry.

Results: We show that mice $miR155^{-/-}$ mice are protected from clinical as well as histological signs of CIA. Analysis of anti-collagen antibodies revealed strongly reduced levels in $miR155^{-/-}$ mice compared to wt. However, relative numbers and expression of costimulatory molecules on B cells were not different between the two groups. Furthermore $miR155^{-/-}$ mice showed reduced antigen-specific proliferation of T cells. In addition, T cells of $miR155^{-/-}$ mice produced significantly diminished levels of the Th17 cytokines IL-17 and IL-22, whereas Th1 and Th2 cytokine IL-4 and IFN-γ were not different. Using K/BxN serum transfer arthritis, which is only dependent of innate effector mechanisms, we show that both wt and $miR155^{-/-}$ mice develop arthritis. However, $miR155^{-/-}$ mice showed significantly reduced local bone destruction due to reduced generation of osteoclasts.

Conclusions: MiR155 deficiency protects from the development of CIA by inhibiting the generation of pathogenic self reactive T as well as B cell responses. Furthermore, miR155 controls the development of local bone destruction by inhibition of osteoclastogenesis. These data identify miR155 as a possible novel target in the therapy of autoimmune arthritis.

Down-Regulated MicroRNA-152 Induces Aberrant DNA Methylation in Scleroderma Endothelial Cells by Targeting DNA Methyltransferase 1. Yongqing Wang, Omar R. Kahaly and Bashar Kahaleh. University of Toledo, Toledo, OH

Objectives: The underlying mechanism of epigenetic imprinting in SSc microvascular endothelial cells (MVEC) remains unknown. MicroRNAs (miRNAs), which are noncoding RNAs that regulate gene expression, are involved in diverse biological functions. In this study, we investigated whether miRNAs are aberrantly expressed in SSc-MVEC and if they are involved in the regulation of epigenetic imprinting in SSc.

Methods: The expression levels of the 376 most abundantly expressed miRNAs in the human genome were determined in SSc and control MVEC (derived from 6 SSc and matched control subjects) by RT^2 microRNA PCR array. Control and SSc MVEC were transfected with 1.0ug of miRNA isolated from SSc or control MVEC. After 48 hours, cells were harvested and the expression levels of endothelial nitric oxide synthase (*NOS3)* and DNA methyltransferases1 (*DNMT1)* were measured by real-time PCR. The expression levels of miR-152 were determined by quantitative PCR. Finally, miRNA-152 was forced expressed or inhibited in SSc and control MVEC.

Results: Significant differences in the expression levels of miRNAs were noted in SSc-MVEC. To understand the role of altered miRNAs expression in SSc, control-MVEC were transfected with SSc- derived miRNAs which resulted in significant increase expression of *DNMT1* (2.5± 0.3 folds, mean ±SD) and reduced *NOS3* expression level (25±9%, percent of control). While, the transfection of SSc-MVEC with control miRNAs resulted in decreased expression of *DNMT1* and increased expression of *NOS3.* Since *DNMT1* is one of the predicted direct targets of miR-152, we investigated the expression levels of miR-152 in SSc and control MVEC. Levels were frequently down-regulated in SSc-MVEC and were inversely correlated to *DNMT1* expression levels. Forced expression of miR-152 in SSc-MVEC led to a reduction in *DNMT1* expression at both the mRNA and protein levels in comparison with the negative control, while inhibition of miR-152 expression in control- MVEC enhanced *DNMT1* expression levels in association with reduced *NOS3* expression level.

Conclusions:

· SSc-miRNAs transfection into control-MVEC can induce SSc-MVEC phenotype.

· miR-152 expression is down regulated in SSc-MVEC and inversely correlates with DNMT1 expression level.

· The forced expression of miR-152 corrected SSc-MVEC phenotype and its inhibition induced SSc phenotype in control MVEC.

· miR- 152 may play a causal role in DNA methylation changes in SSc-MVEC.

SNAPIN: A Novel Endogenous TLR Ligand in Rheumatoid Arthritis. Bo Shi[3], Qiquan Huang[3], Margriet J. Vervoordeldonk[1], Paul P. Tak[2] and Richard M. Pope[4]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands, [2]Academic Medical Center, University of Amsterdam, [3]Northwestern University, Chicago, IL, [4]Northwestern University

Background: Toll-like receptor (TLR) signaling may contribute to the pathogenesis of rheumatoid arthritis (RA) resulting in the persistent activation of macrophages and the expression of inflammatory cytokines, mediated by endogenous TLR ligands produced and released locally within the joint. While a number of potential ligands have been identified, it is unclear which, if any, is clinically important. Therefore, a yeast-two hybrid system was employed to identify TLR2 and TLR4 binding proteins by screening a cDNA library generated from RA joint tissue.

Methods: In yeast-two hybrid system, the extracellular domains of TLR2 or TLR4 were used as bait. The prey was a cDNA library generated from highly inflammatory RA synovial tissues. Positive colonies were selected by growing yeasts on nutritional dropout agar plates. The plasmids from the positive yeast colonies were isolated and the cDNA inserts were sequenced. Co-immunoprecipitation was performed using HA-tagged *in vitro* translated SNAPIN with TLR2-Fc or TLR4-Fc fusion proteins. The agonistic function of SNAPIN was examined using HEK-TLR2 and HEK-TLR4 reporter cells.

Results: The TLR2 bait interacted with 60 protein sequences, which represented 11 unique proteins, while the TLR4 bait identified 54 sequences, which represented 34 unique proteins. 33 of the 60 sequences interacting with TLR2 and 7 of the 56 interacting with TLR2 represented SNAP-associated protein (SNAPIN), a protein important in endosomal fusion. SNAPIN co-immunoprecipitated with TLR4-Fc, but more strongly with the TLR2-Fc fusion protein. In the functional assays, recombinant SNAPIN activated HEK cell lines expressing TLR2 and TLR4. Heat inactivation of SNAPIN for 10min at 96 °C and pre-incubation with 50mg/ml protease K completely abolished TLR activation, while treatment with polymyxin B did not inhibit TLR activation, suggesting that the effects were not due to endotoxin contamination. Furthermore, neutralizing anti-TLR2 antibody inhibited SNAPIN's effect on TLR2 signaling, suggesting the SNAPIN specifically targets TLR2. SNAPIN was expressed in synovial fluid macrophages, determined by immunoblot analysis.

Conclusion: We identified SNAPIN as a novel endogenous TLR2 and TLR4 ligand in the synovial tissue of patients with RA. SNAPIN is known to function as a regulator for membrane docking and fusion for synaptic vesicles as well for late endosomal-lysosomal fusion. Studies are underway to determine the potential role of SNAPIN in the pathogenesis of RA.

TLR9 Induced Macrophage Activation Syndrome Is Driven by IFNγ Produced by Lymphocytes and Natural Killer Cells but Is Dampened by Lymphocyte Produced IL-10. Edward M. Behrens[2], Katharine Slade[3], Sheila Rao[3], Portia A. Kreiger[1], Michele Paessler[3], Taku Kambayashi[5] and Gary A. Koretzky[4]. [1]A.I. DuPont Hospital for Children, [2]Childrens Hospital of Phil, Philadelphia, PA, [3]The Children's Hospital of Philadelphia, [4]University of Pennsylvania, Philadelphia, PA, [5]University of Pennsylvania

Purpose: Macrophage Activation Syndrome (MAS) is a clinical entity consisting of massive inflammation, cytopenia, and multi-system organ failure associated with an overproduction of IFNγ. Previous murine models implicate genetic defects in CD8+ T-cell cytotoxicty as the cause of the syndrome. However, this model does not explain the link of MAS with genetically normal patients having rheumatologic disease or Epstein Barr Virus (EBV) infections. To investigate the pathoetiology of MAS in inflamed, genetically normal animals, we utilized a system of chronic inflammation driven by Toll-like receptor (TLR) stimulation.

Methods: Mice treated with every other day i.p. injection of CpG (TLR9 agonist) for 10 days. Cytokines were measured by ELISA, cell surface markers by flow cytometry, and organs were taken for histology. Natural killer (NK) cells were depleted using the PK136 anitbody (100 μg i.p. every day).

Results: CpG treated mice develop pancytopenia, splenomegaly, microthrombosis, hepatitis, hyperferritinemia, and elevated serum IFNγ consistent with MAS. None of these changes occur in PBS injected control mice. Only a small population of CD8+ T-cells are activated by the CpG treatment as measured by CD69 levels. In contrast, Natural Killer (NK) cells show a more robust CD69 upregulation. Consistent with previous MAS models, disease is dependent on IFNγ as IFNγ−/− CpG treated mice are protected from disease. Unlike previous models, CpG treated β2m−/− mice lacking CD8+ T-cells develop disease to the same extent as wild type mice showing that CD8+ T-cells are not required. Furthermore, Rag−/− mice develop CpG induced disease, showing that all B- and T-cells are dispensable. NK cell depleted mice develop disease suggesting NK cells are dispensable. However, Rag/common gamma chain (Rag/cgc −/−) doubly deficient mice missing B-, T- and NK cells have greatly reduced disease. Thus, in the absence of adaptive immunity, NK cells are required for full disease expression. Interestingly, consistent with incomplete protection, Rag/cgc −/− CpG treated mice produce half as much IFNγ as Rag−/− mice suggesting that an IFNγ producing myeloid cell also contributes to disease. IL-10 is also produced by CpG treated mice, but is reduced in IFNγ−/− mice suggesting it is produced in response to IFNγ induced inflammation. IL-10 is also reduced in CpG treated Rag−/− mice, which develop enhanced liver disease, suggesting both that the source of IL-10 is from lymphocytes, and that its production is protective.

Conclusions: Our novel mouse model shows that MAS can result from TLR stimulation. This provides a rationale for the link between MAS and rheumatic diseases such as Still's Disease and lupus, both of which are associated with TLR activation, as well as the association of MAS with EBV, a TLR9 stimulating virus. We show that NK cells are important mediators of disease, a cell population implicated in the etiology of Still's Disease. We show that IFNγ is critical for driving disease, but that IL-10 from a lymphocyte origin is protective. Interestingly, these studies also suggest a role for an IFNγ producing myeloid cell, a population whose relevance has been controversial, in driving this disease process.

Genome-Wide Association Study of Ankylosing Spondylitis Identifies New Loci, a Tag SNP for HLA-B27, and an Interaction between HLA-B27 and Variants in ERAP1. Matthew A. Brown, on Behalf of the Wellcome Trust Case-Control Consortium 2 and Australo-Anglo-American Spondyloarthritis Consortium. The University of Queensland Diamantina Institute, Brisbane, Queensland, Australia

In order to identify genetic variants predisposing to risk of Ankylosing Spondylitis (AS), we performed a gwas of 1782 British and Australian cases fulfilling modified New York Criteria, and 5167 historical controls from the Wellcome Trust Case Control Consortium 2 (WTCCC2). After imputing to Hapmap, the study was combined with existing results from the Australo-Anglo-American AS Consortium (TASC) involving a non-overlapping cohort of Australian, British and North American cases and ethnically matched controls, using inverse variance meta-analysis. Replication was then performed in 2109 cases and 4410 controls from Australia, Britain, and the Canadian SPARCC consortium.

As well as confirming known associations at *HLA, IL23R, ERAP1, KIF21B*, 2p15 and 21q22, we identified and subsequently replicated risk predisposing variants in *RUNX3* (combined $p=3.3 \times 10^{-12}$), *IL12B* ($p=1.8 \times 10^{-8}$), and *LTBR* ($p=4.5 \times 10^{-10}$), and found suggestive association at *PTGER4* ($p=7.8 \times 10^{-8}$), and *TBKBP1-TBX21* ($p=5.9 \times 10^{-8}$), as well as providing further support for previously reported loci with suggestive association with AS, including *ANTXR2* ($p=3.8 \times 10^{-7}$), *CARD9* ($p=1.2 \times 10^{-6}$), and *TRADD* ($p=4.1 \times 10^{-6}$).

We also identified a single SNP, rs4349859 near the gene *MICA*, which tagged HLA-B27 with near perfect sensitivity (98%) and specificity (99%) in 531 cases and 729 controls of Australian and British origin. These findings were confirmed in independent sets of Sardinian and Azorean cases, and show that whilst rs4349859 tagged the non-AS associated *HLA-B*2709* subtype, it did not tag the AS-associated *HLA-B*2707* subtype, indicating that rs4349859 is not AS causative, and further reducing the likelihood that a B27-linked gene is responsible for the association of B27 with AS.

In most common diseases the proposed genetic model involves interaction between loci, but to date no convincing examples of such interaction have been demonstrated. In the current study however, we identified an interaction between HLA-B27 and variants within *ERAP1* in the WTCCC2 ($p=0.008$), TASC ($p=0.004$) and replication datasets ($p=0.004$). Specifically, risk variants in *ERAP1* increased odds of disease in HLA-B27-positive, but not B27-negative, cases (combined interaction $p=1.4 \times 10^{-6}$). In contrast, *IL23R* was associated with disease in both B27+ve and –ve cases. This result indicates that B27+ and B27-ve forms of disease have substantially different but overlapping aetiologies. The findings support mechanisms of association of B27 and ERAP1 with AS that involve peptide presentation, and that ERAP1 contributes to disease risk through its action in trimming peptides prior to loading into nascent HLA class I molecules, rather than by cleaving pro-inflammatory cytokine receptors on the cell membrane.

In summary, we have identified several new loci that affect risk of AS, bringing the total number of confirmed AS genetic susceptibility loci to 14,

report a single SNP variant that tags HLA-B27 which may be used in the future as a cheap alternative to expensive B27 typing, and have discovered one of the first convincingly replicated examples of a genetic interaction affecting risk of a complex disease.

ACR Concurrent Abstract Sessions
Antiphospholipid Syndrome
Tuesday, November 9, 2010, 2:30 PM–4:00 PM

1356

TLR-4 and Annexin A2 Involvement in Endothelial Cell Activation by Anti-Phospholipid Antibodies: Specific Silencing by Small Interfering RNAs. Elena Raschi[2], Valentina Broggini[3], Maria Orietta Borghi[4], Claudia Grossi[2] and Pierluigi Meroni[1]. [1]Instituto G. Pini University, Milano, Italy, [2]IRCCS Istituto Auxologico Italiano, Milan, Italy, [3]University of Milan, Italy, [4]University of Milan; IRCCS Istituto Auxologico Italiano, Milan, Italy

Background: Antiphospholipid Syndrome (APS) is characterized by recurrent fetal losses and arterial/venous thrombosis in the presence of antiphospholipid antibodies (aPL). aPL are directed against anionic phospholipid binding proteins: mainly prothrombin and b2 glycoprotein I (b2GPI). The complex formation between circulating aPL and b2GPI expressed on the cell membranes induces signalling and triggers cell activation. Accordingly, aPL-mediated endothelial cell (EC) perturbation is thought to be a key pathogenic event leading to the prothrombotic diathesis as supported by in vitro and in vivo models. The exact nature of the EC receptors for b2GPI is still matter of research: β2GPI has been shown to bind heparan sulphate, Annexin A2 and apoER2 (on platelets). Furthermore there is also evidence that aPL trigger TLR-4.

Objectives: to address the role of TLR4 and AnnA2 in anti-b2GPI Abs-mediated EC activation pathway.

Methods: we performed: i) in vitro experiments with or without blocking antibodies directed to Annexin A2 and TLR-4 ii) small interfering RNA experiments for silencing TLR-4 and Annexin A2 expression in suitably transfected HUVEC.

Results: aPL binding to HUVEC was partially inhibited by both anti-Annexin A2 and anti-TLR-4 blocking antibodies. Anti-TLR-4 also reduced aPL-induced E-Selectin and ICAM-1 expression. TLR-4 silencing by siRNA significantly inhibited both binding and activation of aPL-exposed HUVEC, while Annexin A2 silencing only affected binding.

Conclusion: Our results suggest that more than one receptor may be involved in aPL-mediated EC activation. As Annexin A2 is unable to transduce signals into the cells owing to the lack of a cytoplasmic tail, TLR-4 could act as coreceptor. Understanding the nature of the receptor/co-receptor and its interaction with β2GPI will lead to identify new strategies for treatment and prevention of pro-thrombotic and pro-inflammatory state in APS.

1357

Role of Reactive Oxigen Species and ROS-Dependent Downstream Signalling in the Prothrombotic State Elicited by Antiphospholipid Antibodies from Primary Antiphospholipid Syndrome Patients. Chary Lopez-Pedrera[1], Patricia Ruiz-Limon[1], Maria Angeles Aguirre[1], Nuria Barbarroja[1], Antonio Rodriguez-Ariza[1], Carlos Perez-Sanchez[1], Eduardo Collantes-Estevez[1], Jose Manuel Villalba[4], Francisco Velasco[1], Munther A. Khamashta[2] and Maria Jose Cuadrado[3]. [1]Reina Sofia Hospital-IMIBIC, Cordoba, Spain, [2]The Rayne Institute, London, United Kingdom, [3]The Rayne Institute, London, United Kingdom, [4]University of Cordoba, Cordoba, Spain

Background: The role of antiphospholipid antibodies (aPL) in the induction of a procoagulant state is clearly established; yet, the precise intracellular mechanisms are poorly understood. Besides their role in tissue vascular injury, reactive oxygen species (ROS) may act as important signalling molecules, activating redox-sensitive signalling cascades that potentially link the activation of receptors by their agonists to gene expression.

Aim: We investigated the relevance of ROS in the prothrombotic/proinflammatory state elicited by aPL and studied ROS-dependent downstream signalling pathways leading to monocyte activation.

Design and Methods: Monocytes from healthy individuals were treated with affinity purified IgG from 7 APS patients (aPL-IgG), or IgG normal human serum (IgG-NHS) from 7 healthy donors. Then, time and dose-dependent ROS production was analyzed. Inhibitory studies on ROS production were performed by preincubation of the treated monocytes 1h with antioxidants N-acetyl-L-cysteine (NAC), and vitamin C (vit C), as well as with the mitochondrial inhibitor, rotenone. Peroxides, peroxynitrite generation and mitochondrial membrane potential (MMP), were analysed by flow cytometry using specific fluorescent probes. As procoagulant/proinflammatory markers, cell surface TF, VEGF and Flt1 expression were evaluated by flow cytometry and western blot respectively. Nitric oxide (NO) levels and Total Antioxidant Capacity (TAC) were measured in the supernatant of the cell cultures. N-Tyr, iNOS expression, p38MAPK activation and IkappaB degradation were evaluated by Western blot. NFkB activity was quantified by EMSA.

Results: Independent incubation of monocytes with aPL-IgG from 7 patients increased cellular ROS production and mitochondria depolarization, which were prevented by the antioxidants Vit C and NAC. Inhibition by rotenone further indicated an involvement of the mitochondrial transport chain as a source of ROS. The reduction of supernatant TAC after aPL-IgG treatment was abolished by ROS inhibitors. Moreover, aPL-induced iNOS, N-Tyr, and NO expression levels were reduced by treatment with ROS inhibitors. ROS produced by aPL-IgG treatment activated p38 MAPK and its subsequent target, the nuclear factor kappa B (NFκB), and controlled the up-regulation of TF, VEGF, and Flt1 in monocytes.

Conclusions: Our data indicate that the binding of aPL-IgG to the monocyte membrane elicited a redox-sensitive signalling pathway that controls the procoagulant phenotype of that cells in the setting of APS. Thus, oxidative stress by aPL-IgG represents a new pathway potentially contributing to the thrombotic complications of APS. Supported by JA0042/2007, JA0246/2009, P08CVI04234 and PS09/01809.

Peptide & NMR Spectroscopy Studies of Recombinant Domain I Confirm Conformationally Correct Domain I and Non-Linear Epitope Binding to Anti-Domain I Antiphospholipid Antibodies. Charis Pericleous[2], Toluwape Disu[4], Jennifer Miles[1], Diego Esposito[1], Acely Garza-Garcia[1], Paul C. Driscoll[1], David S. Latchman[4], David A. Isenberg[3], Ian Giles[4], Anisur Rahman[4] and Yiannis Ioannou[4]. [1]National Institute of Medical Research, London, UK, [2]University College London, London, United Kingdom, [3]University College London, London, United Kingdom, [4]University College London, London, UK

Purpose: Recombinant Domain I (DI) is increasingly being utilised in the development of diagnostic assays and being developed as an inhibitor of pathogenicity. The critical epitope R39-R43 as well as the DI/DII interlinker region have been shown to be important in binding antiphospholipid antibodies. We undertook NMR spectroscopy studies as well as linear epitope peptide binding assays to confirm that recombinant DI was indeed conformationally correct and ascertain the potential binding abilities of different linear peptides based on the defined epitopes.

Methods: Sera from 8 patients with APS (8/8 female; mean age 46.7$\pm$16.4; 7/8 Caucasian, 1/8 Asian; 8/8 with previous thrombosis, 4/8 with previous pregnancy morbidity) were tested in a standard direct anti-β2GPI assay and the appropriate dilution corresponding to 50% of maximal binding (MBD) was identified. Linear peptides containing region R39-R43 (PEP1, 9aa, 1kDa), DI-II interlinker (PEP2, 9aa, 1kDa), or both (PEP3, 26aa, 3kDa) were designed and synthesised (Sigma, UK). 7KDa wild type recombinant human (WT) DI was expressed in E.coli cells and folded in vitro in a cysteine/cystine-rich buffer for disulfide bond formation. Sera at a dilution that conferred 50% MBD anti-β2GPI activity were incubated (2h, RT) with increasing doses of WT DI (0, 20, 40, 60, 80 or 100μg/ml) or equimolar doses of PEP1–3, and their anti-β2GPI activity was assessed. Percentage binding was calculated based on the change in OD405nm in the presence of inhibitor. To confirm WT DI was conformationally correct, NMR spectroscopy was employed following standard triple resonance 3D NMR protocols. The Chemical Shift Index (CSI) and TALOS computer programs were used to compare the secondary structure of WT DI alone with that in whole human β2GPI based on the published 3D crystal structure.

Results: The inhibitory ability of WT DI was statistically superior compared to all peptides, throughout the entire range of inhibitor concentrations tested ($p<0.05$ for 20μg/ml WT DI and equimolar PEP1–3; $p<0.001$ in all other cases). By calculating the mean percentage binding ($\pm$standard deviation) of all 8 sera tested, a clear positive correlation between the concentration of WT DI and level of inhibition was identified (from 75.7$\pm$29.9% with 20μg/ml WT DI to

25.0±22.0% with 100μg/ml WT DI), as opposed to PEP1–3 where binding did not fall below 91.3±30.3% (with PEP3 at the highest dose). NMR-derived parameters of WT DI were entirely consistent with the secondary structure of crystallised DI in whole β2GPI. The 3D structure of WT DI superimposed well with the β2GPI crystal structure, indicating that in solution WT DI adopts the anticipated polypeptide fold.

Conclusions: NMR studies demonstrate that bacterially expressed recombinant DI adopts its native conformation supporting the use of this peptide in diagnostic assays and as an inhibitor of pathogenicity. Furthermore, whole DI peptide is necessary to inhibit as patient anti-DI sera failed to recognise linear epitope peptide derivatives.

A Novel, Simple Fluid Phase Binding Assay for the Detection of Serum Anti-Domain I Antibodies in Patients with the Antiphospholipid Syndrome. Charis Pericleous[2], Acely Garza-Garcia[1], Paul C. Driscoll[1], David S. Latchman[4], David A. Isenberg[3], Ian P. Giles[4], Anisur Rahman[4] and Yiannis Ioannou[4]. [1]National Institute of Medical Research, London, UK, [2]University College London, London, United Kingdom, [3]University College London, London, United Kingdom, [4]University College London, London, UK

Purpose: Domain I (DI) of beta-2-glycoprotein I (β2GPI) has been established as a critical immunodominant region for pathogenic antiphospholipid antibodies (aPL) in patients with the antiphospholipid syndrome (APS). A direct enzyme-linked immunosorbent assay (ELISA) to detect anti-DI antibodies in APS sera could be affected by conformational changes in immobilised DI and has required considerable efforts to optimise by multiple groups including our own. Here we present an alternative concept for detecting anti-DI activity based upon inhibiting anti-β2GPI activity with recombinant DI in the fluid phase.

Methods: Sera from 15 anti-β2GPI positive patients fulfilling APS classification criteria (15/15 female; mean age 47.4±11.9; 14/15 Caucasian, 1/15 Asian; 14/15 with a thrombotic history, 7/15 with previous pregnancy morbidity), and 5 patients with circulating anti-β2GPI aPL (but without APS, aPL+/APS-) were serially diluted (from 1:50) and tested in triplicate using a standard solid phase anti-β2GPI ELISA. The appropriate dilution of serum corresponding to 50% of maximal binding (MBD) was identified for each patient. In each case this gave an OD405nm >0.4. For the new anti-DI assay, each serum sample at the 50% MBD was firstly incubated (2hr, RT) with increasing doses of in-house bacterially-expressed recombinant human DI (0, 20, 40, 60, 80 or 100 μg/ml) and then a standard anti-β2GPI assay was performed. For each patient sample the percentage binding was calculated based on a change in OD405nm in the presence of DI.

Results: Mean percentage binding (± standard deviation, SD) to β2GPI for all 15 APS sera was calculated in the presence of increasing concentrations of DI; the same was performed for the 5 aPL+/APS- samples. The presence of DI significantly reduced binding for APS samples compared to aPL+/APS- samples, in a dose-dependent manner (Table 1).

Table 1. The inhibitory ability of recombinant human DI in the fluid phase

Concentration of DI added (μg/ml)	Mean (SD) binding for APS samples as a percentage of binding in the absence of inhibitor (n=15)	Mean (SD) binding for aPL+/APS- samples as a percentage of binding in the absence of inhibitor (n=5)	P value
20	75.0 (20.3)	96.3 (12.4)	<0.01
40	62.0 (15.6)	99.7 (12.0)	<0.01
60	56.9 (18.1)	94.0 (13.2)	<0.01
80	44.3 (22.9)	89.1 (17.1)	<0.01
100	37.5 (21.7)	85.1 (16.1)	<0.01

Conclusions: Using the well-established direct anti-β2GPI assay, serum inhibition of anti-β2GPI activity by fluid phase recombinant DI is both remarkably simple and selective of pathogenicity in this small sample of patients. The ability to express recombinant human DI in a bacterial system allows for the cost-effective production of large amounts of DI for use in this assay. The findings from this proof-of-concept novel and simple approach to measuring anti-DI activity in an anti-β2GPI positive patient warrant further exploration to further characterise specificity and sensitivity, and hence clinical diagnostic and prognostic utility.

Apolipoprotein E Receptor (apoER2) Is Involved for Thrombotic Complications in a Murine Model of Antiphospholipid Syndrome. Z. Romay Penabad[1], T. Shilagard[1], G. Vargas[1], R. Aguilar-Valenzuela[1], P. de Groot[2] and S. Pierangeli[1]. [1]Univ of TX Med Branch, Galveston, TX, [2]University Hospital Utrecht, Utretch, The Netherlands

Background: Antiphospholipid antibodies (aPL) recognize $\beta_2$glycoprotein I(β_2GPI)-bound to receptor(s) in target cells (i.e.: endothelial cells [EC], platelets, monocytes) and trigger a pro-coagulant/pro-inflammatory phenotype (i.e.: up-regulation of tissue factor [TF] that lead to thrombosis). The interaction of β_2GPI with target cells may involve more than one protein. Previous publications suggest that β_2GPI-aPL antibody complex binds to apoER2 in cell surface, inducing activation of platelets or EC. Moreover, it has been shown that a soluble binding domain I of apoER2 (sBDI) inhibits the binding of β_2GPI to apoER2.

Objectives:: To determine whether apoER2 mediates pathogenic effects of murine and human aPL antibodies in vivo.

Methods: Wild type (apoER2$^{+/+}$) and apoER2-deficient (apoER2$^{-/-}$) mice were injected twice with IgG purified from one patient with "primary" antiphospholipid syndrome (IgG-APS) or with control IgG (IgG-NHS) or with a murine monoclonal anti-β_2GPI antibodies (named E7) or with control murine monoclonal antibody [1kMPOC-21(Sigma Aldrich)](MuMoAbC). Some wild type mice were also injected i.p. twice with 50 μg of soluble binding DI of apoER2 (sBD1), 30 minutes before each injection with aPL antibodies. Several procedures were done in treated and controls mice to study pathogenicity of aPL antibodies: a) dynamics of thrombus formation, b) TF activity in homogenates of carotid arteries and in peritoneal macrophages, and c) TF expression in macrophages using quantum dot nano crystals and two-photon excitation laser scanning microscopy.

Results: Significantly larger thrombi and increased TF activity in carotid artery homogenates and in peritoneal macrophages was observed in apoER2$^{+/+}$ mice treated with (IgG-APS or E7) when compared to controls. Importantly, apoER2$^{-/-}$mice treated with murine or human aPL antibodies shown partial but significantly abrogation of thrombogenic effects compared with their counterparts injected with control antibodies. In addition, thrombogenic effects of IgG-APS were significantly abrogated in apoER2$^{+/+}$ mice by sBD1, hence confirming the ApoER2 involvement in vivo.

Mice/ treatment	Thrombus size (μm^2)	TF activity carotids (pmol/mg · mL^{-1} protein)	TF activity macrophages (pmol/mg · mL^{-1} protein)	TF expression (AU)
apoER2$^{+/+}$ IgG-APS	*4094 ± 1037	*21.4 ± 8.4	*10.1 ± 1.2	*11.9 ± 2.8
apoER2$^{+/+}$ IgG-NHS	287 ± 110	5.8 ± 0.9	3.2 ± 0.8	3.2 ± 0.4
apoER2$^{-/-}$ IgG-APS	**1675 ± 781	14.6 ± 1.8	**5.9 ± 1.5	4.8 ± 0.9
apoER2$^{-/-}$ IgG-NHS	514 ± 115	5.3 ± 1.7	2.7 ± 0.8	5.9 ± 0.9
apoER2$^{+/+}$ IgG-APS + sBD1	†665 ± 173	†14.7 ± 1.6	†4.4 ± 0.6	†4.3 ± 0.9
apoER2$^{+/+}$ IgG-NHS + sBD1	486 ± 164	4.5 ± 3.3	3.1 ± 2.5	3.2 ± 0.6
apoER2$^{+/+}$/E7	*2599 ± 766	*70.3 ± 15.2	*13.9 ± 2.8	n/a
apoER2$^{+/+}$ MuMoAbC	827 ± 294	13.5 ± 1.8	4.2 ± 1.7	n/a
apoER2$^{-/-}$ E7	**827 ± 294	**24.3 ± 10.5	**9 ± 0.6	n/a
apoER2$^{-/-}$ MuMoAbC	436 ± 125	11.8 ± 2.5	4.3 ± 0.2	n/a

(*) statistically significant different from their negative controls in apoER2$^{+/+}$ mice.
(**) statistically significant different from their negative controls and apoER2$^{+/+}$ mice counterparts.
(†) statistically significant different from apoER2$^{+/+}$ mice treated with IgG- APS

Conclusions: Altogether these data show that apoER2 is a mediator of aPL thrombogenic effects *in vivo*. These data may have important implication in the design of new targeted treatments for APS.

C6-Deficient Mice Are Protected from the Pathogenic Effects of Antiphospholipid Antibodies. A. L. Carrera-Marin, R. Aguilar-Valenzuela, Z. Romay Penabad, E. Papalardo and S. Pierangeli. Univ of TX Med Branch, Galveston, TX

Background: The pathogenic mechanisms mediated by antiphospholipid (aPL) antibodies are partially understood. Recent studies have demonstrated the complement involvement in the thrombogenic effects of aPL antibodies. Furthermore, inhibitors for the C5 axis can abrogate aPL effects. The complement membrane attack (C5b-9 MAC) complex has been shown to induce tissue factor (TF) expression (procoagulant effect). However whether C5b-9 MAC plays a role in the pathogenesis of thrombosis in Antiphospholipid Syndrome (APS) is unknown.

Objective: To study the effects of human and murine aPL antibodies on thrombosis in C6 deficient ($C6^{-/-}$) mice.

Methods: $C6^{-/-}$ mice and the corresponding wild-type ($C6^{+/+}$) were injected twice with either a] 500 μg/ml IgG isolated from two patients with APS (IgG-APS1 and IgG-APS2) or with normal IgG (IgG-NHS), b) 100 μg/ml murine anti β2GPI monoclonal antibodies (4G4) or with mouse IgG 1κMPOC-21(MuMoAb) (Sigma Aldrich) as control or c) 500 μg/ml IgM isolated from a patient with APS (IgM-APS3). Seventy two h after the first injection the size of induced thrombi in the femoral vein was determined. TF activity was determined in homogenates of carotids and peritoneal macrophages using a chromogenic assay. TF expression in macrophages was also determined using quantum dot nano crystals and two-photon excitation laser scanning microscopy.

Results: Thrombus sizes were significantly larger in $C6^{+/+}$ mice treated with all different IgG-APS and IgM-APS when compared with healthy controls ($p<0.001$). Similarly, MuMoAb 4G4 shown significantly difference in thrombus size compared with control MuMoAb. Importantly, $C6^{-/-}$ mice treated with IgGs -APS or IgM- APS or MuMoAb 4G4 had smaller thrombi compared to their $C6^{+/+}$ counterparts ($p<0.001$) and there were not significant differences among the control groups.

Thrombus size (μm^2)

Treatments	$C6^{+/+}$ mice	$C6^{-/-}$ mice
IgG-NHS	544 ± 99	383 ± 119
IgG-APS 1	*1649 ± 493	732 ± 272
IgG-APS 2	*1914 ± 386	936 ± 514
MuMoAbC	419 ± 122	416 ± 178
MuMoAb 4G4	*1366 ± 332	388 ± 111
IgM-NHS	334 ± 117	393 ± 113
IgM-APS 3	*2268 ± 1004	356 ± 122

(*) statiscally significant different from their controls and $C6^{-/-}$ mice counterparts.

TF activity in carotids and in peritoneal macrophages in $C6^{-/-}$ mice treated with IgG-APS1 were significantly diminished. Similarly result was obtained in macrophages TF expression.

All mice injected with IgG-APS had medium-high titers of aCL.

	TREATMENTS			
	IgG-NHS		IgG-APS 1	
Tissue Factor	$C6^{+/+}$ mice	$C6^{-/-}$ mice	$C6^{+/+}$ mice	$C6^{-/-}$ mice
TF *activity* in carotids (pmoles/mg · ml^{-1} protein)	17.3 ± 0.2	19.2 ± 1	*51.1 ± 5.6	29.9 ± 1.8
TF *activity* in peritoneal macrophages (pmoles/ mg · ml^{-1} protein)	12.6 ± 4.3	4.6 ± 1.2	*28.5 ± 13.3	14.8 ± 9.1
TF *expression* in peritoneal macrophages (AU)	16.0 ± 2.1	3.7 ± 2.7	*40.7 ± 18.2	9.2 ± 8.5

(*) statiscally significant different from their controls and $C6^{-/-}$ mice counterparts.

Conclusions: These data indicate that the C6 component of the complement system mediates aPL-thrombogenic effects. The data underscore the possibility of complement inhibition as a new therapy for clinical manifestations of APS.

1362

Short-Term Effects of Caffeinated Beverage Intake on Risk of Recurrent Gout Attacks. Tuhina Neogi[1], Clara Chen[3], Christine Chaisson[3], David J. Hunter[4] and Yuqing Zhang[2]. [1]Boston Univ Schl of Med, Boston, MA, [2]Boston Univ School of Medicine, Boston, MA, [3]Boston Univ School of Medicine, [4]University of Sydney, Boston, MA

Purpose: Long-term caffeine intake has been associated with decreased risk for incident gout attacks and lower serum uric acid levels. Acute effects of caffeine, however, can potentially increase uric acid, for example, through a diuretic effect with volume depletion, and impaired glucose tolerance. Further, caffeine, which is a methyl xanthine, can competitively inhibit xanthine oxidase, and therefore may have effects similar to allopurinol in terms of precipitating a flare in the short-term. Given these potential conflicting effects on gout attack risk, we evaluated whether caffeinated beverage intake was associated with risk for recurrent gout attacks.

Methods: We conducted an internet-based case-crossover study to assess a set of putative risk factors thought to trigger recurrent gout attacks. This methodology uses each participant as his/her own control by comparing the frequency of a particular risk factor during periods of gout attacks with that during periods when they are not having an attack, thereby eliminating between-person confounding. Subjects with gout who had an attack within the past year were recruited online and asked to provide access to medical records pertaining to their gout diagnosis. Data were obtained on the amount of caffeine (coffee, tea, other caffeinated beverages) consumed over the 24-hour period before a gout attack and over a 24-hour period during an intercritical period, as well as non-caffeinated beverages (non-caffeinated coffee, tea, sodas, juices). We did not ask about use of sugar in the beverage. We examined the relation of amount of caffeinated beverage intake (0, 1, 2, 3, 4, 5–6, >6 servings per 24-hours) with the risk of recurrent gout attacks using conditional logistic regression adjusting for diuretic use, alcohol consumption, and purine intake, and additionally for all other fluid intake. We repeated the same analyses for non-caffeinated beverage intake.

Results: Of the 633 participants who experienced recurrent gout attacks during the study period, 78% were male, 89% were White, and 58% had a college education. Of the 486 medical records reviewed to date, 82% met the ACR classification criteria for gout. Higher levels of caffeinated beverage intake in the prior 24 hours were associated with increased risk for recurrent gout attacks, even after accounting for other fluid intake, while non-caffeinated beverages were not associated with risk for recurrent gout attacks (Table).

Table. Association of Caffeinated and Non-Caffeinated Beverage Intake, respectively, with Risk for Recurrent Gout Attacks

Caffeinated beverage servings, # (prior 24 hours)	Case/ Control periods	Crude OR	Adjusted* OR (95% CI)	Adjusted** OR (95% CI)

5–6	94/56	1.56	1.02 (0.67–1.55)	1.06 (0.70–1.61)
>6	71/51	1.81	0.93 (0.55–1.58)	0.96 (0.56–1.63)
P for trend			p=0.6	p=0.7

* adjusted for diuretic use, purine and alcohol intake
** additionally adjusted for all other fluid intake (including non-caffeinated beverages, dairy, and water for the caffeinated beverage analyses: including caffeinated beverages, dairy, and water for non-caffeinated beverage analyses).

Conclusions: Increases in or episodic caffeinated beverage intake in the short-term appears to increase risk for recurrent gout attacks. In contrast, we did not find such associations with non-caffeinated beverages. Since these beverages may have had varying amount of fructose that we did not measure, further study is warranted to evaluate the effects of caffeine independent of fructose.

Prevalence of Hyperuricemia in the US General Population: The National Health and Nutrition Examination Survey (NHANES) 1999–2008. Yanyan Zhu[1], Bhavik Pandya[2] and Hyon Choi[1]. [1]Boston University of School of Medicine, Boston, MA, [2]Takeda Pharmaceuticals International, Inc, Deerfield, IL

Objective: There is a direct causal relation between serum urate (sUA) levels and the risk of gout. Thus, the population's sUA levels are accurate surrogate indicators for the scope of the disease burden of gout in the population. Our objective was to estimate the trends of sUA levels and prevalence of hyperuricemia based on a recent, nationally representative sample of US men and women (NHANES 1999–2008).

Methods: Using data from 24,693 participants (11,816 men and 12,877 women) aged 20 years and older from NHANES 1999–2008, we estimated overall, gender-specific, and age-specific mean sUA levels and prevalence of hyperuricemia. sUA was measured by oxidization with the specific enzyme uricase to form allantoin and hydrogen peroxide, using participants' blood samples collected during home interview or examination session. We used an NHANES definition of hyperuricemia (sUA level >7.0 mg/dL in men and >5.7 mg/dL in women). We estimated the number of people with hyperuricemia by applying our prevalence estimates to the corresponding US population estimates from the Census Bureau.

Results: The overall prevalence of hyperuricemia among US adults was 20.1%, which corresponded to an estimated 31.9 million individuals with hyperuricemia. The prevalence of hyperuricemia among men was 21.1% (16.1 million) and 19.2% (15.8 million) among women. The overall mean sUA level was 5.41 mg/dL (95% CI, 5.38 to 5.44 mg/dL). The mean sUA level was 6.10 mg/dL (95% CI, 6.06 to 6.14 mg/dL) among men and 4.77 mg/dL (95% CI, 4.73 to 4.80 mg/dL) among women. The prevalence of hyperuricemia increased with age, ranging from the lowest (15.6%, 4.5 million) in individuals aged 20 to 29 years to the highest (36.7%, 2.4 million) in individuals aged 80 years or older. The prevalence of hyperuricemia among individuals aged 65 years or older was 31.3%, which corresponded to an estimated 8.4 million US adults with hyperuricemia (Table).

Table. Prevalence of Hyperuricemia and Mean sUA Levels in NHANES 1999–2008

	Hyperuricemia Estimates (in Millions)	Prevalence, % (95% CI)	Mean sUA Level, mg/dL (95% CI)
Overall	31.9	20.1 (19.2–21.0)	5.41 (5.38–5.44)
Gender			
Male	16.1	21.1 (19.8–22.4)	6.10 (6.06–6.14)
Female	15.8	19.2 (18.0–20.3)	4.77 (4.73–4.80)
Medicare Age Category (Yrs)			
20–64	23.5	17.8 (16.8–18.8)	5.34 (5.31–5.38)
65+	8.4	31.3 (29.7–32.9)	5.73 (5.67–5.78)
Age Category (Yrs)			
20–29	4.5	15.6 (13.9–17.2)	5.26 (5.21–5.31)
30–39	4.7	15.3 (13.4–17.2)	5.24 (5.16–5.31)
40–49	5.9	17.0 (15.3–18.6)	5.33 (5.27–5.39)
50–59	6.0	21.4 (19.4–23.4)	5.48 (5.42–5.54)
60–69	4.7	27.1 (24.7–29.5)	5.63 (5.56–5.69)
70–79	3.7	30.0 (27.8–32.2)	5.70 (5.62–5.77)
80+	2.4	36.7 (32.9–40.5)	5.84 (5.72–5.97)

Conclusions: These findings from the latest nationally representative sample of US adults in NHANES 1999–2008 suggest that the prevalence of hyperuricemia is substantial, particularly among older individuals.

Obesity Is Associated with a Younger Age at Gout Incidence. Mara A. McAdams[4], Janet W. Maynard[2], Judith A. Bolton Hoffman[4], Alan N. Baer[3], Allan C. Gelber[1] and Josef Coresh[4]. [1]Baltimore, MD, [2]Johns Hopkins Univ, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD, [4]Johns Hopkins, Bloomberg School of Public Health

Background: Obesity is an established risk factor for gout; however, the influence of obesity on the age of gout onset is unclear. We tested the hypothesis that obesity is associated with an earlier age of incident gout diagnosis in a population-based cohort, CLUE II.

Methods: At cohort entry (1989), CLUE II enrolled 26,147 individuals residing in Washington County, Maryland. We included participants who reported on 2003 and 2007 follow-up questionnaires that they had been diagnosed with gout by a healthcare professional and recalled their age at gout diagnosis. We limited this study to incident gout cases that developed gout after 1989. In 1989, participants reported their current weight and height as well as their weight at age 21. Body mass index was calculated (kg/m^2) and obesity defined as BMI $\geq$ to 30 kg/m^2. We compared the mean age at gout incidence by obesity status, both at baseline and at age 21, using t-tests. Multivariate linear regression was used to estimate the independent association of BMI with age at gout incidence.

Results: There were 281 participants with incident gout. 70% were male, and 49% reported alcohol consumption. At baseline, the mean BMI was 25.8 kg/m^2, systolic blood pressure was 126.5 mm Hg and the diastolic blood pressure was 80.7 mm Hg. After adjustment for sex, blood pressure and alcohol intake a one kg/m^2 change in BMI was associated with a 0.15 year decrease in the age at gout incidence (p-value=0.38). For every one kg/m^2 increase in BMI at age 21 years, there was a 1.13-year, adjusted, decrease in the age at gout incidence (p-value<0.001).

Participants who were obese at baseline had a younger age at gout incidence compared to non-obese participants (Table, p-value=0.009). The relationship was statistically significant in men and women but more significant in the group of men with gout. Obese men, at cohort entry, developed gout on average 5.5 years earlier than their non-obese counterparts. Obesity at age 21 was associated with a 12-year earlier age of gout incidence compared to non-obese participants (p-value<0.001) in both men and women.

One limitation of the study is that participants had to be alive to report gout incidence on the 2003 and 2007 questionnaires. However, sensitivity analysis suggest that prevalent gout was not related to reporting on the 2003 and 2007 questionnaires.

Age at gout incidence according to obesity status, at baseline and age 21, in CLUE II cohort

	Total		Women		Men	
	N	Mean age in years (SD)	N	Mean age in years (SD)	N	Mean age in years (SD)
Baseline BMI						
Not obese*	194	59.7 (12.7)	52	63.8 (13.9)	142	58.2 (11.8)
Obese*	87	55.3 (13.6)	30	60.2 (14.4)	57	52.7 (12.6)
Difference (95% CI)		4.4 (1.1, 7.7)*		3.6 (−2.8, 10.1)		5.5 (1.74, 9.3)*
BMI at age 21						
Not obese*	262	59.2 (12.8)	77	63.6 (13.6)	185	57.4 (12.1)
Obese*	18	46.9 (9.4)	5	45.4 (11.9)	13	47.5 (8.7)
Difference (95% CI)		12.3 (6.3, 18.4)**		18.2 (5.8, 30.6)*		9.9 (3.2, 16.7)*

** P-value <0.001
* P-value <0.01

Conclusion: Obese men and women are more likely to develop gout at an earlier age than non-obese counterparts. Those who were obese at age 21 years developed incident gout 12 years earlier than those who were not obese. Physicians should be aware that obesity impacts the age at gout incidence in this population-based cohort.

Health Related Quality of Life (HRQOL) in Tophaceous vs. Non-Tophaceous Gout. Puja Khanna[2], Jay Persselin[3], Ron Hays[1], Daniel Furst[1], Harold Paulus[1], Paul Maranian[1] and Dinesh Khanna[1]. [1]UCLA, [2]UCLA and West LA VA, [3]West LA VA

Objective: Gout is a chronic disorder of uric acid metabolism resulting in acute painful episodes of arthritis. Tophaceous gout is associated with greater number of attacks, more erosive disease, inadequate pain control, and results in joint destruction when untreated. We assessed the impact of chronic tophaceous gout on HRQOL in an ongoing, prospective, 1-year observational study.

Methods: 71 patients with tophaceous and non-tophaceous gout were recruited at VA and University Hospitals. Tophi were assessed by a physician and HRQOL was assessed at baseline using SF-36 v2, HAQ-DI and a disease-specific Gout Impact Scale (GIS). Health utilities were elicited using computerized software, U-Maker ® in structured interviews. Direct preference-based measures to evaluate disutility of gout included health rating scale (RS, 0–100), time tradeoff (TTO, 0.0–1.0), and standard gamble (SG, 0.0–1.0). Disutility was assessed by subtracting preference scores for current health states with gout from those for current health without gout. Patients were questioned on how much money they would be willing to pay out of pocket as a one time payment to cure their gout permanently. Patients were also asked to list their comorbidities and rank them from most to least concerning.

Results: Non-tophaceous were similar to tophaceous subjects in age (68 years), number of flares (3 per year), disease duration (12.4 years), Charlson comorbidity index (3.0), and serum urate levels (7.1 mg/dl, $p > 0.05$). Patients with tophi had greater evidence of radiographic damage ($p < 0.05$), worse HAQ-DI score ($P = 0.06$) and rated their gout as more severe ($p = 0.0008$). The 2 groups did not differ in SF-36 and GIS scores. However, tophaceous subjects assigned greater disutility to their gout on RS (12.4 vs. 7.4) and (SG 0.07 vs. 0.009), were willing to pay a significantly higher dollar amount out of pocket for a cure ($p = 0.04$), and had worse functional capacity to perform usual activities of daily living ($p = 0.008$) compared to the non-tophaceous. Gout was ranked as the top most health concern in 25% with tophaceous gout compared to 17% with non-tophaceous gout.

Conclusion: Although the patients with chronic tophaceous and non-tophaceous gout were comparable in demographics, the tophaceous group had worse functional disability, assigned higher disutility to gout, and was willing to pay more for a cure. SF-36 and GIS were not able to discriminate between 2 groups. Our data quantifies the decrement in quality of life of patients with tophaceous gout and their willingness to pay for treatment of a debilitating and disabling disease. Our finindgs have implications for decision and cost-effectiveness analyses.

Cherry Consumption and Risk of Recurrent Gout Attacks. Yuqing Zhang[3], Clara Chen[1], David J. Hunter[4], Christine E. Chaisson[1], Hyon K. Choi[5] and Tuhina Neogi[2]. [1]Boston Univ Medical Ctr, Boston, MA, [2]Boston Univ Schl of Med, Boston, MA, [3]Boston Univ School of Medicine, Boston, MA, [4]Sydney University, Sydney, Australia, [5]Univ of British Columbia, Vancouver, BC, Canada

Anecdotal evidence implicates that consumption of cherries and cherry products may reduce levels of serum uric acid (SUA) and the risk of gout attacks. A recent study of 10 healthy women reported that SUA levels were reduced by 15% 5 hours after consuming two servings (280 grams) of cherries. Other studies have also reported that cherry fruit/cherry products may provide anti-inflammatory benefits. To date, no large-scale study has examined whether cherry consumption reduces the risk of recurrent gout attacks.

Methods: We conducted an online case-crossover study to assess a set of putative risk factors for recurrent gout attacks. Subjects who had experienced a gout attack within the past year were recruited online and were asked to provide access to medical records for verification of gout diagnosis. Subjects were asked to log onto the study website when they experienced a gout attack. Risk factors, including cherry fruit and cherry products (i.e. cherry extract) intake, occurring each day over the two-day period prior to an acute gout attack (case-period) were assessed using an online questionnaire. The same questionnaire was used over each of the two days during an intercritical period (control-period). We examined the relation of cherry fruit and cherry products intake over the 2-day period to the risk of recurrent gout attacks using conditional logistic regression, adjusting for alcohol consumption, purine intake, and diuretic use.

Results: Included in this analysis were 633 subjects who experienced recurrent gout attacks during the study period. Participants were predominantly white (88%), men (78%), and 58% had a college education. Of the 468 medical records obtained to date, 82% fulfilled the ACR Classification Criteria for Gout. The median time between the onset of a gout attack and logging on to the website was 3 days. Compared with no cherry fruit intake over the 2-day period, the odds ratios (OR) of recurrent gout attacks were 1.0, 0.5, 0.4, and 0.6, respectively, for 1, 2, 3 and ≥4 servings (one serving is one-half cup or 10 cherries) over the past two days (p for trend <0.001). Intake of cherry products over the past 2 days was also associated with a decreased risk of recurrent gout attacks (OR=0.6, 95% CI: 0.3–1.0) (Table).

Conclusions: Intake of cherry fruit and cherry products over the past 2 days were associated with a reduction in risk for recurrent gout attacks. Cherry consumption may provide a safe, non-pharmacologic option that can help prevent recurrent gout flares among patients with preexisting gout.

Intake over past 2 days	No. of Case-periods	No. of Control-periods	Crude OR	Adjusted OR* (95% CI)
# Servings of cherry fruit				
0	1074	1318	1.0	1.0
1	53	71	0.9	1.0 (0.6–1.4)
2	56	98	0.6	0.5 (0.3–0.8)
3	16	35	0.5	0.4 (0.2–0.8)
≥4	48	67	0.7	0.6 (0.4–1.0)
Use of cherry product				
No	1212	1520	1.0	1.0
Yes	35	69	0.6	0.6 (0.3–1.0)

* Adjusted for diuretic use, purine and alcohol intake

Serum Urate Levels in Young Adults Are Associated with the Risk of Incident Hypertension: Findings from the Coronary Artery Risk Development in Young Adults (CARDIA) Cohort. Angelo L. Gaffo[1], David R. Jacobs[6], Femke Sijtsma[5], Cora E. Lewis[3], Ted R. Mikuls[2] and Kenneth G. Saag[4]. [1]Birmingham VAMC and University of Alabama at Birmingham, Birmingham, AL, [2]Univ of Nebraska Med Ctr, Omaha, NE, [3]University of Alabama at Birmingham, [4]University of Alabama-Birmingham, Birmingham, AL, [5]University of Minnesota, [6]University of Minnesota and University of Oslo

Purpose: to determine if serum urate concentrations in young adults are associated with the subsequent development of hypertension.

Methods: Women and men were analyzed separately because of intrinsic differences in their serum urate levels at the ages studied. Blood pressure (BP) was measured at cohort baseline (1985–1986) and at years 2, 5, 7, 10, 15, and 20 of follow-up. Using Cox-proportional hazard regressions, the associations between sex-specific categories of serum urate at baseline with subsequent development of hypertension (defined as BP ≥ 140/90 or being on blood pressure medication) were examined. Baseline covariates included in the models were age, race/ethnicity, body mass index, physical activity scores, total alcohol intake, smoking status, HDL and LDL cholesterol levels, serum triglyceride levels, serum insulin levels, education completed, and center of recruitment.

Results: 4933 participants free of hypertension at baseline were included in the longitudinal analysis. Mean age (standard deviation) at initiation of follow-up was 24.8 (3.6) years for men and 24.9 (3.7) years for women. The cumulative incidence of hypertension at 20 years of follow-up was 28.5% for men and 30.2% for women. Categories cutpoints of serum urate were higher in men than in women. After multivariable adjusted analyses men showed consistent dose-dependent increases in the risk of developing hypertension with higher levels of serum urate at the beginning of follow-up.

Figure 1. Table showing the multivariable adjusted risk of developing hypertension over 20 years of follow-up by baseline serum urate among men

Serum urate category	Hazard ratio	95% CI
1: <5.4 (REF) (n=521)	1.00	REF
2: 5.4–6.09 (n=533)	1.64	1.22–2.21
3: 6.1–6.79 (n=568)	1.87	1.39–2.50
4: 6.8–7.49 (n=312)	1.62	1.16–2.28
5: ≥ 7.5 (n=290)	2.40	1.73–3.32
Linear HR (p<0.001)	1.19	1.10–1.27

For women the increases in risk were inconsistent and did not conform with a linear trend, but the risk of incident hypertension did increased across all but the relatively small highest serum urate category.

Figure 2. Table showing the multivariable adjusted risk of developing hypertension over 20 years of follow-up by baseline serum urate among women

Serum urate category	Hazard ratio	95% CI
1: <3.8 (REF) (n=630)	1.00	REF
2: 3.8–4.39 (n=693)	1.25	0.97–1.60
3: 4.4–5.09 (n=696)	1.37	1.08–1.75
4: 5.1–5.59 (n=332)	1.54	1.16–2.04
5: ≥ 5.6 (n=358)	1.09	0.81–1.47
Linear HR (p=0.21)	1.04	0.98–1.11

Conclusions: We demonstrated an association between higher urate concentrations in young men and the subsequent risk for incident hypertension, even at concentrations considered to be within the normal range for serum urate (< 6.8 mg/dl). Lack of a consistent trend among women could relate to their comparatively low concentrations of serum urate. Our findings are consistent with previous reports generated in populations followed later in life and provide additional support to the hypothesis that higher levels of serum urate play a role in the development of hypertension.

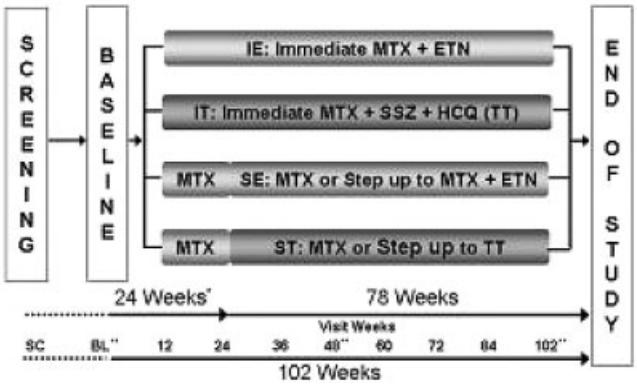
Two-Year Radiographic Results from the TEAR Trial. Larry W. Moreland[7], James R. O'Dell[9], Harold E. Paulus[1], Jeffrey R. Curtis[8], Joan M. Bathon[3], E. William St Clair[2], S. Louis Bridges[6], Xiao Zhang[5], George Howard[5], Desiree M. Van Der Heijde[4], Stacey S. Cofield[5] and for the TEAR Trial Investigators. [1]Encino, CA, [2]Duke University, Durham, NC, [3]Johns Hopkins Univ Ste, Baltimore, MD, [4]Leiden University Medical Center, Meerssen, The Netherlands, [5]The University of Alabama at Birmingham, [6]Univ of Alabama-Birmingham, Birmingham, AL, [7]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [8]University of Alabama-Birmingham, Birmingham, AL, [9]University of Nebraska Medical Center, Omaha, NE

Statement of Purpose: To describe radiographic results of the Treatment of Early Aggressive Rheumatoid Arthritis (TEAR) Trial, two-year, longitudinal, multi-center, randomized clinical trial that enrolled 755 early rheumatoid arthritis (RA) participants, comparing immediate combination treatment groups versus step-up from methotrexate (MTX) alone.



*For SE: ETN or ST: SSZ + HCQ added at week 24 if DAS ≥ 3.2.
**X-Rays of hands and feet at BL = Baseline, Weeks 48 and 102.

Figure 1. TEAR Study Protocol

Methods: Participants that were enrolled in TEAR from 2004–2007 with early RA (≤3 years). In addition to demographic and clinical measures, hand/foot radiographs were obtained at weeks 0, 48 and 102 and scored using the modified Sharp/van der Heijde scoring system.

Results: A total of 755 participants were enrolled in TEAR with 476 (63%) completing 102 weeks. As of June 2010: 474 (99.6%) baseline films and 297 completed films sets have been scored (62% of all completers). At baseline, the mean radiographic score was 6.2±15.0 units (median 2, IQR 0.5–6.0) and 22.2% had no damage (p = 0.30 by treatment group); 25.7% had no erosions, 66.9% had no joint space narrowing (p = 0.15 by group). The 297 with week 0 and 102 scores had a mean baseline score 5.4±12.7 (median 2, IQR 0.5–6.0, similar to entire cohort, p = 0.11); 19.5% had no damage.

Table 1. Mean Radiographic Scores for Completers Cohort (N=297)

		Observed Mean ± SD (% without damage)		Baseline Adjusted Change, Week 102-0		
Group	N	Week 0	Week 102	Mean ± SD	95% CI	p-value
IE	105	7.2 ± 19.8 (21.9)	7.9 ± 20.5 (11.5)	0.6 ± 4.2	−0.6, 1.7	0.6884
IT	45	4.4 ± 5.5 (17.8)	7.1 ± 14.8 (11.4)	2.7 ± 12.6	0.9, 4.5	
SE	106	4.1 ± 5.8 (20.8)	4.7 ± 6.1 (8.0)	0.6 ± 2.1	−0.8, 1.8	
ST	41	5.3 ± 7.2 (12.2)	7.4 ± 10.1 (4.0)	2.1 ± 6.4	0.2, 4.0	
By Treatment Only						
ETN + MTX	211	5.7 ± 14.5 (21.3)	6.2 ± 15.2 (9.7)	0.6 ± 3.3	−0.2, 1.4	0.0180
TT	86	4.9 ± 6.3 (15.1)	7.3 ± 12.7 (7.7)	2.4 ± 10.1	1.1, 3.7	
By Timing Only						
Immediate	150	6.4 ± 16.8 (20.7)	7.6 ± 19.0 (11.5)	1.6 ± 7.7	0.6, 2.6	0.8059
Step-Up	147	4.5 ± 6.1 (18.4)	5.4 ± 7.5 (6.7)	1.4 ± 3.9	0.4, 2.5	
All	297	5.4 ± 12.7 (19.5)	6.5 ± 14.5 (14.5)	1.1 ± 6.1	0.4, 1.8	NA

At week 102, the completers cohort had a mean score 6.5±14.5 (median 3, IQR 1.0–7.5), 9.1% had no damage; 10.8% with no erosions, 40.3% with no joint space narrowing. The mean increase from week 0 to 102 was 1.1±6.1 (median 0, IQR 0–1.0) and was not different across the four groups (p=0.69). When only treatment is considered, pooling the two etanercept (ETN) groups and the two triple therapy (TT) groups, to assess main effects, there was a significant difference between those receiving ETN + MTX and TT (increase of 0.6 vs 2.4, respectively; p=0.02). There was no difference by the timing of treatment (immediate versus step-up, p=0.81). The difference between ETN + MTX and TT was also observed in the subgroup of individuals with baseline radiographic damage score > 0 (increase of 0.6 vs 2.8, p=0.02). There was no change at week 102 among patients with no damage at week 0. In addition, 71.4% of participants achieved radiographic remission (change ≤ 0.5), which was not different by the timing or type of treatment. The remaining 38% of x-rays for trial completers are in the process of being scored.

Conclusions: While prior TEAR results showed no significant differences in clinical findings as assessed by DAS28, this preliminary analysis

showed that treatment with ETN + MTX resulted in statistically significant radiographic benefit over TT, regardless of timing of treatment. All results to be updated to the full 476 completion cohort.

Background: Magnetic resonance imaging (MRI) is now frequently being used as an outcome measure in rheumatoid arthritis (RA) clinical trials. The OMERACT RA MRI score (RAMRIS), evaluating bone erosions, bone oedema and synovitis, is generally used in such trials.

Cartilage damage is an important aspect of structural joint damage in RA, and a reliable MRI assessment system of joint space narrowing (JSN), reflecting cartilage damage, would further improve the usefulness of MRI in RA clinical trials.

Objective: The aim of the present initiative was to develop and validate an OMERACT MRI assessment method of JSN in RA, which may be a useful adjunct to the current OMERACT RAMRIS.

Methods: The project, which was undertaken by the OMERACT MRI in inflammatory arthritis group, had 3 phases:

Phase A: Exercise 1 (pilot study): Coronal T1weighted gradient echo MR images of unilateral wrist and MCP-joints from 5 RA patients and 3 controls were scored for JSN at 15 sites in the wrist and each of the 2nd-5th metacarpophalangeal (MCP), without reader pre-training or calibration, by 8 readers (7 readers read once, 1 reader twice), after circulation by DVD.

Phase B: Discussion, review of images and consensus on exact definition and scoring system.

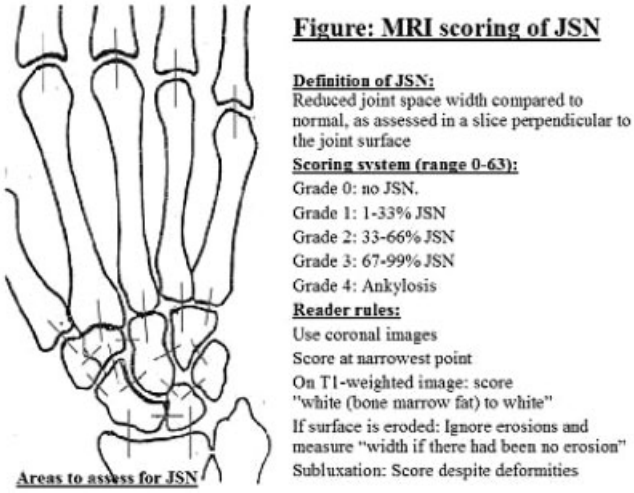
Phase C (Exercise 2): Coronal T1-weighted 3D gradient echo images (voxel size 0.4×0.4×0.4 mm) MR-images of unilateral wrist and 2nd-5th MCP-joints of 15 RA (80% female; age: median 51 (33–78) y, disease duration 7 (4–22) y and 4 controls (75% female; age: median 36 (34–57) y) were scored using a revised score sheet (22 sites, Figure). MRI results were compared with radiographic JSN scores from the same hand (Sharp-van der Heijde method).

Intraclass correlation coefficients (ICCs; single/average measure used for intraobserver/interobserver agreements), and smallest detectable differences (SDDs, for mean of readings) were calculated.

Results: Phase A: Interobserver agreement: ICC 0.93 and SDD 6.4 JSN units (9.9% of observed max). Intraobserver agreement: ICC 0.99 and SDD 2.8 JSN units (4.9% of observed max).

Phase B: Based on experiences from Phase A, agreement was reached on definition, scoring system, and reader rules (Figure).

Phase C: Interobserver agreement: ICC 0.92 and SDD 6.2 JSN units (8.7% of observed max). Intraobserver agreement: ICC 0.90 and SDD: 6.8 JSN units (11.0% of observed max). The correlation (ICC) with the Sharp-van der Heijde radiographic score of JSN in the same hand (which includes MCP-joints, PIP- joints and selected joint areas in the wrist, i.e. not exactly the same joints as the MRI score) was 0.77.



Conclusion: An MRI scoring system of JSN in RA wrist and MCP joints was developed and showed good intra- and interreader agreements. The system may, after further validation in longitudinal data sets, be useful as an outcome measure of cartilage damage in RA, and may thereby further improve the usefulness of MRI in RA clinical trials.

Patterns of MRI Bone Erosion in Rheumatoid Arthritis—Which Bones Are Most Frequently Involved and Show Most Change? Mikkel Østergaard[3], Uffe Møller Døhn[4], Anne Duer-Jensen[3], Merete L. Hetland[3], Kim Hørslev-Petersen[5], Kristian Stengaard-Pedersen[1], Peter Junker[6], Jan Pødenphant[2] and Bo Ejbjerg[7]. [1]Århus University Hospital, Åarhus, Denmark, [2]Copenhagen University Hospitals at Gentofte, Copenhagen, Denmark, [3]Copenhagen University Hospitals at Hvidovre and Glostrup, Copenhagen, Denmark, [4]Copenhagen University Hospitals at Hvidovre and Glostrup, Copenhagen, Denmark, [5]KIng Christian X's Rheumatism Hospital, University of Southern Denmark, Gråsten, Denmark, [6]Odense University Hospital, Odense C, Denmark, [7]Slagelse Hospital, Denmark

Background: Magnetic resonance imaging (MRI) has been shown to be more sensitive for early bone damage than conventional radiography, and MRI of unilateral wrist and 2nd- 5th metacarpophalangeal (MCP) joints is more sensitive to change for erosive progression than radiography of both hands, wrists and forefeet. However, data on the exact distribution of bone erosions, i.e. the pattern of bone involvement are minimal.

Objective: To investigate which bones in RA wrists and MCP-joints that most frequently show bone erosion and which bones most frequently show erosive progression, in early as well as established RA and during disease-modifying anti-rheumatic drug (DMARD) as well as anti-tumor necrosis factor (TNF) therapy.

Patients and Methods: MRI datasets from 258 RA patients (126 with early RA (disease duration <6 months)) were analysed. 223 patients (126 early RA) had 1-year follow-up MRIs. All patients had MRI of one wrist, whereas 86 had additional MCP-joint images, and 46 had additional images of the contralateral wrist. MRIs were evaluated according to the OMERACT RA MRI scoring system (RAMRIS) for erosions, and presence/absence of erosion at baseline was noted in each bone, as was presence/absence of erosive progression.

Results: The distribution of baseline erosions per wrist bone is shown in Figure 1a, whereas the distribution of bones with progression at year 1 is seen in Figure 1b. The capitate, ulna, lunate, triquetrum and scaphoid were the 5 bones with both most frequent baseline erosion and most frequent erosive progression, whereas metacarpal (M) base 3–4–5 were rarely involved. The patterns were similar in early RA and established RA.

In patients with bilateral wrist MRI available, no apparent major difference between dominant and non-dominant was found (269 versus 277 bones

with baseline erosion; 73 versus 85 bones with erosive progression). In the patients in which both wrist and MCP-joint images were available, baseline erosions were still most frequently found in the 5 previously mentioned wrist bones, whereas the 2nd metacarpal head was the most frequently involved MCP-joint bone.

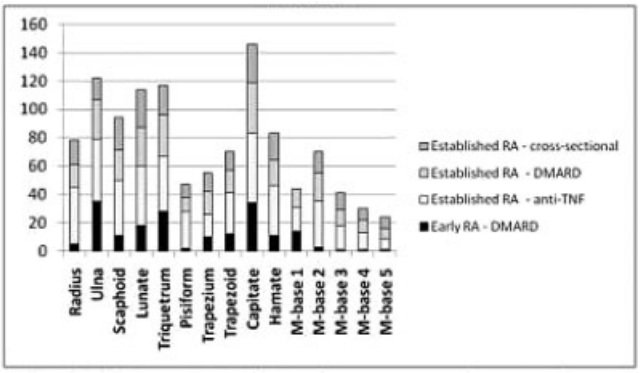

Fig. 1A. Presence of baseline erosion, per bone (n=258).

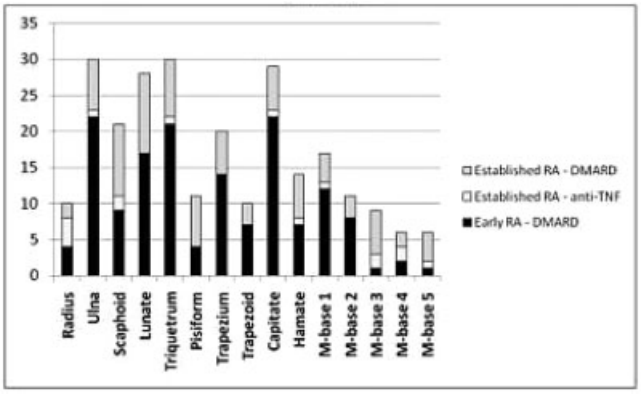

Fig. 1B. Presence of erosive progression, per bone (n=223).

Conclusion: Based on data from 223 RA patients, patterns of MRI bone erosion in RA wrists and MCP joints could be identified. The ulna, scaphoid, lunate, triquetrum and capitate were the most frequently involved bones and showed most change over time. No obvious differences between dominant and non-dominant wrists were identified. Bone involvement patterns should be considered, when joints are selected for MR imaging protocols for clinical trials and practice.

MRI-Proven Bone Edema of Wrist and Finger Joints at Entry Is the Strongest Predictor toward Further Radiografic Progression in Patients with Undifferentiated Arthritis: Results from the Prospective Cohort at Nagasaki University. Junko Kita[7], Atsushi Kawakami[7], Mami Tamai[1], Naoki Iwamoto[7], Shin-ya Kawashiri[8], Kazuhiko Arima[2], Akitomo Okada[7], Tomohiro Koga[7], Satoshi Yamasaki[7], Hideki Nakamura[7], Tomoki Origuchi[5], Kiyoshi Aoyagi[3], Masataka Uetani[4] and Katsumi Eguchi[6]. [1]Center for Health & Community Medicine, Nagasaki University, Nagasaki, Japan, [2]Department of Medical Gene Technology, Atomic Bomb Disease Institute, Nagasaki University Graduate School of BIomedical Sciences, [3]Department of Public Health, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan, [4]Department of Radiology and Radiation Research, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan, [5]Nagasaki University School of Health Sciences, Nagasaki University, Nagasaki, Japan, [6]Sasebo City General Hospital, Sasebo, Nagasaki, [7]Unit of Translational Medicine, Department of Immunology and Rheumatology, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan, [8]Unit of Translational Medicine, Department of Immunology and Rheumatology, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan

Purpose of Study: We have published the importance of autoantibodies and MRI-proven joint damages of wrist and finger joints toward the prediction of development of rheumatoid arthritis (RA) from undifferentiated arthritis (UA) in Arthritis Rheum 2009: 65; 751–8. By using the same patients population, we have tried to find what variables at entry are able to predict the further plain radiografic progression in patients with UA.

Methods: Our cohort included 129 patients of UA. In the present study, we have focused on the 75 out of 129 patients who developed RA at 1 year. Among 75 patients, all of the follow-up data, including serial plain radiography of both hands, were completed in 58 patients. We have examined, by univariate and multivariate analyses, to determine what variables at entry predict the plain radiographic progression at 2 years calculated by Modified Genant Sharp score. Annual progression value greater than 1 was considered as plain radiografic progression.

Results: After the follow-up of 2 years, eighteen patients were classified as having plain radiografic progression (progression group) whereas 40 were not (non-progression group). The multiple logistic regression analysis was conducted to determine the independent effects of variables on radiographic progression. The variables were included in the model if the p value was less than 0.20 in univariate analyses. Duration of morning stiffness, CRP, DAS28-CRP, MMP-3, anti-CCP antibodies, RF, MRI-proven symmetrical synovitis and MRI-proven bone edema were selected. Logistic regression analysis have revealed that MRI-proven bone edema is the first (p=0.023, Odds ratio 13.84) and RF is the second (p=0.049, Odds ratio 6.65) predictors toward plain radiografic progression.

Conclusions: Our data suggest that bone edema of wrist and finger joints at entry is the strongest predictor toward further radiografic progression in patients with UA.

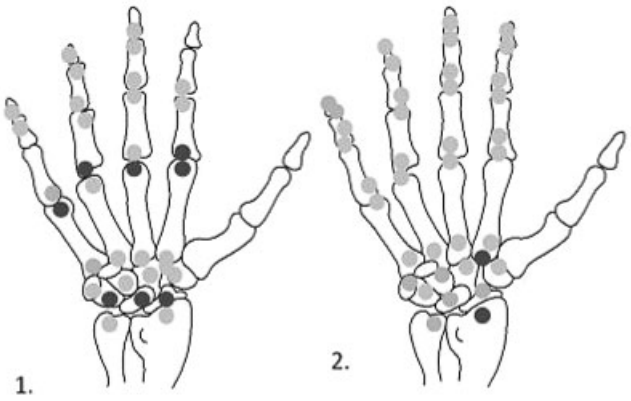
1372

Zoledronic Acid Does Not Reduce Erosive Progression in PsA but May Suppress MRI Bone Oedema. Richard Lloyd[3], Anthony Doyle[3], Nicola Dalbeth[3], Maria Lobo[1], Elizabeth Robinson[5], William Taylor[6], Peter Jones[2] and Fiona M. McQueen[4]. [1]Auckland District Health Board, [2]QEHealth, [3]Univ of Auckland, [4]Univ of Auckland Sch of Med, Auckland, New Zealand, [5]University of Auckland, [6]University of Otago

Magnetic resonance imaging (MRI) can reveal bone pathology in psoriatic arthritis (PsA). Zoledronic acid (ZA) inhibits osteoclast maturation, recruitment to sites of bone resorption and mature osteoclast function. We sought to investigate its effect on bone pathology in PsA using MRI scanning.

Methods: 26 PsA patients (mean age 49 yrs, disease duration 15 yrs) received either 4mg of zoledronic acid (ZA) IV 3 monthly for 1 year or placebo in a blinded manner. A second control group received MRI scans alone (no drug/placebo due to patient concern about risk of side-effects). Paired baseline and 1 year 1.5T MRI scans of the dominant wrist and fingers, using sequences as published (1), were available in 6 ZA and 16 non-ZA (6 placebo) patients for further analysis.

Results: Median MRI erosion scores increased over 12 months but did not differ between groups (ZA group, 35.0 to 39.5; non-ZA group 44.5 to 45.5). However, bone edema scores decreased in the ZA group (15.5 to 8.5) but increased in the non-ZA group (14.0 to 18.0) (p= 0.0056). A site-by-site analysis (maximum of 38 sites for bone oedema and erosion per patient) revealed regression of bone edema at 13.5% of sites in the ZA group compared with 1.3% of sites in the non-ZA group (p = 0.0073) and progression in 1.3% ZA patients compared with 6.9% non-ZA patients (p = 0.072). For bone erosion there was progression at 5.5% of sites in the ZA patients compared with 5.3% in non-ZA patients and regression in 2.6% and 0% of sites respectively (p = NS for all). Bone sites are shown coded as follows: bone edema regression (red), progression (green) and no change (yellow) in 1) a ZA patient and 2) a non-ZA patient.



Conclusions: In this pilot study, there was no evidence that ZA influenced the progression of bone erosions in PsA. However, bone edema scores and number of involved sites fell over 1 year in ZA-treated patients, indicating potential suppression of osteitis. Further studies may be indicated to explore the therapeutic effect of ZA in PsA.

Cartilage Damage and Osteophytes: MRI-Defined Atrophic and Hypertrophic Phenotypes of Knee Osteoarthritis in the Framingham Cohort.
Frank Roemer, Ali Guermazi, Jingbo Niu, Yuqing Zhang and David Felson, Boston University

Purpose: Osteophytes (OPs) are a common feature of moderate to advanced radiographic osteoarthritis (OA). It is not known to what extent advanced cartilage damage detected by magnetic resonance imaging (MRI) correlates with severity of osteophyte formation. On the other hand, it is not known if knees without severe cartilage damage exhibit large osteophytes t.

Our purpose was to describe the prevalence of osteophytes and concomitant cartilage damage in a population-based cohort using semi-quantitative MRI assessment. Focus of the investigation were a.) knees with severe cartilage damage and no or tiny concomitant osteophytes and b.) knees without substantial cartilage damage but with large OPs in order to characterize the atrophic and hypertrophic phenotypes of knee OA respectively.

Methods: Participants of the Framingham Knee Osteoarthritis Study were examined with a 1.5 T MRI system. Cartilage and OPs were assessed according to the WORMS scoring system. "Severe" cartilage damage was defined as cartilage morphology (CM) scores of 5 or 6 in at least 2 of 10 TF subregions. "Without substantial" cartilage damage was defined as none of 10 TF subregions exhibiting CM scores ≥3. Large OPs were defined as OPs grade 5–7. Absent or tiny OPs were defined as OP scores 0–2.

We first calculated the overall prevalence of knees with severe cartilage damage and described concomitant OP status. The odds ratios (OR) of severe cartilage damage according to OP size were estimated using a logistic regression model. Further the association of large OPs according to ROA status was analyzed. In addition we focused on knees with absent or only tiny osteophytes in all 10 TF subregions but with severe cartilage damage as defined above (atrophic phenotype) and knees with large osteophytes and without substantial cartilage damage (hypertrophic phenotype).

Results: 1597 knees of 1248 subjects were included. Mean age was 63.9 years, mean BMI 28.9, 58.3% were women. 197/246 (80.1%) knees with severe cartilage damage exhibited large OPs. The risk of severe cartilage damage increased in a linear fashion with increasing OP size when using the knees without or only tiny osteophytes as the reference. 21 knees showed an atrophic phenotype. Only 3 knees exhibited a hypertrophic phenotype.

Table 1. Association of osteophyte size with risk of severe cartilage damage

Osteophyte status	Subregions with severe cartilage damage[1] n/N (%)	Crude model Odds ratio [95% CI]	Model adjusting age, sex, BMI, race, TF radiographic OA Odds ratio [95% CI] p-value
OPs absent (max. OP size 0–1)	1/498 (0.2)	1.0 (reference)	1.0 (reference)
OPs present (max OP size 2–7)	172/1099 (15.7)	92.9 [16.3, 528.9]	10.6 [1.8, 63.8] <.001*
Maximum OP size: 0 (reference)	1/498 (0.2)	1.0 (reference)	1.0 (reference)
2	20/704 (2.8)	17.1 [1.9, 157.2]	4.2 [0.6, 28.4] 0.15
3–4	98/328 (29.9)	247.3 [27.7, 2208.5]	14.6 [2.2, 98.2] 0.006*
5–7	54/67 (80.6)	2378.1 [249.8, 22,643.4]	108.8 [14.2, 834.9] <0.0001*
p-value for linear trend			<0.0001*

* statistically significant, defined as $p<0.05$
† severe cartilage damage defined as WORMS cartilage morphology scores of 5–6 in ≥2 of 10 TF subregions

Conclusion: The majority of knees with severe TF cartilage damage exhibit moderate to large TF OPs. A linear increase in risk of severe cartilage damage was observed with increasing OP size. A minority of knees exhibits the so-called atrophic phenotype, which also includes knees without ROA. The hypertrophic phenotype is extremely rare. MRI-based prevalence data on the different types of OA phenotypes contributes to understanding disease pathology.

ACR Concurrent Abstract Sessions
Muscle Biology, Myositis and Myopathies: Insights into the Pathogenesis and Outcomes of Myositis
Tuesday, November 9, 2010, 2:30 PM–4:00 PM

1374

The Influence of Regulatory T-Cell Deficiency and Endogenous Muscle Tissue Antigens on the Development of Inflammatory Myopathy in Mice.
N. A. Young, R. Sharma, B. Kaffenberger, A. Friedman and W. N. Jarjour, The Ohio State University Medical Center, Columbus, OH

Background: Myositis is characteristically associated with an inflammatory process that results in pronounced muscle weakness. Myositis is observed in some regulatory T-cell (Treg) deficient mouse models. Scurfy mice lack Treg due to mutation in the X-linked forkhead box P3 (Foxp3) and develop multi-organ inflammation with little inflammation involving muscle tissue. Multiorgan inflammation but not muscle inflammation could be induced in RagI knockout (KO) recipient mice upon intravenous (IV) or intraperitoneal (IP) adoptive transfer of Scurfy lymph node (LN) cells. However, injecting scurfy cells intramuscularly (IM) induces severe inflammation in skeletal muscle suggesting that release of muscle antigen due to injury is a predisposing factor in triggering of muscle inflammation. To investigate the role of muscle antigens and Treg deficiency in the development of muscle inflammation, we crossed scurfy mice with synaptotagmin (Syt) VII deficient mice. The Syt VII mutation results in impaired membrane resealing and has been shown to lead to limited inflammation of muscle.

Methods: Syt VII KO mice were bred with scurfy mice to produce Syt VII/Foxp3 double KO males. Genotyping was performed by PCR analysis of tail clippings and tissue was collected to analyze by H&E staining. LN cells from double KO or Foxp3 single mutant mice were used for injection into RagI KO males through IM and/or IP routes. In conjunction with the IP injection, some mice received muscle cell extract along with LN cells from scurfy mice. Skeletal muscle tissue was collected and analyzed as above.

Results: Double KO mice with Syt VII/Foxp3 mutations developed more severe myositis compared to mice with either mutation alone. Furthermore, IP adoptive transfer of double KO LN cells induced dramatic myopathology in RagI KO recipients. Conversely, a notably limited infiltrate was seen in the skeletal muscle of Rag1 KO mice that received LN cells from Syt VII

sufficient scurfy mice. The muscle antigen effect was then examined through IP adoptive transfer of scurfy LN cells into RagI KO recipients with and without muscle tissue cell extract. These results were compared to RagI KO recipients of scurfy LN cells by IM injection, which readily exhibit severe muscle inflammation. Inflammatory myopathy could only be induced in the RagI KO recipients through IP injection of scurfy LN cells if the mice were co-injected with muscle extract.

Conclusions: This mouse model of myositis illustrates the interplay between two genetic defects in establishing a robust inflammatory process involving the muscle and that regulatory T cells are critical in limiting inflammation in muscles. The results suggest that endogenous muscle tissue antigen exposure either through injection of muscle extract or through leakage of endogenous antigen due to Syt VII mutation is essential in priming autoreactive cells. We have established a novel, reproducible model to study myositis that will be useful to define new autoantigens. Furthermore, extensions of this model can be used to investigate autoimmune phenomena that are triggered by extrinsic factors such as ultraviolet light or exposure to certain drugs.

Blockade of TNFα or IL-1 Ameliorates Established C-Protein Induced Myositis of Mice. Takahiko Sugihara[2], Naoko Okiyama[2], Naoto Watanabe[2], Nobuyuki Miyasaka[1] and Hitoshi Kohsaka[1]. [1]Department of Medicine and Rheumatology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Tokyo, Japan, [2]Department of Medicine and Rheumatology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Japan

Objective: Histological studies of the muscle biopsy specimens suggest that inflammatory cytokines are involved in pathology of inflammatory myopathy. Therapeutic effects of their blockade are controversial with anecdotal reports of clinical efficacy. Systematic pre-clinical studies can be performed by use of animal models. In this regards, C-protein induced myositis (CIM) was established recently as a murine model of polymyositis (PM). Unlike previous models, it represents pathology of PM closely since cytotoxic CD8 T cells are responsible for muscle injury. Using this model, significance of two inflammatory cytokines, interleukin (IL)-1 and tumor necrosis factor (TNF)α was studied as therapeutic targets of the myositis.

Methods: C57BL/6 mice were immunized with recombinant C protein fragments. IL-1 and TNF expression in the CIM muscles was evaluated with immunohistochemistry and real-time PCR. After onset of the myositis, CIM mice were treated with IL-1 receptor antagonist (IL-1ra), anti-IL-1 receptor monoclonal antibody (IL-1R mAb) and TNF receptor (p75)-fused with IgFc (TNFRFc), provided by Amgen as well as with anti-TNFα monoclonal antibody (TNFα mAb), provided by Centocor. Following completion of treatment, the muscles from the treated animals were examined for histological scoring.

Results: IL-1 and TNFα mRNA was expressed in the muscles as early as 7 days after the immunization. This was when mononuclear infiltration and muscle necrosis became appreciable. Their expression was up-regulated at the peak of the myositis. These cytokines were expressed primarily by infiltrating macrophages. To inhibit them in vivo, IL-1ra (0.24, 0.8 and 2.4 mg/day/mouse) was administered continuously with mini-pumps implanted subcutaneously for a week, starting 7 days after the immunization. These treatments suppressed pathology of CIM. While the continuous IL1ra delivery of 0.8 mg/day/mouse was effective (a total of 5.6 mg/mouse), intermittent intraperitoneal injections (three times a week) of a total of 7.2 mg/mouse were not. In contrast, intraperitoneal injections of anti-IL-1R mAb (100 mg and 50 mg/mouse) with the same intermittent protocol succeeded in ameliorating CIM. Next, anti-TNFα mAb (50, 200 and 500 mg/mouse) and TNFRFc (100 mg/mouse) were administered intraperitoneally three times a week for 2 weeks. Both of anti-TNF biological reagents suppressed pathology of CIM.

Conclusions: IL-1 and TNF blockade ameliorated ongoing CIM. Blockade of TNFα or IL-1 may be new strategies for treatment of PM. Previously, we reported that CIM developed in TNFα null mice but not in IL-1α/β null mice. Cytotoxic activity of anti-TNFα mAb does not account for this difference because TNFRFc treatment was also effective. TNFα null mice are reportedly susceptible to collagen-induced arthritis, which can be treated with anti-TNFα mAb. This paradoxical sensitivity of TNFα deficient mice to autoimmunity holds true in CIM, which is driven by autoaggressive CD8 T cells. As for the IL-1 blockade, anti-IL-1R mAb appeared clinically more feasible than IL-1ra presumably because of differences in affinity and pharmacokinetics.

UPR Activation and IFNb Production in Myocytes in Adult and Juvenile Myositis. Ann M. Reed[1], Molly S. Hein[1] and Robert A. Colbert[2]. [1]Mayo Clinic, [2]NIH, NIAMS

Background: The unfolded protein response (UPR) to endoplasmic reticulum (ER) stress in myocytes may contribute to skeletal muscle damage and dysfunction in Inflammatory Myositis (IM). Overexpression of Interferon b (IFNb) has been demonstrated in immune cells in Adult and Juvenile Dermatomyositis (DM JDM), and to a lesser extent in Polymyositis (PM) and Inclusion Body Myositis (IBM), and is hypothesized to contribute to the UPR through upregulation of MHC class I. Since the UPR can contribute to IFNb upregulation in other cell types, we hypothesized that UPR activation in autoimmune myositis might correlate with IFNb expression in myocytes in active disease.

Methods: Intracellular staining of BiP (Grp78/HSPA5), a marker of UPR activation, and IFNb were assessed in muscle biopsy tissue from new onset IM subjects (n=5 each of DM, JDM, PM, IBM and control subjects). Myocyte regeneration marker (MYH3) expression was assessed using immunofluorescence (IF) staining. Co-localization of these proteins and inflammatory cell phenotyping, including CD3 (T cells), CD123 (plasmacytoid dendritic cells (pDCs)), CD4 (T cells and pDCs) and CD19 (B cells), was performed by cell surface staining. Direct comparisons of the number of IF positive cells were normalized per 10X field.

Results: Co-localization of BiP and IFNb expression was seen in 10–25% of the myocytes per high power field (HPF) in all IM subgroups and 20–50% of the mononuclear (MN) cells compared with rare <1% of myocytes and MN cells in control tissue ($p=0.017$ and 0.004). BiP staining in myocytes was seen rarely without IFNb. The IFNb levels were increased in all forms of myositis (JDM 25%, DM 8%, PM 7% and IBM 15%) versus 3% of controls with JDM having the highest values. Regenerating fibers express BiP in 80% of cases. MYH3 co-localized with BiP and IFNb in ~80% of myocytes, with 20% staining for MYH3 alone. BiP+ pDCs were also greater in JDM (average of 44 cells/HPF vs. 6 in controls ($p<0.0001$) and 7 cells/HPF in DM/PM/IBM). IFNb co-localized with pDCs (72 JDM, 23 DM, 25 PM, 15 IBM and 8 control cells per HPF (all groups vs controls $p<0.003$)). The co-localization of BiP and IFNb in myocytes suggests that non-immune cell production of IFNb including regenerating cells, may be important in IM pathogenesis, and that the UPR may contribute to its production, possibly creating a positive feedback loop.

Conclusions: The UPR is associated with Type-I IFN (IFNb) expression in myocytes in several forms of IM.

A New ELISA System for Detecting Autoantibodies to aminoacyl-tRNA Synthetases: Usefulness in Myositis and Interstitial Pneumonia. Ran Nakashima[2], Yoshitaka Imura[4], Shio Kobayashi[3], Yuji Hosono[4], Naoichiro Yukawa[4], Daisuke Kawabata[4], Takaki Nojima[4], Koichiro Ohmura[2], Takashi Usui[4], Takao Fujii[1], Minae Seto[6], Akihiro Murakami[5] and Tsuneyo Mimori[2]. [1]Department of Rheumatology and Clinical Immunology, Kyoto University Graduate School of Medicine, Sakyo-ku Kyoto, Japan, [2]Department of Rheumatology and Clinical Immunology, Kyoto University Graduate School of Medicine, Kyoto, Japan, [3]Department of Rheumatology and Clinical Immunology, Kyoto University Graduate School of Medicine, Kyoto, Japan, [4]Department of Rheumatology and Clinical Immunology, Kyoto University Graduate School of Medicine, [5]Medical and Biological Laboratories CO., LTD, [6]Medical and Biological Laboratories Co., Ltd., Nagano, Japan

Purpose: Autoantibodies to aminoacyl-tRNA synthetases (ARS) are the most frequent myositis-specific antibodies and patients with anti-ARS antibodies show a spectrum of common clinical manifestations known as anti-synthetase syndrome. Detecting anti-ARS antibodies is useful in diagnosis, classification and management of polymyositis (PM)/dermatomyositis (DM) and interstitial pneumonia (IP). Immunoprecipitation assay is utilized currently to detect anti-ARS antibodies but can be

done only in limited numbers of laboratories. For easy detection of anti-ARS antibodies, we established enzyme-linked immunosorbent assay (ELISA) system using a mixture of five known recombinant ARS antigens for detecting anti-Jo-1, anti-PL-7, anti-PL-12, anti-EJ and anti-KS antibodies at once.

Methods: We prepared 6 recombinant ARS antigens; GST-Jo-1, His-PL-12, His-EJ and GST-KS expressed in *E. coli*, and His-PL-7 and His-OJ expressed in *Trichoplusia* Hi-5 cells. After confirming antigenic activity of all recombinant proteins except His-OJ using immunoblot and ELISA, we made an ELISA system using mixture of the five recombinant ARS. In order to confirm the efficiency of this newly established ELISA, we screened a total of 241 sera from patients with various connective tissue diseases (PM 57, DM 46 and other diseases 138), 62 from idiopathic IP (IIP) and 30 from healthy controls. The results of ELISA were compared with those of standard RNA immunoprecipitation assay.

Results: Except for one false-negative and two false-positive samples, all of the results on anti-ARS positivity by ELISA were consistent with those by RNA immunoprecipitation. Sensitivity and specificity of the ELISA compared with RNA immunoprecipitation were 97.5% and 99.3%, respectively. Anti-ARS antibodies were detected in 33% (19/57) of PM, 28% (13/46) of DM, 2% (1/49) of SLE, 2% (1/49) of RA and 11% (7/62) of IIP. None of healthy controls was positive for anti-ARS antibodies. Among 32 anti-ARS-positive PM/DM patients, 30 (94%) had IP, 18 (56%) arthralgia, 12 (38%) fever, 12 (38%) Raynaud's phenomenon and 8 (25%) mechanic's hand. Two anti-ARS-positive patients either with SLE or RA revealed IP but no evidence of myositis.

Conclusion: We established the new anti-ARS ELISA system using a mixture of five recombinant ARS antigens and demonstrated that it detected anti-ARS antibodies as efficiently as RNA immunoprecipitation. This system will make possible to detect anti-ARS antibodies in patients with PM/DM and IP more easily and be used widely in daily practice.

1378

Atherosclerotic Cardiovascular Disease among Hospitalized Dermatomyositis Patients in the US. Eleni Linos[3], David Fiorentino[3], Bharathi Lingala[3], Eswar Krishnan[2] and Lorinda Chung[1]. [1]Stanford Univ Medical Center, Palo Alto, CA, [2]Stanford University, Palo Alto, CA, [3]Stanford University School of Medicine

Purpose: Increasing evidence suggests that atherosclerotic cardiovascular disease is more prevalent among patients with rheumatologic diseases, including rheumatoid arthritis and systemic lupus erythematosus, compared with the general population. Cardiac involvement in patients with dermatomyositis (DM) has been reported and is associated with a poor prognosis, but the prevalence of atherosclerotic cardiovascular disease is unknown. Our aim was to evaluate the prevalence of atherosclerotic cardiovascular comorbidities and their associated mortality risk among hospitalized DM patients in the US.

Methods: We examined the in-hospital frequency and mortality rates of specific diagnoses and procedures associated with atherosclerotic cardiovascular disease among hospitalized adult patients with DM using data from the Nationwide Inpatient Sample (NIS) from 1993 to 2007. The NIS is a national, annual, representative survey of hospitalized patients in the US. The following diagnoses and procedures were identified by ICD-9 codes: coronary artery disease, congestive heart failure, angina, myocardial infarction, and cerebrovascular accidents; coronary artery bypass grafts, coronary catheterization, and percutaneous transluminal coronary angioplasty. We compared the odds of death among hospitalized DM patients with each cardiovascular diagnosis or procedure to those without using logistic regression. Analyses were weighted so results are standardized to the US population as a whole.

Results: A total of 50,323 hospitalizations of DM patients occurred in the US between 1993 and 2007. The mean patient age was 58 years, and 73% of patients were female. Of all DM hospitalizations, 20% were associated with a concurrent atherosclerotic cardiovascular diagnosis or procedure. The overall in-hospital mortality rate was 57 per 1000. DM patients with any of the specified atherosclerotic cardiovascular diagnoses or procedures were twice as likely to die during the inpatient stay compared to DM patients who did not have atherosclerotic cardiovascular disease (OR=2.0 95% CI 1.7–2.5, $p<0.0001$). The highest odds of death were noted for patients with congestive heart failure (OR=2.3 95% CI 1.9–2.8, $p<0.001$) and cerebrovascular accidents (OR=2.3 95% CI 1.7–3.3, $p<0.001$).

Conclusions: In this large US-based hospitalization database, approximately one fifth of hospitalizations in DM patients were associated with an atherosclerotic cardiovascular diagnosis or procedure. These patients have double the risk of in-hospital death, making identification of these groups important for both prognostic purposes and clinical care. Further prospective studies are necessary to confirm our findings and to analyze the relative contribution of disease activity, concomitant risk factors, and corticosteroid treatment.

Predictors of Response to B Cell Depleting Therapy in Adult and Juvenile Myositis. Ann M. Reed[1], Kelly T. McNallan[1], Cindy S. Crowson[1] and Chester V. Oddis[2]. [1]Mayo Clinic, [2]University of Pittsburgh

Background: Idiopathic inflammatory myopathy (IIM) is associated with significant morbidity and mortality. There are no curative therapies and markers to predict therapeutic response are lacking. Type I interferon (IFN) regulated genes and cytokines/chemokines are known biomarkers of disease activity in IIM and predict response to therapy while autoantibody production and B cell survival factors including BAFF are hypothesized as important biomarkers in IIM. The Rituximab (Rtx) in Myositis (RIM) Study collected longitudinal patient (pt) samples and assessed the efficacy of Rtx in refractory adult polymyositis (PM) and dermatomyositis (DM) and juvenile DM (JDM) pts. We investigated if a biological signature predicts disease responsiveness to B cell depletion (BCD) therapy in the RIM Study.

Methods: Peripheral blood samples and clinical/laboratory data were collected at baseline and 16 and 24 weeks after Rtx in 75 RIM Study pts to: (a) determine biomarkers of disease activity, (b) predict treatment response, and (c) determine whether biomarkers predict disease flare. Multiplexed sandwich immunoassays (Meso Scale Discovery) quantified serum levels of IFN-regulated chemokines and other pro-inflammatory cytokines. B cell regulating factor transcripts were determined by quantitative PCR. Cytokines (IL-1β, IL-2, IL-12, IFNα, MIP1α, MIG and TNF-α), chemokines (MCP-1, MCP-2, ITAC and IP-10) and B cell regulating factors (BAFF, ΔBAFF, APRIL, BAFFR, BCMA, and TACI) were measured. Clinical response and disease activity were assessed utilizing a consensus-driven definition of improvement (DOI) in IIM and the Physician's Global Activity (PGA). Spearman's rank correlation coefficient (r) described the relationship between biomarkers and disease activity/response.

Results: Changes in serum biomarkers correlated with disease activity and response to Rtx. Disease activity measured by PGA at week 16 correlated with IL-12 at week 0 ($r=-0.22$ $p=0.018$), and with change from week 0 to 16 in IL-12 ($r=0.33$; $p<0.001$), IL-1β ($r=0.21$; $p=0.023$), MIG ($r=0.21$; $p=0.025$), and TNF-α ($r=0.20$; $p=0.028$). Predictive treatment responses were detected in pts with higher IL-2 levels at week 0 who had an 80% likelihood of achieving DOI (hazard ratio: 1.84; 95% CI: 1.04, 3.27; $p=0.036$). Serum levels of IFN regulated cytokines and chemokines declined from week 0 to 16 and correlated with change in PGA from week 0 to 16 and predicted responsiveness to Rtx [IL-12 ($r=0.19$; $p=0.04$), IL-1β ($r=0.21$; $p=0.02$), MIP-1α ($r=0.21$; $p=0.02$), TNFα ($r=0.19$; $p=0.03$), ITAC ($r=0.26$; $p=0.007$) and IP-10 ($r=0.24$; $p=0.01$)]. Peripheral blood RNA levels of BAFFR, BCMA, CD20, and TACI decreased significantly between week 0 and 24 and clinical improvement (decrease in PGA) was significantly correlated with change in DBAFF ($r=0.26$; $p=0.01$) and full length BAFF ($r=0.25$; $p=0.022$). Markers of disease worsening, defined by a 10% increase in PGA between weeks 0 and 24, included BCMA/BAFFR ratio ($p=0.04$) and BAFFR/TACI ratios ($p=0.06$).

Conclusion: These studies show that cytokine and chemokine levels correlate with disease activity and physician-assessed worsening and predict response to BCD in adult and juvenile myositis.

Clinical Improvement and Structural Tissue Repair by Joint Distraction, in Treatment of End-Stage Knee Osteoarthritis. F. Intema[2], K. Wiegant[3], P. M. van Roermund[3], A. C. A. Marijnissen[3], S. Cotofana[1], F. Eckstein[1], S. C. Mastbergen[3] and F. P. J. G. Lafeber[3]. [1]Institute of Anatomy and Muscoskeletal Research, Paracelsus Medical University, Salzburg, Austria, [2]Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht, The Netherlands, [3]Rheumatology & Clinical Immunology, University Medical Center Utrecht, The Netherlands

Background: End-stage knee osteoarthritis (OA) is frequently treated by total knee replacement (TKP). In 40% of the cases this expensive treatment is performed under the age of 65 years, while the procedure has a higher risk of failure in younger patients, due to higher physical demands.

Knee joint distraction (KJD) is an experimental treatment for end-stage knee OA, aimed at unloading the joint cartilage and subchondral bone by use of a 'fixateur externe'. The technique proved to be clinically effective for end-stage ankle OA. The present study describes an exploratory, open, uncontrolled trial to verify whether KJD has the potency to postpone a TKP by inducing clinical improvement and cartilage repair.

Methods: Twenty patients, under 60 years of age, with end-stage knee OA were treated with KJD for 2 months. Two monotubes with internal coil springs were placed parallel (medial and lateral) bridging the knee joint and were distracted for 5 mm. Patients were encouraged to load the knee during distraction, in order to achieve intermittent intra-articular fluid pressures. During the treatment most patients (n=17) suffered from single or multiple pin tract infections, all being successfully treated with antibiotics.

After 2 months, tubes and pins were removed, and function was actively practiced.

The primary clinical outcome was pain and function by use of the WOMAC questionnaire. For secondary clinical outcome VAS pain was documented. Primary structural outcome was cartilage thickness by use of quantitative MRI and digital analyses of standardized X-rays. Secondary outcome parameters were MRI determined decrease in area of denuded bone, increase in cartilage area and volume as well as biochemical markers of cartilage. All structural parameters were analyzed blinded.

Results: One year after distraction, the total WOMAC score improved significantly from 45% at baseline to 77% ($p<0.001$). This improvement is supported by a decrease in VAS pain score from 73 to 31 mm ($p<0.001$).

Complementary, quantitative MRI analysis showed an increase in cartilage thickness of the affected compartment from 2.4 to 3.0 mm ($p<0.01$), both femur and tibia. The total area of denuded bone decreased from 22% to 5% ($p<0.01$). Cartilage area and volume increased from 15.6 to 18.9 cm^2 and 2.3 to 2.8 cm^3 (both $p<0.05$).

X-ray analysis corroborated the MRI findings by an increased mean, as well as minimum JSW from 2.7 to 3.6 mm ($p<0.05$) and 1.0 to 1.9 mm ($p<0.01$), respectively.

Increase in cartilage area and thickness and decrease in denuded bone area correlated with the increase in the mean radiographical JSW ($r=0.571$, $r=0.553$, $r=-0.613$ resp. all $p<0.05$)

Long term changes in biomarkers showed a decrease of collagen type II breakdown marker CTXII (−11%; $p=0.04$) and an increase of collagen type II synthesis marker PIIANP (+103%; $p=0.03$). The average change in the ration of PIIANP/CTXII of each patient was in favor of synthesis ($p<0.03$).

Conclusion: In treatment of end-stage knee OA it is proven to induce significant intrinsic joint cartilage repair by use of joint distraction, based on MRI, X-ray and biochemical marker analyses. These significant tissue structure changes are accompanied by clinical improvement in pain and function.

TNF Blockade during Elective Orthopaedic and Hand Surgery in Arthritis Patients: Friend or Foe? Elisabet Pettersson, Pierre Geborek and Anders Gülfe. Lund University, Dept of Clinical Sciences, Lund, Section for Rheumatology, Lund, Sweden

Background: Data on the risk for surgical site infections (SSI) in patients with inflammatory arthritis who continue TNF blockade perioperatively, compared to those who stop treatment, is sparse and contradictory. Patients withholding treatment may experience a flare in their arthritis, hampering postoperative mobilisation.

Methods: Patients with inflammatory arthritis, admitted to the Dept of Rheumatology, Lund University Hospital, Jan 1st, 2003–Sep 30th, 2009, were evaluated 1–4 weeks preoperatively. Demographic data, previous and current treatment and core set variables of disease activity were recorded. In 2003–2005, infliximab, etanercept and adalimumab were discontinued for 8, 1 and 4 weeks preoperatively and reintroduced 1 week after surgery if there were no infection signs (group A). After Jan 1st, 2006, TNF blockers were continued before and during surgery (group B). Patients were followed up for at least 6 months. Infections were recorded according to the Centers for Disease Control 1992 criteria. Surgical procedures were classified as Foot, Hand, Implant or Other.

Results: There were 312 and 515 procedures in group A and B, respectively. 67% had rheumatoid arthritis, and about 5% each had spondyloarthritis including ankylosing spondylitis, psoriatic arthritis and juvenile idiopatic arthritis in both group A and B. 49 and 48% were on prednisolone, 43 and 51% were on methotrexate, 30 and 37% on biologics, whereof 14 and 21% on biologics + methotrexate in groups A and B, respectively.

Total SSI rate were 12 (3.8%) in group A and 33 (6.4%) in group B. The difference was not statistically significant. When analysed by type of procedure, there were no significant differences, except higher SSI for foot surgery in group B. Total number of infections in the various medication groups were also similar, except higher rates in patients on methotrexate monotherapy in group B; 3.0 vs 8.7%, $p=0.027$. In a multivariate regression model, correcting for various baseline variables, methotrexate without biologics was the only predictor of SSI in groups A and B combined (OR 2.66, 95% CI 1.18–6.02).

Conclusion: We found no overall increased risk for SSI in patients continuing TNF blockade in the perioperative period in our cohort. Higher SSI rates in foot surgery in group B owed to extremely low rates in group A. Methotrexate without biologics was the only medication group with an elevated SSI rate, while biologics and prednisolone were not. However, low event rates preclude firm conclusions.

Guided Mesenchymal Stem Cell Layering Technique for Treatment of Osteoarthritis of the Knee. Nathan Wei[1], Sheila Beard[1], Sheila K. Delauter[1], Carla Bitner[1], Rebecca Gillis[1], Laura Rau[1], Colleen Miller[1] and Thomas B. Clark[2]. [1]Arthritis Treatment Center, Frederick, MD, [2]Musculoskeletal Ultrasound, Vista, CA

Current treatments for osteoarthritis of the knee (OAK) relieve pain and improve function somewhat, but do not restore articular cartilage.

While described in animal models, the use of autologous stem cells has not been extensively studied in humans.

We have employed an ultrasound-guided procedure using autologous mesenchymal stem cells, growth factors, and fat matrix (GMSCL) in patients with severe OAK.

Twenty-two patients underwent GMSCL for OAK. They ranged in age from 36 to 84 years. There were 16 men and 6 women. BMI for the patients ranged from 21 to 36.1. Kellgren-Lawrence status was 6 grade II, 10 grade III, and 6 grade IV.

Bone marrow (60 mls) was harvested from the posterior iliac crest and centrifuged to isolate marrow stem cells. In addition, peripheral blood (60 mls) was obtained in order to isolate growth factors in a platelet-rich plasma sample. In addition, 15 mls of subcutaneous fat was also harvested from the flanks.

Ultrasound guided fenestration at joint capsule sites including the joint line, adductor tubercle and medial patellar facet was conducted. Stem cells, platelet-rich plasma subcutaneous fat, and calcium chloride and thrombin were injected into the fenestrated areas and also into the joint.

Post-procedure, patients were placed at both a non-weight-bearing as well as limited weight-bearing protocol using a brace to unload the narrowed compartment for four-six weeks.

There were three treatment failures defined as patients who did not improve above baseline.

The following is a summary of results at baseline, six months, and twelve months in evaluable patients at the time of abstract submission.

Patient Pain VAS
Baseline - (22 pts) 36.1 6 Months - (11 pts) 15.6 12 Months - (8 pts) - 11.7
Patient Global Assessment of Disease
Baseline - (22 pts) 34.4 6 Months - (11 pts) 21.4 12 Months - (8 pts) - 13.1
Physician Global Assessment
Baseline - (22 pts) 72.3 6 Months - (11 pts) 28.6 12 Months - (8 pts) - 16.1
50 Foot Walk Pain
Baseline - (22 pts) 27.7 6 Months - (11 pts) 14.6 12 Months - (8 pts) - 8.4
WOMAC
Baseline - (22 pts) 27.1 6 Months - (11 pts) 13.7 12 Months - (8 pts) - 8.0

Ultrasound measurement of patellofemoral cartilage thickness at 7 standardized points (medial to lateral) was performed. Reproducibility error was reduced by confirming the original site and repeating measurements three times. Measurements showed:

Mean improvement from baseline to 6 months (11 pts) - 0.4 mm
Mean improvement from baseline to 12 months (8 pts) - 0.8 mm

While it is an uncontrolled study, GMSCL demonstrates some promise as a treatment for OAK. Further study is recommended.

Increased Fat Mass Is Associated with High Levels of Low Back Pain Intensity and Disability. Donna Urquhart[4], Patricia Berry[4], Anita Wluka[4], Boyd Strauss[3], Yuanyuan Wang[4], Joseph Proietto[5], Graeme Jones[2], John Dixon[1] and Flavia Cicuttini[4]. [1]Baker IDI Heart and Diabetes Institute, [2]Menzies Research Institute, [3]Monash Medical Centre, [4]Monash University, [5]University of Melbourne

Background: The relationship between obesity and low back pain and disability is unclear. No study has examined the role of body composition in low back pain and disability. The aim of the study was to determine whether body composition is associated with low back pain intensity and/or disability in a cross sectional study.

Methods: 135 participants (25 to 62 years), with a range of body mass indicies (BMI) (18 to 55 kg/m^2), were recruited for a study examining the relationship between obesity and musculoskeletal disease. Participants completed the Chronic Back Pain Grade Questionnaire, which examines individuals' levels of low back pain intensity and disability. Body composition was assessed using dual x-ray absorptiometry.

Results: BMI was associated with higher levels of back pain intensity (Odds ratio (OR) 1.35, 95% CI 1.09, 1.67) and disability (OR 1.66, 95% CI 1.31, 2.09). Higher levels of pain intensity were positively associated with total (1.19, 95% CI 1.04, 1.38) and lower limb fat mass (OR 1.51, 95% CI 1.04, 2.20), independent of lean tissue mass. There were also positive associations between higher levels of low back disability and total (OR 1.41, 95% CI 1.20, 1.67), upper (OR 1.67, 95% CI 1.27 2.19) and lower limb (OR 2.29, 95% CI 1.51, 3.49) fat mass. Similar relationships were observed with trunk, android and gynoid fat mass. After adjusting for confounders, no measures of lean tissue mass were associated with higher pain intensity or disability ($p>0.10$).

Conclusions: Greater fat, but not lean tissue mass, was associated with high levels of low back pain intensity and disability. While this needs to be confirmed in longitudinal studies, it suggests that weight loss strategies aimed at reducing fat mass may be important in the prevention of low back pain and disability. Understanding the mechanism for these relationships may provide novel approaches to managing low back pain.

Creatine Supplementation Associated to Resistance Training in Post-Menopausal Women with Knee Osteoarthritis Improves Physical Function: A Randomized, Double-Blinded, Placebo-Controlled Clinical Trial. Manoel Tavares Neves Junior[1], Bruno Gualano[2], Hamilton Roschel[2], Marcelo Tatit Sapienza[2], Fernanda Rodrigues Lima[2], Ana Lucia de Sa Pinto[2], Ricardo Fuller[2], Rosa Maria Rodrigues Pereira[2], Antonio Herbert Lancha Junior[2] and Eloisa Silva Dutra de Oliveira Bonfa[2]. [1]Universidade de Sao Paulo, Sao Paulo, SP, Brazil, [2]Universidade de Sao Paulo

Background: Quadriceps muscle strength is associated with functional impairment in osteoarthritis (OA), reinforcing the relevance of strategies to optimize muscle strength in this disease. Creatine supplementation has been found to significantly increase muscle strength and hypertrophy in adults, particularly when associated with a resistance training regime.

Methods: We conducted a randomized, double-blinded, placebo-controlled trial investigating the efficacy and safety of creatine (CR) supplementation in sedentary post-menopausal women (50–65 years old) with knee osteoarthritis (grades II and III) submitted to resistance training. Subjects ($n=16$) were randomly allocated to receive treatment with either CR (5 g day-1 over 3 months) or placebo (PL) (dextrose). All of the subjects undertook moderate intensity resistance training, three times a week for three months. The patients were submitted to a physical function test (timed-stands test - measured by the number of repetitions performed over time), lower limb maximum dynamic strength test (1RM), body composition using a dual energy X-ray absorptiometry and renal function assessed by 51Cr-EDTA clearance before and after the training period. Data were analyzed by a mixed model for repeated measures.

Results: Functional testing revealed a significant improvement (pre to post) in the timed-stands test for the CR group (16.6 $\pm$ 1.06 vs. 19.1 $\pm$ 1.83 repetitions, $p=0.02$) while no change was observed for the PL group (15.1 $\pm$ 1.45 vs. 16.7 $\pm$ 1.11 repetitions, $p=0.17$). Additionally, between-group comparison revealed a statistically significant difference for CR when compared to PL ($p=0.03$). Body composition data showed a significant increase over time (pre to post) in total body weight (64.7 $\pm$ 7.65 vs. 67.1 $\pm$ 7.15 kg, $p=0.02$) and lean mass (39274.78 $\pm$ 5384.17, vs. 40595.16 $\pm$ 4932.96 g, $p=0.01$) for the CR group, whereas the PL group showed no alteration in any of the body composition parameters ($p=0.95$ and $p=0.99$, respectively). Moreover, 1RM significantly improved in both, CR (81.25 $\pm$ 16.71 vs. 98.83 $\pm$ 16.22 kg, $p=0.02$) and PL (85.98 $\pm$ 19.43 vs. 106.10 $\pm$ 27.43 kg, $p=0.01$) groups, thus indicating the efficacy of the training protocol in improving strength. Finally, renal function remained stable throughout the study (pre to post) for CR (88.00 $\pm$ 17.11 vs. 88.65$\pm$16.45 mL/min/1.73 m2, $p=0.89$) and PL (83.43$\pm$6.62 vs. 83.0$\pm$5.29 mL/min/1.73 m2, $p=0.99$) groups, with no between-group differences. Creatine supplementation had no side-effects.

Conclusion: Our findings highlight that creatine is a promising treatment to help OA patients to perform daily living tasks since it safely improves lean mass and function. The underlying mechanism probably involves an additive effect of the CR supplementation and resistance training on the increase in muscle mass and work capacity, thus ameliorating muscle function. Clinical Trial Identification-NCT00749983

Role of Central Sensitization in Persistent Pain Post-Knee Replacement: The MOST Study. Tuhina Neogi[3], Jingbo Niu[4], Laura Frey-Law[9], Lars Arendt-Nielsen[1], Jasvinder Singh[8], Joachim Scholz[2], Clifford Woolf[2], Irina Tolstykh[7], Jessica L. Maxwell[4], Barton Wise[6] and David T. Felson[5]. [1]Aalborg University, Denmark, [2]Boston Childrens Hospital, [3]Boston Univ Schl of Med, Boston, MA, [4]Boston Univ School of Medicine, Boston, MA, [5]Boston University School of Medicine, Boston, MA, [6]UCDavis, Sacramento, CA, [7]UCSF, [8]University of Alabama at Birmingham, Minneapolis, MN, [9]University of Iowa

Purpose: Pain persists post-knee replacement (KR) in ~20–30% of patients. The reason for this pain persistence is unclear. One possibility is that long-standing mechanical and inflammatory stimuli in osteoarthritis (OA) can lead to changes in the peripheral and central nervous system, with subsequent peripheral and central sensitization resulting in heightened pain sensitivity. We hypothesized that central sensitization may be associated with persistent pain post-KR.

Methods: The Multicenter Osteoarthritis (MOST) Study is cohort study of persons with or at high risk of knee OA. This analysis was limited to those with KR at any time during the study, confirmed by medical records and/or x-ray. At the 60-month clinic visit, participants had knee x-rays, answered a knee-specific WOMAC pain questionnaire, and had temporal summation (TS) assessed at the wrist. TS is an augmented pain response to repetitive mechanical stimuli thought to reflect central sensitization. TS was defined as being present when, after touching the skin with a 60g monofilament repeatedly at a frequency of 1Hz for 30 seconds, the subject reported increased pain at the site being tested. For cross-sectional analyses, we defined

presence of knee pain (of the KR knee) as moderate or greater pain vs none/mild based on the maximal score of any of the 5 WOMAC pain questions. For longitudinal analyses, we defined knee pain improvement post-KR as a decrease of ≥5.6/20 in WOMAC pain (of the KR knee) from pre- to post-KR (Escobar, OA&C, 2007) using the closest clinic visits to those time-points. We examined the relation of presence of TS with presence of knee pain among all persons with KR, and with having pain improvement post-KR among those with a new KR during follow-up, using Poisson regression with GEE to obtain prevalence ratios (cross-sectional) and risk ratios (longitudinal). All analyses were adjusted for age, sex, BMI, depressive symptoms, race, clinic site, and time since KR. Only the cross-sectional analysis could be adjusted for catastrophizing due to unstable estimates in the longitudinal analysis.

Results: There were 114 subjects with 151 knees that had a KR at baseline (22) or during follow-up (129) who also had TS measured at the 60-month visit (mean age 71.2, mean BMI 32.9, 74.6% female, mean time since KR 3.7 yrs (range <1–15 yrs)). Maximal WOMAC knee pain was rated as ≥moderate in 26.5% of KR knees. Cross-sectionally, presence of TS was associated with 2.06 times higher prevalence of knee pain compared with no TS (95% CI 1.12–3.79, p=0.02). Pain improvement from pre- to post-KR occurred in 42% of KR knees. In the longitudinal analysis, presence of TS was associated with a 67% lower chance of having a pain improvement post-KR (RR 0.33, 95% CI 0.17–0.63, p=0.0009).

Conclusions: Temporal summation was associated with presence of, and less improvement in, post-KR pain. Central sensitization may therefore partially explain why some individuals have pain persistence post-KR. These findings suggest that consideration for performing KRs earlier in the course of OA, when central sensitization is still potentially reversible, may be warranted.

Thrombin-Activatable Carboxypeptidase B (CPB) Plays a Central Role in Down-Regulating Inflammatory Responses in Rheumatoid Arthritis by Cleaving C5a. Jason J. Song[3], Inyong Hwang[3], Tiffany Wang[4], Annette T. Lee[1], S. Louis Bridges[5], Peter K. Gregersen[1], Lawrence Leung[4] and William Robinson[2]. [1]North Shore-LIJ Research Institute, Manhasset, NY, [2]Stanford Univ School of Med, Stanford, CA, [3]Stanford University, Palo Alto, CA, [4]Stanford University, [5]Univ of Alabama-Birmingham, Birmingham, AL

Purpose: Thrombin-activatable CPB is known to play an anti-fibrinolytic role by removing C-terminal lysine residues from fibrin, thereby preventing the cleavage of fibrin by plasmin. Recently, C3a, C5a, thrombin-cleaved osteopontin, and bradykinin have been identified as additional substrates of CPB. CPB removes arginine residues from the C-terminus of these inflammatory mediators, thereby altering their biological functions. Here we investigate the molecular mechanisms underlying the anti-inflammatory role of CPB in rheumatoid arthritis (RA).

Methods: We evaluated arthritis in CPB−/− mice, osteopontin−/− mice, C5−/− mice, and bradykinin B2 receptor−/− mice after injection of anti-collagen antibody. Arthritis was assessed visually and by caliper measurement of paw thickness daily for 10 days after injections. To determine the effect of CPB on C5a-mediated chemotaxis in vivo, we injected intact C5a or CPB cleaved C5a into mouse peritoneum and assessed neutrophil migration. To study the role of CPB in human RA, CPB and C5a levels were measured in synovial fluids derived from RA and osteoarthritis (OA) patients using commercial ELISA kits. To investigate the role of CPB genetic variants in RA, we genotyped two nonsynonymous CPB2 SNPs (rs1926447 and rs3742264) and evaluated the association with modified Sharp score (MSS) in the SONORA cohort (n=109, 70% female, 100% Caucasian) and the CLEAR Registry (n=118, 100 % female, 100% African-American).

Results: We found that anti-collagen antibody-induced arthritis was much more severe in CPB−/− mice than in wild-type mice. In contrast, C5−/− mice were protected from arthritis, while bradykinin B2 receptor−/− mice and osteopontin−/− mice developed arthritis equivalent in severity to that in wild-type mice. In vivo studies showed that C5a chemotactic effect is decreased with CPB incubation (peritoneal neutrophil of intact C5a vs CPB cleaved C5a; 15.66% vs 5.14%, p<0.01). We found that levels of CPB and C5a are increased in RA synovial fluid compared to OA synovial fluid (CPB 644.2 vs 374.1%, p<0.0001; total C5a 24.0 vs 9.6 ng/ml, p <0.05). CPB level is correlated with C5a level (p<0.01, r=0.41). CPB SNP rs1926447 is associated with radiologic progression of RA: (MSS for CT/TT vs CC; SONORA (year 2), 4.5 vs 8.4, p=0.03; CLEAR I (year 3), 1.8 vs 5.9 p<0.01).

Conclusions: These results suggest that thrombin-activatable CPB plays a critical role in down-regulating inflammatory responses in anti-collagen antibody-induced arthritis, and that CPB exerts its anti-inflammatory effects by cleaving, and thereby inactivating, C5a. We also demonstrate that CPB is elevated in RA synovial fluid, and is associated with synovial C5a level. Our SNP analysis results suggest that CPB variant 1064T (minor allele of rs1926447) that has been reported to produce a CPB protein with a two-fold longer half-life, results in less radiographic damage in Caucasians and African-Americans with RA, further suggesting that CPB plays a central role in down-regulating inflammatory responses in RA.

The Liver × Receptor (LXR) Regulates Arthritis Fibroblast-Like Synoviocyte NFκB Activity, IL-6 Production and Cell Invasion. Carl Petrus Linge[2], Teresina Laragione[3] and Percio S. Gulko[1]. [1]Feinstein Institutue Med Rsch, Manhasset, NY, [2]The Feinstein Institute for Medical Research, Manhasset, NY, [3]The Feinstein Institute for Medical Research

Background: Fibroblast-like synoviocytes (FLS) produce several pro-inflammatory cytokines, chemokines, and proteases that mediate the development of synovial hyperplasia, inflammatory infiltration, and pannus invasion and destruction of cartilage and bone in rheumatoid arthritis (RA). We have recently determined that the expression and transcriptional activity of the anti-inflammatory nuclear receptor LXRα is down-regulated in the synovial tissues of arthritis-susceptible and erosive DA rats, compared with resistant strains. Furthermore, two recent studies demonstrated that LXR agonists ameliorate rodent models of RA and reduce cytokine levels and joint erosions. Those observations led us to hypothesize that a state of deficient LXRα activity in the arthritic FLS could favor the increased production of pro-inflammatory cytokines such as IL-6 as well as the increased FLS invasive and destructive properties. We tested this hypothesis using an LXR agonist to modulate these cellular functions in FLS from DA rats and RA.

Methods: FLS were isolated from synovial tissues obtained from DA rats 21 days after the induction of pristane-induced arthritis (PIA), and from RA patients. Cells were passaged at least three times before use. The effect of the LXR agonist T0901317 (10 μM) was determined in a) IL-1β-induced (10 ng/ml) IL-6 production (ELISA) using FLS culture supernantants; b) IL-1β-induced NFκB activation using DA FLS transfected with a NFκB luciferase reporter construct; c) FLS invasion using a well-established in vitro model through Matrigel-coated chambers; d) actin cytoskeleton distribution (phalloidin staining), lamellipodia formation and phospho-FAK expression and localization.

Results: T0901317 significantly increased LXR activity as evidenced by a 42-fold up-regulation of SCD1 expression, a known LXR target gene. T0901317 reduced the IL-1β-induced IL-6 production in DA FLS (n=7) by 61% (P≤0.001, Mann-Whitney test). The reduction in IL-6 production also correlated with a significant reduction in the NFκB reporter activity. T0901317 nearly completely blocked DA FLS invasion, reducing it by 99% (P≤0.001, n=8). A nearly identical major effect was observed in RA FLS where a 96% inhibition of invasion was detected (P≤0.001, n=7), compared with control vehicle. The reduced invasion caused by T0901317 was associated with reduced levels of active MMP-2, reduced actin distribution and reduced polarized formation of lamellipodia (including reduced levels of phospho-FAK) both in DA and RA FLS.

Conclusion: This is the first time that LXR is implicated in the regulation of FLS production of IL-6 and FLS invasion. Our data show that this inhibitory effect is mediated, at least in part by NFκB, and suggest that LXR agonists have the potential to become useful therapies aimed at reducing both inflammation and FLS-mediated invasion and destruction in RA.

Cadherin-11 Engagement Increases Matrix Metalloproteinase Production by Rheumatoid Arthritis Fibroblast-Like Synoviocytes. Erika H. Noss, Sook-Kyung Chang and Michael B. Brenner. Brigham and Women's Hospital, Boston, MA

Background: Cadherin-11 is expressed on fibroblast-like synoviocytes (FLS) and mediates homophilic cell-to-cell adhesion by binding of cadherin-11 on one cell to cadherin-11 on an adjacent cell. Absence of cadherin-11 in mouse rheumatoid arthritis (RA) models led to a striking reduction of cartilage erosion independent of bone erosion, suggesting this molecule modulates the ability of FLS to degrade cartilage. Matrix metalloproteinases (MMPs) are a family of enzymes produced by FLS important in cartilage erosion. The aim of this study was to determine if FLS MMP production is regulated by cadherin-11, providing a possible mechanism to explain diminished cartilage erosion in the absence of cadherin-11 in RA models.

Methods: To test whether cadherin-11 engagement increases MMP production, human RA FLS were incubated with chimeric constructs containing human IgG1 Fc linked to the cadherin-11 extracellular domain (cad-11-Fc) in the presence or absence of tumor necrosis factor-a (TNF-a). MMP-1 and MMP-3 production were assessed by enzyme-linked immunosorbent assay (ELISA) and quantitative reverse transcription-polymerase chain reaction (qRT-PCR). Both mutagenesis to reduce cad-11-Fc binding affinity and lentiviral short-hairpin RNA infection to silence cadherin-11 were used to test the specificity of cad-11-Fc stimulation for surface cadherin-11. Immunoblotting with phospho-specific antibodies was used to determine signaling protein activation, and specific chemical inhibitors of these proteins were used to examine their role in cad-11-Fc MMP activation.

Results: Human cad-11-Fc upregulated protein production of MMP-1 and MMP-3 in RA FLS culture supernatants both alone and in synergy with TNF-a. MMP upregulation by cad-11-Fc was specific for engagement of cell cadherin-11, as a cad-11-Fc mutant construct lacking two tryptophan residues important for cadherin binding induced significantly less MMP production. Also, cadherin-11 silencing by lentiviral shRNA infection almost completely reduced the ability of cad-11-Fc to stimulate MMP expression compared to control-infected cells. Cad-11-Fc stimulation increased MMP transcription as measured by qRT-PCR. Since mitogen-activated protein kinase (MAPK) signaling pathways are important for induction of MMP synthesis, the ability of cad-11-Fc to activate these pathways was tested. Phosphorylation of the MAPKs jun N-terminal kinase (JNK) and extracellular signal-related kinase (ERK) was induced upon cad-11-Fc stimulation of RA FLS. Inhibitors of JNK and ERK phosphorylation partially blocked RA FLS MMP-3 expression by cad-11-Fc, providing evidence that these pathways help transduce the signal to upregulate MMP synthesis after surface cadherin-11 engagement.

Conclusions: Cadherin-11 binding by cad-11-Fc induced production of MMP-1 and MMP-3 by increasing MMP synthesis in RA FLS. Since MMPs are important mediators of cartilage degradation, these results point to a novel pathway by which cadherin-11 may influence joint destruction in RA.

Rheumatoid Synovial Fibroblasts Support Aid Expression and IG Class-Switching in B Cells Via a BAFF-Dependent TLR3-Stimulated Pathway. Michele Bombardieri[1], Yvone N. W. Kam[1], Fabia Brentano[1], Ken Choi[1], Diego Kyburz[3], Steffen Gay[3], Iain B. McInnes[2] and Costantino Pitzalis[1]. [1]Queen Mary University London, London, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom, [3]University of Zurich, Zurich, Switzerland

Background and Aims: Rheumatoid arthritis (RA) is characterized by the presence of synovial niches of autoreactive B cells which express activation-induced cytidine deaminase (AID), the enzyme initiating Ig class-switching (CSR), and sustain in situ autoantibody production. Importantly, B cell niches remain functional in the RA-SCID model in the absence of recirculating cells, suggesting that autocrine mechanisms support ongoing B cell activation in the RA synovium. Here we investigated whether RA synovial fibroblasts (RASF), which are known to contribute to RA synovitis, are capable of directly regulating B cell activation, AID expression and CSR. In addition, we dissected the molecular basis of stromal cell/B cell interactions with particular emphasis on the role of Toll-like receptors (TLRs) signaling and B cell survival/proliferating factors.

Methods: mRNA and protein expression of B cell survival factors BAFF and APRIL in RASF and OASF stimulated with TLR2, TLR3 and TLR4 ligands was assessed by Taqman PCR (QT-PCR) and ELISA, respectively. Un-switched IgD+ B cells were isolated from human tonsils using magnetic cell sorting. Isolated B cells were co-cultured via transwell or cell-cell contact with RASF/OASF for 24h and 72h in the presence or absence of TLR ligands and with or without blocking of soluble BAFF/APRIL. AID mRNA expression and IgM/A/G production were measured to assess functional activation of B cells. In addition, Iγ-Cμ and Iα-Cμ circular transcripts (CT, molecular by-products of ongoing CSR from IgM to IgG and IgM to IgA, respectively) were assessed by rt-PCR.

Results: In vitro stimulation of TLR3, and to a significantly lesser extent TLR4, but not TLR2 on RASF led to strong induction of BAFF (~1,000-fold increase with TLR3) and APRIL mRNA expression. In response to TLR3, BAFF was time-dependently released in the supernatant of RASF (~600pg/ml) and, to a lesser extent, OASF. TLR3 stimulation of RASF in co-culture with B cells strongly enhanced AID expression, ongoing CSR to IgG, but not IgA, as shown by detection of Iγ-Cμ CT and release of IgG. In contrast, TLR3 stimulation alone had no direct effect on B cells. Conversely, blockade of soluble BAFF/APRIL inhibited TLR3-induced RASF-dependent production of AID mRNA, Iγ-Cμ CT as well as the secretion of IgG.

Conclusions: Here we demonstrated that RASF are able to release high levels of B cell survival factors upon TLR3 stimulation at both mRNA and protein level. The release of these factors was functional, as demonstrated by the capacity of RASF to directly modulate AID expression, CSR and production of class-switched antibodies in co-cultured un-switched B cells. This effect was abrogated by blockade of soluble BAFF and APRIL. Overall, these data strongly support a fundamental role for TLR3-dependent release of BAFF and APRIL by RASF in sustaining functional B cell activation and antibody production in the RA synovium.

Characteristic Oral and Intestinal Microbiota in Rheumatoid Arthritis (RA): A Trigger for Autoimmunity? Jose U. Scher[7], Carles Ubeda[3], Michael H. Pillinger[2], Walter Bretz[6], Yvonne Buischi[6], Pamela B. Rosenthal[7], Soumya M. Reddy[7], Jonathan Samuels[4], Peter M. Izmirly[7], Rennie N. G. Howard[7], Gary Solomon[8], Yusuf Yazici[8], Mukundan Attur[8], Michele Equinda[3], Nicholas Socci[3], Agnes Viale[3], Eric Pamer[1], Dan R. Littman[9], Gerald Weissmann[5] and Steven B. Abramson[10]. [1]Lucille Castori Center for Microbes, Inflammation, and Cancer/MSKCC, [2]Manhattan VA Med Hospital, New York, NY, [3]Memorial Sloan-Kettering Cancer Center (MSKCC), [4]New York University Hospital for Joint Disease, New York, NY, [5]New York University Medical Center, New York, NY, [6]NYU College of Dentistry, [7]NYU Hospital for Joint Diseases, New York, NY, [8]NYU Hospital for Joint Diseases, [9]NYU School of Medicine, [10]NYU School of Medicine, NYU Hospital for Joint Diseases, New York, NY

Purpose: The etiology of RA remains unknown, but genetic and environmental factors have been implicated. An infectious trigger has been sought but conventional microbiologic techniques have been uninformative. The human intestine contains a dense, diverse and poorly characterized (≥80% uncultured) bacterial population whose collective genome (microbiome) is ≥100 times larger than its human host. We (DRL) have recently shown in mice that gut-residing bacteria drive autoimmune arthritis via Th17 cell activation (*Immunity* 2010). Multiple lines of investigation also suggest a link between RA and oral microbes.

Methods: As part of an NIH ARRA grant, the NYU Microbiome Center for Rheumatology and Autoimmunity was established to study gut and oral microbiota in RA and related conditions. A cross-sectional study and prospective proof-of-concept antibiotic intervention trial are ongoing. Fecal samples are collected, periodontal status assessed and oral samples obtained by subgingival biofilm collection. To date, oral/intestinal microbiomes have been analyzed in 8 RA patients, 3 psoriatic arthritis (PsA) patients and 9 healthy controls. Periodontal status was characterized in 30 RA, 4 PsA and 8 controls. DNA was purified and variable 16s rRNA gene regions amplified. PCR products were pyrosequenced (454 Life Sciences), and DNA sequences compared to the RDP and BLAST catalogs. rDNA-based phylogenetic trees were created, and the UNIFRAC metric used to compare bacterial communities across individuals. Sera from all subjects were evaluated for anti-citrullinated peptide antibodies (ACPA).

Results: Prevotellaceae family was significantly overrepresented in fecal microbiota from ACPA+ RA patients (range 13%-85%; mean=38%) vs ACPA- individuals (mean=4.3%); p=0.003. One ACPA+ healthy individual and 1 ACPA+ PsA patient shared similar microbiomes with ACPA+ RA. Subgingival microbiomes in patients with new-onset drug-naive RA exhibited overabundance of the Spirochetaceae/Prevotellaceae/Porphyromonaceae families (mean=53%) compared to chronic-active RA and healthy controls (mean=18.5%). Periodontal assessment revealed 78% of examined sites bled upon probing in RA patients (mean age 39; 73% female), significantly more than controls (38% PsA, 12% healthy; p<0.001 vs RA); 66% of RA patients also presented with moderate periodontitis compared to PsA (25%) and controls (12%).

Conclusions: This is the first study using high-throughput technologies to assess oral and intestinal microbiota in RA. Our data corroborate prior reports demonstrating an underappreciated high prevalence of periodontal disease at a young age in patients with RA. Moreover, our preliminary data suggest that ACPA generation may be associated with larger populations of Prevotellaceae in both oral and intestinal microbiomes. In response to such altered microbial flora, certain predisposed individuals may develop auto-inflammatory disease, through mechanisms that may include the generation of cyclic citrullinated peptides or Th17 cell activation in the intestinal mucosa. Thus, the oral and intestinal microbiota merit further investigation as potential triggers for autoimmunity and clinical RA.

Toll-Like Receptor 2 Activation Induces Angiogenesis, ICAM-1 Expression and EC Invasion in Rheumatoid Arthritis. Tajvur P. Saber[2], Sinead NicUltaigh[3], Jennifer McCormick[2], Douglas J. Veale[4], Mary Connolly[2] and Ursula Fearon[1]. [1]Dublin, Ireland, [2]Dublin Academic Medical Centre, Dublin, Ireland, [3]Dublin Academic Medical Centre, Dublin, Ireland, [4]St Vincents Univ Hospital, Dublin, Ireland

Background: Angiogenesis is a critical early event in inflammatory arthritis, facilitating leukocyte migration into the synovium resulting in invasion and destruction of articular cartilage and bone. This study investigates the effect of TLR2 on angiogenesis, EC adhesion and invasion using microvascular endothelial cells and RA whole tissue synovial explants *ex-vivo*.

Methods: Microvascular endothelial cells (HDEC) and RA synovial explants *ex vivo* were cultured with the TLR2 ligand, Pam3CSK4 (1μg/ml). HDEC tube formation was assessed using Matrigel matrix assays. Angiopoietin 2 (Ang2) was measured by ELISA. ICAM-1 cell surface expression was assessed by flow cytometry. Cell migration was assessed by wound repair scratch assays. ECM invasion, MMP-2 and 9 expression were assessed using transwell invasion chambers and zymography.

Results: Pam3CSK4 significantly increased angiogenenic tube formation (p<0.05). Pam3CSK4 significantly upregulated Ang2 production in HDEC (p<0.05) and RA synovial explants (p<0.05). Pam3CSK4 induced cell surface expression of ICAM-1, from basal level of 149 ± 54 (MFI) to 617±103 (p<0.01). TLR-2 activation induced an 8.8 ± 2.8 fold increase in cell invasion compared to control (p<0.05). Pam3CSK also induced cell migration and induced MMP-2 and -9 from RA synovial explants. Neutralisation of TLR2 with a blocking monoclonal antibody (OPN 301, 1μg/ml) inhibited Pam3CSK4-induced wound repair and EC tube formation.

Conclusion: Pam3CSK4 activation of TLR2 promotes angiogenesis, cell adhesion and invasion, key mechanisms involved in the pathogenesis of RA.

Radiological Progression in Patients with Early RA and a Good Clinical Response to MTX Monotherapy: Predictors and Clinical Implications. Hamed Rezaei[3], Ronald Van Vollenhoven[2], Kristina Forslind[1], Kristina Albertsson[3], Helena Wallin[3], Pierre Geborek[4], Sofia Ernestam[3], Ingemar Petersson[5] and Johan Bratt[3]. [1]Helsingborgs Hospital, [2]Karolinska University Hospital, Stockholm, Sweden, [3]Karolinska University Hospital, [4]Lund University Hospital, [5]Spenshult Hospital

Background: In patients with early RA, several randomized trials have demonstrated the superiority of methotrexate (MTX) + anti-TNF over MTX alone. However, these trials also showed that some patients did have excellent responses to MTX monotherapy. In the SWEFOT trial, all patients were given an initial 3–4 months trial period with MTX alone; patients achieving a low disease activity state with this treatment were not randomized in the controlled portion of the trial. We previously demonstrated that this was the case for appr. 30% of the patients. In a separate report (Wallin et al, abstract submitted) we showed that these patients had an excellent clinical course during the first two years, but that some radiological progression did nonetheless occur. Here, we investigated specific details of and predictors for radiological progression in this cohort.

Objective: To analyze in detail the radiological course in patients from the SWEFOT study who responded adequately to initial MTX monotherapy and who were not included in the randomized trial.

Methods: A total of 487 patients with early RA (symptom duration <1 year) were started on MTX at a rapidly escalating dosage up to at least 20 mg/week. After 3–4 months, the 147 patients who had a DAS28<3.2 were not randomized but continued on MTX and followed in "regular care", including 3-monthly assessments. These patients were analyzed here. Van der Heijde modified Sharp scores (SvdH) were done by two experienced readers. Scores at different times were compared by Wilcoxon paired test. Complete x-ray data were available for 114 patients.

Results: At baseline, the mean±SEM total SvdH score (median, IQR) was 3.8±0.7 (1, 0–5). After 1 year, it had increased to 6.0±0.8 (4, 0–8; p<0.0001 vs. baseline) and after 2 years to 7.9±0.9 (4, 0–8; p<0.0001 vs both BL and 1 year). Highly significant progression was seen for both erosion score and joint space narrowing score. The increase in total score after 2 years was 3.9±0.7 (2, 0–6). At baseline, 48.1% of patients had no x-ray damage (total score= 0); at 1 year 26.9%, and at 2 years 20.2%. An increase in total score ≥ 10, was seen in 15% of patients. RF positive patients had a trend towards greater progression than RF-negative ones: 4.78±0.91 (2, 0–7) vs. 1.90±0.78 (0, 0–5; p=0.067). For ACPA positive vs. negative, a smaller, non-significant difference was seen. Double-positive patients had the highest progression: 5.27±1.21 (2, 0–9). Single-positive RF had significantly higher progression than single-positive ACPA. Men had numerically more progression than women (5.00±1.05 (2, 0–9) vs 3.08±0.88 (1, 0–3; p=0.119).

Conclusions: Patients who responded to an initial 3–4 months trial of MTX monotherapy with a DAS28<3.2 showed statistically significant (but on average numerically modest) radiological progression during the first 2 years of disease. Progression was associated with RF- and double-positivity. About half of all patients had no damage at baseline but the majority of these did develop damage over 2 years.

An initial good clinical response to MTX does not preclude a less favorable radiological course.

Supported in part by the Swedish Rheumatism Association and Schering-Plough.

1393

In Early RA, Patients with a Good Initial Response to MTX Monotherapy Have Excellent Clinical Outcomes over Two Years of Therapy, but Radiological Progression Is Not Completely Prevented. Helena Wallin[4], Ronald Van Vollenhoven[2], Kristina Albertsson, Kristina Forslind, Sofia Ernestam, Ingemar F. Petersson[3], Pierre Geborek, Hamed Rezaei, Johan Bratt[1] and The SWEFOT Study Group, [1]Karolinska Univ Hosp Huddinge, Stockholm, Sweden, [2]Karolinska University Hospital, Stockholm, Sweden, [3]Lund University Hosp, Lund, Sweden, [4]The Karolinska Institute, Stockholm, Sweden

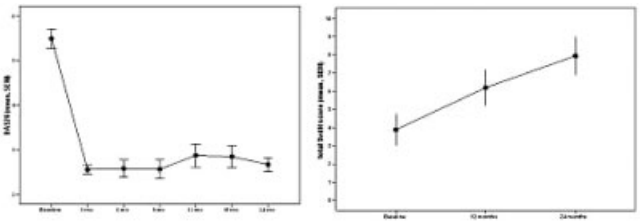
Background: In the SWEFOT trial, all patients were initially given MTX monotherapy for 3–4 months; patients achieving a DAS28≤3.2 were not randomized in the controlled portion of the trial. We previously demonstrated that this was the case for 30% of the patients, most of whom maintained remission during the first year. Here, we investigated the clinical and radiological results in these patients over two years of follow-up.

Objectives: To analyze the clinical and radiological course in patients from the SWEFOT study who responded adequately to initial MTX monotherapy and were not included in the randomized trial.

Methods: A total of 487 patients with early RA (symptom duration <1 year) were started on MTX at a rapidly escalating dosage up to at least 20 mg/week. After 3–4 months, the 147 patients who had a DAS28≤3.2 were not randomized but continued on MTX and were followed in "regular care", including 3-monthly assessments. These patients were analyzed here. Complete data at 24 months were available for 65% of patients.

Results: The majority of patients continued on MTX monotherapy. In 15 patients MTX was replaced by or complemented with another DMARD or a biologic. DAS28 values in all patients are shown in the figure, and demonstrate low values throughout. At the 6, 12, 18 and 24 months time-points, 61.1%, 61.0%, 64.2%, and 72.7% of patients, respectively, were in DAS28 remission, and 82.1 – 87.6% had a low disease activity state.

The mean (SEM) progression in total Sharp-vdHeijde score at 24 months was 3.90 (0.68). For the subset of patients who had been in sustained remission at each time point from 3 to 24 months (n=18) the progression was 4.06 (1.85). Progression in patients on MTX monotherapy throughout follow-up was 3.97 (0.85).



Conclusion: Patients who respond to an initial 3–4 month trial of MTX monotherapy with a DAS28≤3.2 continue to have very good clinical responses for two years, and additional treatment is needed infrequently. However, radiographic progression does occur and is seen even in those patients who have sustained remission and/or stay on MTX monotherapy. An initial good response to MTX appears to portend a good clinical prognosis but close monitoring of radiological disease is warranted.

Genetic Polymorphisms in Key Methotrexate (MTX) Pathway Genes Associated with Response to MTX Treatment in Rheumatoid Arthritis. Sally-Anne Owen[2], Stephen Eyre[2], Paul Martin[2], Samantha Hider[1], Ian N. Bruce[2], Anne Barton[2] and Wendy Thomson[2]. [1]ARC National Primary Care Centre, Keele University, Staffordshire, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom

Background: Methotrexate (MTX) is the cornerstone of treatment for rheumatoid arthritis (RA). However, up to a third of individuals will fail to respond to MTX treatment or suffer adverse events (AE). The main determinates of MTX response in RA remain unclear although evidence suggests that part of this variability is genetic. Genes within the MTX metabolic pathway represent good candidates as predictors of response. We investigated SNPs spanning 11 MTX pathway genes on the efficacy and occurrence of AE in MTX treated patients with RA.

Methods: Subjects included 309 RA patients with a defined response to MTX. Patients were included if they were (i) good responders (n=147) (with an ESR <20 and/or normal CRP and on a stable dose of MTX for at least 6mths) (ii) inefficacy failures (n=101) (physician statement and failure to reduce ESR/CRP by 20%) or (iii) AE failures (n=61) (verified by medical record review). Tagging SNPs were selected for genes: *AMPD1, ATIC, DHFR, FPGS, GGH, ITPA, MTHFD1, MTHFR, SHMT1, SLC19A1* (RFC) and *TYMS* using an r^2 cutoff ≥ 0.8 and MAF ≥ 0.05 within 10kb up and down stream of each gene. Genotyping was performed using the Sequenom iPlex® MassARRAY platform. Three different analyses were conducted: 1) responders vs inefficacy failures 2) responders vs AE failures and 3) responders vs inefficacy and AE failures combined. Genotype frequencies were compared between the groups using the trend test implemented in PLINK and allelic odds ratios with 95 % confidence intervals (CI) calculated in STATA 9.2.

Results: Of the 150 SNPs tested, 9 were found to be significantly associated (p-trend ≤ 0.05) with MTX response and 2 with MTX related AE. Interestingly 3 of these (rs12995526, rs7563206 and rs16853834) were found in the 5-aminoimidazole-4-carcoxamide ribonucleotide transformylase (*ATIC*) gene which encodes an enzyme that is important in the de novo purine synthesis pathway. Individuals carrying these SNPs had an increased risk of poor response to MTX (OR 1.48, 95%CI (1.01–2.17), OR 1.47, 95%CI (1.00–2.17) and OR 1.47 95% CI (1.01–2.76) respectively). Other associations included 6 SNPs in the *SLC19A1* gene (rs11702425, rs2838956, rs7499, rs2274808, rs9977268, rs7279445) all conferring an increased risk of poor response to MTX and two SNPs in the *DHFR* gene (rs12517451, rs10072026) were associated with AE. In addition there were a further 2 SNPs in the *FPGS* gene associated with AE under a recessive model (rs1054774, rs4451422) and 1 additional SNP in the *ATIC* gene approaching statistical significance (rs4673990) (p-trend<0.1) warranting further investigation.

Conclusion: Genetic variations in a number of key MTX pathway genes have been found to be significantly associated with MTX response and AE in RA patients. Further studies will be required to validate these findings. If confirmed these results could contribute towards a better understanding of and ability to predict MTX response in RA.

Observational Study To Evaluate the Relationship of Methotrexate to Interstitial Lung Disease in Rheumatoid Arthritis. Liron Caplan[7], Anne E. Hines[15], Jay R. McDonald[10], Angelique L. Zeringue[10], Alyse Mann[6], Paul H. Sufka[13], Kevin G. Osgood[2], Ted R. Mikuls[14], Jasvinder Singh[3], Itziar Quinzanos[5], Lela Mansoori[11], Chrysoula Pappa[12], Leah M. Haverhals[6], Andre Barkhuizen[8], Douglas Phelps[1], Roderick S. Hooker[4], Hong Xian[10], Prabha Ranganathan[9], Fran Cunningham[17] and Seth Eisen[16]. [1]Albancy VAMC, [2]Austin Diagnostic Clinic, Austin, TX, [3]Birmingham VAMC, Minneapolis, MN, [4]Dallas VAMC, Dallas, TX, [5]Denver Health, [6]Denver VAMC, [7]Denver VAMC, Aurora, CO, [8]Portland Rheum Clinic LLC, Lake Oswego, OR, [9]St. Louis VAMC, St. Louis, MO, [10]St. Louis VAMC, [11]Univ of Colorado, [12]Univ of Florida Jacksonville, Saint Augustine, FL, [13]Univ of Minneapolis, Minneapolis, MN, [14]Univ of Nebraska Med Ctr, Omaha, NE, [15]University of Colorado, [16]VA HSR&D, [17]VA PBM

Purpose: The relationship of methotrexate (MTX) to interstitial lung disease (ILD) remains controversial, with some studies supporting an association, while others dispute this association. We sought to identify risk factors for incident ILD in a population of veterans with rheumatoid arthritis (RA), with special attention on the disease modifying anti-rheumatic drug (DMARD) methotrexate (MTX).

Methods: We used a retrospective case-control study design where controls consist of subjects with RA and cases consist of subjects with both RA and ILD. We identified subjects based on ICD-9-CM diagnostic codes and prior DMARD or glucocorticoid treatment (n=442). Validation of ICD-9-CM codes for ILD relied upon medical records, as well as radiographic and pulmonary function results. All demographics, putative risk factors, and pharmaceutical data were abstracted using a detailed review of the medical record and defined abstraction algorithms. We performed unconditional multivariate logistic regression, controlling for multiple RA and ILD risk factors. Methotrexate was forced into the final model as the variable of

interest. All analyses were performed using Stata software version 10.2. Confidence intervals were established at 95%.

Results: In the multivariate regression adjusting for all covariates, patients with ILD were no more likely to have been exposed to MTX than patients without MTX exposure. Conversely, rheumatoid factor, C reactive protein and history of emphysema were all associated with presence of ILD (see table).

Conclusions: Though markers of RA disease severity and activity are associated with ILD in patients with RA, MTX exposure does not demonstrate this relationship in our observational study. There is a strong relationship between prior emphysema and subsequent ILD in RA patients.

Table 1. Factors associated with the odds of interstitial lung disease in rheumatoid arthritis patients

Induction Therapy with Methotrexate and Prednisone in Rheumatoid or Very Early Arthritic Disease: IMPROVED Study. K. V. C. de Boer[5], K. Visser[6], H. K. Ronday[4], A. A. Schouffoer[3], J. H. L. M. Groenendael[2], A. J. Peeters[9], I. Speyer[1], G. Collée[7], P. B. J. Sonnaville[8], B. A. M. Grillet[10], T. W. J. Huizinga[6] and C. F. Allaart[5]. [1]Bronovo Hospital, The Hague, [2]Franciscus Hospital, Roosendaal, [3]Groene Hart Hospital, Gouda, [4]Haga Hospital, The Hague, [5]LUMC, Leiden, The Netherlands, [6]LUMC, Leiden, [7]MCH, the Hague, [8]Oosterschelde Hospital, Goes, [9]Reinier de Graaf Gasthuis, Delft, [10]Zorgsaam, Terneuzen

Aim: To assess the rate of remission after 4 months of treatment with methotrexate (MTX) and a tapered high dose prednisone in patients with recent onset rheumatoid or undifferentiated arthritis (RA and UA), in relation to clinical and demographic baseline criteria.

Methods: IMPROVED is a multicenter single blind clinical study in patients with recent onset RA and UA, with an open label induction phase with MTX 25 mg/wk and prednisone 60 mg/day tapered to 7.5 mg/day in 7 weeks, aimed at achieving DAS < 1.6, which will be followed by tapering to drug free if remission persists, or randomization to multi-DMARD or MTX + adalimumab if DAS ≥ 1.6 after 4 months. To date, 161 patients with UA (arthritis > 1 joint, at risk for developing RA by estimation of a rheumatologist) and 261 patients with recent onset RA (ACR 1987 criteria, symptom duration $<$ two years) were included. Clinical outcomes (% remission DAS <1.6) and functional ability measured with the Dutch Health Assessment Questionnaire (HAQ) after 4 months of treatment were compared between RA and UA patients. Independent predictors at baseline for achieving remission after 4 months were established by univariable followed by multivariable regression analysis.

Results: At baseline, UA patients were younger, less often RF positive and had lower DAS, HAQ and ESR values, than RA patients (table 1). After four months of treatment, clinical remission was achieved in 107/161 UA patients (66.5%) and in 153/261 RA (58.6%) ($P = 0.12$). Improvement in mean DAS was 1.32 (0.95) in the UA patients and 1.90 (1.05) in the RA patients ($P < 0.001$), improvement in mean HAQ was 0.57 (0.65) and 0.81 (0.65), respectively ($P < 0.001$) (table 1). Low baseline DAS was predictive for achieving remission after 4 months in both UA and RA (OR 0.36, 95% CI 0.18–0.67). In UA patients, but not in RA patients, other predictors for achieving clinical remission were male sex (OR 2.76, 95% CI 1.13–6.73) and ACPA-positivity (OR 2.83, 95% CI 1.07–7.51)

Conclusion: After 4 months of treatment with MTX and a tapered high dose of prednisone in patients with recent onset RA or UA, clinical remission (DAS < 1.6) was achieved in 63% of all patients, with similar outcomes for mean DAS and HAQ. Only in UA patients, ACPA positivity is an independent predictor for achieving remission. This suggests that ACPA negative UA patients, who did not benefit from treatment with MTX monotherapy in the PROMPT study, also benefit less from prednisone. ACPA negative UA may be a different disease that requires different therapy than ACPA positive UA.

Table 1. Baseline characteristics, and clinical outcomes after 4 months of treatment of patients with UA or recent onset RA.

Baseline	UA N = 161	RA N = 261	P-value
Age, years (mean, SD)	**48.3 (13.3)**	**53.5 (14.2)**	**<0.001**
% Female	64.6	66.3	0.72
Symptom duration, months (median, IQR)	4.0 (2.0–7.0)	4.0 (2.0–7.0)	0.57
% RF positive	33.1	61.1	<0.001
% ACPA positive	48.4	59.7	0.47
ESR mm/hr (median, IQR)	17.0 (8.0–30.0)	29.0 (13.0–42.5)	<0.001
CRP mg/l (median, IQR)	7.0 (3.0–19.0)	12.5 (6.0–34.0)	<0.001
DAS (mean, SD)	2.74 (0.74)	3.44 (0.91)	<0.001
HAQ (mean, SD)	0.96 (0.62)	1.24 (0.64)	<0.001
Follow up (4 months)			
DAS (mean, SD)	1.43 (0.90)	1.54 (0.88)	0.57
HAQ (mean, SD)	0.40 (0.49)	0.43 (0.52)	0.13
Improvement DAS (mean, SD)	1.32 (0.95)	1.90 (1.05)	<0.001
Improvement HAQ (mean, SD)	0.57 (0.65)	0.81 (0.65)	<0.001
% Remission	66.5	58.6	0.12

The Role of Low-Dose Oral Prednisone Treatment in Early Rheumatoid Arthritis: Effects on Clinical and Ultrasonographic Remission and Functional Outcome. Garifallia Sakellariou[1], Monica Todoerti[2], Carlo A. Scirè[2], Serena Bugatti[2], Carlomaurizio Montecucco[2] and Roberto Caporali[2]. [1]Chair and Division of Rheumatology, Università degli Studi di Pavia, Fondazione IRCCS Policlinico San Matteo, Pavia, Lombardia, Italy, [2]Chair and Division of Rheumatology, Università degli Studi di Pavia, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: Glucocorticoids are widely used in treating patients with rheumatoid arthritis (RA), providing rapid clinical improvement, reduction of radiographic progression and higher rates of clinical remission. Nevertheless, there is evidence of persistent subclinical synovitis even in clinical remission, and ultrasonography (US) is considered a sensitive tool to detect it. In this study we investigated the effect of low-dose oral prednisone co-medication on the occurrence of clinical and US remission, and the impact of these statuses on the development of future disability in a cohort of patients with early RA.

Methods: 210 patients with early RA (symptom duration$<$1 year) were assigned to receive (P) or not (no-P) low-dose oral prednisone in association with a DAS-driven DMARD therapeutic protocol. Patients started with a dosage of 12.5 mg/day of prednisone, tapered to 6.25 mg/day after two weeks. Disease Activity Score 28 (DAS28) was assessed at the beginning of the study and after 12 months. A DAS28$<$2.6 identified patients in clinical remission. The US assessment of patients included 12 joints (MCPs and wrists). A single operator unaware of the clinical findings carried out all scans

with a GE Logiq 9 scanner, using a multi-frequency linear array transducer (8–15MHz), under standardized settings. Grey-scale (GS) and power Doppler (PD) synovitis were subjectively scored (0 to 3) for each joint. US remission was defined as absence of intra-articular PD signal (PD grade 0). Health Assessment Questionnaire (HAQ) was completed at the beginning of the study, at 12 and 24 months; disability (mild) was defined as a value of HAQ>0.5. Patients with complete data both on clinical and US variables were included in the analyses.

Results: Out of 210 patients, 105 were on prednisone plus DMARDs (P) and 105 on DMARDs alone (no-P). Age, disease duration, DAS28, HAQ, ESR, CRP, US findings did not differ between P and no-P at baseline. At 12 months, 44% of P patients, and only 28% of no-P patients were in DAS28 remission (p=0.018). US remission occurred in 71.2% of P patients, and in only 55.4% of no-P patients (p=0.041). At 24 months, the odds ratio of progression to disability in patients who were in DAS 28 remission, compared to those with active disease, was 0.18 (95% confidence interval, CI, 0.063–0.55, p=0.001). In this subgroup, patients who were also in PD remission carried the lowest risk of development of disability (OR 0.16, 95% CI 0.01–0.62, p=0.008).

Conclusions: low-dose oral prednisone co-medication gave an advantage over DMARD monotherapy in terms of higher rates of clinical and US remission. Patients in clinical and US remission showed the lowest rate of progression to disability at two years. These findings suggest a more complete suppression of joint inflammation in patients with early RA receiving glucocorticoids, resulting in a positive influence on functional outcome.

Repeat Kidney Biopsies Fail To Detect Differences between Azathioprine and Mycophenolate Mofetil Maintenance Therapy for Lupus Nephritis: Data from the MAINTAIN Nephritis Trial. Maria Stoenoiu[1], Selda Aydin[1], Carlos Vasconcelos[4], Maria Tektonidou[5], Isabelle Ravelingien[6], Véronique le Guern[2], Geneviève Depresseux[1], Ricard Cervera[3], Jean-Pierre Cosyns[1] and Frédéric A. Houssiau[1], [1]Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Bruxelles, Belgium, [2]Hôpital Cochin, Paris, France, [3]Hospital Clinic, Barcelona, Spain, [4]Hospital Santo Antonio, Porto, Portugal, [5]National University of Athens, Athens, Greece, [6]O.L. Vrouwziekenhuis, Aalst, Belgium

Introduction: In the MAINTAIN Nephritis Trial, an investigator led randomized study, azathioprine (AZA) and mycophenolate mofetil (MMF) were compared as maintenance immunosuppressive treatment of proliferative lupus nephritis (LN) after a short course of low-dose (6 × 500 mg q2w; Euro-Lupus) intravenous cyclophosphamide. Although more renal flares were observed in AZA (25%) compared to MMF patients (19%), time to renal flare by Kaplan-Meier analysis did not statistically differ. Per protocol repeat kidney biopsies were available in 26 patients. Here we compare the pathological findings between the two groups.

Methods: 105 lupus patients with biopsy-proven proliferative nephritis were included in the MAINTAIN Nephritis Trial. Per protocol repeat renal biopsies were performed between month 18 and 30 in 26 patients (all females; 15 AZA and 11 MMF). All 26 patients had been treated exactly according to the protocol, i. e. had stayed on the same immunosuppressant and had tapered the steroids as requested. Biopsies were classified according to the ISN/RPS classification. The activity index (AI, max 42) and the chronicity index (CI, max 6) were calculated using the semi-quantitative scoring system of Morel-Maroger. Statistics were by non-parametric tests.

Results: Baseline and follow-up renal parameters of AZA and MMF patients did not differ. Time (SD) to repeat renal biopsy was 24.7 (1.7) and 25.1 (2.1) months in AZA and MMF patients, respectively. In both groups, the activity index dramatically and statistically decreased at follow up compared to baseline, while the chronicity index slightly but statistically increased. No between groups differences could be detected. In a second analysis, we added 4 patients for whom a repeat renal biopsy was also available, within the same time frame, but who had been switched to another immunosuppressant due to a renal flare which had occurred before the second biopsy. Baseline and follow up AI and CI on these 30 (26+4) paired renal biopsies were exactly comparable to the data obtained on the 26 patients.

Conclusion: No differences were observed on repeat kidney biopsies between patients treated with AZA or MMF.

C4d on Circulating Cells and Renal Tissues in Lupus Nephritis as Novel Biomarkers. Kelly V. Liang[4], Ibrahim Batal[2], Sheldon Bastacky[4], Lawrence Kiss, Theresa McHale, Nicole Wilson, Barbara Paul, Apinya Lertratanakul, Joseph M. Ahearn[1], Susan Manzi[5] and Amy H. Kao[3]. [1]Wexford, PA, [2]Pittsburgh, PA, [3]Allegheny Singer Research Institute, Pittsburgh, PA, [4]University of Pittsburgh, Pittsburgh, PA, [5]West Penn Allegheny Health System, Pittsburgh, PA

Background: Immune complex deposition and complement activation via the classical pathway play a key role in the pathogenesis of lupus nephritis (LN), a severe manifestation of systemic lupus erythematosus (SLE). Traditional serologic tests such as anti-double stranded DNA titers and serum complement levels (C3 and C4) are inconsistent predictors of renal pathology in LN. The complement activation product C4d bound to circulating erythrocytes (E-C4d), reticulocytes (R-C4d) and platelets (P-C4d) has been shown to reflect disease activity in SLE but has not been systematically studied in LN. The aims of this study were to: 1) compare C4d deposition on circulating cells and in renal tissues between LN subjects and two control groups (non-SLE renal disease and SLE subjects without LN), and 2) determine the association of C4d deposition with LN disease activity.

Methods: We prospectively evaluated C4d on circulating cells in 15 LN subjects and two control groups: 13 non-SLE renal subjects (control A) and 239 SLE subjects without LN (control B). Circulating cell-bound C4d levels were measured by flow cytometry. C4d deposition in different anatomic renal compartments was semiquantitatively assessed in LN and control A using immunoperoxidase staining performed on formalin-fixed, paraffin-embedded renal tissue.

Results: LN renal tissues had higher glomerular C4d scores than those of control A (p=0.003). Glomerular C4d stain was detected in the majority (12/13, 92%) of LN samples and was associated with more frequent granular glomerular immunofluorescence staining and electron-dense, immune complex deposits (p<0.001). C4d score in other anatomic compartments showed no differences. Compared to controls A and B, LN subjects had higher levels of E-C4d (p=0.002 and p=0.005) and R-C4d (p=0.002 and p=0.008), respectively. LN subjects were also more likely to have positive P-C4d compared to control A (p=0.016) but not control B. In LN samples, E-C4d, but neither serum complement (C3, C4) nor renal tissue C4d, correlated with NIH activity index (r=0.55, p=0.04).

Conclusions: Glomerular C4d staining was associated with immune complex deposits in LN biopsies. LN subjects also had higher levels of E-C4d and R-C4d when compared to non-SLE renal subjects and non-LN SLE subjects. E-C4d levels correlated significantly with the NIH activity index. Larger prospective studies are needed to validate our findings and further investigate the role of C4d on circulating cells and renal biopsy tissues as biomarkers for LN.

Are the Current Thresholds for SLE Proteinuric Flare Set Too High? Determining the 99% Confidence Intervals for Spontaneous Variation in Urine Protein/Creatinine Ration in SLE GN Patients Who Are Clinically Stable (Not Flaring). Stacy P. Ardoin[1], Dan J. Birmingham[2], Brad H. Rovin[2], P. Hebert[3], C.-Y. Yu[2] and Lee A. Hebert[2]. [1]Ohio State University, Columbus, OH, [2]Ohio State University, [3]University of Washington

Statement of Purpose: Proteinuria is the most common manifestation of a moderate or severe flare of SLE glomerulonephritis (GN). However, there is no general consensus on the threshold for proteinuric flare and the proposed criteria are based largely on expert opinion. The criteria that have been proposed can be categorized as having low, medium or high thresholds, depending upon the minimum increase in proteinuria deemed necessary to constitute a proteinuric flare. This study provides an evidence-based approach to validate the magnitude of proteinuria increase that should constitute a proteinuric flare.

Methods: This work involved analysis of data collected as part of the Ohio SLE Study (OSS), a prospective observational study of 106 SLE patients with recurrently active disease, 72 of whom had moderate or severe renal disease. Patients were managed by pre-specified protocols. Median follow up was > 46 months with over 2400 visits. >90% of visits occurred bimonthly, within pre-specified windows of ± 1 week. The renal OSS patients provided 24 hour urine collections at 84% of OSS visits and random spot urine collections at remaining visits. At each visit it was determined, using pre-specified criteria (JASN 16: 467–473, 2005), whether a renal or non-renal SLE flare had occurred at the previous OSS visit.

To assess spontaneous variation in protein/creatinine (P/C) ratio in patients with SLE under no-flare conditions, P/C ratios measured within 4 months of a renal flare were excluded. "P/C ratio datasets" were developed and required a minimum of 3 bimonthly consecutive urine collections spanning 4 months. At least 50% of the P/C ratios were required to be measured by 24 hour urine collection. The P/C ratio datasets were stratified into groups according to the mean P/C ratio of the dataset: group 1 (mean P/C ratio <0.15), group 2 (mean P/C ratio ≥0.15 to ≤0.38), group 3 (mean P/C ratio >0.38 to ≤0.77), group 4 (mean P/C ratio >0.77 to ≤1.54), group 5 (mean P/C ratio >1.54). For each group, 99% confidence intervals were developed.

Summary: Of 1168 urine collections in the OSS study, 895 met the above criteria. These were provided by 58 of the 72 SLE GN patients (mean age 34 ± 11 years, 91% female, 38% African American, 58% European American, 4% Other). Mean P/C ratio was 1.5 ± 2.4. 91% were taking prednisone and 88% an immunosuppressant. Confidence intervals (CI) for each group are displayed in Figure 1.

Conclusions: Most of the current thresholds for SLE GN proteinuric flare are set well above the 99% CI for spontaneous variation in P/C ratios under no-flare conditions. This suggests that SLE GN patients by be exposed to unnecessarily prolonged periods of increasing proteinuria before flare is declared and treated. This work is hypothesis generating and needs to be confirmed in a prospective randomized trial to determine whether lowering proteinuric flare threshold would benefit SLE patients.

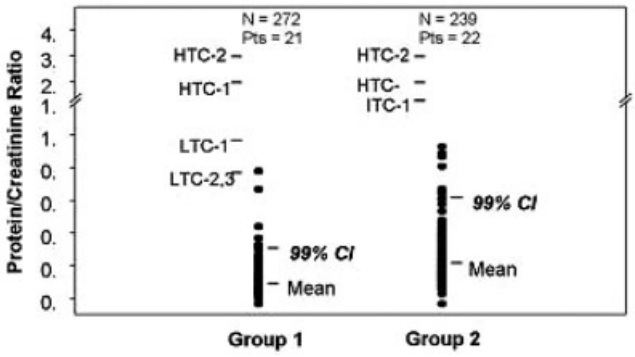

Figure 1.

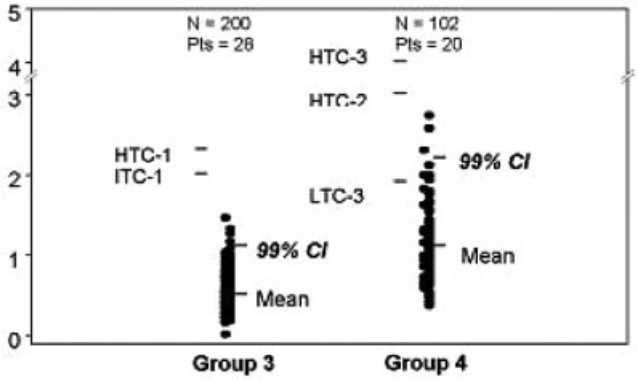

Figure 2.

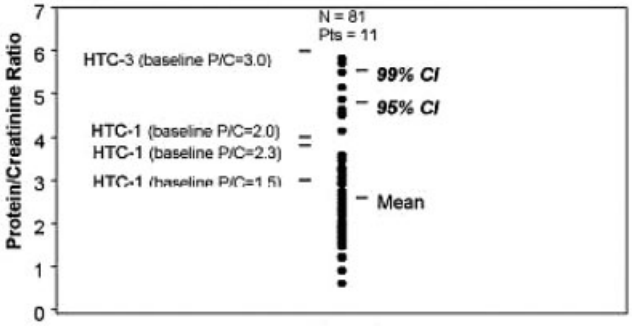

Figure 3.

Figures 1–3. Individial urine protein/creatinine (P/C) ratios measured under non-flare conditions for P/C ratio groups 1 to 5. These ratios are shown in relation to the currently published low (LCT), intermediate (ICT), and high threshold (HTC) criteria for proteinuria flare. The 99% CI for the given P/C ratio group is provided.

Systematic Review and Meta-Analysis of Immunosuppressant Therapy Clinical Trials in Membranous Lupus Nephritis. Vikas Majithia[2], Josh T. Swan[1] and Daniel Riche[3]. [1]Methodist Hospital, Houston, [2]University of Mississippi Medical Center, Jackson, MS, [3]University of Mississippi Medical Center

Background: There is no current consensus on a standard treatment for patients with class V membranous lupus nephritis. Clinical trial data are typically inconsistent in design, small in number of patients, and lacking in control groups.

Objective: The primary objective was to compare remission rates for immunosuppressant therapy to steroid therapy through meta-analysis of currently available data.

Methods: A literature review was conducted from June 2010 by querying PubMed, MEDLINE, and EMBASE databases. Inclusion criteria were trials containing remission data for confirmed pure class V (Va & Vb) membranous lupus nephritis patients. The primary analysis evaluates any immunosuppressant treatment, while subgroup analyses isolate adult patients, azathioprine (AZA), cyclosporine A (CSA), cyclophosphamide (CYP), mycophenolate mofetil (MMF), and steroids only therapies. A proportion meta-analysis using a DerSimonian-Laird random-effects model was performed. Data are reported as pooled proportions in percentages with 95% confidence intervals [CI]. Significant heterogeneity and publication bias was compensated for by trial exclusion.

Results: Of 396 trials in initial search, 92 trials were reviewed for full text analysis. Twenty-three studies met inclusion criteria for meta-analysis, which yielded 34 groups of patient data. Upon meta-analysis, the response rate (complete and partial remission) for immunosuppressant pharmacotherapy is much higher than for steroids alone (81% versus 60%) {shown in figure 1}, even when compensating for significant heterogeneity and publication bias (76% versus 60%). Any response rate is similar amongst azathioprine (88% [95% CI 81–94%]), cyclophosphamide (75% [95% CI 60–88%]), mycophenolate mofetil (81% [95% CI 67–92%]), and cyclosporine A (84% [95% CI 67–96%]). Patients were twice as likely to have no response to steroids alone vs immunosuppressant therapy (39% versus 19%).

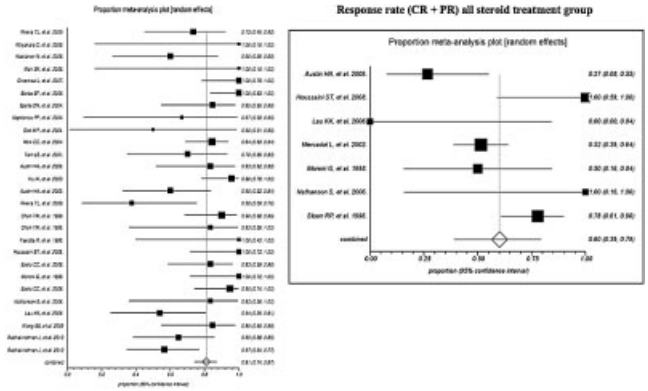

Figure 1. Response rate (CR + PR) for all immunosuppressant therapy.

Discussion: There is a wide range of variation between immunosuppressant studies including: study design (retrospective versus prospective), patient-selection, racial variation, and lack of standard steroid regimens. With all these factors in mind, this pooled analysis was extremely challenging, but important. Our results indicate that treatment with an immunosuppressive agent (e.g., CYP, MMF, AZA, and CSA) should be strongly considered in MLN patients. Subgroup analyses demonstrate a much better response with AZA, CSA, CYP, or MMF when compared to the steroid alone group. The results of this analysis are corroborated by the recently published randomized controlled trials of MLN patients.

Conclusion: Overall, conventional immunosuppressant therapies appears to be more effective than steroids alone for inducing partial or complete remission in patients with MLN and should be considered in treatment of nephritis in lupus MLN patients.

Treatment of Lupus Nephritis with Enteric-Coated Mycophenolate Sodium (EC-MPS)—MyLupus Exploratory Study. Andrea Doria. For the MyLupus Study Group, Padova, Italy

The MyLupus study was designed to compare the non-inferior efficacy and safety of EC-MPS using two different oral prednisolone regimens (standard SD or reduced dose RD) for the induction of remission of a lupus nephritis (LN) flare.

Methods: A 24-week (W) exploratory, multi-center, open-label study was conducted in patients with a LN flare (ISN/RPS Class III or IV documented by renal biopsy within 24 months of study entry). All patients received EC-MPS 1440 mg/day for the first 2W, followed by 2160 mg/day for the remaining 22W, and methylprednisolone iv. (0.5 g/day) for the first 3 days. Patients were randomized to either SD or RD (starting dose of 1.0 mg/kg/day and 0.5 mg/kg/day for 2W, respectively, followed by pre-specified dose reduction). Primary end-point was the proportion of patients with complete response (urine protein/creatinine [P/C] ratio <0.5, urine sediment normalized, and serum creatinine $<10\%$ normal value) of LN after 24W. Partial response was defined as urine P/C ratio reduced by at least 50% from baseline and serum creatinine stable ($<10\%$ of baseline value) or improved.

Results: 81 patients were enrolled, 42 in SD and 39 in RD group. Baseline characteristics were comparable between groups. After 24 W, a similar proportion of patients achieved complete response in both groups (19% SD vs. 18% RD), although non-inferiority was not demonstrated. A higher proportion of patients achieved partial response in SD (48% SD vs. 33% RD). Index scores decreased in both groups from 4 to 24W (British Isles Lupus Assessment Group [BILAG] index: mean change from baseline -8.6 SD vs. -9.4 RD, Systemic Lupus Erythematosus Disease Activity Index [SLEDAI]: -10.4 SD vs. -9.4 RD). There was greater improvement in glomerular filtration rate (mL/min/1.73m^2) in RD (mean change from baseline 9.0 SD vs. 15.2 RD). There were 2 deaths, both in SD group. The incidence of serious adverse events was 16.7% (SD) vs. 10.3% (RD).

Conclusions: This exploratory study suggests that EC-MPS in combination with steroids is a viable therapy for LN. The overall clinical results indicate that RD of CS may offer benefits in terms of tolerability compared to SD of CS while maintaining efficacy.

Machine Learning Models Using Multiple Low Abundance Protein Biomarker Levels Are Superior to Those Using Clinical Laboratory Values in Diagnosing ISN/RPS Class of Lupus Nephritis. Jim C. Oates[2], Michelle A. Petri[1], Jonas S. Almeida[4], Thomas W. Fleury[3], Janech G. Michael[3] and John M. Arthur[3]. [1]Timonium, MD, [2]Medical University of South Carolina, Charleston, SC, [3]Medical University of South Carolina, [4]The University of Texas M. D. Anderson Cancer Center

Objectives: Treatment in lupus nephritis (LN) is often driven by renal biopsy findings, and traditional biomarkers are not predictive of renal pathology. We hypothesized that levels of multiple candidate low abundance urine proteins, when analyzed my multivariable machine learning techniques, would create more effective models of International Society of Nephrology/Renal Pathology Society class of nephritis (ISN/RPS Class) than traditional biomarkers now available to clinicians.

Methods: Subjects from the Charleston and Baltimore LN inception cohorts and the Rituxan in LN (LUNAR) study population were recruited. ISN/RPS Class was determined prior to induction therapy. Urine samples were collected at entry for analysis. Urine levels of 12 candidate low abundance proteins (chemokines, growth factors, cytokines, and renal damage markers) were determined by the multiplex bead array, ELISA or activity assay for all patients. Levels of individual markers were used to create multivariable models of LN Class at baseline. Diagnostic models were trained using machine learning (artificial neural network (ANN) and nearest related neighbor (NRN) algorithms). The diagnostic power of models was reported as the receiver operating characteristics curve area under the curve (ROC AUC), with AUC values for perfect and non-diagnostic tests being 1 and 0.5 respectively. Input variables were traditional biomarkers (anti-double stranded DNA antibodies (DNA), C3, C4, serum Cr) and/or the selected biomarker panel. The output variables were the individual biopsy classes.

Input variables	Number of subjects	Outcome (ISN/RPS Class)	NRN ROC AUC	ANN ROC AUC
Novel biomarkers	99	II	0.91	0.95
		III	0.82	0.68
		IV	75	0.92
		Proliferative	0.84	0.94
		V	0.59	0.94
Traditional Biomarkers	66	II	0.82	0.97
		III	0.64	0.78
		IV	0.62	0.68
		Proliferative	0.63	0.96
		V	0.64	0.57
Novel and traditional biomarkers	66	II	0.84	0.82
		III	0.79	0.85
		IV	0.82	0.96
		Proliferative	0.73	0.89
		V	0.86	0.74

Results: Biomarker data were available for 99 subjects. Combined biomarker clinical data were available for a subset of 66 subjects. In general, ANN and NRN models using biomarkers either alone or in combination with traditional biomarkers were superior to models with clinical variables alone. ANN models tended to have greater diagnostic power than NRN models. 93% of the predictive power from the ANN model of proliferative disease came from GM-CSF, IFNα2 MCP1, NGAL, IL-6, and IL-12 levels.

Conclusions: This study suggests that multiple biomarkers representing diverse pathogenic mechanisms by machine learning modeling techniques are effective in diagnosing ISN/RPS class of nephritis. It demonstrates that when markers of multiple types of cell activation, migration, and damage are combined into a single model, diagnostic power is improved over models using traditional biomarkers alone.

ACR/ARHP Combined Abstract Session

ACR/ARHP Combined Pediatric Rheumatology - Clinical and Therapeutic Aspects Abstracts: Quality of Life in Children and Adolescents with Arthritis

Tuesday, November 9, 2010, 2:30 PM–4:00 PM

1404

Investigating Medication Adherence in Pediatric Rheumatology Using a Medical Claims Database. Caitlin M. Sgarlat[3], Jorge M. Lopez-Benitez[2], Emily Cox[1] and Ira B. Wilson[4]. [1]Express Scripts Inc. Research and Analysis, St. Louis, MO, [2]Tufts Medical Center and Floating Hospital for Children: Division of Pediatric Rheumatology, Boston, MA, [3]Tufts Medical Center and Floating Hospital for Children: Division of Pediatric Rheumatology; Tufts University Sackler School of Graduate Biomedical Sciences, Boston, MA, [4]Tufts Medical Center and Floating Hospital for Children; Tufts University Sackler School of Graduate Biomedical Sciences

Background: Juvenile Idiopathic Arthritis (JIA) or Juvenile Rheumatoid Arthritis (JRA) is the most common pediatric rheumatologic disease. Pharmacologic therapy use in this population is important at the onset of disease as well as throughout its course and adherence to the planned treatment is critical for good outcomes. Adherence to treatment in these conditions and in

this population has not been well studied and little is known about an association between age and adherence. We hypothesized that medication adherence would be better in a younger pediatric population with JRA compared with an adolescent pediatric population with JRA because of parental medication administration and supervision and because of problems reported with medication adherence in adolescents with other chronic conditions.

Methods: We used The MarketScan® Commercial Claims and Encounters Database, a nationwide pharmaceutical database with 12 million enrollees that includes both medical and pharmacy claims. Pediatric patients were identified by ICD-9 codes for a medical claim of JRA from 7/1/07 to 12/31/07. Pharmacy claims were obtained for these patients up to 1 year after the medical claim was made. Claims included the following medications: non-steroidal anti-inflammatory agents, cytotoxic agents, corticosteroids, and biologic agents. For each medication a possession ratio (MPR) was calculated. The denominator for the MPR was the number of days between the first and last prescription in that year, and the numerator was the number of dispensed days of medication between those dates. For patients on more than one medication, the average of the MPRs of the individual medications was used. Age was dichotomized into patients aged 0 to 12 years and 13 to 18 years. T-tests were used to compare the MPR in the different age groups. The data was analyzed using statistical software SAS 9.2.

Results: Of 5,452 patients with a medical claim of JRA, 1,946 patients, or 36%, were on one or more medications. Of those on medication, 64.5% were females and 34.5% were males. 40.6% were 0 to 12 years old and 59.5% were between 13 and 18 years old. The overall MPR of all patients was 0.67 (SD 0.46). The mean MPR for the patients ages 0 to 12 years was 0.77 (SD 0.47) and the mean MPR for the patients ages 13 to18 years was 0.60 (SD 0.44), p-value <0.0001. Adjusting for gender in a multivariable linear regression model did not change these results.

Conclusion: Adherence was significantly worse in teenagers with JRA than in younger children, but even in younger children whose medication taking is presumably supervised by an adult, it was surprisingly low. These low levels of adherence are a potentially serious problem for patients who are likely to have suboptimal clinical outcomes as a result. Pediatric rheumatologists need to be aware of the extent of nonadherence that these data reveal, and endeavor to communicate more effectively with their patients about the issues and problems that they are having taking medications as prescribed. While the challenges to taking care of adolescent patients are not unique to JRA or rheumatologic diseases in general, the need to address poor medication adherence in these patients appears particularly pressing.

Development of a Vision Related Quality of Life Instrument for Children with Juvenile Idiopathic Arthritis-Associated Uveitis. Sheila Angeles-Han[4], Kenneth Griffin[7], Melanie J. Harrison[5], Kerrie Fields[2], Lori Ponder[2], Rachel Reeves-Robb[3], Marla Shainberg[3], Phoebe Lenhart[3], Amy Hutchinson[3], Sunil Srivastava[3], Sampath Prahalad[1], Scott Lambert[3] and Carolyn Drews-Botsch[6]. [1]Emory Children's Center, Atlanta, GA, [2]Emory Children's Center, [3]Emory Eye Center, [4]Emory University, Atlanta, GA, [5]Pfizer, Blue Bell, PA, [6]Rollins School of Public Health, [7]Weill Cornell Medical College

Purpose: Studies on quality of life (QOL) in JIA-associated uveitis (JIA-U) focus on visual acuity (VA) and the presence of flare and cells during the ophthalmologic exam as a measure of visual function. However, these measures do not adequately assess the impact of disease activity on daily life from a child's perspective. Assessment of QOL in JIA-U could improve by including both objective measures of visual function and subjective assessments of the impact of disease activity on daily functioning. However, there are no validated instruments that measure vision related QOL in children 8–18 years old. Hence, we developed a new instrument to evaluate the performance of activities that rely on vision in home and school – Effects of Youngsters' Eyesight on QOL (EYE-Q).

Methods: We interviewed experts in the field and children regarding how vision affects a child's daily activities. In addition to developing new items, we selected relevant items from existing instruments and adapted them to increase their relevance to a U.S.-based sample of children. We administered preliminary versions of the EYE-Q to normal sighted children and those with JIA-U. We then recruited 82 children, 8–18 years old, with various (or no) ocular conditions that affect vision. We measured VA and contrast sensitivity (CS). Patient-based questionnaires were administered -the EYE-Q to measure vision related QOL, and the Pediatric Quality of Life Inventory (Peds QL) to measure overall QOL. The EYE-Q was again completed 10 days after the visit. VA was converted to logmar VA values which are a linear scale for statistical analysis. Test-test reliability over a 10 day period was calculated, and validity was determined by examining associations between the EYE-Q and VA, CS, and QOL using Pearson's correlation.

Results: Of 82 patients, 42.4% were female, 65.9% were Caucasian, 22.4% were African American, and 76.5% had eye disease. Mean age was 11.1 years (range 8–18). Mean scores of the instruments, VA, and CS are shown in Table 1.

Table 1. Mean Scores of Visual Function Measures

	Mean (SD)
EYE-Q[1] score	3.51 (0.52)
2nd EYE-Q[1] score	3.54 (0.52)
PedsQL[2] Physical score	85.91 (15.04)
PedsQL[2] Psychosocial score	75.56 (17.66)
PedsQL[2] Total score	79.18 (15.49)
Logmar VA[3], left eye	0.245 (0.357)
Logmar VA[3], right eye	0.220 (0.510)
Contrast Sensitivity	1.74 (0.18)

[1] Effects of Youngsters' Eyesight on QOL; [2]Pediatric Quality of Life Inventory; [3] Visual Acuity

Correlations between EYE-Q and measures of validity and reliability are shown in Table 2.

Table 2. Correlation Between the EYE-Q and PedsQL With Measures of Validity and Reliability

Measures	R	P value
EYE-Q[1] repeat	0.943	0.00**
PedsQL[2] Physical	0.489	0.00**
PedsQL[2] Psychosocial	0.427	0.00**
PedsQL[2] Total	0.489	0.00**
Logmar Far VA[3], left eye	−0.546	0.000**
Logmar Far VA[3], right eye	−0.609	0.00**
Contrast Sensitivity	0.366	0.019**
PedsQL[2] and Logmar VA[3], left eye	−0.299	0.018**
PedsQL[2] and Logmar VA[3], right eye	−0.197	0.122

[1] Effects of Youngsters' Eyesight on QOL; [2]Pediatric Quality of Life Inventory; [3]Visual Acuity; **$p < 0.05$

There were significant associations between the EYE-Q and standardized measures.

Conclusions: Our study confirms the validity and reliability of our EYE-Q and the contribution of visual function to overall QOL. Studies on QOL in JIA-U should incorporate all components of disability in their analysis and not rely only on objective measurements of vision or measures of overall QOL. Our EYE-Q may be an important instrument in the assessment of vision related QOL in children with JIA-U and a better measure than VA or measures of overall QOL alone.

Sleep in Polyarticular Juvenile Idiopathic Arthritis: An Electronic Daily Diary Study. Maggie H. Bromberg[5], Cecelia R. Valrie[4], Mark Connelly[1], Kelly K. Anthony[3], Lindsey Franks[3], Karen M. Gil[6] and Laura E. Schanberg[2]. [1]Children's Mercy Hospital and Clinics, [2]Duke Univ Medical Center, Durham, NC, [3]Duke University Medical Center, Durham, NC, [4]East Carolina University, [5]University of North Carolina at Chapel Hill, Carrboro, NC, [6]University of North Carolina at Chapel Hill

Purpose: In addition to joint pain and stiffness, children with arthritis may experience sleep problems. Recently, researchers have used electronic surveys to track symptom and behavior fluctuations, including sleep, in home settings. This study compares child- and parent- reported daily electronic surveys describing children's sleep quality.

Methods: The sample consisted of 31 children with active polyarticular arthritis (27 girls; 80.7% Caucasian; mean age 12.7 years, 45% with moderate

to severe disease severity) and their parents (87% mothers; mean age 41.7 years). As part of a larger study, all participants recorded symptoms on an electronic survey via a smartphone three times each day for one month, including ratings of child sleep each morning. Physicians completed disease severity ratings at baseline. Sleep quality was rated on an electronic visual analog scale with the anchors "Did not sleep well" and "Slept very well." Daily sleep quality reports were aggregated, descriptive statistics were performed on all sleep variables, and compliance rates were calculated. Dependent sample t-tests were used to compare average parent and child sleep quality ratings.

Results: Children completed 65% and parents completed 72% of all possible electronic morning reports. Averaging all reports, children in the sample reported moderate to high sleep quality (m = 70.09, SD = 27.77). Parent ratings of child sleep quality were not significantly different (t = −0.59, p >.05). Children and parents' individual sleep quality entries spanned the full range of 0–100mm. Poor sleep quality (>1SD below the mean) was reported by children on 18% and parents on 25% of all morning reports. Self-reported sleep quality did not vary by gender (t=−1.58, p>.05). Neither child nor parent-reported average sleep quality scores correlated with physician-rated disease severity (r =.27, p >.05; r=.22, p >.05) or age (r = −.25, p >.05; r=−.18, p >.05). However, average self-reported pain (m = 28.6, SD =21.9) and self-reported sleep quality were significantly correlated (r = −.45, p <.05), as were parent-reported average pain (m = 28.42, SD = 20.66) and parent-reported average sleep quality (r = −.41, p <.05). Children reported sleeping 4–8 hours on 55.7% of nights and 8–10 hours on 33.4% of nights, and reported mild difficulty with sleep onset and few night wakenings.

Conclusions: Parents and children completed comparable numbers of morning electronic diary surveys, suggesting that children can adequately complete independent entries using this new technology. Self- and parent-ratings of child sleep quality were similar, supporting the use of child self-reported sleep ratings in future studies. Children generally reported adequate sleep duration and few sleep disruptions during the night. Although disease and demographic variables were not related to sleep quality scores, pain intensity reports correlated to sleep quality. Despite adequate sleep quality on average, children reported experiencing poor sleep quality on 18% of morning reports, suggesting daily variability. Additional research is needed to identify factors effecting daily sleep quality and to determine the clinical impact of sleep quality variability.

Background: Systemic inflammation, chronic arthritis and possible joint damage can lead to functional impairment and diminished health-related quality of life (HRQoL) in children and adolescents with juvenile idiopathic arthritis (JIA). In a double-blind (DB), placebo-controlled, randomized withdrawal trial (RWT)[1] in subjects with polyarticular JIA, abatacept significantly improved multiple aspects of HRQoL, pain and sleep quality[2]. Here we report follow-up data on these variables for up to 31 months of treatment, including 21 months of the long-term extension (LTE) of this trial.

Methods: Subjects in the RWT treated with abatacept who achieved an ACR Pedi 30 response in a 4-month open-label lead-in were randomized 1:1 to DB abatacept or placebo for 6 months or until flare[2]. Subjects eligible to enter the open-label LTE (10 mg/kg abatacept) included ACR Pedi 30 non-responders (NR) from the lead-in who did not enter the DB period, and subjects randomized into the DB phase who either flared or completed the 6-month DB period. HRQoL was assessed by the Child Health Questionnaire (CHQ), which includes 15 health concepts, sleep quality by the Children's Sleep Habits Questionnaire (CSHQ) (score 0–100) and parent global assessment of pain by 0–100 mm VAS. Mean CHQ component scores are also presented for healthy children[3]. Data up to Month 21 of the LTE are presented for subjects who entered the LTE (either NR from the open-label lead-in or subjects treated with abatacept during the DB period), and who had data available at the visit of interest (as-observed).

Results: At study entry, subjects had considerably lower HRQoL than the general population[1]. Mean changes in CHQ components from baseline to Month 31 generally indicated improvements in both patient cohorts, with greater changes seen for DB abatacept patients compared with open-label NRs (Table). Mean scores at Month 31 for each CHQ component were generally comparable to scores for healthy children. Reductions from baseline in CSHQ scores and pain also were comparable by Month 31 for the DB abatacept versus NR cohorts: mean (95% CI) changes in CHSQ total scores were –3.5 (–6.5, –0.5) versus –2.9 (–6.3, 0.6), and in parent global assessment of pain were –31.2 (–37.8, –24.6) versus –20.6 (–30.2, –10.9) (n=28, n=16, n=50 and n=22, respectively).

Family cohesion	75.3 (20.4)	76.5 (19.7)	10.9 (3.6, 18.2)	71.8 (24.9)	3.6 (−9.8, 17.1)

*Higher scores on the CHQ indicate better HRQoL; †Note that change in health scores for subjects in this study are on a 1–5 scale, whereas those for healthy children have been transformed to a 0–100 scale; ‡N is the number of patients who entered the LTE from each group, and data shown are for patients with data available at baseline and the visit of interest, with n = 51 for DB abatacept and n = 22 for open-label NRs, except §n = 48, ‖n = 50; **n = 21

Conclusions: Treatment with open-label abatacept for up to 31 months resulted in improvements in multiple aspects of HRQoL, to within the range of healthy children, for subjects with JIA, including those who were ACR Pedi 30 non-responders in the lead-in period. These data suggest that long-term abatacept treatment can provide real-life tangible health-related benefits to children with polyarticular JIA.

Jointly Managing Arthritis: Information Needs of Children with Juvenile Idiopathic Arthritis (JIA) and Their Parents. Jennifer Stinson[4], Brian M. Feldman[5], Ciaran Duffy[3], Adam Huber[2], Lori Tucker[1], Patrick McGrath[2], Shirley M. Tse[5], Ross Hetherington[5], Lynn Spiegel[5], Sarah Campillo[3], Susanne Benseler[5], Navreet Gill[5], Meghan E. White[5] and Abi Vijenthira[5]. [1]BC Children's Hospital, [2]IWK Health Centre, [3]Montreal Children's Hospital, [4]The Hospital for Sick Children, Toronto, ON, Canada, [5]The Hospital for Sick Children

Purpose: This study explores the information needs of children with JIA and their parents in order to develop a web-based program of disease-specific information, management skills, and social support aimed at improving their quality of life.

Methods: A qualitative study design was used. A purposive sample of children (n=41, 73% female) between 8 and 11 years of age diagnosed with JIA and one of their parents (n=48), was recruited from four Canadian tertiary care centers (Vancouver, Toronto, Montreal, Halifax). Parent-child dyad interviews (n=29) and 4 separate child and parent focus group interviews were conducted using semi-structured interview guides. Audiotaped interviews were transcribed verbatim. Nvivo 8.0 (QSR, 2009) was used to assist with sorting, organizing and coding data. The thematic analysis was a collaborative and iterative process. Data were organized into categories that reflected the emerging themes.

Results: Preliminary findings uncovered two major themes: "Living with Arthritis" and "Jointly Managing Arthritis". Major subthemes for "Living with Arthritis" were: pain, maintaining friendships, communicating about the disease, and worry/distress. Two further sub-themes were found under worry/distress: parents expressed concern about their child's future, and children wondered "why me?" Two sub themes were identified under "Jointly Managing Arthritis" where managing JIA was viewed as being a joint responsibility between the parent and child. The first sub theme, "desire for information and disease management strategies", highlighted the need for further information on JIA, medications, tests and procedures, managing pain and emotions, and advocacy and communication strategies. The second sub theme was staying strong and seeking social support. Participants explained that staying strong as a family was essential, and they also wanted the opportunity to connect with others with JIA to help them feel that they are not alone. Finally, children and their parents felt that a web-enabled program of JIA information, disease management strategies and opportunities for social support would be the ideal way to meet their information needs.

Conclusions: In order to jointly manage JIA, children and their parents expressed the need for disease-specific information, management strategies, and social support. Web-enabled treatments are a promising avenue to improve the accessibility and availability of JIA information and disease management strategies for children and their parents. Findings from this study will be used to develop and test an on-line program to help children and their parents jointly manage arthritis.

Follow-Up Survey on Adolescent Rheumatology Patients' Online Activities and Social Support Systems: Opportunities for Transition Program Development. Peter Chira. Stanford University, Palo Alto, CA

Purpose: To evaluate current trends of social support systems and online behaviors of teen patients attending Stanford pediatric rheumatology clinic at Lucile Packard Children's Hospital (LPCH) and to assess opportunities for a transition intervention

Methods: We administered a written survey to consecutive teen rheumatology patients ages 13–22 during routine LPCH rheumatology clinic visits from April-June 2010. Informed consent and assent were obtained from parents (and participants ≥18) and teens <18, respectively. Stanford University's IRB approved the study. The survey is based on one administered in 2003. Descriptive statistics are presented. Trends are compared between surveys.

Results: 120 patients completed the survey (Table 1). Most have discussed their disorder with another, typically parent (95%) or friend (81%); few had spoken to a peer with a similar rheumatic disease (22%), and this is an increase from 2003. Computer and internet use are pervasive: 89% use email but only 38% check daily, and 74% use social networking sites, with 54% checking daily. Online communications such as chat room and IM are used less often than in 2003 (16%, 51% vs 33%, 69%, respectively), with a drop in daily IM from 33% to 24%. 90% have cellphones, and calling (87%), texting (78%), and taking pictures (73%) are the most common uses. 44% send >50 text messages daily.

Teens go online to learn about their rheumatic condition more frequently than in 2003 (73% vs 44%) but still seek a reliable website to find this information as well as an online personal record of their own medical/health information (83% and 80%).

Table 1. Teen Patient Characteristics, Computer and Internet Use, Social Support Systems

Discussion: The Pew Survey on Social Media in Young Adults in March 2010 revealed changing trends of teen internet practices. Our survey demonstrates that teen rheumatology patients have similar online habits, but they are more likely to go online for health information and for sensitive teen topics than the general adolescent population. We note increasing use of cellphones for communication and internet access, which have affected other interactive online modalities. Interest in online meetings with teens with similar conditions is declining, but our teens prefer website development and tools to collect their personal health information that also can be a reliable resource for medical information about their condition. While many teens commonly use online social networking sites, overall interest of their use as a social support resource may be limited.

Conclusion: Technology and social media use by teens with rheumatic diseases are evolving and follow the general young adult population. Further development of programs, especially those using mobile technologies such as cellphones, will help teens to learn about and track their rheumatic conditions, as well as to assist in peer communication– all potential opportunities in the creation of a teen transition program.

TLR7 and IFNα Influence B Cell Selection in the Germinal Center. Ioana Moisini[1], Weiqing Huang[1], Tony Marion[3] and Anne Davidson[2]. [1]Feinstein Institute, [2]Feinstein Institute for Medical Research, Manhasset, NY, [3]University of Tennessee

Background: Male NZW/BXSB.Yaa (W/B) mice express two copies of the TLR7 gene and develop pathogenic autoantibodies whereas females with only one copy of TLR7 have attenuated disease. V_H3H9 is an autoreactive Ig heavy chain that can pair with a variety of light chains generating both autoreactive and non-autoreactive antibodies. Our goal was to analyze the regulation of the autoantibody response in male and female 3H9.W/B mice.

Methods: 3H9.W/B mice were bred and monitored for proteinuria. Some female mice received IFNα adenovirus at 3 months of age. Sera were analyzed for autoantibodies by ELISA. Mice were sacrificed at 8, 24 and 56 weeks of age and single cell PCR and sequencing of heavy and light chain Ig genes performed for all B cell subsets. Selected germline light chains were coexpressed with the 3H9 heavy chain and transfectant supernatants screened for autoreactivity by ELISA.

Results: IgM and IgG anti-CL antibodies appeared in the serum by 12 weeks of age in both males and females. Anti-dsDNA antibodies appeared in the serum of males at 12 weeks and most had high titer IgG anti-CL and anti-dsDNA antibodies and developed >300mg/dl proteinuria and thrombocytopenia by 8 months. Females had only low titer IgG anti-CL antibodies and none developed proteinuria by 1 year.

Using flow cytometry and single cell PCR of 3H9 associated light chains we showed that males had a much smaller marginal zone (MZ) with a repertoire that was distinct from the follicular repertoire, indicating that the loss of MZ B cells was not due to diversion to the follicular compartment. The germinal center (GC) repertoire was more diverse in males than in females. Vk5–45 and Vk5–48 were overrepresented in the GC repertoire of both males and females but the VJ junctions were different between males and females. For example Vk5–48 junctional diversity generated Leu at position 116 of the light chain in 88% of female sequences compared with only 22% of male sequences. In contrast there was a Phe at position 116 in 52% of male sequences but only 5% of female sequences ($p < 0.0001$). Germline 3H9/Vk5–48 with Phe116 had anti-cardiolipin, anti-histone and anti-dsDNA activity whereas 3H9/Vk5–48 with Leu116 did not bind dsDNA or cardiolipin and retained binding only to histones, a specificity associated with low renal pathogenicity. Administration of IFNa to female mice induced anti-cardiolipin and anti-DNA autoantibodies and proteinuria and was associated with a diverse GC repertoire and a male pattern of junctional diversity in Vk5–45 and Vk5–48.

Conclusions: Tolerance to cardiolipin is broken in W/B mice as they age and is regulated independently of anti-DNA reactivity. Analysis of the naïve repertoire suggests a shift in the threshold for negative selection in males resulting in deletion of MZ B cells. In contrast, selection into or expansion in the germinal center is a major checkpoint for regulation of autoreactivity, and female germinal centers are regulated more stringently than those of the males. Our studies are consistent with the hypothesis that TLR7 overexpression or exogenous IFNα relaxes the stringency for selection in the germinal centers resulting in increased autoreactivity of the antigen driven B cell repertoire.

Impaired Somatic Hypermutation in Pre-Switch Memory B Cells and Modulation of Mutational Targeting in Memory B Cells during Tocilizumab Treatment in RA Patients. Khalid Muhammad[1], Petra Roll[1], Stefan Kleinert[2], Thomas Seibold[2], Martin Feuchtenberger[2], Thomas Dörner[3] and Hans-Peter Tony[2]. [1]Department of Medicine II, Rheumatology/Clinical Immunology, University of Würzburg, Würzburg, Bayern, Germany, [2]Department of Medicine II, Rheumatology/Clinical Immunology, University of Würzburg, Würzburg, Germany, [3]Dept. of Medicine/Rheumatology and Clinical Immunology Charite Universitätsmedizin Berlin and DRFZ Berlin, Berlin, Germany

Purpose: Tocilizumab, a humanized anti-IL-6R antibody, is a novel anti-inflammatory drug with documented clinical effects in rheumatoid arthritis. Since IL-6 is a key differentiation factor of B cells, we analysed molecular effects of tocilizumab on pre- (IgD+CD27+) and post- switch (IgD-CD27+) memory B cells in vivo.

Methods: Memory B cell subsets were analyzed from 10 RA patients by using single B cell sorting technique followed by nested PCR and Ig-VH3/VH4 sequencing. 6/10 received tocilizumab (8 mg/kg every 4 weeks) and 4/10 received as a control population anti-TNFα therapy with etanercept.

Results: Pre-therapy analysis of 344 rearranged IgR sequences from 10 RA patients revealed a diversified mutational pattern of pre-switch memory B cells containing mutated and non-mutated sequences. Patients receiving tocilizumab (n=6) showed a reduced mutational frequency in Ig-receptors of pre-switch memory B cells along with a marked reduction of the highly mutated Ig-receptor population at week 12 and 24 after tocilizumab. In detail, the mutational frequency of pre-switch memory B cells decreased from 4.1±0.2 %(mean±SEM) to 2.9± 0.1 % (P=0.0001) at week 12 and 2.5±0.2 %(P=0.0001) at week 24, respectively. Pre-switch memory B cells contained 50.6±2.3% highly mutated sequences (>9 mutations/sequence) before treatment which declined to 28.5±2.0% and 22.5± 4.5% at week 12 and week 24 (P=0.0001), while low mutated sequences (≤9 mutations/sequence) increased significantly from 43.1±2.7% to 65.1±1.8% and 63.6±4.0 (P=0.0001). This included a significant increase of unmutated sequences at week 24(6.3±1.8 vs. 13.9±4.2, P=0.0001) after tocilizumab. The mutational frequency within post-switch memory B cells was unaffected. Analysis of the mutational hotspot RGYW/WRCY(R= A/G, Y=T/C, W=A, T) motifs indicated significantly decreased targeting in pre-switch memory B cells (24.3± 14% before therapy versus 17± 1.0% and 16± 0.6%, P<0.025) as well as in post-switch memory B cells (30.2±3.2% before therapy versus 17.2±2.0% and 16.0±0.5%, P<0.025) at week 12 and week 24 under tocilizumab.

In contrast, anti-TNFα therapy (n=4) had no effect on both, mutational frequency and mutational targeting of hotspot motifs in pre- and post-switched memory B cells.

Conclusions: Our data suggest that pre- and post-switch memory B cells are susceptible to IL-6R inhibition in vivo. Particularly, acquisition of mutations was substantially altered in pre-switch memory B cells, while targeting of mutational hotspots affected both pre- and post-switch memory B cells. The results indicate that pre- and post-switch memory B cells have a differential dependence on the IL6/IL6R system for differentiation in vivo which can be influenced by anti-IL6R therapy.

IL-17 Downregulates NF-κB1/p50 and Upregulates BCL6 To Promote Germinal Center B Cell Differentiation in Autoimmune BXD2 Mice. Shutao Xie[2], Hui-Chen Hsu[2], Jun Li[2], Qi Wu[2], PingAr Yang[2] and John D. Mountz[1]. [1]Univ Alabama at Birmingham, Birmingham, AL, [2]Univ Alabama at Birmingham

Background: Suppression of NF-κB1/p50 by transcription factor BCL6 has been shown to be associated with early germinal center (GC) B cell differentiation. BXD2 mice express high levels of IL-17 and spontaneously develop lupus and erosive arthritis. We previously showed that IL-17 can regulate the migration behavior of B cells *via* the canonical NF-κB P-p65 signaling pathway to facilitate the close contact of B and T cells in spontaneous GCs. This study is to determine if IL-17 can promote GC B cell differentiation through its effects to modulate the expression of BCL6 and NF-κB1/p50.

Methods: Purified splenic B cells from BXD2, BXD2-*Il17ra*$^{-/-}$, B6 or B6-*Il17ra*$^{-/-}$ mice were incubated with or without IL-17 or IL-21 *in vitro*. NF-κB proteins were analyzed by western blot using antibodies against P-p65, p50, p105. Adenovirus (Ad)-IL-17RA:Fc, AdIL-17A, AdLacZ, an anti-IL-17 neutralization antibody and an isotype control antibody were administered into BXD2 mice. Expression of *Rgs, Irf4, Bcl6* and *Nfkb1* were determined by qRT-PCR. Expression of BCL6 in GC B cells was determined by FACS. B cells were stimulated *in vitro* with anti-CD40 (2 mg/ml) + anti-mouse Ig (4 mg/ml) in vitro.

Summary of the Results: IL-17 by itself upregulated the expression of *Bcl6* and downregulated nuclear expression of p50 in BXD2 B cells *in vitro*. IL-17 also acted synergistically with IL-21 to upregulate the expression of *Bcl6* in BXD2 B cells. *In vivo* blockade of IL17Rα signaling by administration of anti-IL-17 decreased BCL6 in BXD2 GC B cells. Consistent with this,

administration of AdIL-17RA:Fc, which blocks IL-17/IL17Rα signaling, to BXD2 mice also resulted in signficantly decreased BCL6, increased p50 and p105, and decreased P-p65 in B cells. Administration of AdIL-17A to BXD2 mice induced opposite effects. Both p50 and p105 in IL-17RA intact B cells were significantly lower than those in *Il17ra*$^{-/-}$ B cells from both B6 and BXD2 mice. BXD2-*Il17ra*$^{-/-}$ B cells also exhibited higher nuclear localization of p50, and when induced with anti-CD40 + anti-IgG, they showed dramatically lower expression of classical NF-κB responsive genes including *Rgs* (>10.0-fold, $p<0.001$) and *Irf4* (>4.0-fold, $p<0.01$), compared with anti-CD40 + anti-IgG stimulated BXD2-*Il17ra*$^{+/+}$ B cells.

Conclusion Reached: Our results reveal a novel mechanism for IL-17 to regulate the development of GC B cells in autoimmune BXD2 mice in that: (i) IL-17 can directly upregulate BCL6 to facilitate GC B cell differentiation; and (ii) IL-17 suppresses the NF-κB1/p50 to promote a global canonical NF-κB P-p65 pathway facilitating GC formation and GC B-cell development.

Targeting the Splicing of mRNA in Autoimmune Diseases: BAFF Inhibition in Sjögren's Syndrome as a Proof of Concept. Nienke Roescher[5], Jelle L. Vosters[2], Ghada Al Saleh[6], Patrick Dreyfus[7], Sebastien Jacques[4], Luis Garcia[7], Gilles Chiocchia[4], Antoine Francois[6], Jean Sibilia[6], Paul P. Tak[1], Jay A. Chiorini[5], Xavier Mariette[3] and Jacques-Eric Gottenberg[6]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Academic Medical Center/University of Amsterdam, [3]Bicetre Hospital, [4]Cochin Hospital, [5]National Institutes of Health, National Institute of Dental and Craniofacial Research, [6]Strasbourg Hospital, EA 4438, [7]UMR 7215 CNRS, Institut de Myologie

Background: B-cell activating factor of the TNF family (BAFF) is a relevant target in autoimmunity. BAFF is increased in various animal models of autoimmunity and in patients with autoimmune diseases, including Sjögren's syndrome (SjS). Moreover, inhibition of BAFF using monoclonal antibodies or soluble receptors improves the course of arthritis, diabetes, and systemic lupus erythematosus in animal models of autoimmunity. There are as yet no data available regarding the efficacy of BAFF inhibition on salivary gland (SG) inflammation and dysfunction in animal models of SjS.

Delta BAFF is a physiological non-secreted inhibitor of BAFF. It prevents the intracellular binding of BAFF to other monomers of BAFF and APRIL, another important factor in the activation and survival of B cells, and inhibits BAFF secretion. Delta BAFF is a splice variant of BAFF and lacks a single exon compared with full length BAFF (exon 3 in humans, exon 4 in mice), which is naturally more abundant than delta-BAFF.

The use of exon skipping to promote the expression of one shorter variant over the predominant full length mRNA has shown encouraging effects for the treatment of the monogenic disease Duchenne's myopathy and offers exciting therapeutic opportunities for many other diseases. We hypothesized that targeting the splicing of BAFF mRNA using exon skipping and thereby decreasing BAFF may improve features of SjS.

Methods: Adeno-associated virus (AAV) and lentiviral vectors were constructed encoding U7 RNA with an antisense sequence targeting the exon of BAFF, which is absent in delta-BAFF. The expression of BAFF and delta-BAFF mRNA was assessed by PCR after infection of U937 and human lymphoma cell lines.

Exon skipping-inducing AAV (AAV 161) or an AAV control vector encoding for beta galactosidase (LacZ) were administered by retrograde canulation of the submandibular glands of 19 NOD mice at the age of 10 weeks. Salivary gland function was assessed and expression of BAFF and SG inflammation was determined by quantitative immunohistochemistry 10 weeks post-treatment.

Results: In vitro transfection of U937 and human lymphoma cell lines with an exon skipping inducing lentivirus resulted in a marked decrease of BAFF and an increase of delta-BAFF mRNA and decreased BAFF protein in the supernatant.

In vivo, BAFF expression in the SG was significantly decreased (48% decrease in optical density per mm2, $p<0.05$) in mice treated with AAV161. Stimulated saliva flow increased with almost 100% from 2.0 (control LacZ mice) to 3.8 (AAV161) ul/20min/gram body weight, $p<0.01$. In addition, treatment with AAV161 decreased the average number of salivary gland lymphocytic infiltrates per cross sectional surface area of the SG (3.9 vs 2.4, $p<0.05$) and reduced the number of B (Δ87%, $p<0.05$) and plasma cells (Δ69%, $p<0.01$), compared with control mice.

Conclusion: These results demonstrate the efficacy of BAFF inhibition on features of SjS in NOD mice and offer a rationale to evaluate BAFF inhibition in patients with SjS. This study also represents a proof of concept of the efficacy of modulating mRNA splicing in autoimmune diseases.

Adoptive Transfer of Long-Lived Plasma Cells from NZB/W Mice Causes Immune Complex Nephritis in Recipient Rag1−/− Mice. Quingyu Cheng[3], Imtiaz M. Mumtaz[1], Bimba F. Hoyer[1], Andreas Radbruch[4] and Falk Hiepe[2]. [1]Charité - Universitätsmedizin, Berlin, Germany, [2]Charité - Universitätsmedizin, Berlin, Berlin, Germany, [3]Charité - Universitätsmedizin Berlin, Berlin, Germany, [4]German Rheumatism Research Center, Berlin, Germany

Background: Previously, we showed that long-lived plasma cells refractory to immunosuppression significantly contribute to autoantibody production in NZB/W mice used as a model of lupus nephritis. Since immunosuppressive and B cell depletion therapy affecting only short-lived plasmablasts and plasma cells can induce remission of the disease, the role of surviving long-lived plasma cells in the pathogenesis of the disease is not well-defined.

Objectives: To elucidate the role of autoreactive long-lived plasma cells in the pathogenesis of lupus nephritis.

Methods: CD138+ plasmablasts and plasma cells were isolated by MACS technology from the spleens of >6-month-old NZB/W mice with high levels of anti-dsDNA antibodies and adoptively transferred to immunodeficient Rag1−/− mice (3 million cells/mouse). Contamination with B cells was about 2% and with T cells 0.02%. To exclude a contribution of these contaminated B cells, the corresponding number of B cells was transferred in a control experiment. Serum antibody levels in recipient mice were measured using ELISA. The recipient mice were sacrificed 21 weeks after adoptive transfer for analysis of plasma cells, including anti-DNA-secreting cells, by flow cytometry and ELISPOT as well as for renal immunohistology.

Results: Total IgG, total IgM and IgG and IgM anti-dsDNA antibody levels were measured in recipient mice starting one week after transfer and remained constant for the entire observation (21 weeks), even after cyclophosphamide treatment. Mature non-dividing plasma cells but not plasmablasts were detected in bone marrow, spleen, and kidneys of the recipient mice. Adoptive transfer of B cells in numbers corresponding to the B-cell contamination levels within the transferred plasmablast fraction did not result in significant antibody (autoantibody) levels. Proteinuria developed 21 weeks after plasma cell transfer. Renal immunohistology showed immune complex nephritis with deposition of IgG, IgM and C3.

Conclusions: Adoptive transfer of plasmablasts results in homing of long-lived plasma cells in spleen and bone barrow. Autoantibodies secreted by long-lived plasma cells can cause nephritis. This supports the suggestion to consider long-lived plasma cells refractory to conventional immunosuppression and B cell depletion as candidate targets for future therapeutic strategies.

B Cells Induced Proteinuria and Glomerulopathy in Absence of Immune Complexes Similar to Minimal Change Disease. Alfred H. Kim[1] and Andrey S. Shaw[2]. [1]Washington Univ School of Med, St. Louis, MO, [2]Washington Univ School of Med

Purpose: B cell depletion therapies have been efficacious in several immunopathologic glomerulopathies, such as minimal change disease. The contributions of B cells to proteinuria and podocyte foot process effacement remain unknown though. Here, we test whether the glomerular localization of antigen, followed by adoptive transfer of antigen-specific B cells, can induce proteinuria and glomerular disease. This would enhance our understanding of immune-based kidney diseases.

Methods: The well-characterized B cell model antigen hen egg lysozyme (HEL) was biotinylated and complexed to avidin. Following intravenous injection in mice, purified naive HEL-specific B cells were adoptively transferred and proteinuria was assessed at various timepoints post-transfer.

Kidneys were processed for immunofluorescence, H&E staining, and transmission electron microscopy. Intravital two-photon microscopy was performed on exteriorized kidneys from live, anesthetized mice.

Results: HEL was found to be embedded within the glomerular basement membrane (GBM) within 30 minutes following intravenous injection as visualized with immunofluorescence microscopy. Induction of proteinuria occurred only after the transfer of HEL-specific B cells, as compared to wild-type polyclonal B cell transfer. The presence of HEL alone in the GBM did not induce proteinuria, nor did the transfer of HEL-specific B cells in the absence of HEL injection. The proteinuria is associated with podocyte foot process effacement as visualized on transmission electron microscopy. The absence of periglomerular infiltrates on H&E stained sections were noted in both proteinuric and control mice, indicating the absence of inflammation. There was no immune complex or complement deposition within the glomeruli during proteinuria. Intravital two-photon microscopy demonstrated that HEL-specific B cells were retained only within the antigen-bearing glomeruli and became activated in situ as measured by calcium flux.

Conclusion: We have demonstrated that B cells were activated within antigen-bearing glomeruli, and induced proteinuria and podocyte foot process effacement in the absence of immune complex deposition, complement deposition, or inflammation. These are observations similar to those found in minimal change disease. These data provide additional evidence that B cells can generate pathophysiologic conditions seen in immune-based diseases in the absence of immune complexes. We hypothesize that B cell-derived cytokines are directly responsible for this phenotype, and this is currently being tested.

Nuclear Factor-κB Inducing Kinase Is Preferentially Expressed in Rheumatoid Arthritis Synovial Tissue Containing Ectopic Lymphoid Neogenesis. Ae-Ri Noort[2], Katinka P. M. van Zoest[3], Mariagrazia Modesti[4], Sander W. Tas[2] and Paul P. Tak[1]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Academic Medical Center/University of Amsterdam, The Netherlands, [3]Academic Medical Center/University of Amsterdam, [4]University of Rome

Background: Approximately 30% of synovial tissues derived from rheumatoid arthritis (RA) patients is characterized by ectopic lymphoid neogenesis (ELN). This results in structures that may resemble germinal centers, containing dendritic cells and aggregates of B and T cells. This process also occurs in other chronic inflammatory diseases. Nuclear factor-κB (NF-κB) transcription factors are essential for the expression of pro-inflammatory cytokines, but can also induce regulatory pathways. These regulatory circuits are thought to be modulated by the non-canonical NF-κB pathway of which NF-κB-inducing kinase (NIK) is a key mediator. Non-canonical NF-κB signaling can be triggered by stimuli like CD40L and lymphotoxin that are abundantly present in ELN. Therefore, the non-canonical NF-κB pathway might play an important role in ELN.

Objectives: To investigate the expression and distribution of NIK in RA synovial tissue (ST) in relation to ELN and to study the functional role of non-canonical NF-κB signaling.

Methods: ST was obtained via mini-arthroscopy from inflamed knee or ankle joints of RA patients with active disease. RA ST samples were analyzed by microarray analysis. Next, we evaluated the expression of NIK in ST of 40 RA patients using immunohistochemistry. NIK expression was scored on a semiquantitative 5-point scale (0–4) by 2 independent observers. Furthermore, we analyzed NIK and von Willebrand Factor (vWF) expression using immunofluorescence microscopy, not only in RA ST, but also in Grawitz tumour tissue and breast cancer tissue.

Results: Microarray analysis showed increased relative expression of non-canonical NF-κB pathway associated genes in ST containing ELN compared to tissue samples without ELN ($p<0.05$). Next, we confirmed these findings by immunohistochemistry. ELN was present in 15 out of 40 RA ST. NIK expression was significantly higher in ST with ELN and more abundantly present within lymphocyte aggregates (1.53 ± 0.32 vs 0.62 ± 0.19; $p<0.05$). Of interest, in the tissue away from the lymphocyte aggregates, NIK was expressed by vascular structures. Further analysis revealed that NIK positive cells were negative for the lymphatic vessel markers LYVE-1 and podoplanin. Immunofluorescence microscopy demonstrated that NIK co-localised with the endothelial cell marker vWF. We observed co-expression of NIK and vWF not only in RA ST, but also in Grawitz tumor and breast cancer tissue. Functional studies on the role of non-canonical NF-κB signaling in endothelial cells are currently being performed.

Conclusion: NIK is preferentially expressed in RA ST containing ectopic lymphoid aggregates. NIK expression in RA ST co-localised with vWF, indicating that NIK is expressed by blood vessel endothelial cells. These findings point towards an important role of the non-canonical NF-κB pathway in either blood vessel formation or in the activation of endothelial cells to attract immune cells. This could be exploited for the development of future new therapies, which would not only be applicable for RA but also for other diseases.

CXCL16 as an Early Response Chemokine in Rat Adjuvant and K/BxN Serum Induced Arthritis Models. Jeffrey H. Ruth[2], Chrisitian S. Haas[1], M. Asif Amin[2], G. Kenneth Haines III[4] and Alisa E. Koch[3]. [1]University of Luebeck - Department of Medicine I, Luebeck, Germany, [2]University of Michigan Medical School, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI, [4]Yale University Medical School

Purpose: We and others have previously shown that the transmembrane chemokine CXCL16 and its counterpart CXCR6 are important in the pathogenesis of rheumatoid arthritis (RA) predominantly via recruitment and stimulation of mononuclear cells. However, the expression pattern of CXCL16 during the development of RA and the optimal time point for therapeutic targeting remain unclear. In the present study we determined the spatiotemporal expression of CXCL16-CXCR6 in rat adjuvant induced arthritis (AIA), a rodent model for RA. We also examined joint swelling in CXCR6 deficient ($CXCR6^{-/-}$) and wild-type (Wt) mice administered K/BxN serum, an acute model of RA.

Method: Rat AIA synovial tissues (STs) were immunostained to determine the percentage of cells expressing CXCL16 and CXCR6. CXCL16 levels were also determined in serum and ankle homogenates using ELISA assays. CXCR6 expression was evaluated on rat macrophages and tested to induce rat macrophage migration towards soluble CXCL16 using a modified Boyden chemotaxis system. Lastly, $CXCR6^{-/-}$ and Wt C57BL/6 mice were primed to develop K/BxN serum induced arthritis and evaluated for joint swelling.

Results: CXCL16 showed constitutive expression on endothelial cells in rat AIA, and was upregulated on both lining cells (LCs) and macrophages on day 14, prior to arthritis onset ($p<0.05$). CXCR6 was virtually absent in normal ST but was expressed on LCs and macrophages on day 14. CXCL16 levels in serum and joints were increased on day 4 of rat AIA, suggesting that CXCR6 positive inflammatory cells migrate very early to the ST in rat AIA. Rat macrophages constitutively expressed CXCR6 *in vitro* and migrated in response to the ligand in a dose-dependent manner. Finally, using the K/BxN serum induced arthritis model, $CXCR6^{-/-}$ mice showed significantly reduced joint swelling compared to Wt mice at day 5 after serum induction.

Conclusion: CXCL16 and CXCR6 are upregulated in the early course of rat AIA. CXCL16 positive macrophages and LCs are found predominantly prior arthritis onset. Rat macrophages express CXCR6 and migrate in response to CXCL16 *in vitro*. In addition, $CXCR6^{-/-}$ mice show significantly less joint swelling using in an acute model of RA, suggesting that CXCL16 and CXCR6 function early in disease development to recruit inflammatory cells to the joint. Our findings may help guide *in vivo* targeting strategies for the CXCL16-CXCR6 pathway in RA.

Angiogenic Potential of HMECs Is Driven by HIF-2α Overcoming the Effects of HIF-1α. Martin Hahne[2], Steffi Luetkecosmann[1], Cam Loan Tran[1], Ferenz Lohanatha[1], Manuela Jakstadt[6], Grit Kasper[4], Georg Duda[4], Paula Kolar[4], Timo Gaber[1], Gerd R. Burmester[3] and Frank Buttgereit[5]. [1]Berlin-Brandenburg Center for Regenerative Medicine, [2]Berlin-Brandenburg School for Regenerative Medicine, Germany, [3]Charite - University Medicine, Berlin, Germany, [4]Charite - University Medicine, [5]Charite University Med-Berlin, Berlin, Germany, [6]German Rheumatism Research Center

Background: Hypoxia and angiogenesis are features of inflamed tissues. For the development of the rheumatoid pannus, subsequent synovial inflammation and joint destruction, the growth of new vessels is necessary. Inhibition of angiogenesis is one potential therapeutic approach to manage inflammatory diseases like rheumatoid arthritis (RA). In this regard the transcription factors Hypoxia inducible factor (HIF)-1α and (HIF)-2α control cellular response to decreased oxygen tension thereby promoting angiogenesis. Although HIF-1α and HIF-2α share structural similarities, they are supposed to have distinct transcriptional targets with implications on the pathogenesis of RA.

Objective: We focused on the effects of HIF-2α in the process of angiogenesis. Therefore, we developed a stable human microvascular endothelial cells (HMEC) lentiviral based knockdown system for HIF-2α. This model allowed us to analyze the ability of HMECs to perform angiogenesis under hypoxia in the absence of HIF-2α.

Methods: Specific knockdown of HIF-2α was achieved using lentiviral-based shRNA technology. Absence of HIF-2α and presence of HIF-1α was proved on transcriptional level by realtime RT-PCR as well as on translational level via Western blot. Angiogenic potential of HMECs was studied using an angiogenesis assay by investigating both tubuli and node formation under hypoxia (<1% O_2). Furthermore, realtime RT-PCR was carried out for expression analysis of hypoxia driven genes *HIF1A*, *HIF2A*, *GAPDH, PGK, GLUT1, LDHA* and angiogenesis related genes *VEGFA* and *IL8*.

Results: Evidencing the successful knockdown of HIF-2α, the gene expression levels of *HIF2A* were reduced by 69% under normoxia (scr vs. HIF2shRNA; p=0.0045) with the same reductive effect of 69% under hypoxia. Moreover, strongly reduced HIF-2α protein levels were detected by Western blot. HIF-1α levels were not affected by HIF-2α knockdown. Targeting HIF-2α led to a significantly decreased node formation by factor 2 under normoxia (Nox) and factor 4.5 under hypoxic (Hox) incubation (Nox scr vs. Nox HIF2shRNA, p=0.0255 and Hox scr vs. Hox HIF2shRNA, p=0.0002). Similar effects were observed at tubuli formation with a reduction by 70% in HIF-2α targeted cells (Nox scr vs. Nox HIF2shRNA, p=0.0128 and Hox scr vs. Hox HIF2shRNA, p=0.0053). Furthermore, targeting of HIF-2α gave rise to reduced levels of *VEGFA* and *IL8* expression, whereas the expression of metabolic relevant genes *GAPDH, PGK, GLUT1, LDHA* were not affected by HIF-2α knockdown under hypoxia.

Conclusions: Our findings show for the first time in a functional assay HIF-2α (i) to be responsible for the angiogenic potential of endothelial cells and (ii) to overcome HIF-1α's impact on angiogenesis. These findings provide new insights into basic principles of angiogenesis in inflamed tissues and therefore could be of clinical importance.

Soluble Junctional Adhesion Molecule-A Promotes Angiogenesis in Rheumatoid Arthritis. Bradley J. Rabquer[1], George Boychev[2], Jeffrey H. Ruth[2], Thilo Stehle[3] and Alisa E. Koch[4]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, [3]University of Tubingen, [4]Unversity of Michigan, Ann Arbor, MI

Purpose: Angiogenesis is a highly regulated process of new blood vessel formation that may occur from pre-existing blood vessels. Rheumatoid arthritis (RA) is characterized by synovial hyperplasia, inflammatory cell infiltration, and neovascularization. In RA, angiogenesis is regulated by the expression of angiogenic and angiostatic growth factors, cytokines, and adhesion molecules. Junctional adhesion molecule-A (JAM-A) is a novel member of the immunoglobulin supergene family expressed by epithelial cells and endothelial cells (ECs) and mediates EC permeability, leukocyte adhesion and migration, and angiogenesis. Interestingly, JAM-A was recently found in soluble form (sJAM-A). The aim of this study was to determine if sJAM-A is present in RA synovial fluid, if it mediates angiogenesis, and which signaling pathways sJAM-A utilizes to promote angiogenesis.

Methods: We designed and performed an ELISA to determine if sJAM-A was present in normal serum and synovial fluid from patients with RA and osteoarthritis (OA). To determine if sJAM-A mediates specific angiogenic events *in vitro*, human microvascular endothelial cell (HMVEC) chemotaxis assays and Matrigel EC tube formation assays were performed. To determine if sJAM-A mediates *in vivo* angiogenesis, we performed a Matrigel plug angiogenesis assay. HMVECs were stimulated with sJAM-A to determine which signaling pathways were activated.

Results: Our results indicate that sJAM-A is present in RA synovial fluid and that sJAM-A promotes angiogenesis. sJAM-A was detectable in normal serum (n=the number of patients=8, 0.9 (mean) ± 0.2 (SEM) ng/ml) and was significantly elevated in OA (n=9, 3.0 ± 0.5 ng/ml) and RA (n=10, 2.3 ± 0.5 ng/ml) synovial fluid (both $p<0.05$). sJAM-A stimulated HMVEC migration in a dose dependent manner that was significantly greater than phosphate buffered saline (PBS, negative control) from 5 nM to 500 nM (n=4 experiments, $p<0.05$). In addition, at 50 nM sJAM-A induced significantly more EC tubes compared to PBS (n=3 experiments, $p<0.05$) in a Matrigel *in vitro* EC tube formation assay. In an *in vivo* Matrigel plug angiogenesis assay, plugs containing sJAM-A had significantly more hemoglobin than those with PBS ($p<0.05$). Lastly, sJAM-A stimulated the phosphorylation of Mek1/2 and Erk1/2 kinases in HMVECs in a time dependent manner.

Conclusions: Our results show that sJAM-A is upregulated in RA and OA synovial fluid compared to normal serum. In addition, we show that sJAM-A promotes *in vitro* and *in vivo* angiogenesis. These results suggest that modulation of sJAM-A may provide a novel route for controlling angiogenesis in RA.

Invasiveness of Rheumatoid Arthritis Synovial Fibroblasts Is Affected by Extracellular RNA and DNA. Birgit Zimmermann[3], Silvia Fischer[1], Stephanie Lefèvre[4], Angela Lehr[6], Jürgen Steinmeyer[5], Henning Stürz[2], Thomas Umscheid[7], Ulf Müller-Ladner[3], Klaus T. Preissner[1] and Elena Neumann[3]. [1]Dept of Biochemistry, Justus-Liebig-University Giessen, [2]Dept of Experimental Orthopedics, University Hospital Giessen and Marburg, [3]Dept of Internal Medicine and Rheumatology, Justus-Liebig-University Giessen, Kerckhoff-Klinik, Bad Nauheim, Germany, [4]Dept of Internal Medicine and Rheumatology, Justus-Liebig-University Giessen, Kerckhoff-Klinik, Bad Nauheim, [5]Dept of Orthopedics and Orthopedic Surgery, University Hospital Giessen and Marburg, [6]Dept of Orthopedics and Trauma Surgery, Markuskrankenhaus Frankfurt, Germany, [7]Dept of Vascular Surgery, Helios William Harvey Klinik

Background: Activated synovial fibroblasts (SF) are one of the main cell populations in the inflamed joints of patients with rheumatoid arthritis (RA). RASF contribute to synovial neoangiogenesis and are cells central for cartilage destruction. In the SCID mouse model, we could recently show the potential of RASF to migrate out of a primary implantation site, to transmigrate through vessel walls, and to leave the vasculature again at a distant implanted cartilage site. Extracellular RNA has been shown to induce neoangiogenesis, increase endothelial cell (EC) permeability and to contribute to inflammation. Extracellular DNA is also known to induce inflammation. We therefore analyzed the effects of RNA/RNase and DNA/DNase on the invasiveness, migratory, and endothelial transmigratory potential of RASF.

Methods: RASF were treated for 15 h with RNase, DNase or control medium. Monolayers of different human EC were cultured on transwell chambers (umbilical venous and primary venous EC, EC of varicose veins). For the transmigration assay, 10% FCS served as chemoattractants. After 8 h, transmigrated cells were counted. Attachment of RASF and OASF to EC was measured in a cell-to-cell binding assay. As control cells, SF from osteoarthritis (OA) patients were used. In the SCID mouse model, healthy cartilage was coimplanted subcutaneously with RASF at the ipsilateral site (I). At the contralateral site (C), cartilage without RASF was implanted. Before implantation and every other day the animals received i.v. injections and were divided in 3 groups: (1) 42 μg DNase/kg body weight (2) 42 μg RNase/kg body weight; (3) saline. After 45 days, implants were removed and scored for cartilage invasion.

Results: Stimulation of RASF with RNase and DNase resulted in reduced synthesis of pro-inflammatory, pro-destructive and pro-angiogenic factors (e.g. IL-6, IL-8, MMP-3, VEGF). RASF showed an increased medium-dependent adherence to EC monolayers in comparison to OASF. RASF were able to pass all investigated EC monolayers. The invasion of RASF at the ipsilateral cartilage was significantly inhibited by RNase as well as DNase in comparison to saline (I saline, 2.3 +/−0.7, I RNase: 1.2 +/−0.6, p=0.048; I DNase: 0.8 +/−0.3, p=0.007). In contrast, the invasion of the contralateral cartilage was not affected by RNase or DNase (Inv C saline, 1.3 +/−0.7 vs. C RNase: 1.2 +/−1.2, p=0.74; C DNase: 1.1 +/−0.6, p=0.73). RNase or DNase did not inhibit the migration of RASF to and invasion into the contralateral implant (Inv I RNase vs. C RNase: p=0.77; I DNase vs. C DNase: p=0.35).

Conclusion: RASF are able to attach to EC and to pass different EC monolayers, reflecting the ability for vascular transmigration. Extracellular DNA and RNA reduce the secretion of pro-inflammatory and pro-destructive factors by RASF. In the SCID-mouse model, the migration to the contralateral implantation site and the invasive behavior of RASF was not influenced by RNase or DNase treatment, whereas RASF at the primary implantation site showed a significant decrease in their invasiveness. Interestingly, the results show different properties in the response to RNase and DNase treatment of migratory and non-migratory RASF in the SCID mouse model.

Citrullination of Extracellular Matrix Proteins Inhibits Synovial Fibroblast Invasion and Migration. Miriam A. Shelef[1], David A. Bennin[3] and Anna Huttenlocher[2]. [1]Department of Medicine, University of Wisconsin, Madison, WI, [2]Medical Microbiology & Immunology and Pediatrics, University of Wisconsin, Madison, WI, [3]Medical Microbiology & Immunology and Pediatrics, University of Wisconsin, Madison, WI

Purpose: The inflamed joint in rheumatoid arthritis (RA) has elevated levels of citrullinated proteins including fibronectin and collagen type II. RA patients make antibodies against citrullinated proteins, which are associated with more severe disease. However, how citrullinated proteins affect synovial cells and the development of erosive arthritis remains unknown. Since synovial fibroblasts (SFs) can migrate in the bloodstream and invade cartilage and bone, we examined how citrullinated extracellular matrix affects the migratory and invasive behavior of SFs.

Method: SFs were harvested from mouse ankle joints or synovial fluid from patients with RA or osteoarthritis and cultured. After 4–9 cell passages, SFs were analyzed for appropriate surface marker expression by flow cytometry. We then assessed invasion through citrullinated and normal Matrigel Invasion Chambers, migration across citrullinated fibronectin versus normal fibronectin coated transwells, and speed of adhesion on citrullinated versus normal fibronectin using time-lapse microscopy. Citrullination was accomplished by incubating Matrigel Invasion Chambers or fibronectin with peptidyl arginine deiminase type 2, isolated from rabbit skeletal muscle. To determine if citrullination alters integrin-mediated signaling, phosphorylation of focal adhesion kinase (FAK) and paxillin was examined by western blot analysis.

Results: SFs had dramatically impaired invasion through citrullinated invasion chambers compared to normal invasion chambers. They also displayed defective migration, slower adhesion, and reduced spreading on citrullinated fibronectin compared to normal fibronectin. SF cell lysates revealed decreased phosphorylation of FAK and paxillin after attachment to citrullinated fibronectin compared to normal fibronectin.

Conclusion: Citrullination of extracellular matrix proteins impairs SF invasion. The defects in migration, adhesion, and spreading on citrullinated fibronectin suggest abnormal integrin-mediated signaling. This idea is supported by the observed decrease in phosphorylation of FAK and paxillin, downstream targets of integrin signaling. Since fibronectin is thought to facilitate the adhesion of rheumatoid SFs to articular cartilage, potentially an initial step in joint destruction, citrullination may be a protective mechanism to halt invasion of SFs into cartilage and impede joint destruction in RA. This work supports the novel hypothesis that citrullination of extracellular matrix proteins seen in RA may be a protective response leading to decreased invasion of SFs.

The Role of miR-155 in the Activation of RA and PsA Synovial Fluid Monocytes. Mariola S. Kurowska-Stolarska[2], Lucy Ballantine[2], Bartosz E. Stolarski[2], John Hunter[2], Foo Y. Liew[2], J. Alastair Gracie[2] and Iain B. McInnes[1]. [1]Gartnavel General Hospital, United Kingdom, [2]University of Glasgow, United Kingdom

Purpose: MicroRNA (miR) network has emerged recently as an important post transcriptional regulator of immune response. Each individual miRNA species is capable of targeting a large number of distinct mRNA transcripts often belonging to one pathway. In our previous study we identified miR-155 to be strongly up-regulated in RA and PsA synovial fluid (SF) CD14+ cells compared to matched peripheral blood (PB) CD14+ cells suggesting that this miR may be involved in regulation of inflammatory pathways in arthritic joints. The aim of our study was to investigate the impact of miR 155 on the cytokine production and transcriptomic signature of RA and PsA SF monocyte and macrophage.

Methods: CD14+ cells from SF or PB of RA patients (n=14), PsA patients (n=13) and CD14+ cells from PB of healthy controls (n=6) were purified using CD14 MACS MicroBeads. PB CD14+ cells were transfected with miR-155 or scramble mimics (20 nM). Total RNA was isolated by miRNeasy kit. TaqMan miRNA and mRNA assays were used for semi-quantitative determination of the expression of miR-155 and its targets. The expressions of U6B small nuclear RNA or beta-actin were used as endogenous controls. Target prediction program and mRNA transcriptomic signature of RA and PsA SF CD14+ cells were employed to identify the cellular targets of miR-155 in SF CD14+ cells.

Results: Overexpression of miR-155 in PB CD14+ monocytes and PB CD14+ derived macrophages triggered TNF production suggesting that miR-155 may indeed be involved in post-transcriptional control of inflammatory pathways in SF monocyte. A computational target ranking system (TargetScan human 5.1, aggregate Pct above 4.0) predicted 127 mRNA targets for miR-155. To identify mRNAs that are specifically targeted in SF monocytes we cross-referenced TargetScan predictions with a list of 2312 mRNAs that were differentially expressed in SF CD14+ cells compared to PB CD14+ cells of RA (n=8) and PsA (n=7) patients (GeneChip Affymetrix U133 plus 2). This approach produced a list of 26 miR-155 targets that were relevant to SF CD14+ activation. Among them, 24 genes were up-regulated and 2 genes were down-regulated in SF CD14+ cells compared to PB CD14+ cells. Since miRs exert their function by mRNA degradation, we focused on genes that were down-regulated in SF CD14+ cells, namely SHIP1 (Src homology-2 domain-containing inositol 5-phosphatase 1) and ZNF652 (zinc finger DNA-binding protein). Expression of SHIP1 was down-regulated by 9 and 3.9 fold in SF CD14+ cells from RA (n=8) and PsA (n=7) patients, respectively. ZNF652 was decreased by 4.43 and 2.97 fold in SF CD14+ cells from RA and PsA patients, respectively. The decrease of SHIP1 and ZNF652 expression in SF monocyte was confirmed by QPCR on additional patient samples. Experimental validation revealed that the expression of SHIP1 and ZNF652 was inhibited in PB CD14+ cells transfected with miR-155 mimic compared to control mimic transfected cells (48 ± 10% and 43± 7%, respectively).

Conclusion: This study identified functional miRNA-mRNA networks that may be responsible for pro-inflammatory activation of synovial fluid monocyte and macrophage in RA and PsA patients.

Rapid Improvement in Health-Related Quality of Life (HRQoL) in Gouty Arthritis Patients Treated with Canakinumab (ACZ885) Compared to Triamcinolone Acetonide. A. So[6], M. De Meulemeester[4], A. Pikhlak[2], A. E. Yücel[1], U. Arulmani[3], D. Richard[3], K. Stricker[3], A. Ferreira[3], V. Murphy[3], P. Sallstig[3] and N. Schlesinger[5]. [1]Baskent University, Ankara, Turkey, [2]Moscow State University of Medicine and Dentistry, Moscow, Russian Federation, [3]Novartis Pharma AG, Basel, Switzerland, [4]Private PracticeGozée, Gozée, Belgium, [5]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ, [6]University of Lausanne, Lausanne, Switzerland

Background: Gouty arthritis is a painful inflammatory disease with a significant impact on patients' HRQoL. In gouty arthritis, the inflammatory response is initiated by interleukin-1β (IL-1β) release, due to activation of the NALP3 inflammasome by MSU crystals. Canakinumab, a fully human anti-IL-1β antibody has a long half-life and has been shown to control inflammation in gouty arthritis. This study evaluated changes in HRQoL in gouty arthritis patients following treatment with canakinumab or triamcinolone acetonide (TA).

Methods: This was an 8-week, dose-ranging, multi-center, active controlled, single-blind study. Patients ($\geq$18 to $\leq$80 years) experiencing an acute gouty arthritis flare, refractory to or contraindicated to NSAIDs and/or colchicine, were randomized to canakinumab 10, 25, 50, 90, 150 mg sc or TA 40 mg im. HRQoL was assessed as an exploratory endpoint at baseline and different pre-specified time-points using patient reported outcomes evaluating general mental and physical component summary scores and subscale scores of SF-36® (acute version 2) and functional disability (HAQ-DI©). We report HRQoL results for canakinumab 150 mg, the dose that was selected for the Phase III studies.

Results: Baseline assessments showed a major impact on the HRQoL during acute gouty arthritis. Compared to TA, canakinumab 150 mg showed greater improvements in SF-36® physical and mental component summary and subscale scores at 7 days post-dose.

In the canakinumab 150 mg group, the most severe impairment at baseline was reported for physical functioning and bodily pain; levels of 41.5 and 36.0, respectively, which improved within 7 days to 80.0 and 72.2 (mean increases of 39.0 and 35.6) approaching levels of the general US population (84.2 and 75.2). 8 weeks post-dose patients reached levels of 86.1 and 86.6 (mean increases of 44.6 and 50.6 for physical functioning and bodily pain, respectively) and these were higher than levels seen in the general US population. This was in contrast to patients treated with TA, who showed less improvement within 7 days (mean increases of 23.3 and 21.3 for physical function and bodily pain, respectively). None of the scores reached levels of the general US population 8 weeks post-dose. Functional disability scores, as measured by the HAQ-DI© decreased in both treatment groups (Table).

Table. Comparison of HRQoL scores of gouty arthritis patients treated with canakinumab and triamcinolone acetonide

Component	General US population†	Canakinumab 150 mg s.c. Baseline N = 27	Canakinumab 150 mg s.c. 7 days post-dose N = 26†	Canakinumab 150 mg s.c. Reference: 1. Adapted from Ware J et al. SF-35 Physical and Mental Health Summary Scales: A User's Manual, Boston, MA: The Health Institute, 1994

Conclusions: All canakinumab doses showed a rapid improvement in physical and mental well-being of gouty arthritis patients based on SF-36® scores, in particular the 150 mg dose. In contrast to the TA group, patients treated with canakinumab showed improvement within 7 days in physical function and bodily pain approaching levels of the general population. The 150 mg dose of canakinumab was selected for further development in Phase III studies.

Toll-Like Receptor Signals Modify the ER Stress Response. Jane C. Goodall[1], Louise McNeill[2], Lou Ellis[2] and J. Hill Gaston[2]. [1]Cambridge University, Cambridge, Cambs, United Kingdom, [2]Cambridge University

During cellular stress, the decrease in protein translation caused by eIF2α phosphorylation reduces protein load in the endoplasmic reticulum (ER) which allows the cell a window of time to instigate a program of gene expression coined as the unfolded protein response (UPR). To allow the recovery of protein translation, GADD34 is activated in a negative feedback loop which dephosphorylates eIF2α and enables more efficient protein translation and recovery from cellular stress. We have previously shown that ER stress signals are induced following bacterial infection and that these signals synergise with Toll-like-receptor (TLR) signals to enhance the expression of cytokines such as IL-23.

The aim of this study was to determine if TLR signals have a reciprocal activity and modify the ER stress response and in particular the expression of GADD34, the molecule involved in translation recovery from ER stress. Monocyte derived dendritic cells (mDC) were subjected to ER stress using thapsigargin (TP) or tunicamycin (TM) in the presence or absence of different pattern recognition receptor (PRR) agonists. The expression of GADD34 mRNA and protein was induced by the ER stress stimuli, but was substantially enhanced by costimulation with LPS (TLR4), Curdlan (dectin 1) or peptidoglycan (TLR2 and NOD2) agonists.

MyD88 knockdown in the monocyte cell line THP-1, abrogated the ability of LPS to enhance GADD34 expression induced by ER stress stimuli, this effect was not seen in THP-1 cells expressing a control shRNA. This suggests that Myd88 dependent signals are required for LPS upregulation of GADD34 in the presence of ER stimulation. Using specific inhibitors for defined signalling pathways we identified that upregulation of GADD34 by LPS was dependent on the activity of p38Map kinase and ERK but not JNK and NF-κB. These inhibitors did not inhibit the upregulation of GADD34 by ER stress stimuli alone, suggesting that ER stress and LPS stimuli provide independent signals that synergise to enhance GADD34 expression.

ER stress and substantial upregulation of GADD34 expression was detected in mDC and THP-1 following infection with the intracellular bacterium, *Chlamydia trachomatis* (CT). To determine if the upregulation of GADD34 following intracellular bacterial infection was dependent on MyD88, THP-1 cells expressing MyD88 or a control shRNA were infected with CT and GADD34 expression was analysed. The upregulation of GADD34 was substantially reduced in THP-1 cells expressing MyD88 shRNA suggesting that MyD88 dependent TLR signals were required for this effect.

These data show that the regulation of protein translation has not only the potential to be modulated via ER stress but also via the stimulation of PRR pathways. This may have significant implications for the expression of pro-inflammatory or regulatory cytokines. We hypothesize that changes in GADD34 expression induced by TLRs will contribute significantly to the ability of myeloid cells to secrete pro-inflammatory cytokines in response to bacterial infection.

Canakinumab (ILARIS®) Improves Health-Related Quality of Life (HRQoL) in Patients with Cryopyrin-Associated Periodic Fever Syndrome (CAPS): Results of a Phase III, Open-Label Study in a Large Cohort of CAPS Patients. I. Kone-Paut[4], H. J. Lachmann[12], J. B. Kuemmerle-Deschner[6], E. Hachulla[3], R. Cartwright[1], J. Hoyer[2], P. Quartier[11], J. Smith[13], M. Gattorno[5], K. Leslie[10], J. Braun[9], A. Widmer[7], A. Ferreira[7], N. Patel[8], R. Preiss[8] and P. N. Hawkins[12]. [1]Allergy Center at Brookstone, Columbus, GA, [2]Department of Internal Medicine and Nephrology, Universitaetsklinikum Giessen und Marburg GmbH, Marburg, Germany, [3]Hôpital Claude Huriez CHRU, Lille Cedex, France, [4]Hôpital Kremlin Bicetre, CEREMAI, Le Kremlin Bicetre, France, [5]Istituto Giannina Gaslini, Genova, Italy, [6]Klinik fuer Kinder-und Jugendmedizin, Universitaetsklinikum, Tuebingen, Germany, [7]Novartis Pharma AG, Basel, Switzerland, [8]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [9]Rheumazentrum Ruhrgebiet, Herne, Germany, [10]UCSF School of Medicine, San Francisco, CA, [11]Unit'e d'Immunologie, Hematologie et Rhumatologie Pediatrique, Hopital Necker-Enfants Malades, Paris, France, [12]University College London Medical School, London, United Kingdom, [13]University of Wisconsin Hospital and Clinics, Madison, WI

Background: Canakinumab (a fully human anti-interleukin-1β monoclonal antibody) has been recently approved by the FDA for the treatment of familial cold auto-inflammatory syndrome (FCAS) and Muckle-Wells syndrome (MWS) and by the EU for the treatment of cryopyrin-associated periodic syndrome (CAPS). This spectrum of autoinflammatory disease is caused by overproduction of IL-1β and is associated with rash, constitutional inflammatory symptoms and marked fatigue. Health-related quality of life (HRQoL) was assessed during a phase III, open-label, multi-center study to evaluate the direct impact of the disease on patients' well-being and to assess the long-term maintenance of HRQoL.

Methods: The 119 adult CAPS patients in this study were canakinumab-naive (n=71) or rolled-over from earlier Phase II/III studies (n=48). They received canakinumab 150 mg s.c. every 8 weeks and HRQoL was assessed using the following domains: general physical and mental health (SF-36® physical and mental component summary [PCS and MCS]), fatigue (FACIT-Fatigue©) and functional disability (HAQ-DI).

Results: Median duration of exposure to canakinumab in the study was 414 days (range 29–687 days). Of the 119 adult CAPS patients there were 25 FCAS, 80 MWS, 14 MWS/NOMID [6 NOMID] patients. In canakinumab-naive patients the baseline scores (mean [SD]) for physical function (SF-36® PCS: 41.2 [10.9]) and mental health (SF-36® MCS: 45.5 [10.7]) and fatigue (FACIT-F: 32.8 [11.7]) were considerably lower than those expected in the general population (50 [10] for SF-36® PCS and MCS and 43.6 [9.4] for FACIT-F), which demonstrates the significant impact that CAPS has on patients' well-being. The scores improved rapidly after one single dose of canakinumab and approached levels of the general population after 8 weeks (SF-36® PCS, 48.4 [8.7] and MCS, 52.8 [7.7]; FACIT-F, 41.7 [9.3]). This improvement was maintained at one year, as shown by the SF-36® PCS (49.8 [8.6]) and MCS (51.2 [9.9]) and FACIT-F (42.9 [10]) scores. For patients who continued the study beyond one year for up to two years HRQoL scores remained within the range of general population at the final visit. An improvement in functional disability was also observed as shown by HAQ-DI scores, although the level of functional disability in these patients as measured by the HAQ was not marked. Patients who rolled-over from previous studies while maintaining the 8 weeks dosing schedule already had HRQoL scores close to general population levels at baseline and these levels were maintained throughout the study.

Conclusions: Canakinumab administration improved the HRQoL scores to levels seen in the general population in a large cohort of CAPS patients across all severity phenotypes.

Osteoarthritis-Associated Basic Calcium Phosphate Crystals Activate the NLRP3 Inflammasome in a Syk Kinase Dependent Manner. Aisling Dunne[2], Lisa Mielke[2], Jurg Tschopp[3], Kingston H. G. Mills[2] and Geraldine M. McCarthy[1]. [1]Royal College of Surgeons, Ireland & Mater Hospital, Ireland, [2]Trinity College Dublin, Ireland, [3]University of Luasanne, Switzerland

Background: Basic calcium phosphate (BCP) crystals which were traditionally considered markers of osteoarthritis-associated (OA) tissue damage are now themselves considered potent drivers of pro-inflammatory cytokine production. In this study we investigated the ability of BCP crystals to drive IL-1β and IL-18 production through activation of the NLRP3 (NOD-like Receptor (NLR) Protein 3) inflammasome complex. In addition we assessed the ability of these crystals to induce neutrophil influx in an *in vivo* peritonitis model and to skew T cell responses towards a Th17 phenotype.

Methods: Murine and human dendritic cells (DC) were stimulated with BCP crystals, with or without priming with a Toll-like receptor (TLR) agonist and IL-1β and IL-18 production was quantified by enzyme linked immunosorbent assay (ELISA). Specific inhibitors of caspase-1 and NLRP3-deficient cells were used to determine the role of caspase-1 and the NLRP3 inflammasome complex while a role for Syk and PI3 kinase was determined with the use of the inhibitors piceatannol and LY294002, respectively. BCP-activated DC were tested for their ability to promote T cell responses using FACS analysis following treatment of splenocytes or purified $CD4^+$ T cells with supernatants from BCP-treated DC. Finally, BCP-induced neutrophil infiltration was assessed using an *in vivo* peritonitis model.

Results: Physiological concentrations of BCP crystals (50μg/ml) induced robust IL-1β and IL-18 production in a caspase-1 and NLRP3 dependent manner. IL-1β was produced at an average concentration of 2 ng/ml following a 2 hour treatment of LPS-primed DC while IL-18 production averaged at 200 pg/ml under the same conditions. This activity is dependent on lysosomal acidification and potassium efflux as pre-incubation with sub-optimal doses of bafilomycin and quinidine, the potassium channel blocker, caused a 2-fold reduction in IL-1β levels. In addition, pre-incubation with specific Syk and PI3 kinase inhibitors abrogated both IL-1β and IL-18 production. In addition to IL-1β, BCP crystals greatly enhanced the production of the Th17 skewing cytokines IL-1α and IL-23 and incubation of splenocytes or purified CD4+ T cells with supernatants from BCP treated DC promoted Th17 cell differentiation. Finally, BCP crystals promoted robust neutrophil influx in a model of crystal induced peritonitis after 6 hours.

Conclusion: Our findings demonstrate that BCP crystals induce the pro-inflammatory cytokines IL-1, IL-18 and IL-17 via activation of the NLRP3 inflammasome and identify the inflammasome, Syk kinase and PI3 kinase as potential targets for the treatment of BCP crystal-induced inflammation and tissue destruction seen in OA patients.

Lipid-Cytokine-Chemokine Cascade Drives Neutrophil Recruitment in a Murine Model of Inflammatory Arthritis. Nancy D. Kim[3], Richard C. Chou[1], Christian Sadik[2], Edward Seung[2], Yinan Lan[2], Yoichiro Iwakura[4] and Andrew Luster[2]. [1]Dartmouth-Hitchcock Medical Center, Lebanon, NH, [2]Massachusetts General Hospital, [3]Massachusetts General Hospital, Boston, MA, [4]University of Tokyo

Purpose: A diverse array of chemoattractants control leukocyte trafficking, but how these apparently redundant signals collaborate *in vivo* is still unknown. We previously demonstrated an absolute requirement for the lipid chemoattractant leukotriene B_4 (LTB_4) and its receptor BLT1 for neutrophil recruitment into the joint in the development of immune complex-induced arthritis. The purpose of these studies was to further dissect the sequential roles of LTB_4, IL-1β, and chemokine signaling in neutrophil recruitment in this model of inflammatory arthritis.

Methods: Using the K/BxN serum transfer arthritis mouse model, K/BxN serum was injected into C57Bl/6, BLT1−/−, CXCR2−/−, CCR1−/−, and CXCR2−/−/CCR1−/− mice, and arthritis was assessed by hind paw measurement and clinical scoring. Bone marrow neutrophils from IL-1α/β−/− mice were purified and injected for neutrophil adoptive transfer studies. On designated days, synovial fluid leukocytes and neutrophils and synovial tissue were isolated, and chemokine, chemokine receptor, and

cytokine transcription and production were analyzed by quantitative PCR and ELISA. Primary murine fibroblast-like synoviocytes (FLS), endothelial cells, and macrophages were stimulated *in vitro* with recombinant murine IL1-1β or TNF-α, and neutrophil-active chemokine expression was measured by qPCR.

Results: Synovial fluid analysis demonstrated that CCR1 was the predominant neutrophil chemokine receptor in the early phase of disease, and CXCR2 was the predominant neutrophil chemokine receptor in established disease. Synovial fluid neutrophils produced IL-1β and the neutrophil-active chemokines CCL3/MIP-1α and CXCL2/MIP-2. In contrast, synovial tissue expressed greater proportions of the neutrophil-active chemokines CXCL1/KC and CXCL5/LIX. Adoptive transfer of IL-1$\alpha/\beta-/-$ neutrophils into BLT1$-/-$ mice was not able to restore disease or chemokine expression. *In vitro* IL-1β-stimulated FLS and endothelial cells expressed primarily CXCL5/LIX and CXCL1/KC, respectively. Finally, upon induction of K/BxN serum transfer arthritis, CCR1$-/-$ mice had delayed and attenuated disease compared with wild-type mice, while CXCR2$-/-$ mice had normal onset of disease that quickly waned. Importantly, deletion of both CCR1 and CXCR2 in the mice completely abrogated arthritis development.

Conclusions: In this model of acute autoantibody-induced arthritis, we uncovered a sequence of events in which a lipid receptor (BLT1) initiates disease by promoting the influx of neutrophils producing IL-1β, which then induces CXCL1/KC and CXCL5/LIX from surrounding synovial tissue. Synovial fluid leukocytes themselves also produce CCL4/MIP-1β and CXCL2/MIP-2, promoting further neutrophil trafficking into the joint. CCR1 and CXCR2 operate in series to mediate all chemokine-dependent neutrophil recruitment. Thus, we have demonstrated that neutrophil trafficking into the joint is a tightly regulated process requiring the sequential involvement of multiple cytokine and chemoattractant pathways.

The Impact of Patient-Physician Relationship Components on Physician Trust and Treatment Adherence in Patients with Rheumatic Disease. Sofia de Achaval[1], Michael A. Kallen[1], Vanessa L. Cox[1], Marsha N. Richardson[1] and Maria E. Suarez-Almazor[2]. [1]The University of Texas M. D. Anderson Cancer Center, Houston, TX, [2]University of Texas, MD Anderson Cancer Center, Houston, TX

Background: Treatment adherence plays a significant role in the successful management of rheumatic disease. Adherence itself may be influenced by patient-physician relationship factors and a patient's overall physician trust.

Purpose: We investigated whether specific components of the patient-physician relationship were directly associated with the more global concept of physician trust; we then assessed the extent to which these relationship components influenced treatment adherence via their impact on overall physician trust.

Methods: We performed a cross-sectional study of outpatient clinic patients with rheumatic disease, i.e., Rheumatoid Arthritis (RA) or Systemic Lupus Erythematosus (SLE). Six specific components of the patient-physician relationship were measured: doctor informativeness, sensibility to concerns, reassurance and support, patient centeredness, participatory decision-making, and patient disclosure of information. Patient's physician trust was evaluated using the Wake Forest Physician Trust Scale, while treatment adherence was measured via the Compliance Questionnaire Rheumatology (CQR). A conceptual model was developed, with the relationship component variables predicting trust, and trust predicting adherence. We statistically assessed bivariate relationships across all model variables, using Pearson product-moment correlations. We then conducted a path analysis to test our conceptual model and identify statistically significant direct, indirect, and total effects of the conceptual model's patient-physician relationship variables on physician trust and treatment adherence. Path analysis' particular strength lies in its capacity to model and then simultaneously estimate a number of regression equations when exploring complex relationships. For the path analysis we analyzed the model variable covariance structure.

Results: Our sample included 311 patients (201 with RA and 110 with SLE). Eighty percent of patients were female; mean patient age was 46 years. Bivariate correlations were all positive and statistically significant ($p<0.05$) and ranged from 0.25–0.79. In the path analysis, 4 of 6 relationship component variables (doctor informativeness, reassurance and support, patient centeredness and participatory decision-making) were found to have statistically significant direct effects on trust and indirect effects on treatment adherence; trust had a statistically significant direct effect on adherence. The overall path analytic model displayed good fit to the data (chi-square$=2.56$, $p=0.63$, RMSEA<0.01).

Conclusion: Patients' perceptions of multiple specific components of their relationship with their physician are associated with patient trust in their physician, which is strongly related to treatment adherence, with greater trust enhancing adherence. Modifications to specific components of the patient-physician relationship, namely doctor informativeness, reassurance and support, patient centeredness and participatory decision-making, could potentially improve treatment adherence by increasing physician trust.

Development of an ACMGE Core Competency-Based Electronic Portfolio at the USC-LAC Rheumatology Fellowship Program. Karina Marianne D. Torralba[2], Francisco P. Quismorio[3], Beatrice A. Boateng[1] and Shylaja Rachabattula[4]. [1]Arkansas Children's Hospital-University of Arkansas for Medical Sciences, [2]University of Southern California-Los Angeles County Medical Center, Pasadena, CA, [3]University of Southern California-Los Angeles County Medical Center, Los Angeles, CA, [4]University of Southern California-Los Angeles County Medical Center

Portfolios have been utilized in health sciences education over the past 10 years to document and assess progress in training, and as a vehicle for reflection on lifelong learning. The Accreditation Council for Graduate Medical Education (ACGME) has encouraged the use of core-competency based portfolios for postgraduate training, but current and convenient formats have not been widely available. The objectives of this study are to assess the effectiveness of paper-based portfolios in our program in demonstrating achievement of ACGME core competencies, and to develop an electronic portfolio that would conveniently document evidences according to these competencies. We conducted a systematic review of paper-based fellow portfolios over the past 7 years using the following parameters: evidence management, demonstration of fulfillment of core competency criteria, ability to show reflections of lifelong learning. Our fellowship program has 2–3 fellows at each training year level. Our review revealed that evidences of education and performance (eg. conference presentations, letters to patients and insurance companies, Mini-CEX, 360 degree evaluations) were not organized according to competency mainly due to 1) physical limitations of paper portfolios to adequately show that certain evidences had applicability to more than one competency, and 2) lack of perception by learners of what educational activities and evidences were pertinent to specific competencies. There was also a lack of reflection on self-assessment of educational progress. An institution-based software for residency management (Verinform©) which is mainly used by faculty and fellows to access evaluations and procedure logs was inadequate to assess achievement of competencies. As a result, over the past 2 years, a Microsoft© Word-based portfolio was developed and implemented at our institution. We initially asked fellows and key faculty to identify the applicability of core competencies according to the various educational activities and evidences in the program. Activity/evidence-based and competency-based rubrics were then developed to help establish levels of achievement that could help fellows understand criteria for improvement and allow faculty raters criteria for evaluation. The electronic format permitted filing of evidences under multiple competencies using hyperlink and cross-referencing functions. Self-assessments using reflection were also developed. Our MS Word portfolio adequately demonstrates achievements of ACGME competencies. We seek to further evaluate the effectiveness of this portfolio and the evaluation rubrics as mentorship and career development tools.

An Updated Immunology Curriculum for Rheumatology Fellows. Rahul K. Patel[1], Lisa Hodge[1], Jerry Simecka[1] and Bernard R. Rubin[2]. [1]UNT Health Science Center, Fort Worth, TX, [2]UNT Health Science Center, Birmingham, MI

Purpose: Basic immunology is a rapidly advancing area, with numerous clinical advances stemming from basic immunologic insights. Educating rheumatology fellows in training on basic immunology topics remains a challenge. Residents begin rheumatology programs having matriculated in widely different medical school and internal medicine environments. Balancing basic immunology concepts, experimental methods, and review of classic and recent immunology literature is a challenge, while maintaining a clinically relevant approach to the topic.

In an attempt to improve the basic immunology curriculum for our rheumatology fellows in training, we updated the immunology course to incorporate a clinically oriented text, lectures from clinical and basic research faculty, journal club style presentation of papers by fellows, and lectures by clinicians and basic researchers from industry.

Exam scores from a pre-test and post course test are compared.

Methods: 4 fellows (two 2nd year fellows, two 1st year fellows) completed the course. The course is taught from January to April. It consisted of 2 weekly sessions, 2 hours each, for 13 weeks. The text chosen for the course was Chapel et al Essentials of Clinical Immunology, 5th edition, 2006. Fellows were given weekly reading assignments from the text. One weekly session consisted of didactic lectures by immunology and clinical rheumatology faculty, covering key chapters from the text. The second weekly session consisted of discussion of journal papers from immunology literature. Papers were picked by rheumatology fellows to cover recent topics discussed in didactic lectures. Finally, clinical science liaisons and basic researchers from industry were invited to present unbranded talks covering basic immunology topics relevant to therapeutics in rheumatology. Participating fellows in training were given a pre-test at the start of the course, as well as a post-test at the conclusion of the course., with 30 multiple choice questions, written by immunology faculty. The pre and post tests included different questions, covering similar topics in basic immunology.

Results: Pre and post-test results were available for 3 fellows (1 fellow was absent on the pre and post test date). Results for the pre-test were 33 and 33% for both first year fellows, and 73% for 2nd year fellow with post-test results of 73 and 67% for first year fellows, and 87% for 2nd year fellow. All fellows showed an increase between pre to post test results, ranging from absolute increases of 15% to 34%.

Conclusions: Our experience suggests that rheumatology fellows' understanding of immunologic topics, as reflected by increases between pre and post test exam results, showed improvement. Further longer term data, including measuring outcomes from the rheumatology in-service exams and board certification scores, would help support whether this approach can lead to long term successful education of fellows in training on immunologic topics.

Disclosure: R. K. Patel: None; **L. Hodge:** None; **J. Simecka:** None; **B. R. Rubin:** None.

A Case-Controlled Study of a Multimodal Rheumatology Elective for Medical Residents. Deana M. Lazaro[4], Sheen Yee Lim[2], David R. Blumenthal[3], Joshua Scheers-Masters[1], Jeanne Macrae[1] and Matthew Avitable[1]. [1]SUNY Downstate Medical Center, [2]SUNY Downstate-Brooklyn, Brooklyn, NY, [3]VA New York Harbor Healthcare System, Short Hills, NJ, [4]VA New York Harbor Healthcare System and SUNY Downstate Medical Center, Brooklyn, NY

Background: Training medical residents to treat patients with musculoskeletal complaints is highly desirable because of the aging United States population and relative shortage of rheumatologists. To address this concern, we tested whether first year medical residents who have clinical experience in Rheumatology clinic and an enhanced curriculum will perform better than residents without such experience on a multiple choice examination and an objective structured clinical examination (OSCE). We also surveyed the residents on their confidence and attitudes regarding musculoskeletal diseases.

Methods: Thirty-five SUNY Downstate first-year medical residents were randomized to participate in the ambulatory Rheumatology elective or another subspecialty experience for four weeks. All residents reviewed the MedStudy guide for Rheumatology and several Hopkins modules and received a copy of the Primer on the Rheumatic Diseases. The residents assigned to Rheumatology clinic were given access to 12 case-based learning modules with questions based upon the material, a video on the musculoskeletal physical examination, instruction on arthrocentesis and injection techniques using simulators, approximately 3 out-patient Rheumatology clinic sessions each week and weekly journal club. All residents completed a 45 question pre- and post-test, 4 OSCE stations focused on the evaluation and treatment of musculoskeletal diseases and completed a pre- and post-questionnaire to gather information on the confidence of the residents in their knowledge of Rheumatology.

Summary of the Results: All residents improved performance on the multiple choice examination after the clinical rotations, however, there was no significant difference in the improvement rate pre- and post- rotation between the groups ($p=0.18$). Likewise performance on the OSCE was similar with the exception of the station on arthrocentesis. The residents who received a training session on arthrocentesis and injection technique and had the opportunity to interact with patients in the rheumatology clinic performed significantly better ($p=0.02$). The residents assigned to the rheumatology clinic reported greater confidence in their ability to treat patients with arthritis ($p=<0.001$).

Conclusions: Exposure of medical residents to an enhanced curriculum and experience in rheumatology clinic improved performance of arthrocentesis as demonstrated on a simulator and increased their perception of their abilities. Rate of improvement on the multiple choice examination and the other OSCE stations were not significantly different between the two groups.

Funding for this project was provided by the American College of Rheumatology Research and Education Foundation Clinician Scholar Educator Award

Effect of Internal Medicine Resident Participation in Team-Based Learning on In-Training Exam Scores in Rheumatology. Karina Marianne D. Torralba[2], Beatrice A. Boateng[1], Ron Ben-Ari[3] and Francisco P. Quismorio[2]. [1]Arkansas Children's Hospital-University of Arkansas for Medical Sciences, [2]University of Southern California-Los Angeles County Medical Center, Los Angeles, CA, [3]University of Southern California-Los Angeles County Medical Center

Objective: Team-based learning (TBL) has been utilized as a teaching strategy for Rheumatology core curriculum learning sessions (CCLSs) of residents at the University of Southern California-Los Angeles County Internal Medicine Residency program since 2008. TBL is an interactive small group learning technique that encourages accountability, teamwork and has been demonstrated to improve board scores and patient care. This study seeks to examine if there is a correlation between attendance and participation in TBL sessions on the Rheumatology component of the Internal Medicine In-training exam (IM-ITE) scores.

Method: There have been 13 TBL-CCLSs over a two-year period (2008/09 and 2009/10) on various connective tissue diseases including rheumatoid arthritis, osteoarthritis, myopathies and spondyloarthropathies. Resident attendance of TBL sessions and their ITE scores were recorded. Data was collected on two groups: group 1 represents residents who were in their year 1 of residency when the TBL sessions started and group 2 are those who were in year 2. Of 129 residents, 117 participated in the TBL-CCLSs over the 2-year period. Twelve residents did not participate in any TBL session; however their ITE scores are included in the analysis. ANOVA, T-test and Scheffe's post-hoc analysis were used to analyze the data.

Results: TBL-CCLSs were required for residents however they are not always able to attend due to other responsibilities. Data were stratified into quartiles based on total attendance: no attendance; low, $\leq$4 times; medium, 5–9 times, high, $>$9. The average attendance was 3.17 $\pm$2.22 (SD). There was an increase in ITE scores over the two-year period. TBL participation had no significant effect on ITE scores (ANOVA). Scheffe's post-hoc analysis was conducted to determine if there were any significant differences among the three levels of attendance in TBL. There was a significant difference in the mean ITE scores of residents with medium attendance (5–9 sessions) when compared to those with low attendance (1–4 sessions) ($p<.05$). This implies that residents that participated in 5–9 TBL-CCLSs over a two-year period were more likely to have significantly higher Rheumatology ITE scores than those who participated in less than 5 sessions.

Conclusions: There was no statistically significant increase in the overall ITE scores over the two-year period. However, residents participating in 5–9 TBL-CCLSs were more likely to have significantly higher Rheumatology ITE scores when compared to those that did not participate or participated in less than five sessions.

"Rheumapalooza": An Intensive Rheumatology Curriculum for Second Year Medical Students. Helen Emery[1] and Gregory Gardner[2]. [1]Seattle Children's Hospital, [2]University of Washington

Background: Medical students at our institution have little exposure to rheumatology in their preclinical years. The musculoskeletal curriculum included only two hours on arthritis, taught by an orthopedic surgeon. When students scored poorly on rheumatic disease topics in standardized tests, we introduced a course at the beginning of the second year to increase their knowledge and stimulate interest in rheumatic diseases. The course was given in 2008 and 2009 with some adjustments in response to faculty and student input.

Goals: Develop a curriculum to provide exposure to rheumatology

Evaluate students' rheumatology knowledge before and after this curriculum

Review students' assessment of the course

Prepare a manual as a guide for future courses here and at other medical schools.

Methods: The program is divided into two half days.

The first half day is didactic (concepts of inflammation, introduction to adult rheumatology; introduction to pediatric rheumatology; imaging techniques, and laboratory studies in the rheumatic diseases).

The second half day, the students are divided into groups of 14 groups and rotate through fifteen minute stations. Two demonstrate normal knee and shoulder exam; eight have a preceptor and a patient to elicit history and physical findings (adult rheumatoid arthritis, juvenile idiopathic arthritis, lupus, scleroderma, gout, ankylosing spondylitis, juvenile dermatomyositis, and osteoarthritis,) and four stations discuss osteoporosis, bone density interpretation, crystals, and characteristic x-ray, CT and MR images.

A twenty question pretest and post test was administered to evaluate increase in student knowledge from the course, and a student evaluation was completed at the end of the course.

Results: students showed a marked increase in knowledge as assessed by the pre and post tests. Paired t-test is highly statistically significant, with very large effect size (2.7 of the pooled SD). Student evaluations were 4.0/5, (179 respondents/216 participants) and offered useful suggestions for future programs A manual has been prepared to guide others in adapting this curriculum to their own setting.

Conclusions: The one day "Rheumapalooza" program has been effective in providing an intensive exposure to rheumatology, increasing rheumatology knowledge in second year medical students, and establishing a curriculum reproducible to other settings.

Tocilizumab in Patients with Systemic Juvenile Idiopathic Arthritis: Efficacy Data from the Placebo-Controlled 12-Week Part of the Phase 3 TENDER Trial. Fabrizio De Benedetti[1], Hermine Brunner[4], Nicola Ruperto[9], Inmaculada Calvo[5], Ruben Cuttica[10], Clara Malattia[11], Rayfel Schneider[2], Patricia Woo[7], Carine H. Wouters[8], Ricardo Xavier[6], Lawrence S. Zemel[3], Stephen Wright[12], Andrew Kenwright[12], Alberto Martini[9] and Daniel J. Lovell[4]. [1]IRCCS Ospedale Pediatrico Bambino Gesu, Rome, Italy, [2]PRCSG, Toronto, ON, Canada, [3]PRCSG, Hartford, CT, [4]PRCSG, Cincinnati, OH, [5]PRINTO, Valencia, Spain, [6]PRINTO, Porto Alegre, Brazil, [7]PRINTO, London, United Kingdom, [8]PRINTO, Leuven, Belgium, [9]PRINTO, Genova, Italy, [10]PRINTO, Buenos Aires, Argentina, [11]PRINTO, [12]Roche, Welwyn, UK, Welwyn, United Kingdom

Purpose: Systemic juvenile idiopathic arthritis (sJIA) is the most severe form of JIA and is characterized by arthritis and prominent systemic manifestations. Interleukin-6 (IL-6) plays a pivotal role in sJIA pathogenesis. Tocilizumab (TCZ), an anti-IL-6 receptor antibody, was shown to be effective in a Japanese phase 3, placebo-controlled, withdrawal-design trial in patients with sJIA. We report 12-week efficacy data from the global phase 3 TENDER trial in patients with sJIA.

Methods: Patients with active sJIA (age range, 2–17 years; disease duration, ≥6 months; inadequate response to previous NSAIDs and corticosteroids) were randomly assigned 2:1 to receive TCZ every 2 weeks (8 mg/kg for patients ≥30 kg body weight; 12 mg/kg for patients <30 kg) or placebo (control). Stable doses of NSAIDs and methotrexate were continued, and corticosteroid tapering was allowed from week 6. Patients who qualified for rescue therapy received standard of care, were offered open-label TCZ, and were considered nonresponders. Primary end point was the proportion of patients with JIA ACR30 response plus absence of fever at week 12 (ITT analysis).

Results: The ITT population consisted of 112 patients (37 controls, 75 TCZ). Baseline characteristics were similar between groups. By week 12, 3% of patients in both arms (1 control, 2 TCZ) withdrew from the study, and more control than TCZ patients required rescue therapy (54% vs 3%). Significantly more TCZ patients experienced JIA ACR30 response plus absence of fever at week 12 compared with controls (85% vs 24%; $p<0.0001$). Additionally, significantly more TCZ patients than controls achieved JIA ACR50/70/90 response (Table A). Of the patients who had fever at baseline, significantly more TCZ patients than controls had no fever at week 12. Similarly, of those patients with anemia or thrombocytosis at baseline, significantly more patients treated with TCZ than control had normal hemoglobin levels or normal platelet counts, respectively (Table A). A considerable proportion of TCZ patients achieved ACR70/90 responses, even in subgroups whose baseline characteristics included a high number of active joints, fever, or a high platelet count, and in those treated with prior biologic therapy (Table B). Four serious adverse events were reported in 3 TCZ patients—angioedema and urticaria (1), varicella (1), and bacterial arthritis (1)—all of which resolved without sequelae.

Conclusions: These results show that TCZ is highly effective in treating sJIA, as shown by the clinically relevant JIA ACR70 and ACR90 responses, irrespective of baseline characteristics such as active joint disease, fever, high platelet count, and previous biologic therapy.

Table A. Efficacy Outcomes at Week 12

	Control, n = 37	TCZ, n = 75
JIA ACR50 responses, n (%)	4 (11)	64 (85)[a]
JIA ACR70 responses, n (%)	3 (8)	53 (71)[a]
JIA ACR90 responses, n (%)	2 (5)	28 (37)[a]
No fever after having a fever at baseline, n/n (%)	5/24 (21)	35/41 (85)[a]
Normal hemoglobin after having anemia at baseline, n/n (%)	2/29 (7)	40/50 (80)[a]
Normal platelet count after having thrombocytosis at baseline, n/n (%)	1/26 (4)	47/52 (90)[a]

Table B. Efficacy Outcomes at Week 12 by Select Baseline Characteristics, n/n (%)

		TCZ, n = 75		
		ACR 30 + absence of fever	ACR70	ACR90
No. of active joints	0–9	18/20 (90)	13/20 (65)	7/20 (35)

Background: Canakinumab provides sustained interleukin-1β (IL-1β) blockade and is effective in the treatment of CAPS (comprising of familial cold auto-inflammatory syndrome [FCAS], Muckle-Wells syndrome [MWS], chronic infantile neurologic, cutaneous and articular syndrome [CINCA]/neonatal-onset multisystem inflammatory disease [NOMID]). Herein we report the long-term safety, tolerability, and efficacy of canakinumab in the subgroup of pediatric CAPS patients who were enrolled as part of an open-label, single-treatment arm, Phase III study.

Methods: Patients enrolled in this study were canakinumab-naive or rolled-over from earlier Phase II/III studies. Patients received canakinumab 150 mg s.c. or 2 mg/kg s.c. (body weight ≤40 kg) every 8 weeks. Complete response was assessed for canakinumab-naive patients, while roll-over patients entered the study allowing continuous treatment every 8 weeks. In case of an incomplete response patients could be changed to a more intense dosing regimen (received an additional dose of canakinumab 300 mg s.c. or 4 mg/kg s.c. [body weight ≤40 kg]). Adjustment of the dosing frequency was also permissible. Complete response was defined as: physician's global assessment of disease activity and skin assessment score ≤minimal and normal CRP and/or SAA values (<10 mg/L). Relapse was defined as: serum levels of CRP and/or SAA >30 mg/L and (a) physician's global assessment of disease activity >minimal or (b) physician's global assessment of disease activity minimal along with the assessment of skin disease >minimal.

Results: Of 47 pediatric patients (3–17 years) (1 patient did not have CAPS and was discontinued [protocol violation] and of the remaining 46 patients there were 5 FCAS, 23 MWS, 18 MWS/NOMID [includes 8 NOMID] patients), 38 were canakinumab-naive, while 9 had been pre-treated with canakinumab. 43 (92%) completed the study and 3 patients discontinued the study (1 due to adverse event [AE]). The median duration of exposure to study drug was 290 days (range: 29–625 days). Complete response was achieved in most (n=26, 68%) of canakinumab-naive pediatric patients. The majority of canakinumab treated pediatric patients were relapse free (29 out of 35 [83%]) and 6 patients experienced a relapse. Dose adjustments were required in 16 patients (34%). Amongst all NOMID patients (including MWS/NOMID overlap) 15 (47%) received at least one dose or frequency adjustment. In canakinumab-naive patients median CRP and SAA levels rapidly decreased within 7 days (2.5 and 7.4 mg/L [baseline levels were 14.8 and 40.6 mg/L, respectively]) and these levels were maintained at normal levels (<10 mg/L) during the study (both in naive and roll-over patients). The most frequent AEs were rhinitis, nasopharyngitis and headache. Serious AEs were reported in 6 pediatric patients. Most patients (n=43, 91%) had no injection site reactions.

Conclusions: Canakinumab s.c. every 8 weeks induced rapid and sustained clinical and biochemical remission in pediatric patients across all severity of CAPS phenotypes. Adjustment of dose appears to be predominantly applied in pediatric and/or NOMID patients. Long-term tolerability and safety was good.

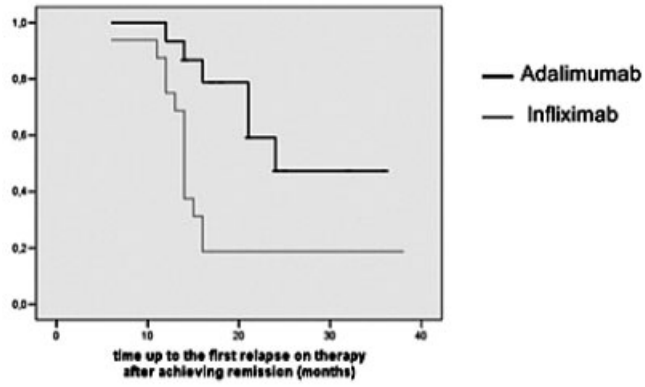
Prevention of Flare Recurrences in Childhood Refractory Chronic Uveitis: An Open-Label Comparative Study of Adalimumab Versus Infliximab. GABRIELE Simonini[5], Andrea Taddio[1], Marco Cattalini[4], Roberto Caputo[3], Cinzia De Libero[2], Cecilia Bresci[5], Monica Lorusso[5], Samuele Naviglio[1], Loredana Lepore[1] and Rolando Cimaz[5]. [1]Department of Sciences of Reproduction and Development, Institute of Child Health, IRCCS Burlo Garofolo, University of Trieste, Trieste, Italy, [2]Opthalmology Unit, A.Meyer's Children's Hospital, Firenze, Italy, [3]Opthalmology Unit, A.Meyer's Childrens Hospital, Firenze, Italy, [4]Pediatric Clinic, University of Brescia, Brescia, Italy, [5]Rheumatology Unit, Dpt of Pediatrics, University of Florence, A.Meyer's Childrens Hospital, Firenze, Italy

Background: Up to now, no data are available about the comparison in efficacy and safety of Adalimumab versus Infliximab in treating chronic, refractory uveitis in childhood.

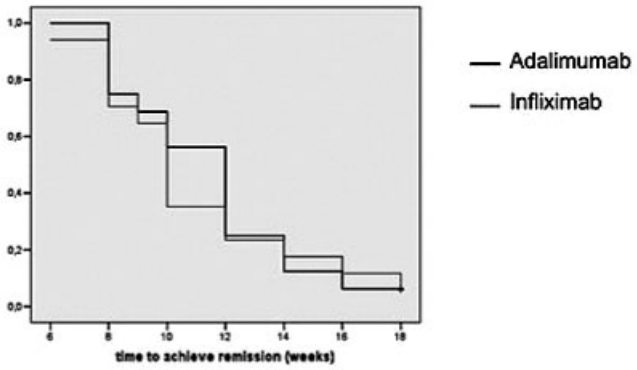
Objective: To compare the efficacy and safety of Adalimumab versus Infliximab in an open-label prospective, comparative, multi-centre, cohort study of childhood non-infectious chronic uveitis.

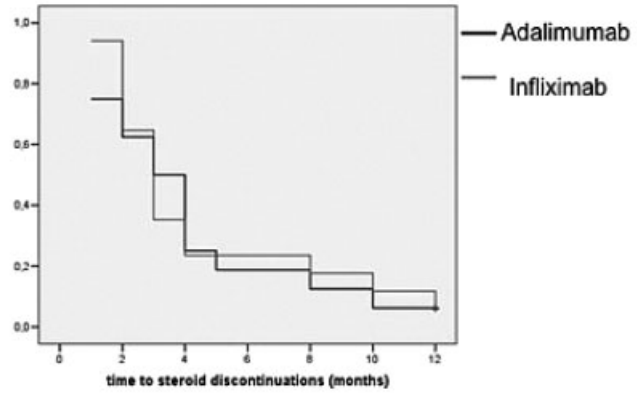
Methods: 33 patients (22 F, 11 M; median age: 9,17 years) with refractory vision threatening non-infectious uveitis, were enrolled, over 28 months, to receive, for at least 1 year, Infliximab (5 mg/kg at weeks 0, 2, 6 and then every 6–8 weeks) or Adalimumab (24 mg/sq.mt, every 2 weeks). Primary outcome was to assess, once remission was achieved, the time of a first relapse during time treatment. Time to remission, time to steroid discontinuation and the number relapses, were also considered.

Results: 16 children (12 with Juvenile Idiopathic Arthritis [JIA], 3 with idiopathic uveitis, 1 with Behçet's disease) were recruited in the Adalimumab cohort; 17 children (10 with JIA, 5 with idiopathic uveitis, 1 with early-onset sarcoidosis, 1 with Behçet's disease) into the Infliximab group. Cox-regression analysis did not show statistical significant differences between the two groups with regard to time to achieve remission, and time to steroid discontinuation, whilst showed a higher probability of uveitis remission on Adalimumab during the time of treatment entered for each cohort (Mantel-Cox $\chi 2$ 6.83, $p<0.001$).



At 40 months follow-up, 9/15 children on Adalimumab (60%) compared to 3/16 children on Infliximab (18.8%) were still on remission on therapy ($p<0.02$).Considering the secondary outcomes, at mean on the above reported covariates, survival Cox-regression analysis did not show statistical significant differences between the two treatment groups with regard to time to remission, and time to steroid discontinuation.





Among children who relapsed, at 40 months follow-up, the median number of relapses resulted statistically significantly higher in Infliximab group than in Adalimumab group: 3, range 1–5, versus 1, range 1–3 respectively, $p<0.001$.

Conclusion: Even if limited to a relatively small group, our study suggests that, at 3 year treatment, Adalimumab is more efficacious than Infliximab in maintaining remission of chronic childhood uveitis.

1437

Safety and Low Seroprotection/Seroconversion Rates of Pandemic Influenza A Vaccine (Anti-H1N1/2009) in Juvenile Systemic Lupus Erythematosus. Lucia M. Campos[3], Clovis A. A. Silva[3], Nadia Aikawa[3], Eloisa Bonfa[5], Guilherme Trudes[3], Ana Cristina M. Ribeiro[5], Carla Gonçalves Saad[5], Vilma Trindade Viana[5], Maria do Carmo Timenetsky[1], Alexander R. Precioso[2] and Rosa M. R. Pereira[4]. [1]Instituto Adolpho Lutz, [2]Instituto Butantã, [3]Paediatric Rheumatology Unit, Faculdade de Medicina da Universidade de São Paulo, [4]Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo, São Paulo, SP, Brazil, [5]Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo

Purpose: To assess immunogenicity and safety of pandemic influenza A (H1N1) 2009 virus vaccine in juvenile systemic lupus erythematosus (JSLE) patients.

Methods: 75 JSLE patients and 64 age-matched healthy controls were vaccinated with the strain influenza A/California/7/2009 (H1N1) vaccine. All participants were older than 9 years and were evaluated pre and 21 days post-vaccination. Anti-H1N1 antibody titer in serum samples was determined by influenza hemagglutination-inhibition (HI) assay. Appropriate endpoints included the percentage of subjects achieving an HI antibody titer $\geq$1:40 (seroprotection) and rates of seroconversion, defined as the percentage of subjects with either a pre-vaccination HI titer $<$1:10 and a post vaccination HI titer $\geq$1:40 or a pre-vaccination HI titer $>$1:10 and a minimum four-fold rise in post-vaccination HI antibody titer.

Results: The mean age was similar in JSLE and controls (16.52$\pm$3.34 vs. 15.92$\pm$4.81 years, $p=0.39$). Among JSLE patients 74.6% were female, the mean follow up was 5.4 $\pm$ 3.6 years and treatments included: antimalarial in 74.7%, glucocorticoids in 68% and immunosuppressors in 60% of patients. Before immunization seroprotection was comparable in JSLE and controls (21.3 vs. 21.9%, $p=1.00$). After vaccination these percentages increased significantly to 74.6% ($p<0.0001$) in JSLE and to 95.3% ($p<0.0001$) in the control group. The percentage of seroprotection was, however, significantly lower in JSLE after immunization (74.6% vs. 95.3%, $p=0.0009$). Seroconversion rates were also inferior in JSLE compared to controls (62.7% vs. 89.1%, $p<0.001$) with a lower median titers in JSLE (160 vs. 320, $p=0.008$). The comparison of 47 seroconverters patients with the remaining 28 nonresponders revealed a similar mean age and disease duration, female predominance, frequency of immunomodulators and prednisone use. Nevertheless, the prednisone dose was lower in seroconverters vs. nonresponders (8.66$\pm$10.81 vs. 16.84$\pm$18.51 mg/day, $p=0.018$). Concerning vaccine safety in JSLE patients, no difference in SLEDAI scores was observed before and after immunization (6.03$\pm$6.10 vs. 5.23$\pm$5.45, $p=0.12$). Nonresponders group had a higher SLEDAI before the vaccination compared to seroconverters (8$\pm$6.13 vs. 4.98$\pm$5.86, $p=0.037$) whereas the post-vaccine SLEDAI was alike in both group (5.36$\pm$4.03 vs. 5.21$\pm$6.15, $p=0.91$). No serious vaccine adverse events were observed during 2 months follow-up.

Conclusions: The pandemic influenza A (H1N1) 2009 virus vaccine is safe in JSLE patients; however the seroprotection/seroconversion rates were lower than healthy controls. This finding suggests the need of a boost, particularly in active lupus patients and those under high dose of glucocorticoid therapy. ClinicalTrials.gov Identifier: NCT01151644

Mortality/Morbidity in Cardiac Neonatal Lupus and Associated Maternal/Fetal Risk Factors. Peter M. Izmirly[1], Amit Saxena[1], Zoey Smith[2] and Jill P. Buyon[1]. [1]NYU School of Medicine, New York, NY, [2]NYU School of Medicine

Purpose: The classic cardiac manifestations of neonatal lupus (cardiac-NL) include a spectrum of conduction dysfunction (1st, 2nd, or 3rd degree heart block (CHB)) and more rarely cardiomyopathy which can be absent any conduction disease. This study was undertaken to update the mortality data of cardiac-NL in a large US based cohort and identify associated risk factors to further understand the pathogenesis of anti-SSA/Ro mediated injury and provide evidence based data for counseling women with these antibodies.

Methods: Three hundred and one children with cardiac-NL (295 with CHB and 6 with isolated cardiomyopathy) enrolled in the Research Registry for Neonatal Lupus (RRNL) had sufficient medical records for review. The RRNL database was analyzed for the following potential mortality maternal risk factors: age at pregnancy, race/ethnicity, anti-SSB/La antibody status, health status and fetal risk factors: time of diagnosis, exposure to maternal non-fluorinated and fluorinated steroids during pregnancy, method of delivery, and gender. In addition, morbidity was assessed by the frequency of pacemaker placement and cardiac transplant.

Results: Follow up of the children ranged from in utero death to adulthood. Of the 301 children with cardiac-NL, 53 (17.6%) died. Thirty percent died in utero or at birth, 41% died prior to six months of postnatal life and the remaining 29% died after 6 months. Mortality was higher among children born to non-Caucasian mothers compared to Caucasian mothers (33% vs 15% $p=.0003$). Maternal age was equivalent between the groups (29.1 dead vs 29.7 live). The maternal presence of anti-SSB/La antibodies was 74% for those whose children died and 63% for those whose children survived, which was not significant. A maternal diagnosis of Sjorgen's

Syndrome and/or Systemic Lupus Erythematosus was not significantly associated with cardiac-NL death (53% in death vs 44%) suggesting that prior knowledge of maternal antibody status did not influence mortality. With regard to fetal factors, 86% of those who died were diagnosed with cardiac-NL during pregnancy compared to 85% who survived. For those diagnosed during pregnancy there was a trend towards early gestational diagnosis for those children that died compared to those that survived (21 vs 23.5 weeks p=.09). There was also a trend toward higher exposure to maternal fluorinated steroids after the diagnosis in children that died (53% vs 40% p=.09), however there was no difference in maternal use of non-fluorinated steroids in those that died vs those that survived (19% vs 16%). Most fetuses were delivered by C-section and this was not significantly associated with death (70% dead vs 75% live). Female gender was also not associated with outcome (49% who died were female vs 52% live). Eighty-five percent of children received a pacemaker, 43% within 9 days of birth, 20% between 9 days and one year. Five children (2%) received a heart transplant.

Conclusion: Based on data from this large cohort, 17.6% of children born with cardiac-NL die from complications of the disease. Eighty-five percent required pacing and two percent required cardiac transplantation. Mortality was more prevalent in children born to non Caucasian mothers.

Methotrexate in Children with Juvenile Localized Scleroderma: A Randomized, Double-Blind, Placebo-Controlled Trial. Francesco Zulian[7], Cristina Vallongo[8], Giorgia Martini[8], Fernanda Falcini[5], Annalisa Patrizi[4], Maria Alessio[3], Francesco La Torre[6], Mario Cutrone[1], Anna Belloni-Fortina[8], Mauro Paradisi[2], Silvana Martino[9], Fabio Vittadello[8] and Giorgio Perilongo[8]. [1]Children's Hospital of Mestre, [2]Dermatology, IDI IRCCS, Rome, [3]University Federico II Naples, [4]University of Bologna, [5]University of Florence, Florence, Italy, [6]University of Messina, [7]University of Padua, Padua, Italy, [8]University of Padua, [9]University of Turin

Background: Juvenile localized scleroderma (JLS) is a chronic progressive fibrotic process of the skin causing permanent disability and aesthetic damage. Although no universally accepted effective treatment is available, recent studies seem to support the use of methotrexate (MTX).

Objectives: We aimed to assess the safety and efficacy of methotrexate in patients with JLS.

Methods: We performed a double-blind, randomised controlled trial. Patients with active JLS, with linear, generalized or deep subtypes, were randomly assigned to receive oral MTX, at a dose of 15 mg/m^2 once a week (max 20 mg), for 12 months or until flare of the disease (MTX arm), or placebo at the same dose and timing (placebo arm). Oral prednisone (1 mg/Kg/day, max 50 mg), in a single morning dose for 3 months then tapered down until stopping in one month, was added to both groups. The randomization rate MTX/PLAC was 2:1. The extension of the skin lesions was evaluated by a computerized scoring system[1] and changes were quantified by the skin score rate (SSR) (skin score at time$_n$/skin score at time$_0$). Clinical examination and serial thermographies monitored the changes of active lesions[2]. The primary endpoint was the rate of response to treatment. Responders were defined those patients who satisfied the following 3 criteria: SSR≤1; decrease of the temperature at thermography of at least 10% compared to baseline; absence of new lesions. Disease relapse was defined when was present at least one of the following: SSR>1; unchanged or increased lesion temperature; appearance of new lesions. All analyses were intention-to-treat.

Results: 85 patients entered the screening phase and 70, aged 6–17 years, from 13 centres in Italy, were enrolled. 46 patients were randomized in the MTX arm and 24 in the placebo arm. Groups were homogeneous as far as clinical and immunological features, mean disease duration was 2,1 years in both groups. After an initial response in all patients, disease relapse occurred in 15 MTX patients (32,6%) and 17 placebo patients (70,8%) (p<0.005), mean SSR value decreased from 1 to 0.79 with MTX vs 1,1 with placebo. The mean target lesion temperature decreased 44% vs 12.1%. New lesions appeared in 3 MTX patients (6.5%) vs 4 on placebo (16.7%). 26 patients (56,5%) of MTX group and 11 patients of the placebo group (45,8%) presented mild side effects related to treatment. None was severe enough to stop treatment.

Conclusion: MTX is an effective and well tolerated treatment for patients with JLS.

Methotrexate but Not TNF-Blockers Reduces Immune Response Following Pneumococcal Vaccination Using 7-Valent Conjugate Pneumococcal Vaccine (Prevenar®) in Adult Patients with Established Arthritis. Meliha C. Kapetanovic[5], Carmen Roseman[5], Göran Jönsson[1], Lennart Truedsson[4], Tore Saxne[3] and Pierre Geborek[2]. [1]Dept of Clinical Sciences Lund, Section of Infectious Diseases, Lund University, Lund, Sweden, [2]Dept of Clinical Sciences Lund, Section of Rheumatology, Lund University, Lund, Sweden, [3]Dept of Clinical Sciences Lund, Section of Rheumatology, Lund University, Sweden, [4]Dept of Laboratory Medicine, Section of Microbiology, Immunology and Glycobiology, Lund University, Lund, Sweden, [5]Section of Rheumatology, Lund University, Lund, Sweden

Aim: To study the influence of anti-inflammatory treatments including methotrexate (MTX) and TNF-blockers on serological response following pneumococcal vaccination using 7-valent conjugate vaccine (Prevenar®) in adult patients with established arthritis.

Patients and Methods: Altogether 506 patients with rheumatoid arthritis (RA) or spondylarthropathy (SpA) including psoriatic arthritis were vaccinated. All patients were stratified into 6 prespecified groups based on diagnosis and type of anti-rheumatic treatment: 1. RA patients treated with methotrexate + in some cases other DMARDs (n=85; 79 % female; mean age 62 years); 2. RA patients on TNF blockers as monotherapy (n=80; 88% female; mean age 60 years); 3. RA patients on anti-TNF +MTX + possibly other DMARDs (n=89; 78% female; mean age 60 years); 4. SpA patients on anti-TNF drugs as monotherapy (n=83; 34% female; mean age 49 years); 5. SpA patients on anti-TNF drugs +MTX (n=83; 53% female; mean age 50 years) and 6. SpA patients on NSAIDs and/or analgesics (n=86; 45% female; mean age 52 years). Group 5 served as a control group. All patients received one dose of 0,5 ml Prevenar intramuscularly. Levels of IgG antibodies against two pneumococcal serotypes (23F and 6B) were measured prior to and 4–6 weeks following vaccination using standardised ELISA.

Results: Postvaccination geometric mean IgG levels increased significantly for both serotypes in all groups compared to baseline (p=0.000). Immune response (IR); i.e ratio between post- and prevaccination antibody levels differed significantly between the groups. Patients with spondylarthropathy on NSAIDs and/or analgesics (controls) had better IR compared to groups treated with MTX or MTX combined with TNF blockers (group 1, 3 and 5). Patients treated with TNF-blockers as monotherapy (group 2 and 4) had numerically somewhat lower IR but not significantly different compared to controls for both serotypes.

Positive immune response (posIR) was defined as ≥ 2 times increase in antibody levels compared to baseline. Patients with RA exhibited reduced responsiveness compared to patients with SpA in univariate analysis. In multivariate analysis only older age and MTX treatment predicted reduced response while ongoing systemic prednisolone treatment elicited better posIR, table1.

Conclusion: Higher age and treatment with methotrexate predicted an impaired immune response to the 7-valent conjugate pneumococcal vaccine in this cohort of patients with chronic arthritis. Concomitant prednisolone treatment was associated with better IR. TNF-blockers did not affect the immune responses significantly.

Table 1. Predictors of positive immune response (pos IR) for both 23F and 6B.

Lipid and Inflammation Parameters: A Translational, Randomized Placebo-Controlled Study To Evaluate Effects of Tocilizumab: The MEASURE Study. Iain B. McInnes[7], Janet S. Lee[6], Wen Wu[6], Jon T. Giles[5], Joan M. Bathon[5], Jane E. Salmon[4], Andre D. Beaulieu[2], Christine E. Codding[3], Christian Delles[1] and Naveed Sattar[1]. [1]British Heart Foundation, Glasgow, United Kingdom, [2]Centre de Rhumatologie St-Louis, Montreal, QC, Canada, [3]Health Research of Oklahoma, Oklahoma City, OK, [4]Hospital for Special Surgery, New York, NY, [5]Johns Hopkins University, Baltimore, MD, [6]Roche, Nutley, NJ, [7]University of Glasgow, United Kingdom

Purpose: Mechanistic data describing changes in lipid parameters upon IL-6R inhibition with tocilizumab (TCZ) are lacking. We report initial results from a randomized, double-blind, placebo-controlled study to evaluate the impact of TCZ on lipid particle subclasses and markers potentially relevant to cardiovascular (CV) risk.

Methods: Serum lipid subclasses characterized by nuclear magnetic resonance (NMR) and a range of inflammatory biomarkers were measured in patients with active rheumatoid (RA) with an inadequate response to MTX. Changes from baseline (BL) to wk 12 were compared between TCZ 8 mg/kg + MTX (N=69) and PBO+MTX (N=63) arms. The data were analyzed using nonparametric analysis of variance, not corrected for multiplicity.

Results: Baseline values and changes from baseline for each parameter by treatment arm are shown in the Table. Within lipid parameters, the largest changes occurred in the VLDL/triglyceride and large VLDL. Within LDL, increases occurred almost exclusively in large, more buoyant particles whereas small, dense LDL particles remained stable. Within HDL, increases occurred primarily in small HDL particles. Among inflammatory markers, Hs-CRP, HDL-associated SAA, and sPLA2-IIA were reduced with TCZ treatment; the prothrombotic marker D-dimer was also reduced. The HDL-associated antioxidative enzyme, paraoxonase I was increased with TCZ treatment.

Conclusion: Small LDL particles, thought to be proatherogenic, did not increase with TCZ treatment, in contrast to large VLDL particles and in small HDL particles with statistically significant increases. The changes in lipid parameters that occur with TCZ treatment, coupled with reductions in a wide range of inflammatory markers, demonstrate the intrinsic linkage of inflammation and metabolic regulation in the context of RA. Furthermore, reductions in HDL-associated SAA and sPLA2-IIA along with increases in paraoxonase reflect qualitative changes in lipoproteins that may favor improvements in CV risk-benefit.

Tumor Necrosis Factor-α Inhibitors and Reduced Risk of Developing Diabetes in Patients with Rheumatoid Arthritis. Jana Antohe[1], Androniki Bili[1], Jennifer A. Sartorius[2], H. Lester Kirchner[2], Stephanie J. Morris[1], Sorina Dancea[1] and Mary Chester Wasko[3]. [1]Geisinger Health System, Danville, PA, [2]Geisinger Health System, [3]Univ of Pittsburgh, Pittsburgh, PA

Background: Tumor necrosis factor-alpha (TNF-α) inhibitors may improve insulin sensitivity and thus would be expected to reduce the risk of diabetes mellitus (diabetes) in patients with rheumatoid arthritis (RA). This study examined the association of TNF-α inhibitor use and the risk of developing diabetes in an RA inception cohort in a rural, tertiary health system using Electronic Health Records (EHR).

Methods: All adult individuals diagnosed with RA between 1/1/2001 – 3/31/2008 were identified (n=1539). RA was defined as ICD-9 code 714.0 at ≥ 2 outpatient encounters with a rheumatologist, and diagnosis was validated against the American College of Rheumatology criteria by manual review of 100 random charts (97% concordance). Prevalent cases of diabetes, defined as 1 or more outpatient visits with ICD-9 250, a non-fasting blood glucose ≥ 200 mg/dl, hemoglobin A1C ≥ 7, or a hypoglycemic medication order, were excluded (n=252). Information on demographic data, medical history, body mass index (BMI), laboratory measures and medications were collected at office visits. Patients were classified as ever (n=352) or never (n=935) users of a TNF-a inhibitor (etanercept, adalimumab, or infliximab). Incident diabetes cases were identified using 2010 American Diabetes Association criteria. Time-varying Cox Proportional Hazard regression models were used to adjust for gender, age, race, hypertension, BMI, positive rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibodies (anti-CCP), erythrocyte sedimentation rate, C-reactive protein (CRP), non-steroidal anti-inflammatory drug (NSAID), glucocorticoid, hydroxychloroquine and methotrexate use. Medication use was considered continuous for lapses ≤ 90 days.

Results: 1287 non-diabetic incident RA patients were included in the analysis. Patients were predominantly women (63%), and 97% were Caucasian, with median age of 61 y and BMI 28.6 kg/m^2. RF and anti-CCP were positive in 80% and 53%, respectively. Patients in the ever TNF-α inhibitor use group had a higher median BMI and CRP levels and were more likely to have positive RF and anti-CCP and to have taken NSAIDs, glucocorticoids or methotrexate. Median follow-up time (last visit or diabetes diagnosis date) for the ever- and never-TNF-α inhibitor users was 34.7 months and 23.1 months, respectively (p<.001).The median duration of TNF-α inhibitor exposure was 33.5 months. Of the 56 cases developing diabetes during observation, 13 wereever and 43 were never TNF-α inhibitor users, yielding incidence rates of 10.5 and 22.0 per 1000 person-years (p=0.019), respectively. Adjusting for covariates, the hazard ratio for incident diabetes among TNF-α inhibitor users was 0.40 (95% confidence interval 0.16–0.98, p=0.046) compared to non-users.

Conclusions: In this inception RA cohort, the use of TNF-α inhibitors was associated with a 60% reduction in risk of developing diabetes after controlling for confounders. These findings need to be confirmed by additional studies in this group of patients at high risk of cardiovascular disease.

Superior Protection Against "Vulnerable" Coronary Plaque in Asymptomatic TNFi-Responders vs. DMARD Responders with Rheumatoid Arthritis (RA). George A. Karpouzas[1], Naser Ahmadi[2], Tae-Young Choi[2], Fereshteh Hajsadeghi[2], Silvia Munoz[2] and Mathew Budoff[2]. [1]Harbor-UCLA, Long Beach, CA, [2]Harbor-UCLA

Background: A lower risk of myocardial infarction (MI) was recently reported in patients (pts) with RA exposed to Tumor necrosis factor-a inhibitors (TNFi). It is unclear, however, whether a good disease response is necessary for the observed benefit. Additionally, the mechanisms, as well as sequalae of disease response on coronary plaque quantity and composition are unknown. We prospectively evaluated the presence, total burden, and differences in the quality of coronary plaque in asymptomatic RA pts treated with TNFi vs. DMARDs alone.

Methods: We report on 74 RA pts recruited from a single center. Pt characteristics, including disease response, coronary risk factors and treatments are shown in table 1. Good EULAR response (DAS28≤3.2 and DAS28 change>1.2) distinguished responders (R) from non-responders (NR). Pts underwent 64+ slice cardiac Computed Tomography Angiography (CTA); this non-invasive modality includes an initial non-contrast phase assessing coronary calcium, followed by a contrast scan that detects plaque with equal accuracy to conventional angiography, and is superior in the assessment of non-calcified, lipid-rich, non-obstructive or "vulnerable" plaque. Individual coronary trees were evaluated for plaque volume and composition by standard methods (American Heart Association). Non-parametric tests were used for data analysis; regression models for plaque prevalence ratios (PR) and relative risk (RR) for plaque burden in TNFi R vs. NR and DMARD R vs NR, adjusted for conventional risk factors were constructed.

Results: No differences in coronary risk factors were present in DMARD vs. TNFi treated pts. Both TNFi and DMARD responders (R) had significantly less plaque prevalence than NR of both categories (table). Both R groups had lower numbers of diseased coronary segments vs. NR (p=0.008 for DMARD and TNFi respectively), and less total plaque burden (p=0.04 for DMARD and p=0.005 for TNFi vs. NR respectively). More importantly, R groups had less NC/mixed plaque (p=0.001 for DMARD and p=0.0001 for TNFi vs. NR respectively). TNFi R had 61% lower risk of having "vulnerable" plaque, and 23% less burden of it compared to DMARD R, after adjustment for age, sex and traditional risk factors. Interestingly, TNFi NR also had 38% lower risk of NC/mixed plaque and 21% less burden, insinuating a superior protective effect of TNFi against plaque progression, independent of RA disease response.

Conclusion: Good EULAR response to TNFi affords superior protection against total, but more importantly, "vulnerable" coronary plaque progression compared to good response to DMARDs. TNFi seem to have an independent- to RA clinical response- protective effect against plaque as evidenced by significantly lower volume and vulnerable plaque features in the TNFi NR group.

Background: Randomised controlled trials have shown that tumour necrosis inhibitor (TNF-I) treatment halts erosive progression in rheumatoid arthritis (RA). In clinical practice, patients often withdraw from or switch TNF-I treatment. The impact of discontinuation or change of TNF-I treatment on radiographic progression in RA clinical practice is unknown.

Objectives: To investigate and compare the annual radiographic progression rates on conventional radiographs (CR) 2 years before and after TNF-I initiation in three subgroups of an observational cohort of RA patients, who

(1) stayed on their first TNF-I,
(2) withdrew from TNF-I treatment or
(3) switched to another TNF-I drug.

Methods: Conventional radiographs (CR) of hands and wrists were obtained ~2 years before start of TNF-I (time-point A), at the start of TNF-I (B) and ~ 2 years after start of TNF-I (C). Clinical data from the DANBIO registry and the patientfiles were collected. The CRs were scored blinded to chronology (modified Sharp score). Annual radiographic progression rates during DMARD (delta A-B)

and TNF-I (delta B-C) treatments were calculated, stratified according to treatment status at timepoint C (Group 1–3, see above). Data were analysed with non-parametric analyses due to a skewed distribution.

Result: 522 patients (76% women, 80% rheumatoid factor positive, age 54(21–86) years (median(range)); disease duration 5 (0–67) yrs) had complete A-B-C series. At time-point B, patients who stayed on TNF-I had a higher rate of concomitant methotrexate (MTX) treatment, while patients who switched TNF-I had a higher DAS28. At time-point A, patients received DMARDs (90%) or no DMARDs (10%). At time-point B, patients started treatment with infliximab (61%), etanercept (15%), or adalimumab (24%). The TNF-I were given in combination with MTX(78%); other DMARDs(10%); or in monotherapy (12%). The duration of Period A-B was median 736 (Interquartile range, IQR 486–1006) days and of period B-C 562 (405–766) days. Patients who withdrew from treatment were treated in 68% (mean) of the follow-up period, and withdrew due to lack of effect (LOE) (46%), adverse events (AE)(37%) or remission (2%), while patients who switched did so due to LOE(68%) and AE(26%), and were treated 99% of the follow-up period.

Radiographic data demonstrated significantly reduced progression rates during TNF-I therapy in all subgroups (Table), and that patients who continued treatment progressed less than patients who stopped.

Timepoint C treatment status	TSS A median (IQR)	TSS B median (IQR)	TSS C median (IQR)	Delta TSS a-b/yr median (IQR)	Delta TSS b-c/yr median (IQR)	P value	Patients progressing A-B (%)	Patients progressing B-C (%)	P value
(1) 1st TNF-I (312 patients)	10 (1–34)	15 (3–42)	15 (3–46)	0.64 (0–2.9)	0.0 (0–0.5)	<0.0001[3]	58	7	<0.002[2]
(2) Withdrawn (60 patients)	7 (0–29)	11 (2–34)	14 (3–34)	1.47 (0–2.9)	0.0 (0–1.2)	0.0007[3]	63	43	0.001[2]
(3) Switched (150 patients)	4.5 (0–23)	9 (2–34)	13 (1–36)	0.71 (0–3)	0.0 (0–1)	<0.0001[3]	58	34	<0.0001[2]
P value	0.01[1]	0.10[1]	0.23[1]	0.72[1]	0.03[1]		0.76[2]	0.03[2]	

[1] Kruskal Wallis
[2] Chi-square
[3] Paired Wilcoxon tests

Conclusion: In this observational study of 522 RA patients, initiation of TNF-I treatment reduced the rate of radiographic progression in the following 2 years, compared to the preceding 2 years of DMARD treatment, irrespective of treatment status after 2 years. The lowest level of radiographic progression was found in patients who continued treatment.

Immunogenicity in a 3-Year Follow-Up Cohort of Adalimumab Treated Rheumatoid Arthritis Patients. Geertje M. Bartelds[1], Charlotte L. Krieckaert[1], Michael T. Nurmohamed[1], Pauline van Schouwenburg[2], Ben A. Dijkmans[3] and Gerrit J. Wolbink[1]. [1]Jan van Breemen Institute, [2]Sanquin Research, [3]VU Medical Center

Background: Short term data regarding the immunogenicity of adalimumab in adalimumab treated rheumatoid arthritis (RA) patients have been reported. After approximately 6 months follow-up anti-adalimumab antibody frequencies ranged from 17 to 44% in different studies, and were associated with low to undetectable serum adalimumab levels and non-response to treatment. [1–3] However, thus far long-term immunogenicity data for adalimumab have not been reported.

Objectives: To examine the course of anti-adalimumab antibody formation during long-term (3 year) follow-up and its effect on treatment.

Methods: Two-hundred-seventy-two consecutive RA patients with active disease were treated with adalimumab in a prospective observational cohort study. All patients were monitored at baseline and 4, 16, 28, 40, 52, 78, 104, 130 and 156 weeks. Trough serum samples were obtained at all visits. Serum adalimumab concentrations and anti-adalimumab antibody titres were determined retrospectively at the end of follow-up using an ELISA and RIA, respectively, designed by Sanquin Research Amsterdam. Patients were defined as positive for anti-adalimumab antibodies if titres were above 12 AU/ml on at least one occasion, in combination with serum adalimumab levels below 5.0 mg/L. A survival analysis including Cox regression analysis was performed.

Results: After three years 76 out of 272 patients (28%) developed anti-drug antibodies (ADA) against adalimumab. Figure 1 shows that 51 patients (19%) developed ADA during the first 28 weeks of treatment. One hundred twenty four patients dropped out of the study before the end of follow-up: 57 (46%) due to treatment failure, 30 (24%) due to adverse events, 11 (9%) due to a combination of failure and adverse events, and 26 (21%) due to other reasons. Patients with ADA significantly more often dropped out of the study due to treatment failure compared to patients without ADA in univariate analysis (figure 2, $p<0.0001$) and after adjustment for confounders MTX use, number of previous DMARDs and C-reactive protein (HR:3.0; 95%CI:1.6–5.5, $p<0.0001$).

Conclusions: Discontinuation of adalimumab treatment due to treatment failure was observed more frequently in patients who developed ADA compared to patients without ADA. The majority of the ADA positive patients developed ADA during the first 28 weeks of treatment. This suggests that monitoring immunogenicity is most effective during the first six months of treatment.

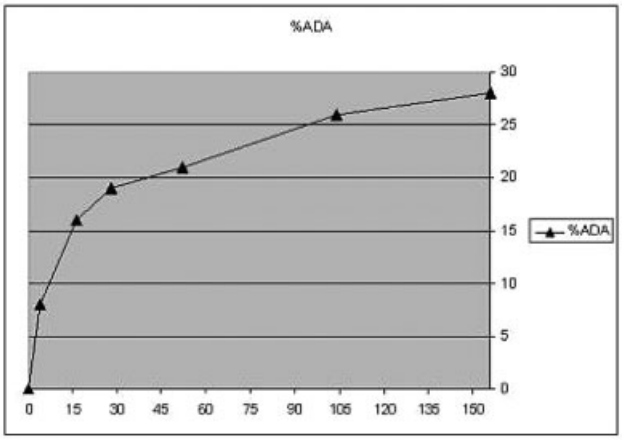

Figure 1. Development of AAA in percentages over 156 weeks follow-up.

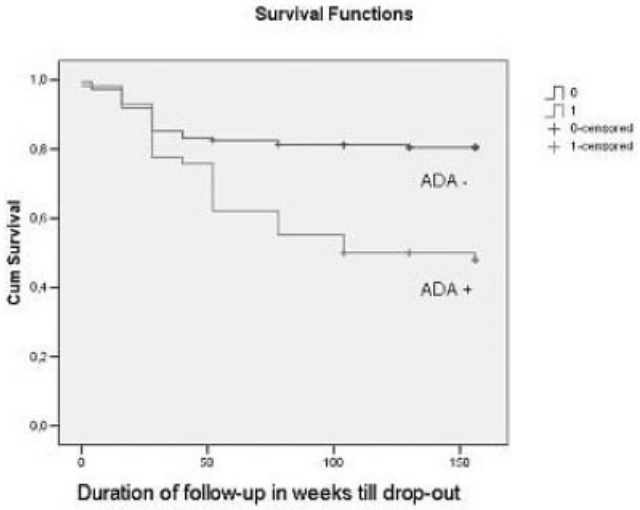

Figure 2. Discontinuation of treatment due to failure for patients with and without ADA ($P<0.0001$).

Fungal beta-Glucan Triggers Spondyloarthropathy and Crohn's Disease in SKG Mice. Merja Ruutu[4], Bijesh Yadav[4], Gethin Thomas[4], Roland Steck[2], Geoffrey Strutton[3], Ai Tran[4], Jared Velasco[4], Mariapia Degli Esposti[1], Martin Zinkernagel[1], Matthew A. Brown[4] and Ranjeny Thomas[4]. [1]Lions Eye Institute, [2]Queensland University of Technology, [3]Queenslande Health Pathology, [4]University of Queensland Diamantina Institute

Background: Recent genome-wide association studies reveal candidate genes for ankylosing spondylitis, psoriatic arthritis and Crohn's disease associated with proinflammatory cytokine production promoting T-helper 17 cells, including IL1R2, IL12B, IL23R, CCR6, JAK2, STAT3 and Card9. However, the functional correlates of these polymorphisms are unclear. This pathway is activated after dectin-1 signaling during fungal infection. Since skg ZAP70 mutant mice over-express these cytokines, and were reported as a model of rheumatoid arthritis triggered by fungal infection, we investigated whether skg mice develop spondyloarthropathy after systemic administration of fungal beta-glucan.

Methods: Skg mice and control BALB/c mice were injected i.p. or s.c. once with 3 mg 1,3-beta-glucan (curdlan). Arthritis, general appearance and weight loss were scored for 10 weeks. Organ pathology was determined by H&E staining of paraffin-embedded tissue sections at sacrifice between 1 and 10 weeks after injection of curdlan. Paws and spines were examined after sacrifice by radiography and micro-CT.

Results: After curdlan administration, BALB/c mice developed mild self-limiting arthritis of the ankles and wrists. By contrast, in skg mice, conjunctivitis, and progressive inflammatory arthritis of ankles and wrists, swelling of the soft tissue of the feet and typical sausage digits were evident from 3 weeks after injection. Over time, the mice developed hunching of the upper body, tail deformity, weight loss and abdominal bloating, but no diarrhea. Histologically and by imaging, we observed severe inflammation and progressive destruction of sacroiliac and vertebral facet joints, longitudinal ligaments and intervertebral discs with new bone formation, as well as enthesitis of Achilles tendon and plantar fascia in curdlan-treated but not naïve skg mice. Analysis of tissues over time showed that inflammation first appeared in ankles, wrists and para-vertebral ligaments from 1 week after injection. Around 6 weeks later, mice began to develop unilateral uveitis and Crohn's-like ileitis with granulomas and crypt abscesses. In contrast, the colon was not inflamed.

Conclusions: These characteristic features indicate that after systemic exposure to beta-glucan, skg mice develop a disease closely resembling human spondyloarthropathy. Since the zap70 mutation decreases T cell receptor signaling and required for disease perpetuation, these data strongly suggest that polymorphisms enhancing signaling of the beta-glucan molecular pattern (present in pollens, fungi and many bacteria), coupled with defects in antigen presentation or T cell response, may increase spondyloarthropathy risk in humans.

Deficiency in IFNγHas Markedly Different Effects on Uveitis Versus Arthritis in the Aggrecan-Induced Mouse Model of Spondyloarthropathy. Holly L. Rosenzweig[3], Jelena M. Kezic[2], Tibor T. Glant[5], Stephen R. Planck[2], Tammy M. Martin[1], Michael P. Davey[6] and James T. Rosenbaum[4]. [1]Oregon Health & Science University, Portland, OR, [2]Oregon Health & Science University, [3]Oregon Health & Science University/VA Medical Ctr, Portland, OR, [4]Oregon Health Science Univ, Portland, OR, [5]Rush Med Ctr Cohn Bldg Rm 708, Chicago, IL, [6]VA Medical Ctr/Oregon Health & Science University, Portland, OR

Purpose: Uveitis, or intra-ocular inflammation, is a commonly associated extra-articular manifestation of spondyloarthropathies such as Behcet's disease or ankylosing spondylitis. However, the mechanisms regulating the eye's susceptibility to ocular inflammation in these diseases remain unknown. Here, we expanded on our initial finding that uveitis occurs in mice in the presence of increased auto-reactive T cells recognizing the proteoglycan (PG) aggrecan in order to elucidate the onset and severity of eye disease as it relates to the joint and spine. We further tested the functional contribution of the Th-1 cytokine (IFNγ) versus the Th-2 cytokine (IL-4).

Methods: BALB/c mice transgenic for the T cell receptor specific for a dominant epitope of aggrecan (TCR-Tg mice) or TCR-Tg mice lacking IFNγ or IL-4 were immunized with PG. Ocular inflammation was assessed by intravital microscopy and histological analysis. Corresponding joint and spine inflammation was examined using an established clinical scoring system, histology and NIR-fluorescence imaging. Immunofluorescence staining of eye tissue was performed to further identify the cellular mediators and the presence of PG in the eye.

Results: Immunofluorescence staining of whole mounts revealed the presence of PG on nerve fibres in the cornea, retina, iris and optic nerve. Upon immunization with PG, a progressive mild uveitis was observed. Intravital microscopic imaging revealed an increased number of rolling, adhering and infiltrating leukocytes within the iris vasculature within 3 weeks post immunization, whilst deficiency in IL-4 significantly impaired the severity of uveitis. By comparison, mice lacking IFNγ expression showed a marked exacerbation of eye disease with a higher number of rolling and adherent cells within the iris. Histological analysis revealed a florid cellular infiltrate in the absence of IFNγ for both the anterior and posterior segments of the eye, with cells in the vitreous, iris, ciliary body, and choroid; along with retinal vasculitis, retinal folding and photoreceptor damage. Immunofluorescence studies have identified a predominance of neutrophils and mononuclear MHC-II-positive cells within the eye. Interestingly, the protective role for IFNγ in the eye is in direct contrast with the joint and spine, wherein we find IFNγ KO mice have reduced severity of arthritis/spondylitis.

Conclusions: We present a newly described model of ocular disease that occurs in the context of murine arthritis/spondylitis. IFNγ and IL-4 appear to play opposing roles within the eye disease. IFNγ promotes joint disease, yet somewhat surprisingly our findings demonstrating exacerbated uveitis in the absence of IFNγ supports a protective role for IFNγ the eye. The disparity in mechanisms between the eye and joint may have potential implications for the treatment of systemic diseases accompanying uveitis.

Autoimmunity to Sperm and Testicular Antigens Precedes Onset of Spondyloarthritis in HLA-B27/Hu-β2-Microglobulin Transgenic Rats. Joel D. Taurog[1], Claudia Rival[3], Martha Dorris[2], Nimman Satumtira[2], Margaret Sun[3] and Kenneth S. K. Tung[3]. [1]U-Texas SW Med Ctr, Dallas, TX, [2]U-Texas SW Med Ctr, [3]U-Virginia HSC

Purpose: In all lines of rats transgenic (TG) for HLA-B27 and human β2m that develop spondyloarthritis (SpA), epididymo-orchitis (EO) develops in nearly all males. In the B27/Huβ2m TG (21-3×283-2)F1 rats (A&R 54:1317, 2006), in which only males develop SpA, EO is evident as scrotal swelling at a median age of 100 d, which is 50 d and 90 d, respectively, before the median time of onset of arthritis and spondylitis,. We have previously found that castration (i.e., bilateral resection of testis and epididymis) by 91 d of age prevents subsequent SpA (A&R 60s:1168, 2009). Here, we sought to investigate the pathogenesis of the EO and to characterize the autoimmune response to sperm and testis antigens.

Methods: B27/Huβ2m TG 21-3×283-2 F1 males underwent either castration, unilateral castration, or sham castration between ages 36 d and 125 d. Castrated rats were given testosterone replacement. Rats were observed for > 300 d for EO, arthritis, and spondylitis. Resected tissue was examined for histopathology and by immunohistology. Serum was examined for anti-sperm and anti-testis cell antibodies by IF and ELISA.

Results: As a rule, inflammation was first evident in the ductuli efferentes (DE, small ducts that link the rete testis to the epididymis) adjacent to the testis. As early as age 36 d, focal periductal neutrophils and mononuclear cells were detected, some penetrating the basal lamina. By 62 d, there was extensive mononuclear cell granulomatous inflammation in the DE. This was more severe by age 77 d, when aspermatogenesis was evident, coinciding with the appearance of anti-sperm and anti-testis cell antibodies in serum. Rats castrated after onset of orchitis showed a decline in these antibodies, even when arthritis developed later.

Immunohistological examination identified massive infiltration of activated macrophages and activated T cells surrounding the granulomatous lesions in the testis, but not elsewhere. In addition, granular deposition of rat IgG, presumed to reflect immune complexes, were deposited at the periphery

of the seminiferous tubules. Indirect IF showed that the serum autoantibodies bind to antigens in the testis cell cytoplasm, sperm acrosome, and sperm tail. Thus both T cell and antibody-mediated mechanisms participate in the autoimmune EO, but the T cell-mediated processes appear first and are primary.

Conclusion: The B27/Huβ2m transgenes initiate characteristic T cell-mediated inflammation in the ductus efferentes that becomes granulomatous. Orchitis appears later, coinciding with the appearance of anti-sperm and anti-testis cell antibodies in serum, presumably as a result of an ongoing autoimmune response to sperm and other testicular antigens. As previously shown, bilateral castration prevented subsequent development of SpA if carried out before the age of onset of arthritis, even if advanced EO was already present. The data therefore suggest that the process of prolonged inflammation and antigenic stimulation within the testis and epididymis is an essential precursor of SpA in (21-3×283-2) F1 B27/Huβ2m TG rats. More generally, persistent autoimmune inflammation in one site seems linked causally to autoimmunity targeting a second site.

Mast Cells Contribute to Synovial Inflammation in Non-Psoriatic and Psoriatic Spondyloarthritis. Troy Noordenbos[1], Nataliya Yeremenko[1], Tineke Cantaert[1], Christine Teitsma[1], Marleen van de Sande[1], Paul P. Tak[1], Juan Canete[2] and Dominique Baeten[1]. [1]Academic Medical Center/University of Amsterdam, [2]University Hospital Barcelona

Objective: We recently observed a striking synovial infiltration with cells positive for C-kit, a marker for mast cells, in psoriatic arthritis (PsA). As mast cells have potent inflammatory functions, including the production of pro-inflammatory cytokines, we performed a systematic analysis of mast cells infiltration in different forms of chronic inflammatory arthritis.

Materials and Methods: Synovial tissue biopsies from active rheumatoid arthritis (RA)(n=21), non-psoriatic spondyloarthritis (SpA)(n=16), and PsA (n=23) was stained by immunohistochemistry and double immunofluorescence. Synovial fluid (SF) from RA (n=18), SpA (n=19), and PsA (n=16) was analyzed by ImmunoCap and ELISA. The effect of C-kit inhibition by imatinib mesylate on proinflammatory cytokine production was tested in vitro on fresh SpA synovial biopsies.

Results: C-kit positive mononuclear cells were found in the synovial sublining in all disease groups. Double stainings with tryptase confirmed that C-kit indeed identified mast cells. C-kit positive mast cells were significantly increased in SpA ($p=0.010$) and PsA ($p=0.001$) versus RA despite similar levels of global inflammation as reflected by CD3, CD20, and CD68 staining. This was confirmed in an independent cohort of early untreated SpA and RA. The synovial infiltration by mast cells was not purely inflammation-driven as it persisted in SpA synovial biopsies taken after 12 weeks of successful treatment with TNF blockers. SF levels of factors involved in chemotaxis and differentiation of mast cells such as SCF, IL-3, and IL-33 were similar in all groups but sST2, the soluble decoy receptor for IL-33, was significantly decreased in SpA. As to the function of mast cells in synovial inflammation, double staining of the c-kit positive cells with toluidine blue and anti-tryptase and SF analysis for mast cell products did not show evidence for enhanced degranulation in SpA versus RA synovitis. Preliminary data, however, show IL-17 signal in the synovial mast cells. Accordingly, C-kit inhibition in ex-vivo synovial cultures strongly reduced the production and secretion of pro-inflammatory cytokines.

Conclusion: There is an increased synovial infiltration with C-kit positive mast cells in non-psoriatic and psoriatic SpA. Inhibition of C-kit in vitro leads to a reduction of proinflammatory cytokine production by synovial biopsies. These data suggest a role for mast cells in driving and/or sustaining the synovial inflammation in SpA.

Gene Silencing of *ERAP1 and ERAP2* Displays Differential Effects on Intracellular Free Heavy Chain Accumulation and Peptide Presentation in B*27 Subtypes Associated with Ankylosing Spondylitis (AS). Nigil Haroon, Florence W. Tsui and Robert D. Inman, Toronto Western Hospital and Research Institute. University of Toronto, Toronto, Canada

Introduction: Ankylosing spondylitis (AS) demonstrates differential association with different HLA subtypes: *B*2704* and *B*2705* are associated with AS while *B*2706* and *B*2709* are not. With the recognition that *ERAP* polymorphisms are associated with AS, we investigated the interaction of AS-associated genes *ERAP1* and *ERAP2* with *HLA B*27* subtypes.

Methods: C1R cells stably transfected with the respective B*27 subtypes (B*2704, *2705, *2706 and *2709) were used. For gene silencing, two duplexes each of Stealth RNAi™ for ERAP1 and ERAP2 or a negative control (NC) siRNA were nucleofected into the respective transfected cells. For flow cytometry, ME1, HC10, W6/32 and MARB4 antibodies were used respectively for intact B27, MHC-I free heavy chains (FHC), intact MHC-I and B27 presenting abnormally long peptides (B27_lp). For intracellular FHC (iFHC) HC10 was used after cell permeabilization. The change in MFI was calculated as a ratio of the MFI with specific siRNA to NC for each antibody. Western blot showed more than 80% suppression of ERAP with specific siRNAs but no suppression with NC.

Results: Silencing of ERAP1/2 was associated with a significant increase in iFHC in B*2704 and *2705 cells compared to *2706 and *2709 cells ($p=0.002$). The median (IQR) increase in IFHC (ΔiFHC) in the B*2704 and *2705 cells was 2.5 (1.8, 4.2) compared to 1.3 (1.1, 1.5) in the *2706 and *2709 cells. There was no significant difference in the level of surface FHC, B27 or MHC-I expression. The median ΔB27_lp expression with ERAP1/2 silencing in B*2704 and *2705 cells was 1.2 (1.1, 1.4) and was significantly higher ($p=0.03$) than the median ΔB27_lp of 0.9 (0.8, 1.0) in *2706 and *2709 cells. There was no significant difference in the results whether ERAP1 or ERAP2 was suppressed.

Conclusion: ERAP1/2 silencing causes accumulation of more iFHC and higher B27_lp in AS-associated B*27 subtypes cells compared to non-associated subtypes. This suggests that interaction of B*27 with ERAP1/2 could be a key determinant underlying the B*27 subtype specific associations with AS.

Multiplex Assay of a Panel of 58 Biomarkers in Ankylosing Spondylitis: Identification of High Priority Candidates for Prediction of Structural Damage. Walter P. Maksymowych[4], Nathalie Morency[4], Stephanie Wichuk[4], Proton Rahman[1], Dafna D. Gladman[2] and Robert D. Inman[3]. [1]Memorial University Newfoundland, St. Johns, NL, Canada, [2]Toronto Western Hospital, Toronto, ON, Canada, [3]Toronto Western Hospital, Toronto, ON, Canada, [4]University of Alberta, Edmonton, AB, Canada

Purpose: Radiographic progression in ankylosing spondylitis (AS) requires 2 years before it can be reliably detected and prospective studies have consistently identified only baseline radiographic damage as an independent predictor of radiographic progression in AS. This presents a major challenge to the study of disease modifying therapies and to the identification of patients at risk for damage progression. We aimed to simultaneously analyze a large panel of serologic biomarkers reflecting pathophysiological processes in AS as potential predictors of radiographic progression.

Method: We used multiplexed sandwich immunoassays (Eve Technologies) to simultaneously quantify a panel of 58 biomarkers that comprised 8 markers reflecting bone turnover, calcium homeostasis and osteoclasis, 8 metalloproteinases (MMP), 6 joint tissue growth factors, 23 cytokines known to regulate inflammation, 9 chemokines, and 4 factors reflecting miscellaneous immunological processes such as T-cell co-stimulation and enthothelial activation. Serum was obtained at a single time point from 60 patients with AS and 60 age- and sex-matched controls. Selection of 30 AS patients was based on phenotypic characterization of their progression status as measured by the modified Stoke AS Spine Score (mSASSS) after patients had been followed for at least 2 years. Progressors were defined as those patients where the baseline mSASSS was at least 10 units, progression over 2 years was at least 5 units, and included at least one new syndesmophyte. Non-progressors were patients meeting all 3 of the following: disease duration at baseline of at least 10 years, baseline mSASSS of less than 5 units, and no change in mSASSS over 2 years. Unpaired t-test analyses were stratified according to radiographic phenotype.

Results: A total of 23 biomarkers demonstrated significant differences between AS patients and controls, the most significant being osteocalcin and Rantes (both $p<0.0001$). Ten biomarkers only demonstrated significant differences from controls when analysis was stratified according to radiographic phenotype: in the progressor subgroup MMP-9, transforming growth factor alpha, and tumor necrosis factor alpha were significantly elevated compared to controls (all $p<0.0001$) while eotaxin, interferon alpha-2, and

monocyte chemotactic protein-3 were significantly increased in the non-progressor subgroup. Three biomarkers, interleukin-17, interferon-gamma, and macrophage inhibitory protein-beta, demonstrated significantly increased levels in AS patients that were further increased in the progressor subgroup. Six biomarkers were significantly increased only in male patients and particularly the progressor subgroup, especially macrophage derived chemokine and CD40 ligand (both $p<0.0001$).

Conclusion: Multiplexed assay of an extensive panel of biomarkers reflecting pathophysiological processes implicated in AS has identified several biomarkers as high priority candidates for prospective validation studies aimed at predictors of structural damage in AS.

Epratuzumab Demonstrates Clinically Meaningful Improvements in Patients with Moderate to Severe Systemic Lupus Erythematosus (SLE): Results from EMBLEM™, a Phase IIb Study. Daniel J. Wallace[1], Kenneth C. Kalunian[5], Michelle A. Petri[2], Vibeke Strand[3], Brian Kilgallen[4], Lexy Kelley[4] and Caroline P. Gordon[6]. [1]West Hollywood, CA, [2]Timonium, MD, [3]Division of Immunology and Rheumatology, Stanford University School of Medicine, Palo Alto, CA, [4]UCB, Smyrna, GA, [5]UCSD School of Medicine, La Jolla, CA, [6]University of Birmingham, Birmingham, United Kingdom

Background: Epratuzumab is a humanized anti-CD22 monoclonal antibody under development for the treatment of patients with moderate to severe SLE. This 12-week, double-blind, Phase IIb study (NCT00624351) was designed to evaluate the efficacy and safety of epratuzumab in SLE, and identify an optimal dose and regimen.

Methods: Patients with moderate/severe SLE (≥1 BILAG 2004 A or ≥2 Bs) were randomized to 1 of 6 intravenous regimens: placebo (PBO, standard of care) or cumulative dose (cd) epratuzumab (200, 800, 2400 or 3600 mg in equal divided doses using 2 every other week [EOW] infusions or 2400 mg cd as 4 equal infusions 1 week apart). Both 2400 mg cd groups (600 mg weekly and 1200 mg EOW) were also combined for analysis. Primary end point was a combined responder index of clinical disease activity at Week 12, defined as reduction of all baseline BILAG A to B/C/D and BILAG B to C/D in all body systems, no BILAG worsening in other organ systems, and no deterioration in SLEDAI or physician's global disease activity assessment, with no increase in corticosteroids, immunosuppressives or anti-malarials over baseline. The combined responder index was analyzed using logistic regression. All drop-outs were counted as nonresponders.

Results: At baseline, in the entire population (N=227) mean age was 38.8 years, 94% were female; with high disease activity (71% with ≥1 BILAG A, mean total scores: BILAG 15.2, SLEDAI 14.8). Combined responder index rates were higher in all epratuzumab groups than in the placebo group (Table), reaching statistical significance in the epratuzumab 600 mg weekly group (2400 mg cd) and the combined group of all 74 patients who received a cd of 2400 mg (600 mg weekly and 1200 mg EOW). In both groups, responder rates were twice those of placebo. Differences in responder rates between the epratuzumab 600 mg weekly and 1200 mg EOW groups, and the placebo group were observed at Week 8, with further improvement to Week 12 (epratuzumab 600 mg weekly vs 1200 mg EOW vs PBO; Week 8: 37.8% vs 35.1% vs 21.1%; Week 12: 45.9% vs 40.5% vs 21.1%). By Week 12, 37.9% and 35.3% of patients in the epratuzumab 600 mg weekly and 1200 mg EOW groups, respectively, achieved enhanced BILAG improvement (improvement of all body systems to BILAG C or better on consecutive visits, with no worsening) vs 22.2% in PBO. Epratuzumab was well tolerated; incidence of serious adverse events and infusion reactions was similar to PBO.

Table. Combined responder index, Week 12 (ITT population)

Dose regimen	PBO (n = 38)	Emab cd 200 mg 100 mg EOW (n = 39)	Emab cd 800 mg 400 mg EOW (n = 38)	Emab cd 2400 mg			Emab cd 3600 mg 1800 mg EOW (n = 38)
				600 mg weekly (n = 37[a])	1200 mg EOW (n = 37)	Combined group (n = 74)	
Responders n (%)	8 (21.1)	12 (30.8)	10 (26.3)	17 (45.9)	15 (40.5)	32 (43.2)	9 (23.7)
Odds ratio (95% CI) vs placebo		1.7 (0.6–4.7)	1.3 (0.5–3.9)	3.2 (1.1–8.8)	2.6 (0.9–7.1)	2.9 (1.2–7.1)	1.2 (0.4–3.4)
				p = 0.03[b]	p = 0.07[b]	p = 0.02[b]	

Emab = epraluzumab
[a] 2 patients randomized but never received drug.
[b] p values were not adjusted for multiple comparisons.

Conclusions: Epratuzumab was associated with meaningful and statistically significant improvements in disease activity in patients with moderate to severe active SLE at a cd of 2400 mg, with responder rates twice those of placebo. Results validate the combined index emphasizing BILAG and support Phase III trials of epratuzumab in SLE.

Aspreva Lupus Management Study (ALMS): Extra-Renal Activity Results from the Maintenance Phase. David A. Isenberg[4], Gerald B. Appel[1], Mary Anne Dooley[6], Ellen M. Ginzler[3], David Jayne[2], David Wofsy[5], Neil Solomons[7] and Laura Lisk[8]. [1]Columbia University, [2]Renal Unit, Addenbrooke's Hospital, [3]SUNY-Downstate Medical Center, Brooklyn, NY, [4]University College London, London, United Kingdom, [5]University of California, San Francisco, San Francisco, CA, [6]University of North Carolina at Chapel Hill, Chapel Hill, NC, [7]Vifor Pharma (formerly Aspreva Pharmaceuticals), Canada, [8]Vifor Pharma, UK

Background: The 36-month maintenance phase of the ALMS study (NCT00377637) compared the efficacy and safety of mycophenolate mofetil (MMF) with azathioprine (AZA) in patients with lupus nephritis (LN) classes III, IV and V achieving a clinical response in the induction phase with corticosteroids (CS) and either MMF or cyclophosphamide (IVC).

Methods: Patients were re-randomized 1:1 to a double-blind comparison of either placebo plus either oral MMF (2 g/day) or oral AZA (2 mg/kg/day). Patients were permitted to receive corticosteroids (maximum dose: 10 mg/day prednisone or equivalent). The primary efficacy outcome measure was time to treatment failure (death, end-stage renal disease, sustained doubling of serum creatinine, and/or renal flare [proteinuric or nephritic]). Patients who withdrew before reaching the primary endpoint were censored at the time of withdrawal. Although this was primarily an LN population, substantial extra-renal assessments were performed. Extra-renal secondary parameters included time to major extra-renal flare (British Isles Lupus Assessment Group [BILAG] score category A in one extra-renal system or three systems with concurrent category B scores) and the characterization of extra-renal activity. Immunology secondary parameters (levels of complement proteins C3 and C4, and titers of antibodies to double-stranded DNA [anti-dsDNA]) and adverse events (AEs) were also assessed.

Results: Of 227 patients randomized (intent-to-treat population), 127 completed the full 3 years (MMF, 73/116 [62.9%]; AZA, 54/111 [48.6%]): MMF was superior to AZA in the primary endpoint ($p=0.003$). Extra-renal disease characteristics and immunology parameters were similar across groups at baseline. There were very few occurrences of major extra-renal flare in either group during the study (8 [6.9%] for MMF, 7 [6.3%] for AZA), and time to major extra-renal flare did not differ between groups ($p=0.936$). However, there were differences in the characteristics of extra-renal activity. The most common manifestation of major extra-renal flare in the MMF group was mucocutaneous and in the AZA group was hematological. In the MMF group, 75 subjects (65.2%) experienced lupus-related AEs compared with 79 (71.2%) in the AZA group, with musculoskeletal events being the most common in both groups (MMF, 39/115 [33.9%]; AZA, 37/111 [33.3%]). At the end of the study, in patients who had completed 3 years, mean C3 and C4

levels were lower in the AZA group and mean anti-dsDNA titers were lower in the MMF group; differences were not statistically significant.

Conclusions: In this population of LN patients who had responded to induction therapy, there were low levels of extra-renal activity in the maintenance phase in both MMF and AZA groups.

Belimumab, a BLyS-Specific Inhibitor, Reduced Disease Activity and Severe Flares in Seropositive SLE Patients: BLISS-76 Study Results through Wk 76. R. Furie,[1] O. Zamani,[2] D. Wallace,[3] D. Tegzová,[4] M. Petri,[5] J.T. Merrill,[6] W. Chatham,[7] W. Stohl,[8] A. Schwarting,[9] S. Cooper,[10] Z.J. Zhong,[10] W. Freimuth,[10] D. Hough,[10] and R.F. van Vollenhoven,[11] for the BLISS-76 Study Group. [1]North Shore-LIJ Health System, Lake Success, NY; [2]Rheumazentrum Favoriten, Wien, Austria; [3]Cedars-Sinai/ UCLA, Los Angeles, CA; [4]Institute of Rheumatology and Rheumatological Clinic, Prague, Czech Republic; [5]Johns Hopkins University School of Medicine, Baltimore, MD; [6]Oklahoma Medical Research Foundation, Oklahoma City, OK; [7]UAB Arthritis Clinical Intervention Program, Birmingham, AL; [8]USC Keck School of Medicine, Los Angeles; [9]Universitätsmedizin der Johannes-Gutenberg-Universität Mainz, Sana Rheumazentrum Rheinland-Pfalz, Bad Kreuznach, Germany; [10]Human Genome Sciences, Rockville, MD; [11]The Karolinska Institute, Stockholm, Sweden.

Purpose: To assess the efficacy and safety of belimumab, a BLyS-specific inhibitor, in seropositive SLE patients.

Methods: In BLISS-76 (NCT00410384), a 76-wk, double-blind, international, phase 3 study, 819 seropositive SLE patients (ANA ≥1:80 and/or anti-dsDNA ≥30 IU/mL) with SELENA-SLEDAI (SS) score ≥6 on stable standard-of-care (SOC) therapy for ≥30 d were randomized to belimumab 1 or 10 mg/kg IV plus SOC vs placebo plus SOC on d 0, 14, and 28, and then q28d, for 72 wk. Efficacy analyses included SS, BILAG, and SS Flare Index (SFI). SLE Responder Index (SRI) response rate at 52 wk: SS improvement (≥4-point decrease), no new BILAG A or 2 new B flares, and no worsening (<0.3-point increase) in Physician's Global Assessment (PGA) vs baseline. SRI at wk 76 was a secondary endpoint.

Results: Belimumab 10 mg/kg plus SOC met the primary efficacy endpoint by achieving a significantly greater response rate vs placebo plus SOC at wk 52 (43% vs 34%; p=0.017); the rate with belimumab 1 mg/kg was 41% (p=0.09). Statistical significance with either belimumab dose was not achieved at wk 76 (32%, 39% [p=0.11], and 39% [p=0.13] for placebo, and belimumab 1 and 10 mg/kg, respectively). In post-hoc sensitivity analyses evaluating more rigorous response thresholds for the SS component of the SRI endpoint (ie, 5–7-point reductions), robust and consistent effects were achieved with belimumab 10 mg/kg at multiple time points, including statistically significant effects at wk 52 and 76. Between wk 24 and 76, belimumab reduced all flares (10 mg/kg; p<0.05) and severe flares (1 mg/kg; p<0.05). Fatigue improved in both belimumab treatment groups at wk 76 (1 mg/kg; p<0.05). Although not statistically significant, there were numeric trends favoring steroid sparing with belimumab. Belimumab was associated with reduction in SLE-specific and short-lived plasma cells, as well as other B-cell subsets including CD20+, activated, and plasmacytoid cells. Moreover, significant normalization of low complement was achieved with belimumab 10 mg/kg. Overall adverse events (AEs), laboratory abnormalities, and infections, as well as serious AEs including infections, malignancies, and deaths, were comparable across groups. Serious or severe infusion reactions occurred in 1.5% of patients with belimumab 10 mg/kg vs 0.7% with placebo.

Conclusion: In BLISS-76, belimumab significantly improved SRI response rate and reduced SLE disease activity in seropositive SLE patients at wk 52. Response rates at wk 76, while not statistically significant, were consistent with wk-52 results. Overall AEs, including serious AEs and infections, were comparable across groups.

Table. BLISS-76 Results Through Wk 76[a]

	SOC + Placebo (n=275)	SOC + Belimumab 1 mg/kg (n=271)	SOC + Belimumab 10 mg/kg (n=273)

Efficacy and Safety of Ocrelizumab, a Humanized antiCD20 Antibody, in Patients with Active Proliferative Lupus Nephritis (LN): Results from the Randomized, Double-Blind Phase III BELONG Study. Eduardo F. Mysler[6], Alberto J. Spindler[9], Renato Guzman[2], Marc Bijl[8], David Jayne[1], Richard A. Furie[5], Romeo Maciuca[3], Saba Shahdad[7], David Close[4], Paul Brunetta[3] and Jorn Drappa[3]. [1]Addenbrookes Hospital, [2]Dept Rheumatology, [3]Genentech, [4]MedImmune Limited, [5]North Shore Long Island Jewish Health System, Lake Success, NY, [6]OMI, Buenos Aires, Argentina, [7]Roche, [8]Univ of Groningen, [9]Universidad Nacional Tucumán, Yerba Buena Tucuman, Argentina

Purpose: B cells are believed to contribute to LN pathogenesis. Ocrelizumab (OCR), a humanized monoclonal antibody that selectively targets $CD20^+$ B cells, was studied to determine the benefits and risks of OCR compared to placebo (PBO) in patients (pts) with active class III/IV LN also receiving corticosteroids plus standard of care (SOC) of mycophenolate mofetil (MMF) or Eurolupus (EL) cyclophosphamide (CYC) regimen.

Methods: Pts with active proliferative LN were randomized equally to PBO, OCR 400 mg, or OCR 1000 mg IV on days 1 and 15; single infusions were then given every 16 wks. Pts received either MMF (up to 3 g/d) or EL (IV CYC 500 mg q2 wks × 6 followed by azathioprine 2 mg/kg) and a protocol-defined steroid taper regimen. The primary endpoint was the Wk 48 overall renal response (ORR) consisting of complete (CRR) and partial (PRR) renal response. We report here interim safety results for all treated pts, and Wk 48 renal responses for pts enrolled ≥32 wks prior to stopping the study.Due to the smaller group sizes, inferential statistics (95% CI, p-value) are provided only for the pooled OCR group vs PBO.

Results: 381 pts were randomized through Sept 2009. 87 % were female, 80% class IV LN, 63% received MMF and 37% EL. Mean 24hr Upr/Cr ratio at entry was 3.9. An imbalance in serious infections (in pts receiving OCR, particularly with MMF, and in pts from Asia across all arms), and in opportunistic infections (7 OCR pts vs 1 in PBO; 6/8 received MMF) led to dosing being discontinued in Oct 2009, with pts continuing into safety follow-up. **Table** shows the Wk 48 renal responses for the 221 "32 Wks" pts: 51% in PBO vs. 63% in OCR had an ORR, a treatment difference of 11.9% (95% CI: −1.9%, 25.7%; p=0.075), with similar overall rates in the 400 and 1000 mg arms. There was no increase in ORR observed in pts receiving 400 mg OCR+MMF vs MMF alone whereas there was an increased ORR rate with both OCR doses in OCR+EL vs EL alone, with higher ORR, and CRR rates in the 400 mg EL group. **Table** shows interim safety results for all treated pts (N=378).

Table. Efficacy and Safety; Renal

	Renal Response at Week 48 All '32 Wks' Pts

MMF	6/81 (7)	10/79 (13)	12/79 (15)
Deaths	5 (4)	3 (2)	5 (4)
Eurolupus	4/44 (9)	0	2/48 (4)
MMF	1/81 (1)	3/79 (4)	3/79 (4)

* Including infections treated with an IV antibiotic. **includes one serious event.

Conclusion: In this '32 wks' population, the ORR rate at 48 wks was overall 12% higher in the OCR group. The addition of OCR 400mg to MMF did not generate additional benefit, with an increased observed rate of serious infections (SIEs). The OCR+EL regimen had a higher ORR rate vs EL alone, in both dose groups, with a lower PBO+EL ORR rate compared to the PBO+MMF group. Incidence of SAEs, SIEs, and IRRs was lower in EL pts compared to MMF pts.

Belimumab, a BLyS-Specific Inhibitor, Reduced Disease Activity across Multiple Organ Domains: Combined Efficacy Results from the Phase 3 BLISS-52 and -76 Studies.

S. Manzi[10], J. Sanchez-Guerrero[2], J. T. Merrill[5], R. A. Furie[4], D. Gladman[8], S. Navarra[11], E. M. Ginzler[7], D. D'Cruz[6], A. Doria[9], S. Cooper[1], Z. J. Zhong[1], D. Hough[1], W. Freimuth[1], M. Petri[3] and on Behalf of the BLISS-52 and -76 Study Groups. [1]Human Genome Sciences, Inc, Rockville, MD, [2]Instituto Nacional de Ciencias Médicas y Nutricíon Salvador Zubirán, Tlalpan, Mexico City, DF, Mexico, [3]Johns Hopkins School of Medicine, Baltimore, MD, [4]North Shore LIJ Health System, Lake Success, NY, [5]Oklahoma Medical Research Foundation, Oklahoma City, OK, [6]St. Thomas' Hospital, London, London, United Kingdom, [7]SUNY Downstate Medical Center, Brooklyn, NY, [8]Toronto Western Hospital, Toronto, ON, Canada, [9]Universita' di Padova, Padova, Italy, [10]University of Pittsburgh School of Medicine, PA, [11]University of Santo Tomas Hospital, Manila, Philippines

Purpose: To assess the efficacy of belimumab in individual organ domains using BILAG and SELENA SLEDAI (SS) in SLE patients after 52 wk of treatment.

Methods: 1684 seropositive (ANA ≥1:80 and/or anti-dsDNA ≥30 IU/mL) SLE patients with SS ≥6 on stable standard-of-care therapy for ≥30 d were enrolled in the phase 3, randomized, double-blind, placebo-controlled, international studies of belimumab 1 or 10 mg/kg vs placebo, plus standard of care (NCT00424476; NCT00410384). Patients were dosed on d 0, 14, and 28, and then q28d, for 48 or 72 wk. Efficacy analyses included SS and BILAG measured every 4 wk. SLEDAI domain scores were determined using methods described by Bombardier et al (1992); traditional scoring methods were used for BILAG domains. Positive shifts in total SS domain scores between baseline and wk 52 defined worsening; negative shifts defined improvement. Improvement in BILAG domain scores was defined as a shift from A or B scores at baseline to a lower score; worsening was defined as a shift to a higher score from B, C, D, or E at baseline. Patients who withdrew and/or took protocol-prohibited/restricted medication were considered to have no improvement. In worsening analysis, missing data were analyzed with last-observation-carried-forward imputation methods, using the last available observation at or prior to withdrawal, or dropout due to use of a protocol-prohibited/restricted medication (whichever occurred earlier).

Results: SS and BILAG organ system involvement at baseline was generally similar in the belimumab and placebo groups, and between studies (table). The most common SS domains involved were dermal (82%), immunologic (80%), musculoskeletal (65%), and renal (16%). The most common BILAG domains involved were musculoskeletal (60%), mucocutaneous (59%), hematology (16%), renal (11%), and general (11%). For SS, there was significant improvement from baseline at wk 52 in the central nervous system (CNS), vascular, musculoskeletal, immunologic, and dermal domains with belimumab (≥1 dose) vs placebo. In patients without involvement at baseline in a specific organ system, there was significantly less worsening at wk 52 in the immunologic, renal, and hematologic domains with belimumab vs placebo. For BILAG, there was significant improvement from baseline at wk 52 in musculoskeletal and mucocutaneous domains, and a trend ($p<0.07$) in the vasculitis domain with belimumab (≥1 dose) vs placebo. There also was significantly less worsening from baseline at wk 52 in the hematology domain, and a favorable trend in the vasculitis and renal domains, with belimumab vs placebo.

Conclusion: Belimumab demonstrated beneficial effects, with reductions in disease activity and prevention of worsening across several SS and BILAG organ systems.

Five-Year Experience with Belimumab, a BLyS-Specific Inhibitor, in Patients with Systemic Lupus Erythematosus (SLE). J. T. Merrill[6], D. J. Wallace[1], R. A. Furie[4], M. A. Petri[3], W. Stohl[10], W. W. Chatham[8], J. McCune[9], A. Weinstein[11], J. McKay[5], Z. J. Zhong[2], L. Pineda[2], J. Klein[2], W. Freimuth[2], E. M. Ginzler[7] and for the LBSL02/99 Study Group. [1]Cedars-Sinai/UCLA, Los Angeles, CA, [2]Human Genome Sciences, Inc, Rockville, Rockville, MD, [3]Johns Hopkins University School of Medicine, Timonium, MD, [4]North Shore LIJ Health System, Lake Success, NY, [5]Oklahoma Center for Arthritis Therapy & Research, Tulsa, OK, [6]Oklahoma Medical Research Foundation, Oklahoma City, OK, [7]SUNY Downstate Medical Center, Brooklyn, NY, [8]UAB Arthritis Clinical Intervention Program, Birmingham, AL, [9]University of Michigan Health System, Ann Arbor, MI, [10]USC Keck School of Medicine, Los Angeles, CA, [11]Washington Hospital Center, Washington, DC

Purpose: To examine 5-year safety of belimumab in an open-label extension study of SLE patients and evaluate long-term efficacy in a subgroup similar to those in recent phase 3 trials.

Methods: 449 SLE patients with SELENA-SLEDAI (SS) ≥4 enrolled in a phase 2, 52-wk, randomized, double-blind study of belimumab 1, 4, or 10 mg/kg q28d vs placebo, plus background SLE therapy (NCT00071487). At wk 56, placebo patients received belimumab 10 mg/kg; prior belimumab patients received the same dose or 10 mg/kg. At wk 80, 296 patients (66%) entered an uncontrolled continuation study (belimumab 10 mg/kg; NCT00583362). The 5-y dataset was divided into ten 6-mo intervals for reporting efficacy and adverse events (AEs). Analyses of disease activity included the SS Flare Index (SFI) and SLE Responder Index (SRI): improvement in SS (≥4 pt), no new BILAG A or <2 new B flares, and no Physician's Global Assessment worsening (<0.3 pt) vs baseline. All efficacy assessments were limited to the seropositive (ANA titer ≥1:80 and/or anti-dsDNA ≥30 IU/mL) patient subgroup (n=321), who were similar to those patients enrolled in the phase 3 trials. Safety assessments were performed in all patients.

Results: 19% of patients dropped out during the placebo-controlled portion of the study, 296 enrolled in the open-label extension at wk 80, and the discontinuation rate has been 3%–9%/y. Total belimumab exposure was 1415 patient-years (pty). Incidence rates (per 100 pty) of AEs remained stable or decreased over 5 y (table). In seropositive patients, SRI rate was 46% at wk 52 (vs 29% with placebo; p<0.05), increased to 55% by wk 76, and was maintained through wk 272 (59%). In this study, adjustments in background SLE therapy were permitted. The frequency of 1 new BILAG A or 2 new B flares decreased from 30% over the 1st 6 mo to 23% over the 2nd 6 mo (vs 33% and 25%, respectively, with placebo) and declined to 11% at the 4.5–5.0-y interval. The frequency of SFI flares decreased from 72% (severe 13%) over the 1st 6 mo to 62% (severe 8%) over the 2nd 6 mo (vs 76% [severe 9%] and 73% [severe 11%], respectively, with placebo) and further declined to 22% (severe 1%) at the 4.5–5.0-y interval. Autoantibody levels (anti-Sm, anti-dsDNA, anticardiolipin immunoglobulin-G) decreased over time with belimumab.

Table. AE Incidence (rate per 100 pty)[a]

	All Patients Treated With Belimumab									
Intervaly	1 (0.0-0.5 y)	2 (0.5-1.0 y)	3 (1.0-1.5 y)	4 (1.5-2.0 y)	5 (2.0-2.5 y)	6 (2.5-3.0 y)	7 (3.0-3.5 y)	8 (3.5-4.0 y)	9 (4.0-4.5 y)	10 (4.5-5.0 y)
No. patients (pty)	424 [206]	398 [183]	353 [166]	314 [147]	284 [136]	261 [128]	252 [122]	240 [116]	227 [111]	221 [100]
Overall AEs	409 (194)	337 (184)	304 (184)	271 (184)	244 (179)	226 (177)	210 (171)	207 (178)	183 (165)	154 (154)
Serious AEs	43 (20.8)	33 (18.0)	28 (16.9)	26 (17.7)	24 (17.6)	28 (21.9)	14 (11.4)	18 (15.5)	18 (16.2)	17 (17.0)
Overall infections	246 (119)	197 (108)	170 (103)	164 (112)	146 (107)	129 (101)	108 (88)	126 (108)	95 (86)	82 (82)
Serious infections	14 (6.8)	10 (5.5)	6 (3.6)	8 (5.4)	4 (2.9)	5 (3.9)	2 (1.6)	6 (5.2)	2 (1.8)	3 (3.0)
Malignancies	0 (0)	2 (1.1)	5 (3.0)	2 (1.4)	1 (0.7)	2 (1.6)	2 (1.6)	3 (2.6)	3 (2.7)	3 (3.0)

[a]Interval 1 includes initial placebo patients who initiated belimumab treatment at wk 56.

Conclusions: Belimumab added to standard-of-care therapy was well tolerated over 5 y. Seropositive patients treated with belimumab showed sustained improvement in disease activity, and a decline in BILAG and SFI flares over 5 y, without changing the background treatment rules.

Effectiveness of the Global Posture Reeducation Method (GPR) and Segmental Stretching in the Treatment of Chronic Back Pain: A Randomized Controlled Trial. Marilene M. dos Santos[3], Larissa S. Guimarães[5], Lorena O. Souza[5], Mariana M. Vasconcelos[5], Taís M. Camargo[1], Priscylla C. Develly[5], Bernardo L. F. Fernandes[4] and Virgínia F. M. Trevisani[2]. [1]Brazil, [2]Federal University of São Paulo-UNIFESP/EPM, São Paulo, SP, Brazil, [3]Federal University of São Paulo-UNIFESP/EPM, Poços de Caldas, MG, Brazil, [4]Pontifical Catholic University of Minas Gerais - PUC Minas, Poços de Caldas, MG, Brazil, [5]Pontifical Catholic University of Minas Gerais-PUC Minas, Brazil

Purpose: The purpose of this study was to evaluate the effectiveness of the Global Posture Reeducation method (GPR) and segmental stretching exercises in the treatment of chronic back pain.

Methods: A randomized controlled blinded assessor trial was conducted. One hundred and fifty patients of both sexes were selected, with a mean age of 40.15 ± 11.55 years-old, who had pain in some segment of the spine for at least three months. They were randomly distributed into three groups (n=50, each): G1 – submitted to GPR method; G2 – received the segmental stretching; and G3 – control. Patients in G1 and G2 received 16 individual treatment sessions, twice a week, for eight weeks. The outcomes measured were pain (visual analogue scale), function (Roland Morris questionnaire), quality of life by the Brazilian Portuguese version of Short Form-36 (SF-36), and pain medication consumption (all patients were instructed to register in a suitable form every time they consume any pain medication). Besides the evaluations before and after the end of the intervention, a follow up was conducted two months after the end of the treatment. Data were statistically analyzed at a significance level of $p<0.05$. An intragroup and intergroup comparison was performed.

Results: The baseline assessment demonstrates the homogeneity of the groups. The outcomes showed significant pain level reduction in the three groups, but in the intergroup's comparison, treated groups were better than control, and G1 (GPR) was still better than G2 (segmental stretching), presenting the largest pain intensity reduction. In quality of life in G1 and G2, there was significant improvement in all SF-36 domains (functional capacity, physical, emotional and social aspects, pain, general health status, vitality, and mental health). In G3 this improvement occurred in pain, social and emotional aspects, and functional capacity. In the intergroup's comparison, G1 and G2 were significantly superior to G3 in physical aspects, pain, and vitality components. The G1, treated with GPR, was still better than G3 when comparing social aspects and mental health. In Roland Morris questionnaire there were significant improvements in all groups, but in the comparison among them, G1 and G2 were significantly better. Regarding the consumption of pain medication, it was observed in the treated groups, G1 and G2, that the drug intake was significantly lower than in the control group (G3).

Conclusion: Based on the findings of our study, we conclude that both methods were effective and superior to control group in pain reduction, in the improvement of function and quality of life, and in the decrease of medication consumption, however, the GPR method proved to be superior to the segmental stretching for the treatment of chronic back pain.

Epidemiology of Restricting Back Pain in Older Persons and Associations with Age, Sex, Obesity, and Depressive Symptoms. Una E. Makris[3], Liana Fraenkel[1], Ling Han[2] and Thomas M. Gill[3]. [1]Department of Veterans Affairs, West Haven, CT, [2]Program on Aging, New Haven, CT, [3]Yale University School of Medicine

Background: Despite the considerable morbidity and costs attributable to back pain, longitudinal data describing the clinical course and risk factors associated with this complaint in older persons are sparse.

Purpose: To describe the epidemiology of restricting back pain in community-living older persons and to evaluate the association of age, sex, obesity, and depressive symptoms with development of restricting back pain.

Methods: Participants, identified from the Yale Precipitating Events Project, included 550 nondisabled, community-living persons, aged 70 years or older, who did not report restricting back pain at baseline. Data were collected monthly for over 10 years. Restricting back pain was defined as staying in bed for at least half a day and/or cutting down on one's usual activities due to back pain. One or more consecutive monthly reports of restricting back pain defined an episode. We first determined the number and duration of restricting back pain episodes. We used Cox regression models to evaluate the association between age, sex, obesity, and depressive symptoms and the development of the first occurrence and recurrence of restricting back pain episodes. Interaction terms between sex and these baseline factors were tested using Cox models in first-event and recurrent events models.

Results: The mean age of our sample was 78.6 years, 63% were women, 92% were white, 19% were obese (BMI ≥30 kg/m2), and 15% reported depressive symptoms. During a median follow-up of 107 months, 126 (61.8%) of the men and 251 (72.5%) of the women participants developed restricting back pain. Among the 377 (68.5%) participants with restricting back pain, the median (interquartile range) number of episodes was 2.0 (1–4) for men and 3.0 (1–5) for women ($p = 0.01$). The median duration of restricting back pain episodes was one month. Of the 1528 total episodes of restricting back pain, only 6.4% were chronic (lasting three or more months). There were no differences in number or duration of restricting back pain episodes by age. The association between restricting back pain and age, sex, obesity, and depressive symptoms are listed in Table 1. Women with depressive symptoms had the highest risk of developing recurrent restricting back pain episodes (HR 2.89, 95% CI 2.03, 4.11) compared to men without depressive symptoms.

Table 1. Association between selected risk factors and restricting back pain (N = 550) estimated using Cox proportional hazard model

Effect*	Outcome	Model 1 (1st event)	Model 2 (Recurrent events)
Age ≥ 85	HR (95% CI)	1.28 (1.01–1.62)	1.03 (0.82–1.29)
	P value	<0.05	0.79
Female Sex	HR (95% CI)	1.27 (1.02–1.57)	1.41 (1.10–1.80)
	P value	0.03	0.01
BMI ≥ 30	HR (95% CI)	1.34 (1.05–1.72)	1.60 (1.21–2.12)
	P value	0.02	0.001
Depressive Symptoms	HR (95% CI)	1.73 (1.29–2.34)	2.04 (1.53–2.72)
	P value	<0.001	<0.001

* Both models simultaneously included these four variables.

Conclusion: Among community-living older persons, restricting back pain is common, short-lived, and frequently episodic. Women with depressive symptoms are most likely to develop restricting back pain. Additional research is warranted to further investigate the relationship between depressive symptoms and back pain, especially in older women.

Life Course Socioeconomic Position and Health Outcomes in People with Self-Reported Arthritis. Jack H. Shreffler[3], Britta Schoster[3], Kathryn Remmes Martin[2] and Leigh F. Callahan[1]. [1]Univ of North Carolina, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of North Carolina, Chapel Hill

Purpose: Childhood and adult socioeconomic status (SES) positions have been demonstrated to be independently associated with health status outcomes in cardiovascular and other chronic diseases. The purpose of this study is to determine if current SES and childhood caregiver SES positions are independently associated with health outcomes, including measures of disability, physical health, and mental health status, in people with self-reported arthritis.

Methods: A practice-based research network of 22 family medicine practices in rural and urban areas of a southeastern state was established in 2001. Participants completed telephone surveys assessing health status, chronic conditions, community characteristics, health attitudes and beliefs, and socio-demographic variables in 2004 and again in 2006. The 2006 follow-up questionnaire obtained participants' current SES and the SES of their parent or caregiver during childhood. Regression models were conducted on 937 people with arthritis for health outcomes including adult/childhood pairs of single SES variables (education, occupation, or homeownership) as main explanatory variables with adjustment for age, BMI, and gender. Outcomes were SF12v2 Physical (PCS) and Mental (MCS) Component Summary scores, Health Assessment Questionnaire disability scale (HAQ), Center for Epidemiological Studies-Depression depressive symptoms scale (CES-D), and the CDC Health Related Quality of Life 5-item general health response (dichotomized to fair/poor versus good/very good/excellent).

Results: The average age of participants was 61 years (23–94) and 74% were female. 16% did not complete high school (NHS), non-homeownership (NHO) was 18%, and low occupational status (LOC) was 42%. The 3 SES measures for the participants were considerably higher than those reported for their primary caregiver during childhood. PCS score, 38(13) [mean (sd)], was significantly ($p<0.05$) reduced by −4.2, −2.7, and −2.7 for caregiver NHS, LOC, and NHO, respectively. General health self-reported as fair/poor (39%)

was more likely, OR=1.54 (95% CI=[1.17, 2.05]), for caregiver NHO, and nearly significantly, OR=1.6 (95% CI=[0.99, 2.70], p=0.056), for caregiver NHS. CES-D score, 11.9(12), was significantly increased by 2.6 and 2.5 for caregiver NHS and NHO, respectively. In addition, CES-D was nearly significant, β=1.6 [95% CI=−0.01, 3.25] (p=0.051) for LOC. Neither HAQ nor MCS was found to have independent, significant association with the three caregiver SES variables when the adult measures were included in the model. In the regression models producing the results above, SES measures for the adult participants were strongly associated with all outcomes, with the notable exceptions of PCS and MCS for homeownership.

Conclusions: SES measures at childhood show significant association with PCS, general health, and CES-D, independent of the participant's current adult SES levels. Healthcare providers should consider the potential influence of patients' SES as children when evaluating their current health status.

1461

Perceived Helplessness as a Mediator between Household Income and Health Status in People with Self-Report Arthritis. Kathryn Remmes Martin[2], Britta Schoster[3] and Leigh F. Callahan[1]. [1]Univ of North Carolina, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill

Purpose: Lower income is associated with poorer health status among people with chronic disease. This study aimed to examine the role of perceived helplessness as a mediator in the relationship between household income and health status in people with self-report arthritis.

Methods: In 2004 and 2005, 439 people with self-reported physician-diagnosed arthritis were recruited from a southeastern Family Medicine Research Network and completed a telephone survey assessing health status, chronic conditions, neighborhood characteristics, health attitudes and socio-demographic variables. Six health status outcomes were: Health Assessment Questionnaire (HAQ), disability index; SF-12v2 Physical Component Summary (PCS), physical functioning; SF-12v2 Mental Component Summary (MCS), mental health; and 3 CDC Health Related Quality of Life Healthy Days measures: mental, physical and limited activity days. The proposed mediator, perceived helplessness, was assessed with the Rheumatology Attitudes Index (RAI). Path analyses were constructed with MPlus to examine the relationship between income, perceived helplessness, and each health status outcome, adjusting for age, race, gender, body mass index (BMI), education, occupation, homeownership, and block-group poverty-level.

Results: Participants were on average 56 years old, female (76.3%), non-Hispanic white (75.9%), had a mean BMI of 31.5, earned less than $45,000 (72.7%), had at or lower than a high school education (51.9%), had lower occupational status (54.7%), and were homeowners (74.3%). Income was directly and indirectly related to health status. Income was directly related to physically unhealthy days (β=−2.42, p=0.003), mentally unhealthy days (β=−2.17, p=0.002), lower MCS (β=1.96, p=0.0.03), limited activity days (β=−3.66, p<0.001), PCS (β=3.40, p<0.001), and disability (β=−0.27, p<0.001). Income was also indirectly related through helplessness. Individuals with lower income have greater perceived helplessness regarding their condition (β=−0.33, p<0.001). Those with greater helplessness reported greater number of physically unhealthy days (β=5.24, p<0.001), mentally unhealthy days (β=4.48, p<0.001), limited activity days (β=4.44, p<0.001), greater disability (β=0.33, p<0.001) and lower scores on MCS (β=−6.15, p<0.001) and PCS (β= −3.98, p<0.001). The Sobel test showed a significant indirect effect for physically unhealthy days (β=−1.74, p<0.001), mentally unhealthy days (β=−1.49, p<0.001), limited activity days (β=−1.48, p<0.001), MCS (β=2.04, p<0.001), PCS (β=1.32, p<0.001), and disability (β=−0.11, p<0.001).

Conclusions: Our findings indicate that lower levels of helplessness partially mediate the relationship between lower levels of income and poorer mental and physical health status outcomes in people with self-report arthritis. Enhancing perceived control in individuals with lower income levels may be a mechanism for reducing health disparities.

An Examination of How Coping with Prescription Medication Costs and Medication Underuse Influences Physical and Mental Health of Individuals with Arthritis. Kathryn Remmes Martin, Britta Schoster, Jack Shreffler and Leigh F. Callahan, University of North Carolina at Chapel Hill

Purpose: Our purpose is twofold: 1) to identify the overall frequency and characteristics of individuals who self-report prescription medication cost coping strategies, and 2) to examine the association between coping strategies and medication underuse and physical and mental health outcomes among a cohort of participants with arthritis from a southeastern state.

Methods: In 2006 and 2007, 729 people with self-reported physician-diagnosed arthritis completed a telephone survey assessing health status, chronic conditions, neighborhood characteristics, health attitudes and socio-demographic variables. Five health status outcomes used were: Health Assessment Questionnaire (HAQ), disability index; SF-12v2 Physical Component Summary (PCS), physical functioning; SF-12v2 Mental Component Summary (MCS), mental health; Center for Epidemiological Studies-Depression (CES-D) (<16; ≥16), depressive symptoms; self-rated health (excellent, very good, & good; fair & poor). Helplessness was also assessed with the Rheumatology Attitudes Index (RAI). Linear and logistic regression analyses using Stata v11 were conducted for each outcome to explore associations with the medication cost coping strategies while adjusting for age, race, gender, body mass index (BMI), co-morbid conditions, and participant education, income, occupation and homeownership.

Results: Participants were on average 61 years old, female (75.0%), non-Hispanic white (76.8%), had a mean BMI of 30.2, and a median income of below $45,000 (55.7%). Overall, participants reported spending less on food, heat, or basic needs (22.4%), borrowing money from a friend or relative outside of their household (16.1%), increased the amount of credit-card debt carried month-to month (11.7%) to pay for medications and taking fewer medications than prescribed due to medication costs (20.2%). Individuals who borrowed money had lower mental health (MCS) (β= −3.87, p=0.003) and greater disability (β=0.14, p=0.044). Individuals increasing credit card debt had worse physical functioning (β= −4.63, p=0.001), and self-rated health (OR =0.43, p=0.005), and reported greater helplessness associated with their condition (β= 0.47, p<0.001). Individuals who reported medication underuse had worse mental health (β= −4.24, p<0.001), greater disability (β=0.13, p=0.028), depressive symptoms (OR=2.03, p=0.004), and a trend for worse self-rated health (OR=0.62, p=0.066). Age, race, BMI, comorbid condition count, education, and income were statistically significant covariates in some of the models dependent on the outcome.

Conclusions: Our findings indicate that individuals with arthritis do use strategies to cope with mediation costs, one of which is medication underuse, and that these strategies have adverse mental and physical health outcomes. Health care practitioners should be alert to issues of medication cost to ensure optimal patient health and medication adherence.

Disability and Knee Osteoarthritis: Associations with Individual and Community Socioeconomic Status. Leigh F. Callahan, Joshua B. Knight, Jack H. Shreffler, Britta Schoster, Jordan B. Renner and Joanne M. Jordan. University of North Carolina, Chapel Hill

Purpose: Individual level socioeconomic status (SES) measures have been shown to be associated with disability and restricted function in osteoarthritis (OA), and limited studies have also demonstrated associations with community level SES measures independent of one's individual SES. To date this has not been evaluated in persons with knee OA. This study examined associations between educational attainment, occupation, and community poverty with disability in persons with knee radiographic OA (rOA) or symptomatic OA (sOA) in a population-based OA cohort in a southeastern state.

Methods: A cross-sectional analysis was conducted on individuals (64% Caucasian, 36% African American) with knee rOA (n=733) or knee sOA (n=487) who were assessed in the 2001–2003 time period. rOA was defined as Kellgren-Lawrence grade ≥ 2 in at least one knee. sOA was defined as K-L grade ≥ 2 and symptoms (pain, aching or stiffness) in the same knee. Educational attainment (<high school (HS) or ≥HS) and occupational status (managerial or non-managerial) were individual SES measures. Census block group poverty rate (<12%, 12–25%, >25%) was the community SES

measure. Disability was measured by the Health Assessment Questionnaire (HAQ). Covariates were age, gender, race, BMI, occupational activity score, and presence of hip symptoms. Race was not an effect modifier and was included as a covariate. Unadjusted and adjusted analyses were used to find associations of disability with each SES effect separately. Multivariable analyses were conducted using all SES variables, adjusting for covariates.

Results: In persons with knee rOA, education (β=0.21, C.I.= [0.11, 0.32]), occupation (β =0.15, C.I.=[0.05, 0.25]) and >25% poverty (β=0.22, C.I. = [0.07, 0.36]) were all significantly associated with disability in unadjusted models. All SES variables were also significantly associated with HAQ disability in persons with sOA: education (β=0.22, C.I.= [0.09, 0.35]), occupation (β =0.16, C.I.=[0.03, 0.29]) and >25% poverty (β=0.23, C.I. = [0.05, 0.41]). In adjusted models, occupation and community poverty were no longer significantly associated with rOA or sOA. In multivariable models, education was the only SES variable (in both rOA and sOA) significantly associated with disability (β=0.18, C.I.= [0.08, 0.29]) and (β=0.22, C.I.= [0.09, 0.36]), respectively. Covariates positively associated with disability were hip symptoms, female gender, obesity, and strenuous occupational activities.

Conclusions: In persons with knee rOA or knee sOA, education remained the important SES predictor of disability after adjusting for key risk factors. Occupation and community poverty were not independently significant when education was a main explanatory variable. These data underscore the importance of educational attainment with outcomes in knee OA.

Radiographic Knee Osteoarthritis and Knee Pain: Findings from 5 Racial/Ethnic Populations. Ke Wang[2], Noriko Yoshimura[7], Ling Xu[5], Jianhao Lin[6], Inje Kim[4], Michael Nevitt[8], Hiroshi Kawaguchi[7], David Felson[1], Xiaozheng Kang[6], Yuqing Zhang[1] and Hyun Ah Kim[3]. [1]BU. Sch. of Med., Boston, [2]BU. Sch. of Med., [3]Hallym Univ., Sacred Heart Hosp., Anyang, Korea, Republic of, [4]Hallym Univ., Sacred Heart Hosp., Korea, Republic of, [5]Peking Union Medical College, Beijing, China, [6]Peking University, Beijing, China, [7]The University of Tokyo, Tokyo, Japan, [8]Univ. of California at San Francisco, San Francisco, CA

Background: There is a consensus that the association between knee radiographic osteoarthritis (ROA) and knee pain is modest and only limited to knees with severe ROA. However, utilizing a novel approach comparing knees discordant for pain, recent results from both Framingham OA Study and Multicenter OA Study suggested that ROA was strongly associated with both frequent knee pain (FKP) and pain severity, even among knees with moderate ROA. To investigate whether such findings are consistent in other ethnic populations, we examined the relation of knee ROA to FKP and pain severity among 5 ethnic populations using data collected from 5 OA studies.

Methods: Subjects included were from 5 studies: urban Chinese (Beijing OA Study, BOA), rural Chinese (Wuchuan OA Study, Wuchuan), Japanese (Research on OA Against Disability, ROAD), Korean (Hallym Aging study, HAS), White (OA Initiative, OAI), and African American (OAI). Participants in each study were asked knee-specific questions regarding presence of FKP (i.e., pain lasting for ≥ a month in the past 12 months) and pain severity. We performed a within-person knee-matched case-control analysis among subjects whose FKP status or pain severity categories (no pain, mild/moderate pain, severe/extreme pain) were discordant between the two knees. We examined the relation of knee ROA to prevalence of FKP using a conditional logistic regression and to pain severity using a stratified proportional odds model by amalgamating conditional likelihood.

Results: Included were 252 urban Chinese (71% female, mean age 68, mean BMI 26), 221 rural Chinese (55% female, mean age 57, mean BMI 23), 297 Japanese (71% female, mean age 71, mean BMI 24), 98 Koreans (54% female, mean age 70, mean BMI 25), 556 Whites (46% female, mean age 62, mean BMI 29), and 141 African Americans (71% female, mean age 62, mean BMI 32). As shown in Table, knee ROA is strongly associated with presence of FKP across all 5 racial/ethnic populations (p for trend for all studies <0.01). The association is strong even for knees with moderate ROA: knees with K/L=2 had 6.8 (BOA), 3.8 (Wuchuan), 6.6 (HAS), 3.0 (ROAD), 7.2 (OAI White), and 17.6 (OAI African American) times higher prevalence of FKP than those with K/L=0. Knee ROA was also strongly associated with knee pain severity (p for trend for all studies <0.01).

Conclusion: Severity of knee ROA was strongly associated with FKP and pain severity in all ethnic groups.

Studies		BOA (Urban Chinese)	Wuchuan (Rural Chinese)	HAS (Korean)	ROAD (Japanese)	OAI (White)	OAI (AA)

Impact of *Buenos Dias, Artritis*, a Spanish Health Communications Campaign Promoting Physical Activity among Spanish-Speaking People with Arthritis. Teresa J. Brady[2] and Jed Lam[1]. [1]Aeffect Inc., [2]Center for Disease Control, Atlanta, GA

Background: *Buenos Dias, Artritis* is a health communications campaign designed to promote physical activity among Spanish-speaking people with arthritis. The purpose of this study was to evaluate the effects of that campaign as implemented by 4 state health departments.

Methods: A quasi-experimental design was used. 4 state health departments conducted the campaign in one community in their state by placing radio ads and/or outdoor advertising, brochures in community locations and newspaper ads or other print materials. Data were collected from these Test communities (TC) and well as 2 Control communities (CC), selected to have similar proportions of Hispanic populations, at baseline (T1), immediately following campaign completion (T2) and 6 months after baseline (T3). Data were collected by random-digit dial telephone survey from purchased lists of randomly generated telephone numbers in geographic areas known to have higher rates of Hispanics with lower income and education levels. T1 respondents were ineligible for T2 survey.

Results: By design, T1 and T2 data were collected for approximately 1200 respondents (1213 and 1167 respectively), and 600 T3 respondents. Characteristics of T1 sample: 41% ages 55–64, (range 45–75), 68% from Mexico, 69% education less than high school graduate, and 75% female.

Changes in knowledge and confidence were seen. TC demonstrated significant increase in the percentage who believed that "moderate exercise can help you beat arthritis" at T3, (T1=84%, T3=89%)but control respondents also had a significant increase (T1=84%, T3=91%). However, the TC significant increase in beliefs that "moderate exercise can be helpful even if done 10 minutes at a time" (T1=84%, T3=91%), and that they could "reduce my arthritis pain by exercising regularly" (T1=76%, T3=82%) were not matched by increases in CC.

Exercise behavior increased significantly in TC but not CC at both T2 and T3. TC demonstrated significant increases in percentages "exercising at least 10 minutes per day" at T2 and T3 (T1=72%, T2=76%, T3=86%), and "exercising at least 3 days per week" at T2 and T3 (76%, 82%, 81% respectively). No comparable increase was seen in the CC.

Recognition of campaign tag line increased significantly in TC at T3, but recognition of 4 other taglines also increased significantly in TC. Unaided awareness of campaign sponsors increased in TC at T2 and most persisted at T3. There was no significant increase in CC. However, unaided recognition of the National Institutes of Health, which was not a sponsor, also increased in TC at T2.

Respondents in TC reported significant increases in 2 selected behavioral responses to the campaign's call to action at T3 (thought about exercising more, T1=66%, T3=78%; increased my exercise T1=42%, T3=53%). 2 other behavioral responses increased significantly in both TC and CC at T3.

Conclusion: B*uenos Dias, Artritis* health communications campaign produced significant increases in physical activity at T2 and T3, though few significant changes in knowledge or confidence were found. Unaided recognition of campaign sponsors increased at T2, but these increases did not persist at T3.

A Novel Serum Biomarker of Cartilage Destruction, Measured in OA and RA Patients, Is Significantly Associated with Kellgren-Lawrence Score. Anne C. Bay-Jensen[1], Erik B. Dam[3], Inger Byrjalsen[2], Tanja Schubert[4], Phillip Vergnaud[4], Per Qvist[1] and Morten A. Karsdal[1]. [1]Cartilage Biology and Biomarkers, Denmark, [2]CCBR-Synarc, Denmark, [3]Nordic Bioscience Imaging, Denmark, [4]Synarc-Lyon, France

Background: Type II collagen is the primary matrix protein in articular cartilage. In joint degenerative diseases, such as osteoarthritis (OA) and rheumatoid arthritis (RA), the collagens are degraded by matrix metalloproteinases (MMPs) and fragments of the protein are released into the circulation. We identified one such fragment of MMP-derived type II collagen (CIIM).

Methods: Type II collagen was cleaved with MMP *in vitro* and analyzed by mass spectrometry. A collagen type II specific neoepitope, CIIM, was identified (RDGAAG^{1053}). Monoclonal antibodies were raised against the neoepitope and used to develop an ELISA. CIIM assay was measured in the synovial fluid of 18 OA patients aged 62–81 and in serum of an adult population aged 21–80 (n=156). Knee OA was graded by standard Kellgren-Lawrence (KL) score. Serum levels was measured in serum samples from RA patients and age-matched controls (n=66).

Results: The CIIM ELISA showed good technical performance; a quantification range of 0.2–14.9ng/ml, inter- and intra assay variations below <15% and a dilution recovery of approximately 100%. CIIM was immunolocalized to classical arthritis features in OA cartilage. A high median level of CIIM [1.2ng/ml] was found in synovial fluid. Serum CIIM levels were significantly higher ($p<0.05$) in those individuals with OA detected by KL scores of 1–2 [0.9ng/ml] and 3–4 [1.0ng/ml] than in those with KL score of 0 [0.6ng/ml] (Fig. 1). The level of CIIM in RA serum [0.284ng/ml] was significantly higher ($p<0.01$) than age-matched controls [0.532ng/ml].

Conclusion: We developed and validated an ELISA for CIIM; a novel biomarker which we demonstrated is derived from MMP-degraded type II collagen. We found serum CIIM levels to be highest in those with the lowest KL score and with RA.

A Small Molecule c-Fos/AP-1 Inhibitor T-5224 Inhibits Osteoclastogenesis and Bone Resorption. Hidetoshi Murao[3], Yukihiko Aikawa[4], Akira Hashiramoto[1], Tetsuya Yamamoto[4], Hisaaki Chaki[4], Hirokazu Narita[4], Shuichi Hirono[2] and Shunichi Shiozawa[1]. [1]Department of Biophysics, Kobe University of Graduate School of Health Sciences/The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan, [2]Department of Pharmaceutical Sciences, School of Pharmacy, Kitasato University, Tokyo, Japan, [3]Research Laboratories, Toyama Chemical Co., Ltd, Toyama, Japan, [4]Research Laboratories, Toyama Chemical Co., Ltd, Toyama, Japan

Purpose: c-Fos/activator protein-1 (AP-1) is an important transcription factor for cytokine production and joint destruction in rheumatoid arthritis (RA) and a potential target for the treatment of RA. We have previously reported a small molecule c-Fos/AP-1 inhibitor T-5224 prevented the development of arthritis and joint destruction in mouse collagen-induced arthritis (CIA). The purpose of this study was to investigate the effects of T-5224 on the osteoclastogenesis and bone resorption.

Methods: 1) *in vitro*: Macrophage-osteoclast precursor RAW264.7 cells were cultured with receptor activator for nuclear factor κB ligand (RANKL) (50 ng/mL) and/or T-5224 for 6 days. Osteoclastogenesis was examined by tartrate-resistant acid phosphatase (TRACP)-staining and pit formation assay. The expressions of cathepsin K, c-Fos, and NFATc1 were determined by Western blot analysis. 2) *in vivo*: CIA was induced in DBA/1J mice by the immunization with bovine type II collagen twice on day 0 and 21. T-5224 was orally administered once daily. The levels of serum TRACP 5b were measured using ELISA, and the mRNA expressions of RANKL and osteoprotegerin (OPG) in the hind paw were measured by RT-PCR. Bone mineral density (BMD) of the femur was assessed using micro-CT. The region of interest was positioned at a metaphyseal region at a point of 3% of the length of the femur from the growth plate.

Results: T-5224 suppressed the induction of TRACP-positive multinucleated cells under the RANKL-stimulation in RAW264.7 cells. The expressions of cathepsin K and NFATc1 were also inhibited by T-5224 in RANKL-stimulated cells. Meanwhile, the expression level of c-Fos was no difference with or without T-5224. Furthermore, T-5224 inhibited the formation of bone resorption pits *in vitro*. In mice with CIA, the marked elevation of serum TRACP 5b, a bone resorption marker, was observed on day 35, and this change was significantly suppressed by the administration of T-5224 from day 21. In addition, T-5224 dose-dependently inhibited the increase of RANKL mRNA and the decrease of OPG mRNA in the arthritic hind paws. The BMD of the femora of mice with CIA was lower than that of normal mice on day 50, and T-5224 inhibited the trabecular bone loss.

Conclusions: These findings suggest that T-5224 inhibits the osteoclastogenesis and bone resorption in arthritic lesions and is able to correct the imbalance of RANKL-OPG which leads to bone loss. Thus, c-Fos/AP-1 inhibitor appears to be a promising drug for rheumatoid bone destruction.

Activation of Wnt and Bone Morphogenetic Protein Signalling Pathways in the Articular Cartilage in *Frzb*$^{-/-}$ Mice. Liesbet Lodewyckx[1], Jeroen Eyckmans[3], Frank P. Luyten[2] and Rik Lories[1]. [1]KU Leuven, Leuven, Belgium, [2]KU Leuven, Leuven, Belgium, [3]KU Leuven

Objective: Frizzled related protein (FRZB/sFRP3) is a secreted WNT antagonist isolated from articular cartilage and expressed in developing skeletal elements. Polymorphisms in the human *FRZB* gene are associated with susceptibility for osteoarthritis. Induction of experimental osteoarthritis in *Frzb*$^{-/-}$ mice results in enhanced cartilage degradation associated with increased Wnt signaling, *Mmp3* expression, Mmp activity and cortical bone thickness. In this study we used a whole mouse genome micro-array analysis and a bioinformatics approach to investigate differences between healthy cartilage in wild-type and *Frzb*$^{-/-}$ mice.

Methods: Articular cartilage from the tibia was isolated from 6 weeks old *Frzb*$^{-/-}$ mice and wild-type littermates. RNA was isolated using the Rneasy Fibrous tissue mini kit (Qiagen). RNA quality was assessed using an Agilent 2100 Bioanalyzer and RNA nanochips (Agilent technologies Inc). The transcriptional profiles were analysed using the whole genome Affymetrix GeneChip® Mouse Genome 430 2.0 Array. Articular cartilage from one tibia from 3 wild-type mice and 2 *Frzb*$^{-/-}$ mice was used (3 vs. 2 chips comparison). Gene expression analysis was based on the RMA expression values and the MAS 5.0 detection calls. PANTHER Classification System software, DAVID bioinformatics resources and FUNNET transcriptional analysis were used for pathway analysis.

Results: Using Benjamini-Hochberg corrected P-values ($p < 0{,}001$) in combination with a cut-off fold change $|\log2\text{-ratio}|>1$ the analysis showed that 696 transcripts were significantly upregulated in the *Frzb*$^{-/-}$ sample group. PANTHER pathway analysis identified overrepresentation of genes linked to the Integrin, Wnt and Cadherin signalling pathways (corrected p-values $3*10^{-9}$, $5*10^{-5}$ and $6*10^{-4}$ respectively). Not surprisingly, genes linked to skeletal development and extracellular matrix were enriched in the

analysis. DAVID analysis similarly identified the Wnt and Integrin pathways but also EGF signalling. FUNNET identified both Wnt and TGF/BMP signalling. With the Wnt signalling pathway both different Frizled receptor, Wnt9a ligand and distinct intracellular and extracellular antagonists were upregulated suggesting compensatory mechanisms in the absence of *Frzb*. In addition, upregulation of bone morphogenetic protein and other transforming growth factor beta superfamily members and receptors suggests compensatory upregulation of this pathway. The link with integrin upregulation further supports our earlier data that support of role for *Frzb* in mechanobiology.

Conclusions: In this study we demonstrated that loss of *Frzb* results in the upregulation of the WNT signalling pathway and a possible compensatory upregulation of BMP signalling. The upregulation of the integrin and cadherin signalling pathway suggest an important role for *Frzb* in the interactions of cells with surrounding cells and extracellular matrix.

Adenosine A_1 Receptors Regulates RANKL-Induced Osteoclast Formation Via Regulation of c-fos and NFATc1 Expression. Wenjie He[2], Tuere Wilder[2] and Bruce N. Cronstein[1]. [1]New York Univ Med Ctr, New York, NY, [2]NYU School of Medicine

Purpose: Adenosine is a purine molecule necessary for normal cell metabolism and growth. Recent work from our laboratory using adenosine A_1 -deficient mice has demonstrated that adenosine A_1 receptors play a critical role in regulating bone turnover, raising the intriguing possibility of targeting A_1 receptors for therapeutic advancement in osteoporosis and other bone diseases. In the present study, we investigated the mechanism by which A_1 receptors regulate mouse osteoclast differentiation induced by macrophage-colony stimulating factor (M-CSF) and the receptor activator of NF-kappaB ligand (RANKL) from monocyte/macrophage cell lineage of bone marrow cells.

Methods: Osteoclast differentiation was studied in vitro as the M-CSF/RANKL stimulated formation of multinucleated (>3 nuclei), TRAP-positive cells from primary murine (C57Bl/6) bone marrow-derived precursors. Signaling events were studied by Western Blot for activated (phosphorylated) signaling molecules and changes in message were determined by RT-PCR.

Results: As we have previously demonstrated, the A_1 –receptor specific antagonist 8-Cyclopentyl-1,3-dipropylxanthine (DPCPX) dose-dependently inhibited RANKL-stimulated tartrate-resistant acid phosphatase (TRAP)-positive osteoclast formation from bone marrow cells and the bone-resorptive activity of mature osteoclasts ($p<0.001$, $n=3$, $IC_{50}=0.1\mu M$). This inhibition is accompanied by reduction of osteoclast-specific target genes including MMP9, Integrin αv, Integrin $\beta 3$, Cathepsin K and TRAP ($p<0.05$, $n=4$). Furthermore, DPCPX inhibited accumulation of the RANKL-stimulated c-fos mRNA at day 3 in bone marrow cells ($p<0.05$, $n=3$); c-fos is a key transcription factor for the differentiation of osteoclasts. DPCPX also dose-dependently suppressed RANKL-induced gene expression of nuclear factor of activated T-cells, cytoplasmic 1 (NFATc1) at day 4 in bone marrow cells ($p<0.05$, $n=3$). Among the RANK signaling MAPK pathways, DPCPX ($1\mu M$) inhibited phosphorylation of JNK ($p<0.001$, $n=4$), which is upregulated in response to RANKL in bone marrow macrophages.

Conclusion: Collectively, these data suggest that Adenosine A_1 receptor blockade inhibits RANKL-induced osteoclast formation by inhibiting activation of JNK/c-Jun pathway, thereby suppressing the gene expression of c-fos and NFATc1 in osteoclast precursors. These results are consistent with the hypothesis that endogenously released adenosine, acting at A_1 receptors, is critical for the expression and activation of critical signaling intermediates required for osteoclastogenesis. Moreover, these results further support the notion that blockade of adenosine A_1 receptors may be useful in the treatment and prevention of osteoporosis and premature bone loss.

Adenosine A_{2A} Receptor Agonists: Can They Prevent/Treat Joint Prosthesis Loosening? Aranzazu Mediero[1], Sally R. Frenkel[2], Tuere Wilder[1], Igor Immerman[3], Scott Hadley[3], R. Damani Howell[3], Maya Hawly[4], Elie Sellam[4] and Bruce N. Cronstein[5]. [1]Department of Medicine, NYU Langone Medical Center, New York, NY, [2]Department of Orthopaedic Surgery, NYU Hospital for Joint Diseases, New York, NY, [3]Department of Orthopaedic Surgery, NYU Hospital for Joint Diseases, [4]Institut Supérieur des Bio-Sciences de Paris, France, [5]New York Univ Med Ctr, New York, NY

Purpose: Survival of bone implants depends on biological fixation, and prosthesis loosening can be catastrophic leading to replacement of prostheses. Inflammation and osteoclast-mediated bone resorption in response to wear particles near prostheses contribute to loosening. Because we have demonstrated that adenosine A_{2A} receptor activation is anti-inflammatory and prevents osteoclast formation and function we hypothesized that adenosine A_{2A} receptor agonists might prevent osteoclast-mediated bone resorption at the site of prosthesis wear in a calvarial model of wear particle-induced bone resorption.

Methods: Eighteen C57Bl/6 mice age 6–8 weeks were anesthetized by intraperitoneal injection of ketamine and xylazine and a 1cm midline sagittal incision was made over the calvarium anterior to the line connecting both ears. Six animals received no particles (control), and 12 received 15 μl of polyethylene particle suspension. Of the 12 mice receiving particulate, 6 were injected subcutaneously at the surgical site with 20 μl of 10 μM CGS21680 (A_{2A} receptor agonist), and 6 mice were injected with saline 0.9%, beginning immediately after incision closure and continuing every other day until sacrifice. Animals were sacrificed after 14 days and the calvaria were removed, fixed, and prepared for microCT and histological staining with TRAP.

Results: Histologic examination of calvaria demonstrated lymphocytic infiltration in both particle-exposed groups. TRAP staining revealed a reduction in osteoclast differentiation after treatment with CGS21680. mCT showed pitting and increased porosity in both particle-exposed groups compared to controls, although in CGS21680-treated mice the reduction in cortical bone was significantly less than in the untreated particle-exposed mice ($p<0.01$). Control bone volume/trabecular volume was significantly greater ($p<0.005$) than in either particulate group, however, calvarial bone from CGS21680-treated mice had significantly greater mean bone volume than did the untreated group ($p<0.0005$). Trabecular thickness was significantly reduced in both CGS21680-treated and untreated particle-exposed groups as compared to control mice ($p<0.05$). Finally, digital morphometric analysis of microCTs reveals that CGS21680 significantly reduced the area of bone pitting compared to control particle-treated mice ($p<0.05$).

	Bone Volume/ Trabecular Volume	Bone Mineral Density	Trabecular Thickness	% Area of bone pitting
Control	0.7964 ± 0.0002	821.11 ± 138.79 mg/cc	0.1080 ± 0.00001 mm	4.6 ± 0.6%
Particulate	0.7436 ± 0.0005	810.28 ± 153.07 mg/cc	0.1041 ± 0.00003 mm	10.2 ± 1.1%
Particulate + CGS21680	0.7765 ± 0.0003	809.14 ± 161.64 mg/cc	0.1079 ± 0.00003 mm	7.8 ± 1.2%

Conclusions: Adenosine A_{2A} receptor activation reduces inflammation and bone destruction due to prosthetic wear particles. This observation suggests that delivery of an adenosine A_{2A} agonist in the cement may enhance orthopedic implant survival, delaying or eliminating the need for revision arthroplasty surgery.

Adenosine A_{2A} Receptor Ligation Inhibits Osteoclast Formation. Aranzazu Mediero[1], Firas M. Kara[1], Maya Hawly[2], Elie Sellam[2] and Bruce N. Cronstein[3]. [1]Department of Medicine, NYU School of Medicine, New York, NY, [2]Institut Supérieur des Biosciences de Paris, Creteil, Ile de France, France, [3]New York Univ Med Ctr, New York, NY

Purpose: Adenosine is a nucleoside that is generated at sites of injury and hypoxia and which mediates its physiologic and pharmacologic effects via activation of one or more G protein coupled receptors (A_1, A_{2A}, A_{2B} and A_3). We have previously reported that adenosine A_1 receptor ligation is required for osteoclast formation and that blockade or deletion of adenosine A_1

receptors leads to increased bone density. Because all four adenosine receptors are expressed on osteoclasts and osteoclast precursors we determined whether adenosine A_{2A} receptors also regulate osteoclast formation *in vivo* and *in vitro*.

Methods: Osteoclast differentiation was studied *in vitro* as the GM-CSF/RANKL stimulated formation of multinucleated (≥3 nuclei), TRAP-positive cells from primary murine (C57Bl/6) bone marrow-derived precursors. Signaling events were studied by Western Blot for activated (phosphorylated) signaling molecules and changes in message were determined by RT-PCR. Histological examination of bones from A_{2A} knockout and wild type mice was carried out with TRAP and alcian blue stains. Murine bone was further analyzed by micro CT and electron microscopy.

Results: The highly selective A_{2A} receptor agonist CGS21680 inhibited osteoclast differentiation as much as 38±1% with an IC_{50} of approximately 50nM ($p<0.05$), reversed by the selective high affinity antagonist ZM241385. CGS21680 (1uM) stimulated phosphorylation of ERK1/2 (122±3 and 134±3% of control at day 3 and 7 of differentiation, $p<0.001$ for both) and JAK1 (107±1% of control phosphorylation at day 7 of differentiation, $p<0.01$), activation that was reversed by ZM241385 (not shown). Moreover, CGS21680 inhibited NFkB translocation to the nucleus (nuclear NFkB decreased by 44±5% at day 3, $p<0.001$). There was also a marked increase in cellular IkB levels (maximal IkB increased by 19±1% at day 7, $p<0.001$) whereas pretreatment with ZM241385 increased phosphorylation of IkB (maximal pIkB increased by 13±0.4% at day 6, $p<0.001$) and enhanced nuclear translocation of NFkB (by 14±2% at day 3, $p<0.01$). MicroCT analysis of femurs from A_{2A}KO mice showed significantly decreased bone volume/total volume ratio (17.49±0.95 for A_{2A}KO vs. 22.61±2.15 for wild type, $p<0.05$), trabecular number (4.4±0.2 for A_{2A}KO vs 5.8±0.07 for wild type, $p<0.001$) and increased trabecular space (0.19±0.006 for A_{2A}KO vs. 0.13±0.0004 for wild type, $p<0.001$). There were more osteoclasts in the TRAP-stained femurs of A_{2A}KO (50±13/lpf) than wild type mice (35±1/lpf, 6 fields each from femurs of 2 different mice each). Electron microscopy of osteoclasts in femurs from A_{2A}KO mice showed marked osteoclast membrane folding and increased osteoclast bone resorption.

Conclusions: These results indicate that adenosine A_{2A} receptors inhibit GM-CSF/RANKL-stimulated osteoclast differentiation and thereby regulate bone turnover. Because adenosine mediates the anti-inflammatory effects of methotrexate we further speculate that the capacity of methotrexate to inhibit bone erosion in patients with Rheumatoid Arthritis may be mediated by methotrexate-stimulated increases in adenosine concentration.

Alarmins S100A8 and S100A9 Skew Human Chondrocytes towards a Cartilage Breakdown Phenotype. Rik F. P. Schelbergen[4], Peter L. van Lent[5], Arjen B. Blom[5], Annet Sloetjes[5], Thomas Vogl[2], Johannes Roth[1] and Wim B. Van Den Berg[3]. [1]Children's Hospital Eastern Ontario, Ottawa, ON, Canada, [2]Institute of Immunology, Muenster, [3]Radboud Univ Nijmegen Med Cntr, Nijmegen, The Netherlands, [4]Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, [5]Radboud University Nijmegen Medical Centre

Background: Alarmins S100A8 and S100A9 are members of the S100 family of Ca2+-binding proteins that are associated with inflammation and cartilage and bone erosion during human rheumatoid arthritis (RA). Recently, we found that S100A8 and S100A9 are also associated with cartilage degradation in murine collagenase-induced osteoarthritis (OA). We also showed that S100A8 and S100A9 stimulate expression and activity of matrix metalloproteinases (MMPs) and pro-inflammatory cytokines in murine chondrocytes. We now investigated whether S100A8, S100A9 and/or the S100A8/S100A9 complex could also activate human chondrocytes from OA patients and skew them towards a cartilage breakdown phenotype.

Methods: Cartilage was collected from human OA patients undergoing joint replacement. Immunostaining was performed on paraffin sections of OA cartilage using antibodies against S100A8 and S100A9 and against VDIPEN and NITEGE, which are MMP- and A disintegrin and metalloproteinase with thrombospondin motifs (ADAMTS)-induced cartilage breakdown neoepitopes. Chondrocytes were isolated from OA cartilage and stimulated with recombinant S100A8, S100A9, S100A8/A9 heterodimer and/or interleukin 1β (IL-1β). mRNA levels of MMPs, cytokines and cartilage matrix molecules were determined with RT-qPCR and protein levels of MMP and cytokine using Luminex.

Results: Immunostaining on OA cartilage showed that both S100A8 and S100A9 protein were expressed in and around chondrocytes. Furthermore, immunostaining of breakdown neoepitopes VDIPEN and NITEGE was found in the same areas as the S100 proteins.

Stimulation of OA chondrocytes with the monomers S100A8 and S100A9 for 24 hours strongly stimulated cartilage degrading molecules like MMPs and cytokines. mRNA expression of MMP1, -3, -9 and -13 was upregulated 6.0, 5.2, 4.3, and 2.8-fold respectively. Protein levels of MMP1, -3 and -13 were upregulated 3.4, 1.3 and 2.4-fold respectively. Moreover, particularly interleukin 6 (IL-6) levels were strongly upregulated on mRNA level (11-fold) and protein levels reached 10 ng/ml.

Apart from stimulating cartilage degradation, S100A8 and S100A9 monomers also inhibited new formation of cartilage matrix molecules. mRNA levels of aggrecan and collagen type II were significantly decreased 2- to 3-fold, suggesting that these proteins inhibit repair.

The S100A8/A9 heterodimer neither had effect on cartilage degradation nor on cartilage matrix production.

The effect of S100A8 and S100A9 was similar to IL-1β effects, but there was no additive effect of S100 with IL-1β, suggesting independent mechanisms.

Conclusions: S100A8 and S100A9 expression is found in areas with cartilage breakdown. Moreover these proteins inhibit new formation of matrix molecules and stimulate production of cartilage degrading molecules *in vitro* thereby skewing human chondrocytes towards a cartilage breakdown phenotype.

S100A8 and/or S100A9 may serve as therapeutic targets for the treatment of cartilage damage.

Analysis of Secretome from Mesenchymal Stem Cells from Human Umbilical Cord Strome during the Chondrogenesis. María C. Arufe[1], Alexandre De la Fuente[2], Jesús Mateos[4], Patricia Fernández-Puente[4], Esther Rendal[4], Silvia Díaz[2], Isaac Fuentes[2], Francisco J. De Toro[2] and Francisco J. Blanco[3]. [1]INIBIC-Universidad de A Coruna, A Coruna, Osteoarticular and Aging Research Laboratory, Proteomics Unit-Associated Node to ProteoRed-Biomedical Research Center (INIBIC), Hospital Universitario A Coruna, La Coruna, Coruña, Spain, [2]INIBIC-Universidad de A Coruna, A Coruna, Spain, [3]INIBIC-Universidad de A Coruna, A Coruna, Spain. Osteoarticular and Aging Research Laboratory, Proteomics Unit-Associated Node to ProteoRed-Biomedical Research Center (INIBIC). Hospital Universitario A Coruna, La Coruna, Spain, [4]Osteoarticular and Aging Research Laboratory, Proteomics Unit-Associated Node to ProteoRed-Biomedical Research Center (INIBIC), Hospital Universitario A Coruña. La Coruña, Spain

Our goal is study the secreted proteins from Mesenchymal Stem Cells –MSCs- from umbilical cord stroma during their differentiation towards chondrocyte-like cells to discern the pathways which could be determinant in this chodrogenesis.

Material and Methods: Umbilical cord tissues were obtained from caesareans from normal women in the Maternity Facility at Complejo Hospitalario Universitario de A Coruña under the supervision of the hospital ethic committee. We isolated and growth MSCs from umbilical cord stromal tissue by enzymatic digestion and cultured the cells adhered to the plastic plate(1). The cells were characterized (2) using flow cytometry, immunohistochemistry and RT-PCR techniques. Chondrogenic process was performed using our previously published model (3). Briefly, we grow the cells during two days in medium suplemented with FCS 10%. After 2 days we washed the cells with PBS and added medium supplemented with KO serum and TGF-β3. Spheroids were formed by two days in culture and this three-dimensional structure help to produce the characteristic proteins which form part of the extracellular matrix of the cartilage. The spheroid were situated in a well with the chondrogenic factors plus RPMI during 12 h to recover the protein secreted to the medium by the spheroids at 4, 7, 14, 28 and 46 days of differentiation avoiding the serum contamination.

SDS-PAGE was done using pre-cast NuPAGE® NOVEX gels (Invitrogen) to ensure reproducibility in the separation of the proteins. Gels were stained with Silver Nitrate and the entire lane was divided in 16 sections. Each section was excised and subjected to in-gel digestion with trypsin. The peptide mixture was cleaned and desalted with home-made Poros R2

columns, injected and separated in a nanoLC system, mixed with α-cyano and deposited in a MALDI plate using an automatic MALDI spotter. The MS run for each fraction was analyzed in an ABI 4800 MALDI-TOF/TOF instrument and fragmentation was done using a CID system.

Results: 87 identified proteins were related with the chondrogenic differentiation process from a total of 209 proteins. Some of the proteins related with chondrogenesis obtained with this method were:

Name	SwissProt Accession #	Type	Day
Collagen alpha-1	P02452	Collagen	4, 7
Collagen alpha-2	P08123	Collagen	4, 7
Decorin	PO7585	Proteoglycan	4, 7
Calreticulin	P27797	Chaperone	4, 7
Collagen alpha-3	P12111	Collagen	14, 28
Lumican	P51884	Proteoglycan	7, 14, 28
Fibulin	P23142	Glycoprotein	14, 28
Biglycan	P21810	Proteoglycan	46
Nidogen	P14543	Glycoprotein	46

Conclusions: 1. This technique is suitable to analyze medium complexity samples as secretome.

2. The chondrogenesis differentiation designed through spheroid formation have revealed be an excelent method to obtain chondrocytes-like cells from mesenchymal stem cells of human umbilical cord stromal tissue.

3. Pathways related with differentiation process are been activated during the chondrogenesis process.

Biochemical Markers of Bone Balance (CTX-I/Osteocalcin) Improve with Tocilizumab Treatment in a Population of RA Patients with an Inadequate Response to Anti-TNF Therapy. Morten Karsdal[2], Thasia G. Woodworth[3], Andy Kenwright[4], Inger Byrjalsesn[1], Adam Platt[4] and Georg Schett[5]. [1]CCBR Synarc, Ballerup, Denmark, [2]Nordic Bioscience, Herlev, Herlev, Denmark, [3]Roche Products Ltd., Welwyn, Welwyn Garden City, United Kingdom, [4]Roche, Welwyn, United Kingdom, [5]University of Erlangen-Nuremberg, Erlangen, Germany

Background: Bone resorption and bone formation are maintained in a dynamic equilibrium required for optimum bone and joint maintenance and integrity. In active RA, inflammation is associated with bone resorption, which characteristically dominates bone formation, resulting in osteopenia, bone fragility, and fracture. Biochemical markers of bone and cartilage turnover can provide an assessment of the effect of therapeutic intervention on the restoration of the balance between bone resorption and formation; indeed, previous analyses of tocilizumab (TCZ)-treated MTX inadequate response populations from OPTION and LITHE studies demonstrated dose-dependent improvement in markers of bone formation (osteocalcin [OC], PINP) and bone balance (CTX/OC ratio).

Objectives: To evaluate changes in biochemical markers of bone metabolism in an anti-TNF refractory RA patient population utilizing the 24-week RADIATE study, in which TCZ 8 mg/kg and 4 mg/kg every 4 weeks showed efficacy superior to that of weekly MTX/pbo in patients refractory to one or more anti-TNF agents. In addition, MMP-3 and ICTP, a biochemical marker of MMP activity, were measured.

Methods: Assays for OC, PINP, ICTP, CTX-I, and MMP-3 were conducted on serum acquired from 299 consenting patients (out of 499 in RADIATE) at BL and week 16. Approximately 50% were receiving low-dose corticosteroids (<10 mg qd).

Results: Patients were refractory to at least one anti-TNF with highly active RA (mean DAS28 ~6.8) and had mean disease duration of 12 years. Both TCZ doses decreased CRP and significantly inhibited cathepsin K–mediated bone resorption, as measured by decrease in CTX-I. OC levels remained stable, resulting in an overall improvement in bone balance with TCZ added to MTX, as measured by CTX-1/OC ratio. Further, MMP-3 and ICTP levels decreased, consistent with lower type I collagen turnover in joint tissue.

Conclusions: In these anti-TNF refractory patients, TCZ and MTX significantly reduced the levels of biochemical markers of cathepsin K bone resorption and MMP-mediated tissue destruction. This observation suggests that this treatment regimen has a positive effect on bone balance, the equilibrium between formation and resorption, which will ultimately lead to improved joint health. TCZ dose-related decrease in CRP provides further evidence that TCZ treatment may limit joint damage in these patients.

Chondrogenic Differentiation of Bone Marrow Mesenchymal Stem Cells Grown on Type I Collagen and Heparan Sulfate Scaffolds. Silvia Díaz-Prado[4], Emma Muiños[3], C. G. Trejo-Iriarte[1], D. Lozano[2], N. García-Honduvilla[1], Isaac Fuentes[3], Francisco J. De Toro[3], P. Esbrit[2], Julia Buján[1] and Francisco J. Blanco[3]. [1]Department of Medical Specialties. A Coruña, Coruña, Spain

Background: Articular cartilage lesions are not able to repair. To avoid the need for prosthetic replacement different cell treatments were developed with the aim of generating a repaired tissue. The transplantation of mesenchymal stem cells (MSCs) has been suggested as an alternative therapeutic approach for treatment of cartilage defects.

Aim: Evaluate the chondrogenic potential of bone marrow mesenchymal stem cells (BM-MSCs) grown on type I collagen and different concentrations of heparan sulfate (HS) scaffolds.

Materials and Methods: BM-MSCs and chondrocytes were cultured on type I collagen and different concentrations of HS scaffolds for 16 and 30 days. BM-MSCs were cultured in chondrogenic medium or DMEM with 20% FBS plus 100 nM PTHrP. Chondrocytes were grown in DMEM with 10% FBS plus 100 nM PTHrP. Chondrogenic differentiation was confirmed by histochemical and immunohistochemical analysis.

Results: BM-MSCs and chondrocytes were able to proliferate on type I collagen and various concentrations of HS scaffolds, since cells showed high percentages of positivity for PCNA proliferation marker. Increased cell proliferation has been associated with a high rate of scaffold degradation, although the thicker collagen fibers take longer to be degraded. The results indicated that BM-MSCs proliferated better in chondrogenic medium than in the usual growth medium (DMEM 20%). The study groups with BM-MSCs

grown in chondrogenic medium +100 nM PTHrP, regardless the HS concentration, showed high percentage of cells regarding the scaffold area (more than 80% after 16 days in culture and more than 90% after 30 days in culture). Moreover, they also showed high percentages of positivity for safranin O (Saf O), aggrecan Agg) and type II collagen (Col II) (Table 1 and Figure 1). Masson′s trichrome (Mt) staining showed that cells formed aggregates and produced extracellular matrix. Von Kossa (VKos) stainings, performed in BM-MSCs grown for 30 days in chondrogenic medium, exhibited the presence of calcifications.

	16 DAYS				30 DAYS

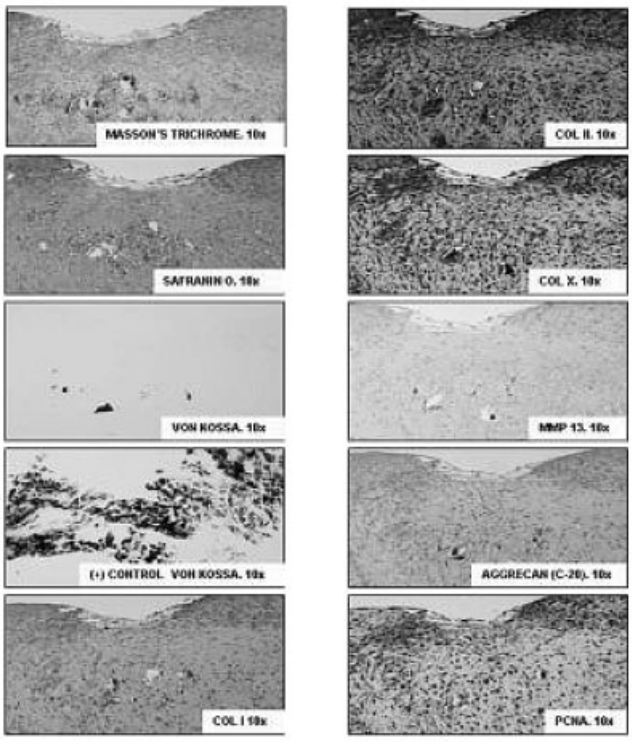

Figure 1. Histochemical and immunohistochemistry analysis of BM-MSCs cultured over type 1 collagen and 3% HS scaffolds on chondrogenic medium after 30 days in culture.

Conclusions: Our data demonstrated that type I collagen and heparan sulfate scaffolds were optimal for BM-MSCs and chondrocyte growth and that BM-MSCs cultured over these scaffolds on chondrogenic medium were able to differentiate to chondrocyte-like cells.

CXCR1/2 Signalling Is Required but Is Not Sufficient To Maintain the Phenotypic Stability of Human Articular Chondrocytes. Joanna C. Sherwood[1], Pramod Achan[2], Giovanna Nalesso[2], Costantino Pitzalis[2] and Francesco Dell'Accio[2]. [1]Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom, [2]Barts and The London School of Medicine and Dentistry, Queen Mary University of London

Background: The production of ELR+ CXC chemokines is widely studied in arthritis and has been postulated to contribute to the inflammatory phenomena that eventually lead to cartilage breakdown. Articular chondrocytes however, also express their own chemokine receptors. The function of CXC chemokine receptors in these cells is puzzling because chondrocytes are encased in a dense extracellular matrix and are not known to migrate in vitro. In this study we have hypothesized that ELR+ CXC chemokine signalling via the receptors CXCR1 and CXCR2 in chondrocytes is required for the phenotypic stability of human articular chondrocytes, but is not sufficient to maintain the stable phenotype of these chondrocytes during in vitro expansion.

Methods: Adult human articular chondrocytes (AHAC) were enzymatically released and expanded in monolayer culture under standard conditions for blockade experiments and in the presence of CXCL6 or CXCL8 for phenotype preservation experiments. The expression of CXCR1 and CXCR2 was confirmed using PCR, Western blot and immunocytochemistry, and functionality was tested using an in vitro calcium influx assay. CXCR1/2 signalling was blocked at a downstream level using pertussis toxin and at specific receptor level using blocking antibodies. The expression of molecular markers associated with the cartilage phenotype was assessed using real time PCR. The content of highly sulphated proteoglycans in chondrocyte micromasses was analysed using Alcian blue staining at pH0.2 followed by guanidine extraction and quantification.

Results: Early passage articular chondrocytes expressed CXCL1, CXCL8 and CXCL6 as well as their receptors CXCR1 and CXCR2. Receptor expression was confirmed at protein level by Western blotting. Confocal microscopy confirmed the localization of both receptors in both in vitro cultured cells and in human cartilage explants at the cell membrane as well as within the cytoplasm, as expected for the well known internalization and recycling of these receptors and for the autocrine/paracrine production of their ligands. The blockade of CXCR1/2 signalling at both G protein and at receptor level in early passage AHAC resulted in a downregulation of some but not all molecular markers associated with the cartilage forming capacity of AHAC, including type II collagen, aggrecan and the cartilage specific transcription factor SOX9. Both methods resulted in the decrease of sulphated proteoglycan levels of cells cultured in micromass. However, the addition of CXCR1 and CXCR2 ligands during cell expansion did not allow for the maintenance of phenotypic molecular markers at gene expression level.

Conclusions:

- CXCR1 and CXCR2 are expressed and are functional in adult human articular chondrocytes.
- CXCR1 and CXCR2 blockade results in the downregulation of some but not all molecular markers associated with the capacity of AHAC to form stable cartilage in vivo.
- CXCR signalling is required for the phenotypic stability of articular chondrocytes in vitro and therefore may play a role in cartilage homeostasis in vivo.
- CXCR1 and CXCR2 signalling are not sufficient to maintain the phenotypic stability of articular chondrocytes during in vitro expansion.

Effects of NSAIDs and the Cyclooxygenase-Inhibiting Nitric Oxide Donator (CINOD) NCX 429 on Human Chondrocytes and Cartilage from OA Patients. Manlio Bolla[1], Serena Viappiani[2], Mandar Dave[4], Jyoti Patel[4], Steven B. Abramson[3] and Mukundan Attur[3]. [1]NicOx Research, Sophia Antipolis, France, [2]NicOx Research, [3]NYU Hospital for Joint Diseases, New York, NY, [4]NYU Hospital for Joint Diseases

Background: The role of nitric oxide (NO) in osteoarthritis (OA) is controversial. NO, particularly when metabolized to peroxynitrite, is a recognized mediator of inflammation, which induces catabolic effects and promotes chondrocyte apoptosis. Conversely, NO delivered at low concen-

trations by NO donors exerts anti-inflammatory effects. Cyclooxygenase-Inhibiting Nitric Oxide Donators (CINODs) are anti-inflammatory compounds designed to inhibit both COX-1 and COX-2 while releasing nitric oxide, an important modulator of vascular tone. We studied the effect of naproxen and the CINOD NCX 429 in human chondrocytes and cartilage tissues from OA patients, to understand whether NO donation from CINODs may modulate the inflammatory/metabolic response.

Methods: The experiments were performed with human cartilage and chondrocytes isolated from OA cartilage. Isolated chondrocytes stimulated with IL-1β to induce inflammation, followed by measurement of inflammatory and matrix parameters, such as iNOS, COX-2, MMP1 and 13, PGE2, NO, matrix metalloproteinases, collagen degradation and NF-κB nuclear translocation. Reference NSAIDs naproxen and celecoxib were used in comparison to NCX 429 (10 and 50 μM), and incubated 16 h before IL-1β challenge. Cartilage explants culture supernatants (untreated and treated with modulators) were harvested at 24 and 72 hours post-treatment. RNA was extracted from chondrocytes and estimated by qPCR. NF-κB binding was assessed using Marligen Bioscience kit and both cytoplasm and nuclear p65 subunit of NF-κB was also assessed by Western blot.

Results: The reference NSAIDs and the CINOD similarly upregulated MMP1 but inhibited MMP13, showing comparable net effect on collagen degradation as assayed by CTX-II ELISA. They similarly inhibited ADAMTS4, but only 50 μM NCX 429 downregulated COX-2 expression. In isolated OA chondrocytes, NCX 429 (10 and 50 μM) significantly and completely inhibited IL-1β-induced PGE2 production, and both the constitutive and IL-1β-stimulated induction of NF-κB activity. Western blot analysis of p65 subunit isolated from nuclear fraction showed that the cells treated with CINOD (both in unstimulated and IL-1β stimulated cells) had increased p65 accumulation although decreased NF-κB binding and also inhibited NF-κB promoter mediated luciferase reporter assay.

Conclusions: Reference NSAIDs and the CINOD NCX 429 appear to similarly modulate human OA chondrocytes, both in unstimulated and stimulated conditions. NO has been considered detrimental for chondrocytes; however, donation of low concentrations of NO is recognized to be beneficial in a variety of conditions. Here, the CINOD NCX 429 does not differ from reference NSAIDs, indicating that CINODs do not adversely affect chondrocytes via NO donation. In addition, NCX 429 showed inhibition of the NF-κB signalling, therefore presenting interesting anti-inflammatory features to be further explored.

Endogeneous TIMP3 Induce Death Receptor Ligand-Independent Apoptosis in Mesenchymal Cells. Christina Wunrau[2], Doreen Wendholt[3], Noreen Pundt[3], Thomas Pap[1] and Berno Dankbar[3]. [1]IEMM, University Hospital Muenster, Münster, Germany, [2]Institute of Experimental Musculoskeletal Medicine-IEMM, University Hospital Muenster, Münster, Germany, [3]Institute of Experimental Musculoskeletal Medicine-IEMM, University Hospital Muenster, Muenster, Germany

Background: The tissue inhibitors of metalloproteinases (TIMP) 1–4 are a family of natural inhibitors that control the activity of matrix metalloproteinases (MMP) in the extracellular matrix. Among all TIMP, TIMP3 plays a special role and has been shown to induce apoptotic cell death. As little is known about the underlying mechanisms, we set out to investigate the pro-apoptotic effect of recombinant and lentiviral overexpressed TIMP3 in the human mesenchymal cell line Cal78.

Methods: Mesenchymal Cal78 cells were transduced with pLenti6/V5-D-TOPO-TIMP3 or the control vector pLenti6/V5-GW/lacZ. The induction of apoptosis was evaluated using the Caspase 3/7 assay after transduction with or without administration of 100 ng/ml Fas ligand, TNFα and TRAIL for 16 hours. Furthermore, the cell proliferation was assessed by BrdU incorporation. To identify underlying mechanisms we performed Western blot analysis to find out the MAPK activation using specific anti phospho-antibodies.

Results: To determine the induction of apoptosis we measured Caspase activity and these data show a strong apoptosis induction reflected by a five-fold increase in lentiviral infected cells overexpressing TIMP3 compared to control (pLenti6/V5-GW/lacZ) or uninfected cells. The induction of apoptosis was further increased by TNFα, FasL and TRAIL. Interestingly, exogenous TIMP3 (recombinant hTIMP3, 2μg/ml) did not induce caspase 3 and 7 activity. Proliferatiion analyses revealed a four-fold higher proliferation after lentiviral infection with TIMP3. In addition, the withdrawal of serum leads to an enhanced TIMP3-induced apoptosis. Moreover, lentiviral overexpression of TIMP3 resulted in a decreased phosphorylation of cRaf, Erk1/2, p90RSK and Akt.

Conclusion: Taken together, these findings demonstrate that TIMP3 directly induce apoptosis in mesenchymal cells, which is independent of death receptor ligands. The fact that the withdrawal of serum leads to an enhanced TIMP3-induced indicates the importance of serum-derived survival factors. TIMP3-mediated induction of apoptosis involves the inhibition of MAPK/Erk1/2 as well as the Akt signaling pathway.

Endogenous Joint Repair after Damage in the Red-Spotted Newt. Matthias Geyer[1], Thilo Borchardt[2], Carina Schreiyaeck[1], Ulf Müller-Ladner[1] and Robert Dinser[1]. [1]Department of Rheumatology, Justus Liebig University Giessen, Kerckhoff-Klinik, Bad Nauheim, [2]Max Planck Institute for Heart and Lung Research, Bad Nauheim

Background: Mammalian joint structures fail to repair after severe trauma or in osteoarthritis. Adult newts are able to regenerate lost extremities. We have previously shown that they are also able to rebuild a damaged knee joint after induction of joint instability through intraarticular injection of collagenase. We wanted to extend this observation on other modes of damage and start studying molecular mechanisms.

Methods: To induce apoptotic cell death in chondrocytes, monoiodoacetate was injected into the knee joints of red spotted newts. Alternatively, the femoral cartilage was removed surgically. The time course of clinical and histological damage was analysed. In parallel, RNA was extracted from whole joints 10, 20, and 40 days after damage with collagenase or surgery and hybridized to a cDNA array derived from regenerating newt hearts.

Results: Monoiodoacetate induced chondrocytic cell death predominantly in the deep zone of the articular cartilage in newts, associated with a loss of proteoglycans, in the absence of clinical disease. Histology returned to normal after 20 days. Surgery induced severe joint damage associated with complete loss of function of the joint, reflected in severe histological changes. Within 40 days, clinical function normalised. Histologically, cartilage reformed, leading to intact joint structures within 90 days. A number of genes was found to be deregulated. No gene was downregulated in both damage models, but several genes were found upregulated. These include matrix proteins like fibronectin, decorin, and collagens I, II, and III. Several complement factors and clusterin were found in addition to factors like periostin and olfactomedin that have not been previously associated with joint formation. Several enzymes of vitamin A metabolism that have been implicated in chondrogenesis were also upregulated.

Conclusion: Newts are able to regenerate joint structures irrespective of the exact mode of damage (apoptosis, instability, surgical loss of tissue). A cDNA analysis reveals several genes that may be key factors determining the enhanced repair potential of newts compared to mammals.

Experimental Osteoarthritis in Rats Is Attenuated by Treatment with a Selective Inhibitor of Sphingosine Kinase 2. Leo R. Fitzpatrick[3], Cecelia Green[1], Lynn W. Maines[1] and Charles D. Smith[2]. [1]Apogee Biotechnology Corporation, [2]Apogee Biotechnology Corporation and Medical University of South Carolina, [3]Penn State College of Medicine, Hummelstown, PA

Osteoarthritis (OA) is a progressive degenerative disease characterized by cartilage degradation and chondrocyte apoptosis, which may involve aberrant sphingolipid metabolism. Sphingosine kinases (SK1 and SK2) catalyze the formation of sphingosine-1-phosphate (S1P) from sphingosine, and are potential drug targets for a variety of hyperproliferative and inflammatory diseases. ABC294640 (ABC) is a novel orally bioavailable compound that selectively inhibits SK2, and has therapeutic activity in models of rheumatoid arthritis.

Aims: The goals of the present study were to utilize the Monosodium Iodoacetate (MIA) model of OA to assess the effects of ABC294640 on: 1) cartilage and bone destruction in the knee joints of MIA-treated rats; and 2) the resultant pain to the animals.

Methods: Differential hind-limb weight-bearing (measured with an incapacitance meter and calculated as the % right (R)\R+ left (L) leg measure-

ments) was used as an indicator of knee pain throughout the study, and baseline data were collected on Day 0. To induce OA, anesthetized male Wistar rats (n = 22) were injected with 3 mg of MIA into the R knee joint and saline into the L knee. A control group of rats (n = 4) received saline injections in both knees. On Day 0, MIA-treated rats were randomized to receive either sham oral dosing (n = 13), ABC (50 mg/kg bid, n = 9) or Tramadol (100 mg/kg, one hr before incapacitance readings only, n=4). Oral ABC dosing continued until study Day 27. Incapacitance readings were obtained weekly during this period. On Day 28, the R knee joints were harvested for histological evaluations. Safranin-O was used to evaluate cartilage proteoglycan staining in the knee joints. Cartilage thickness measurements were done from images of the joint histology sections.

Results: Weight bearing (%) in sham/MIA rats significantly ($p < 0.01$) decreased from 48.8 ± 0.8 (Day 0) to 41.9 ± 2.9 (Day 28). In contrast, these values in ABC treated rats were virtually the same on Day 0 (49.0 ± 0.5%) and Day 28 (48.8 ± 2.6%). The ABC results were similar to data with Tramadol treatment. Knee joint histology scores (48 point scale) were reduced from 30.9 ± 3.3 (sham treatment) to 24.1 ± 4.0 (ABC treatment) demonstrating that ABC-treated rats had less evidence of cartilage and bone destruction. There was a significant ($p=0.0036$) inverse correlation between histological damage and weight-bearing in rats. Of note, proteoglycan staining in the tibia (figure 1) and femur were less disrupted in ABC/MIA animals than in sham/MIA rats.

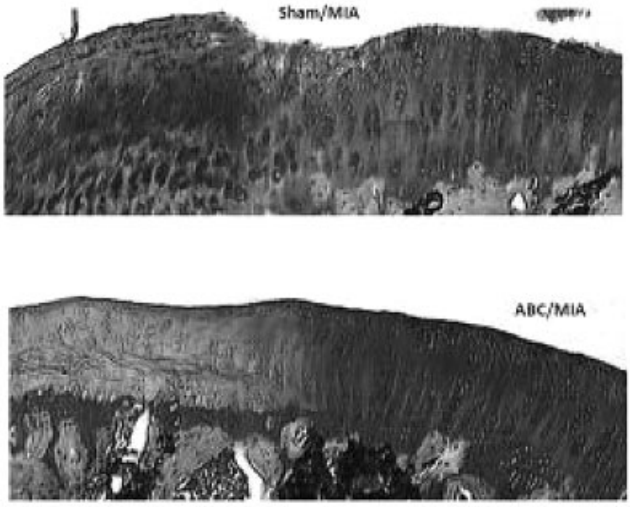

Figure 1. Cartilage proteoglycan staining: rat tibia.

Similarly, cartilage thickness in the knee joints of ABC/MIA-treated rats (0.30 ± 0.05 mm) was not different from control rats (sham/saline, 0.36 ± 0.03 mm); whereas that of sham/MIA rats was substantially decreased (0.21 ± 0.03 mm).

Conclusion: The selective SK2 inhibitor ABC294640 attenuated histological damage and joint pain in the MIA-induced OA model in rats. Therefore, clinical studies of this agent may be warranted.

Expression of MMP-13 and ADAMTS-5 Is Mediated Via Nuclear Orphan Receptor NR4A3 Signalling in Human Chondrocytes. Martin H. Stradner[2], Hannes Angerer[3], Daniela Krusch[1], Florentine C. Fürst[3], Marie-Luise Kremser[3], Daniela Setznagl[3] and Winfried B. Graninger[3]. [1]Karl-Franzens University Graz, [2]Medical University Graz, Graz, Austria, [3]Medical University Graz

Purpose: Nuclear orphan receptors act as ligand-independent transcriptionally activated regulator proteins. In a global analysis of nuclear receptor expression in OA cartilage by Collins-Racie et.al. the nuclear orphan receptor NR4A3 was found to be highly deregulated. As its function in chondrocytes is still unknown, we evaluated the influence of NR4A3 on chondrocyte gene expression.

Methods: Human cartilage specimens were obtained from patients undergoing total knee joint replacement. Chondrocytes were isolated using collagenase B. Primary human chondrocytes and the human chondrocyte cell-line C28I2 were grown in monolayer and cultured in Ham′s F-12/DMEM (1:1) and 10% FCS. Expression of NR4A3 was evaluated by reverse-transcriptase PCR. For siRNA knock-down of NR4A3 C28I2 cells were transfected with specific anti-sense oligonucleotides using lipofectamine. After 24h gene expression of ADAMTS-4 and -5, MMP-13, iNOS, aggrecan and pro-collagen II, was investigated using real-time PCR.

Results: NR4A3 mRNA was found to be expressed in OA chondrocytes and the C28I2 cell-line. siRNA knock-down achieved 60% (± 4%) reduction of NR4A3 mRNA expression. The decrease in NR4A3 expression led to a decline of MMP-13 expression by 52% (± 9%). Furthermore ADAMTS-5 mRNA expression was reduced by 50% (± 3%). Gene expression of ADAMTS-4, iNOS, aggrecan and pro-collagen II remained unaltered in the presence of diminished NR4A3 expression.

Conclusions: We confirmed the expression of the nuclear orphan receptor NR4A3 in OA chondrocytes and C28I2 cells. Furthermore its presence is required for maintenance of MMP-13 and ADAMTS-5 expression. Therefore NR4A3 could be a novel promising therapeutic target in OA chondrocytes.

Histamine Contributes to Inflammatory Joint Disease by Regulating the Expression of RANKL and OPG through Altered NR4A Activity in Human Chondrocyte Cells. Viviana Marzaioli[2], Jason P. McMorrow[2], Alice McEvoy[1] and Evelyn P. Murphy[2]. [1]Dublin Institute of Technology, Kevin Street, Dublin, Ireland, [2]UCD Veterinary Sciences Centre and Conway Insitute for Biomolecular and Biomedical Research, University College Dublin, Ireland

Background: Mast cells, a major source of histamine *in vivo*, are found in increased numbers in rheumatoid arthritis synovial tissue. In the K/BxN arthritis model, mast cells are required to promote autoantigen-induced inflammatory arthritis. It has recently been shown that IL-33 enhances autoantibody-mediated articular inflammation via IgG mast cell degranulation and pro-inflammatory mediator release. Furthermore, histamine stimulates chondrocyte production of matrix metalloproteinases and osteoclast differentiation directly, and indirectly, through altered RANKL and OPG expression in osteoblasts. The aim of this study was to elucidate the receptor mediated signalling pathways and transcriptional events regulated by histamine in human chondrocytes.

Methods: Histamine receptors (HR1,-2, 3,-4), nuclear transcription factors (NR4A1,-2,-3), RANKL and OPG mRNA levels were measured in human chondrocytes using real-time PCR (qPCR). HR subtype involvement was monitored using selective HR antagonists. NR4A protein levels and transactivity were evaluated by western blot, immunocytochemistry and luciferase reporter assays. ShRNA for control and NR4A1, 2, 3 were generated using lentivirus transduction.

Results: Differential expression of histamine receptor subtypes (HR1–4) was detected. HR1 and HR2 receptors are highly expressed in chondrocyte cells with minimal expression of HR3 and HR4. Histamine robustly modulates RANKL and OPG levels, in a time-and concentration-dependent fashion, leading to significantly increased RANKL/OPG expression ratio ($p<0.005$). Histamine rapidly and differentially modulates expression of all three NR4A transcription factors. Within 2-hours, histamine maximally modulates NR4A3 (300-fold), NR4A2 (100-fold) and NR4A1 (10-fold) transcript levels. The study of HR receptor antagonists reveals that histamine selectively signals through HR1 and HR2 in chondrocyte cells to modulate RANKL, OPG and NR4A1–3 expression. Our data further demonstrates histamine-dependent activation of NF-kB and CREB signalling pathways through HR1 and HR2 receptors, respectively. Consistent with mRNA analysis, histamine promotes NR4A nuclear localization and significantly enhances the capacity of NR4A proteins to mediate target gene expression. Specific knockdown of NR4A-1,-2,-3 mRNA and protein levels (>50%) results in significantly reduced endogenous production of OPG (>60%) by chondrocytes. Finally, in NR4A-depleted cells, histamine regulation of RANKL and OPG expression is completely lost.

Conclusion: These data reveal that histamine, through HR1 and HR2, contributes to the development of inflammatory joint disease by regulating the expression of RANKL and OPG through altered NR4A activity in human chondrocyte cells.

INIBIC-University of A Coruña, A Coruña, Spain, [4]Osteoarticular and Aging Res. Lab. CIBER-BBN. Rheumatology Div. INIBIC-Complejo Hosp. Univ. A Coruña, Coruña, Spain

Introduction: Human amniotic membrane (HAM) is a highly abundant and easily accessible tissue that may potentially be an important chondrocyte carrier for cartilage regeneration *in vivo*.

Objective: Develop an *in vitro* repair model of focal injuries of human articular cartilage, based on the usefulness of cryopreserved HAM as support for chondrocyte proliferation.

Materials and Methods: Four *in vitro* repair models of focal injuries of human articular cartilage were developed. For this purpose chondrocytes, isolated from cartilage slices obtained from femoral heads, were grown on the basement layer of HAM for 3–4 weeks. Then a chondrocyte pellet was implanted into 2 mm focal defects of human articular cartilage and the HAM providing chondrocytes was placed in direct contact with the cartilage surface to be repaired. These implants were cultured in DMEM supplemented with 10% FBS for 8 weeks. The repair tissues were analyzed by histochemistry (hematoxylin-eosin, Masson′s trichromic, toluidine blue and safranin O) and immunohistochemistry for type I and II collagen and aggrecan.

Results: Human chondrocytes cultured on HAM and transplanted onto focal injuries of human articular cartilage penetrated into the nearby surface of the chondral defect producing a more regular area and contributed on the closing of the chondral defect. The chondrocyte pellet implanted in the lesion filled the chondral defect and showed good integration between the repair tissue and native cartilage. Stainings were done to detect specific major components of the extracellular matrix to obtain more detailed information about the structure and composition of the repair tissue. Type II collagen, safranin O, toluidine blue and Masson′s trichromic stainings of repair tissue were positive, whereas aggrecan and type I collagen stainings were weak (Table 1 and Figure 1). The morphology of the newly-formed tissue exhibited a fibrocartilaginous appearance and high cellularity.

Table 1. Semi-quantitative histochemical and immunohistochemistry analysis of the in vitro human articular cartilage repair model.

TYPE STAIN	Native Cartilage		Focal Injure	
	Matrix	Cells	Matrix	Cells
Modified Masson's trichromic	+++	−	−	−
Safranine O	+++	−	++	−
Toluidine Blue	+++	−	++	−
Type I Collagen	+	++	+	++
Type II Collagen	+++	+++	+	+++
Aggrecan	+	−	−	+

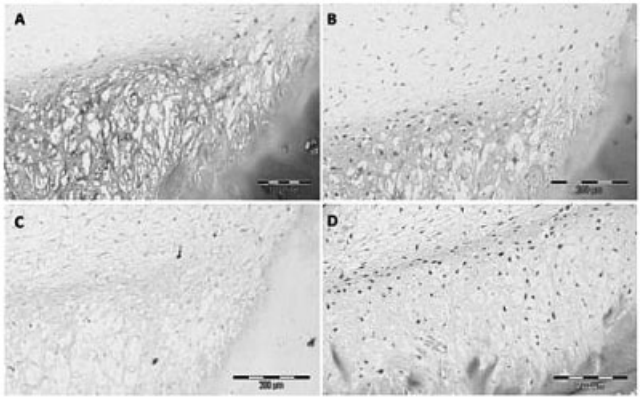

Figure 1. Histochemical and immunohistochemistry analysis of the in vitro human articular cartilage repair model. **A.** Toluidine blue. **B.** Safranin O. **C.** Col I. **D.** Col II.

Conclusions: These results indicated that cryopreserved amniotic membrane could be used as support for chondrocytes proliferation in cell therapy to repair focal injuries of human articular cartilage.

Support: Project funded by Servizo Galego de Saúde (PS07/84), Catedra Bioiberica de la Universidade da Coruña and Instituto de Salud Carlos III CIBER BBN CB06-01-0040. Silvia Diaz Prado is beneficiary of an Isidro Parga Pondal contract from Xunta de Galicia, A Coruna, Spain.

Increased Expression of Arthritic Marker Genes in the Cartilage of SirT1 Null Mice. Odile H. Gabay[2], Eun Jin Lee[2], Richard Booth[2], Viktoria Gagarina[2], Mona Dvir-Ginzberg[1] and David J. Hall[2]. [1]Hebrew University, Jerusalem, Israel, [2]NIH, Bethesda, MD

Background: Osteoarthritis (OA), the most frequent age related disease present in the west, is a multi-factorial imbalance between cartilage anabolism and catabolism. To understand the mechanisms underlying OA, we focused on the protein deacetylase SirT1, a factor known to prolong organism lifespan. SirT1 has been previously shown to regulate apoptosis and cartilage-specific gene expression in human chondrocytes. Recent data also indicates that SirT1 is a potent inhibitor of the matrix metalloproteinases (MMPs). MMPs are the most well known of arthritis marker genes that play a central role in cartilage degeneration. In order to evaluate the role of SirT1 in cartilage homeostasis, we assessed MMP and ADAMTS expression in the cartilage of SirT1 null mice.

Method: We used SirT1 Wild-type (WT) and SirT1 Null mice in the analysis. The SirT1 Null mice do not express SirT1. Articular cartilage was harvested from hind paws in 1 to 3 week and 4 months old mice. The cartilage was processed for both immunohistochemistry and subculture of chondrocytes.

Results: Articular cartilage tissue sections from SirT1 Null mice exhibited low levels of type 2 collagen, aggrecan and glycosaminoglycans (GAG) compared to SirT1 WT mice at 1 week or 3 weeks. Protein levels of aggrecan and type 2 collagen were also decreased in the chondrocytes derived from SirT1 Null mice. In contrast, protein levels of MMP-3, MMP-8, MMP-9 and MMP-13 were elevated in the SirT1 Null mice compared to WT. Finally, DBC1 (deleted in breast carcinoma 1), a known Sirt1 associated protein that represses SirT1 enzymatic activity, was found to be elevated in the SirT1 Null mice compared to WT.

Conclusion: The data from this animal model indicate that SirT1 is a negative regulator of the genes responsible for cartilage degradation in arthritis; namely the MMPs and DBC1. The role of SirT1 as a putative anti-arthritic gene is consistent with its general function as an anti-aging/anti-inflammatory protein.

Increasing Osteoclastic Bone Loss Inspite of Fewer Osteoclast Precursors during Chronic Autoimmune SKG-Arthrtitis Evaluated by 3D Stereological Estimators. Kresten K. Keller[3], Kristian Stengaard-Pedersen[2], Frederik Dagnæs-Hansen[5], Jens R. Nyengaard[6], Shimon Sakaguchi[1] and Ellen-Margrethe Hauge[4]. [1]Department of Experimental Pathology, Institute for Frontier Medical Science, Kyoto University, [2]Dept. of Rheumatology, Aarhus University Hospital, Aarhus, Denmark, [3]Dept. of Rheumatology, Aarhus University Hospital, Århus, Denmark, [4]Dept. of Rheumatology, Aarhus University Hospital, Denmark, [5]Institut of Medical Microbiology and Immunology, Aarhus University, Denmark, [6]Stereology and Electron Microscopy Research Laboratory, Aarhus University, Denmark

Background: Bone destruction in rheumatoid arthritis (RA) is the result of osteoclastic bone resorption and is mediated through the receptor activator of NFκB ligand (RANKL) system. Experimental models and designs that allow detailed studies of osteoclast number and activity are therefore important. The aim of this study was to quantify arthritic changes in a new mouse model of rheumatoid arthritis focusing on osteoclast number using new 3D design-based stereological methods.

Methods: Arthritis was induced in 7-week-old female SKG-mice with intraperitoneal injection of 2 mg Zymosan A. Quantitative histology was

made on 4 control mice and 4 arthritic mice euthanized after 6 and 12 weeks. The right hind paw was embedded undecalcified in methylmethacrylate and cut exhaustively generating 7-μm-thick vertical uniform random sections from approximately 10 section levels spaced by 350–800 μm depending on the random rotation of the sectioning plane. Sections were stained with Masson-Goldner Trichrome and enzymatic TRAP staining. A computer controlled microscope and stereological software (NewCAST) was used for histological quantification. Total volumes were estimated according to the Cavalieri principle, total surfaces were estimated using the vertical sections design, and the number of TRAP-positive cells was counted in a physical disector. TRAP-positive cells on the bone surface were defined as active osteoclasts and TRAP-positive cells in inflammatory tissue were defined as osteoclast precursors. All analyses were performed blinded by a single observer. Spearman's rank correlation or the Kruskal-Wallis test followed by the Mann-Whitney U-test were used. Data are given as the correlation coefficient (r) or median(range).

Results: The arthritis score increased during the 12-week period and was paralleled by an increase in the volume of inflammatory tissue ($r=0.90$, $p<0.001$). The number of osteoclasts on bone ($r=0.77$, $p<0.05$) and osteoclast-covered bone surface ($r=0.62$, $p<0.05$) increased significantly leading to a decrease in the volume of bone ($r=-0.65$, $p<0.05$). However, the number of osteoclast precursors declined between week 6 (14072 (10869–19040)), and 12 (7610 (3126–7893)) ($p<0.05$). Furthermore, the total cartilage surface ($r=-0.74$, $p<0.05$) and cartilage volume ($r=-0.65$, $p<0.05$) decreased during the 12 weeks of arthritis.

Conclusions: We showed that the SKG-model of autoimmune polyarthritis in mice developed osteoclastic bone erosion leading to loss of bone. The loss of bone and the bone surface attacked by actively resorbing osteoclasts continued in the chronic stage although fewer osteoclast precursors were present in the inflamed synovium. Thus bone erosion may progress although osteoclastogenensis is slowing. Bone loss was prominent, but loss of cartilage also occurred. Furthermore, for the first time 3D quantitative histology has been applied in a mouse model of RA. The methods proved valuable, and are expected to be important for studying the *in vivo* effect of anti-inflammatory and anti-resorptive interventions in experimental arthritis.

Influence of NPP1 on Osteoarthritis (OA)-Associated Cartilage Calcification. Jessica Bertrand[3], Martin Fürst[5], Wolfgang Rüther[1], Frank Rutsch[2], Yvonne Nitschke[2] and Thomas Pap[4]. [1]Centre for Orthopaedics and Trauma Surgery, [2]Department of Pedriatrics, [3]Insitute for Experimental Musculoskeletal Medicine, Münster, Germany, [4]Insitute for Experimental Musculoskeletal Medicine, [5]MedBaltic

Background: Calcification of cartilage is a common finding during osteoarthritis and is directly linked to the severity of cartilage degradation. The pyrophosphate pathway functions to keep a sensitive balance of pyrophosphate (PPi) and phosphate (Pi), thereby preventing the generation of calcium crystals. Based on previous data that have linked the expression of the nucleotide pyrophosphatase phosphodiesterase (NPP1) to pathological matrix calcification and have demonstrated a regulation of NPP1 by inflammatory mediators, we sought to study the expression of NPP1 in OA cartilage and its association with cartilage calcification.

Methods: In a cohort of 120 consecuitve OA patients, we analysed the calcification of cartilage using digital contact radiography (DCR). We used cartilage samples of these patients to isolate RNA and assessed the NPP1, ANK and TNAP expression by quantitative real time PCR. The tip-toe walking (ttw/ttw) mouse that carries a mutation in the enpp1 gene encoding for NPP1 was used as an animal model. The calcification of cartilage was analysed using advanced imaging technology, including fluorid PET-scanning and μCT. Using van Kossa in combination with safranin orange stainings of knee sections we assessed the calcification of articular cartilage and meniscus histologically. We analysed the expression of NPP1 in an ACL model of induced OA using immunhistochemical stainings.

Results: In our cohort of OA patients, we found a correlation of NPP1 expression with cartilage calcification ($p<0.05$), whereas we found no correlation for ANK. These data could be confirmed in the ttw/ttw mice, in which we could show an enhanced calcification activity in the joint regions as well as in cartilage of non weight bearing areas such as in ear cartilage. Using both histological analysis and in vivo imaging, we found typical OA like changes in the knees of these mice, such as formation of osteophytes and roughening of the cartilage surface. In addition we could show that NPP1 expression was also increased in the animal model of OA in comparison to uninduced controls.

Conclusion: We conclude from our data, that NPP1 is an important player in OA associated cartilage calcification and might constitute a promising target for the development of novel therapeutics for the disease.

1487

Inhibitory κBα Is a Direct Bone Morphogenetic Protein Target Gene and an Essential Mediator of Anti-Catabolic Effects of BMPs. Olexandr Korchynskyi[3], Paul-Peter Tak[3], Alisa E. Koch[2], Peter ten Dijke[1] and Dhavalkumar D. Patel[4]. [1]Department of Molecular Cell Biology, Leiden University Medical Cente, Leiden, The Netherlands, [2]Department of Veteran's Affairs and the University of Michigan, Ann Arbor, MI, [3]Division of Clinical Immunology & Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands, [4]Thurston Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Loss of articular cartilage in the joints and structural changes to the intervertebral discs, are common problems in patients with degenerative spine and joint disease, but also in those with chronic inflammation-driven arthritis. Increasing evidence supports a role for BMP7 in preventing joint and intervertebral disk damage and in disk regeneration in part by rescuing the catabolic effects of TNF-α and IL-1β. The precise molecular mechanism mediating the preventive and regenerative effects of BMP7 is unknown. NF-κB signaling is a major pathway triggered by proinflammatory cytokines. Our transcriptional profiling studies revealed that the activation of BMP signaling leads to increased expression of Inhibitory κBα (IκBα), that is a key negative regulator of the NF-κB pathway. We therefore explored whether anti-catabolic effects of BMPs on cartilage and bone are mediated by BMP-induced IκBα expression.

Methods: cDNA microarrays-based gene expression profiling was used to identify novel BMP target genes. Positive hits were confirmed using Northern and Western blotting and Real-Time PCR. Luciferase reporter assays and ChIP assays were used to characterize the BMP-responsive region in the IκBα promoter. Anti-catabolic effects of BMPs were validated in vitro using preosteoblastic cell lines and primary human bone marrow-derived mesenchymal stem cell (hMSC) osteoblast differentiation, EMSA and lentiviral shRNA approaches.

Results: Real-Time PCR showed that activation of IκBα mRNA by BMPs does not require de novo protein synthesis, thus suggesting IκBα is a direct BMP target gene. Using ChIP assays we demonstrated that intracellular mediators of BMP signals Smad1/5 and Smad4 bound to the highly conserved proximal region of the IκBα promoter. A proximal fragment of the IκBα promoter was found to be activated by BMP2 and BMP7. EMSA assay showed that BMP7-induced IκBα expression blocked formation of the TNF-α-induced NF-κB transcriptional complex. Furthermore, BMP treatment was found to inhibit the TNF-α and LPS-induced NF-κB transcriptional response in mouse preosteoblasts and hMSC and rescued the differentiation of MSC from inhibition by proinflammatory stimuli. shRNA-mediated knockdown of IκBα expression confirmed an essential role of IκBα in mediating the anti-catabolic effects of BMPs. Anti-catabolic effects of BMPs in vivo and their mechanism were further validated using transgenic TNF-α mice model.

Conclusion: BMP-induced IκBα expression is a key mechanism mediating preventive and regenerative effects of BMP7 on cartilage and bone. These results may lead to the development of novel strategies for cartilage and bone regeneration, using the combination of BMP7 with pharmacological agents.

Interleukin-10 Regulates Bone Metabolism by Suppressing Osteoclastogenesis In Vivo. Seungwoo Han[4], Younkwan Jung[3], Eunsoo Kim[2] and Gunwoo Kim[1]. [1]CIHR Group in Skeletal Development and Remodeling, Department of Physiology and Pharmacology, University of Western Ontario, London, ON, Canada, [2]Dongsan Medical Center, Keimyung University, Daegu, Korea, Republic of, [3]Laboratory for Arthritis and Bone Biology, Fatima Research Institute, Korea, Republic of, [4]Laboratory for Arthritis and Bone Biology, Fatima Research Institute, Department of Internal Medicine, Daegu Fatima Hospital, Daegu, Korea, Republic of

Background: Interkeukin (IL)-10 is a potent anti-inflammatory cytokine which is produced primarily from T cells and activated macrophages and acts on the macrophage lineage. IL-10 also has potent inhibitory effects on osteoclastogenesis, but the molecular basis of its action is poorly understood. Recent studies showed IL-10 may down-regulate osteoclastogenesis through inhibition of the expression of NFATc1, c-Fos and c-Jun (1) and inhibition of calcium signaling downstream of RANK by inhibiting transcription of TREM-2 (2). However, there has been no study about the role of IL-10 in osteoclastogenesis in vivo and under inflammatory condition such as TNF-α induced osteoclastogenesis.

Objective: To elucidate the role of IL-10 in osteoclast formation under physiological and pathological condition.

Methods: 3-month old male IL-10 KO and WT littermates were used (n = 7 mice/group). We compared the bone phenotype by microcomputed tomographic analysis, histologic analysis and TRAP staining. And we conducted in vitro induction of osteoclast formation by bone marrow monocytes from IL-10 KO and WT mice.

Results: We analyzed the IL-$10^{-/-}$ mice for abnormal bone phenotypes. Microcomputed tomographic analyses showed that these mice had severe osteoporosis accompanied by markedly lower trabecular bone volume, number, and thickness, as well as a smaller number of bone nodules compared to wild-type mice. Histomorphometric analysis also revealed reduced bone mass in the IL-$10^{-/-}$ mice. Notably, TRAP stain showed higher osteoclast numbers and larger osteoclast surface areas in these mice. Moreover, we observed a higher rate of bone formation accompanying the accelerated bone resorption rate in the IL-$10^{-/-}$ mice, suggesting that their osteoporosis was caused by enhanced bone turnover and remodeling. Together, these observations indicate that IL-10 has a suppressive role in osteoclastogenesis during in vivo bone remodeling.

We then attempted to investigate the roles of IL-10 in the processes underlying pathological bone destruction. We examined the effect of TNF-α on osteoclastogenesis using IL-$10^{-/-}$ precursors, because TNF-α is a major mediator of inflammation induced by TLRs and has been suggested to be able to induce osteoclastogenesis. Consistent with previous reports, TNF-α induced the development of a small number of osteoclasts in cultures of wild-type precursor cells. Notably, osteoclastogenesis was enhanced in cultures of IL-$10^{-/-}$ precursor cells treated with TNF-α. The mRNA expression levels of Nfatc1 and Acp5 in the IL-$10^{-/-}$ osteoclast precursors were also augmented by TNF-α, indicating that IL-10 also has a suppressive role in TNF-α–induced osteoclastogenesis.

Conclusion: Our results show that IL-10 inhibits osteoclast formation under physiological and pathological conditions and suggest a model where downregulation of IL-10 contributes to RANKL-mediated osteoclastogenesis.

Interleukin-1-Induced Cyclooxygenase-2 and Inducible Nitric Oxide Synthase Expression in Human OA Chondrocytes Is Associated with Histone H3K4 Methylation. Fatima Ezzahra El-Mansouri[3], Nadir Chabane[3], Nadia Zayed[3], Johanne Martel-Pelletier[2], Jean-Pierre Pelletier[1] and Hassan Fahmi[3]. [1]CHUM-Notre-Dame Hospital, Montreal, QC, Canada, [2]CR-CHUM, Notre-Dame Hospital, Montreal, QC, Canada, [3]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, Canada

Objective: Increased expression of inducible NO synthase (iNOS) and cyclooxygenase (COX)-2 plays a key role in the pathogenesis of osteoarthritis (OA). Methylation of lysine 4 on histone H3 (H3K4) was shown to be of fundamental importance in the regulation of gene expression. In the present study, we investigated the role of H3K4 methylation in interleukin-1b (IL-1)-induced COX-2 and iNOS expression in human OA chondrocytes

Methods: Chondrocytes were stimulated with IL-1 for various time periods and the expression of iNOS and COX-2 mRNAs and proteins were evaluated using real-time reverse transcriptase-polymerase chain reaction (RT-PCR) and Western blotting, respectively. H3K4 methylation at the iNOS and COX-2 promoters was evaluated using chromatin immunoprecipitation (ChIP) assays. The role of histone methylation was further evaluated using the methyltransferase inhibitor, 5′-deoxy-5′(methylthio) adenosine (MTA).

Results: IL-1 induced iNOS and COX-2 mRNA and protein in a dose- and time-dependent manner. The induction of iNOS and COX-2 expression by IL-1 was associated with H3K4 di- and trimethylation at the iNOS and COX-2 promoters, whereas the levels of H3K4 monomethylation remained unchanged. Treatment with MTA inhibited IL-1-induced H3K4 methylation as well as IL-1-induced iNOS and COX-2 expression.

Conclusion: These results indicate that H3K4 methylation contributes to IL-1-induced iNOS and COX-2 expression and suggest that this pathway could be a potential target for pharmacological intervention in the treatment of OA.

miR-7 and miR-130b Are Differentially Regulated during Mesenchymal Stem Cell Commitment. Glyn Palmer[4], Laura S. Danielson[2], Mukundan Attur[3], Steven B. Abramson[1] and Eva Hernando[2]. [1]Hospital for Joint Dis/NYU, New York, NY, [2]NYU-Department of Pathology, [3]NYU-Hospital for Joint Diseases, [4]NYU-Hospital for Joint Diseases, New York, NY

Purpose: Stem cell-based therapies aimed at introducing progenitor cells into cartilage lesions hold great promise for the restoration of damaged articular surfaces following joint injury or osteoarthritis. Key to the generation of a functional repair tissue is the controlled differentiation into the desired phenotype. To this end microRNAs (miRNAs) may be important molecules that regulate this process. By acting as transcriptional repressors, their modulation during differentiation may enable commitment to a specific lineage by suppressing the expression of other lineage markers. In this study we profiled MSCs for miRNA expression following induction into the chondrocyte (C), osteoblast (O) and smooth muscle (SM) lineages.

Results: Human bone marrow-derived Mesenchymal Stem Cells (MSCs) were obtained from NIH, or from the discarded hips of patients undergoing joint replacement surgery. SM differentiation was induced by treating monolayer cultures with 1 mM thromboxane-A2 [DP1] in the presence of 0.25% serum. C differentiation was induced by seeding MSCs in aggregate cultures in the presence of dexamethasone and TGF-b1 (10 ng/ml). O differentiation was induced by treatment of monolayer cultures with dexamethasone, ascorbate and beta-glycerolphosphate. Profiling of miRNAs by microarray (Agilent) or QPCR (SA Biosciences) revealed differential regulation of miR-7 and miR-130b, among 376 probes. Following SM and C differentiation, miR-7 expression was down-regulated up to 6.9-fold and 3-fold respectively. Conversely, during O differentiation, its expression was induced approximately 7-fold. Analysis of theoretical mRNA targets using TargetScan online software (www.targetscan.org) identified conserved sites in several genes associated with chondrocyte and myoblast lineages. Putative chondrogenic targets were found to include COL2A1, IGFR1, and GDF5, while potential smooth muscle modulators included EGFR1, PIK3CD, IRS1/IRS2, KLF4, CNN3 and IGF1R. Following a similar trend to miR-7, miR-130b was down-regulated up to 3.2-fold and 3.1-fold in C and SM differentiation respectively, while O differentiation induced its expression 2-fold. TargetScan analysis identified putative chondrogenic targets, TGF-BRII, Sox5, BMP-2 and IGF1; Potential smooth muscle regulators included ESR1, TGF-BRII, MBLN1, TGFBR1 and IGF2BP1. Together these observations suggest that miR-7 and miR-130b act to negatively regulate myogenic and chondrogenic cell fates via regulation of lineage specific genes.

Conclusion: Our findings suggest that miR-7 and miR-130b, via the targeting of lineage specific molecules, regulate cell fate in adult human MSCs by inhibiting smooth muscle and chondrocyte differentiation, thereby promoting ‘default’ differentiation into the osteoblast lineage.

MMP-3 and DKK-1 Levels in Juvenile Idiopathic Arthritis. Matthew L. Stoll[2], Michelle L. Christadoss[2], Marilynn G. Punaro[2] and Nancy J. Olsen[1]. [1]Penn State Hershey Medical Center, Hershey, PA, [2]UT Southwestern Med Ctr, Dallas, TX

Purpose: MMP-3 and DKK-1 are markers of cartilage and bone breakdown, respectively. Prior studies in children and adults with arthritis have shown that MMP-3 levels are elevated and correlate with markers of disease activity(1,2). In RA, DKK-1 has been shown to be a marker of radiographic progression(3). There are no published studies of DKK-1 levels in children, healthy or otherwise.

Methods: For DKK-1 measurements, serum was obtained from 29 children with oligoarticular JIA and 11 healthy control subjects. For MMP-3

measurements, serum was obtained from 67 children with JIA and 12 healthy control subjects. MMP-3 and DKK-1 values were measured through ELISA assays using kits provided by the manufacturer (Alpco).

Results: MMP-3 levels were significantly elevated in each JIA subtype as compared to the healthy controls (Figure 1), and among JIA patients showed a modest but statistically significant correlation with joint count ($r = 0.294$, $p = 0.007$) and ESR ($r = 0.344$, $p = 0.005$) at the time of the study. Differences between the arthritis sub-groups were not statistically significant. 8/27 oligoarticular JIA children, but none of the other arthritis patients, had undetectable MMP-3 levels ($p = 0.004$); this difference remained significant when the three subjects in long-term remission, all of whom had undetectable levels, were excluded ($p = 0.032$). One subject thought to be a healthy control based upon her physical exam had an elevated MMP-3 level, and subsequently had an MRI and physical exam that were consistent with inflammatory arthritis. Another subject thought to have oligoarticular JIA had negative MMP-3 levels; MRI revealed a synovial cyst.

DKK-1 levels were only measured in oligoarticular JIA patients and healthy controls. Values were comparable, with median levels of 25.3 (IQR 22.8–36.6) and 27.9 ng/ml (IQR 22.5–30.4) in patients and controls, respectively ($p = 0.942$). These levels were an order of magnitude higher than those reported in most prior studies in adults(4,5). There was no association with DKK-1 levels and the age of the child.

Conclusions: Measurement of serum MMP-3 may be a useful biomarker in children with an unclear presentation of joint pain and may help assess severity of the condition. However, perhaps because growing children have considerable bone turnover at baseline, DKK-1 may be a less useful biomarker in this population as compared to adults.

Modeling Osteoclast Precursor Master Fusogens and Mononuclear OCP Donors with Raw Cell Line Clones. Yawen Ju, Masahiko Takahata, Kofi Mensah, Grace Chiu, Christopher T. Ritchlin, Lianping Xing and Edward M. Schwarz. University of Rochester

Purpose: Osteoclasts (OC) are multinucleated bone-resorbing cells derived from mononuclear osteoclast precursors (OCP) following stimulation with RANKL and M-CSF. Raw264.7 cells are a heterogeneous murine monocyte/macrophage cell line, of which some can form OCs and others cannot. DC-STAMP is a receptor on OCP, and is required for cell fusion to form multinucleated OC. Recently we demonstrated that the surface expression of DC-STAMP by RANK+ OCPs defines OCP fusion potential. RANKL induces DC-STAMP^{lo} OCPs to function as master fusogens, and DC-STAMP^{hi} OCPs to serve as mononuclear donors that cannot fuse on their own to form mature OCs. In order to investigate the molecular mechanisms by which DC-STAMP contributes to OCP fusion and OC formation, we aimed to isolate and characterize Raw cell clones with OCP master fusogen vs. mononuclear donor phenotypes based on their DC-STAMP expression before and after RANKL stimulation.

Methods: Raw 264.7 cells were cloned by limiting dilution: diluted 50 cells in 10ml alpha-MEM media, seeded 100ul/well in 96 well-plate and selected single cell clones. The clones were treated with 100ng/ml RANKL, and their osteoclastogenic potential was assess by TRAP staining. The surface expression of DC-STAMP was determined by flow cytometry following 7AAD staining to gate the live cells, and FITC-conjugated 1A2 monoclonal anti-DC-STAMP antibody.

Results: Seven Raw cell clones were obtained and their OC formation and DC-STAMP surface expression were examined. Clone 5 formed large multinucleated TRAP+ OCs three days after RANKL treatment, while it took five days for the parental raw cell line to form OCs under a same culture condition. Clone 5 also expressed a low basal level of surface DC-STAMP (MFI= 32.0), which was similar to DC-STAMP^{lo} (MFI=16.5) identified in the parental cells following three days of RANKL treatment. In contrast, the Clone 1 could not form OCs after five days of RANKL treatment. Clone 1 also had a high basal level of surface DC-STAMP expression (MFI= 60.8), which was similar to RANKL-induced DC-STAMP^{hi} (MFI=55.4) of the parental cells.

Conclusions: Two Raw 246.7 cell sub-clones were isolated to investigate DC-STAMP-mediated OCP fusion in response to RANKL treatment. Clone 5 forms OCs faster and has low basal DS-STAMP expression, while Clone 1 forms OCs much slower, and expresses high basal DC-STAMP. These clones mimic the heterogeneous DC-STAMP expression levels and OC forming potential of the parental Raw cells, and can be used as cell models of master fusogens (Clone 5) or mononuclear OCP donors (Clone 1). Our ongoing studies to clone DC-STAMP ligand using these clones via differential microarray analysis will be discussed.

Multi-Targeted Kinase Inhibitor PKC412 Diminishes Osteoclastogenesis and Counteracts Osteoclast Mediated Bone Resorption *In Vitro*. Despoina Sykoutri[1], Silvia Hayer[3], Josef S. Smolen[4] and Kurt Redlich[2]. [1]Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria, [2]Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria, [3]Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, [4]Krankenhaus Lainz, Vienna, Austria

Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by osteoclast mediated bone erosions. Small molecule multi-kinase inhibitors are being explored as potential therapeutic targets in RA. PKC412 is a small molecule multi-kinase inhibitor targeting class III tyrosine-protein-kinases such as FMS-like tyrosine kinase 3 (FLT-3) and multiple isoforms of serine/threonine protein kinase C. PKC412 has been shown to inhibit macrophage function *in vitro*. However, the role of PKC412 in modulating the commitment of the monocyte/macrophage lineage to osteoclast precursors, their differentiation into pre-osteoclasts and their differentiation into mature osteoclasts has not been fully elucidated. We aimed to investigate the effect of PKC412 on osteoclast differentiation and function.

Methods: We differentiated mouse bone marrow derived cells in the presence of macrophage-colony stimulating factor (M-CSF) and receptor activator of nuclear factor kappaB ligand (RANKL) into tartrate-resistant acid phosphatase positive (TRAP+) mononuclear osteoclasts (pre-osteoclasts) and TRAP+ multinucleated mature osteoclasts, and added PKC412 in increasing concentrations (10nM to 10μM) to the culture. We also assessed the role of PKC412 in the bone resorbing capacity of osteoclasts by culturing osteoclasts on dentine slices. To further characterize the effect of PKC412 on cell proliferation we performed MTT assays. We used quantitative PCR to evaluate expression levels of mRNA encoding for osteoclast specific markers such as nuclear factor of activated T-cells cytoplasmic 1 (NFATc1), matrix metalloproteinase 9 (MMP-9), Cathepsin K and TRAP. Flow cytometry analysis for Annexin V and 7-AAD was performed to determine potential apoptotic effects of PKC412 on pre-osteoclasts and osteoclasts.

Results: We found that increasing concentrations of PKC412 (IC50:

250nM) dose-dependently reduced osteoclast numbers. Furthermore, numbers of pre-osteoclasts were also significantly decreased after addition of PKC412, indicating an effect of PKC412 on early stages of osteoclastogenesis. In line with this finding, we could show a dose-dependent reduction of pre-osteoclast proliferation using MTT proliferation assays. Moreover, we detected a significant time- and dose-dependent increase in the ratio of apoptotic cells in the PKC412-treated cells by Annexin V and 7-AAD staining. Additionally, in the presence of PKC412 we obtained a significant reduction in osteoclast size and nuclei number, as well as in the size of resorption pits on dentin slices. This indicates that the bone resorbing capacity of osteoclasts is altered by PKC412. Consistently, we were able to demonstrate a dose dependent downregulation of mRNA coding for osteoclast markers, such as NFATc1, MMP-9, Cathepsin K and TRAP in the presence of PKC412.

Conclusion: These results suggest a regulatory role of PKC412 in pre-osteoclast differentiation und osteoclastogenesis through apoptosis induction.

Potential Role of the LKB1-AMPK and CaMKKb-AMPK Pathways in Controlling the Progression of OA. Robert Terkeltaub[3], Bing Yang[4], Martin K. Lotz[1] and Ru L. Bryan[2]. [1]Scripps Rsch Inst, La Jolla, CA, [2]UCSD/VAMC, San Diego, CA, [3]VA Medical Ctr, San Diego, CA, [4]VA Medical Ctr

Purpose: LKB1, a tumor suppressor, and CaMKKb (Ca^{2+}/calmodulin-dependent protein kinase kinase beta) are serine/threonine protein kinases that act upstream of AMPK (AMP-activated protein kinase), a super-regulator of energy homeostasis. AMPK exists as a heterotrimer composed of an alpha catalytic subunit and two regulatory beta and gamma subunits. Phosphorylation of AMPK (Thr-172) within the catalytic domain of the a subunit by upstream kinases is essential for AMPK activation. We have previously observed that articular chondrocytes express functional AMPK, and activation of AMPK attenuates pro-catabolic responses of chondrocytes to inflammatory cytokines. In addition, phosphorylation of AMPKa is significantly decreased in human OA knee articular chondrocytes. Here, we investigated the role of two AMPK upstream kinases LKB1 and CaMKKb in regulation of chondrocyte matrix catabolism.

Methods: Expression and activation status (Ser428 phosphorylation) of LKB1 were examined in cultured human knee articular chondrocytes (first passage) and in human knee articular cartilage sections from different normal and OA (grade I to IV) donors. Knockdown of LKB1 and CaMKKb in human chondrocytes was achieved via transfection with LKB1 and CaMKKb siRNA. Activation of AMPK (AMPKa Thr172 phosphorylation) and pro-catabolic responses including nitric oxide (NO) generation and expression of MMP-13 in response to IL-1b and TNFa in normal human chondrocytes were assessed and compared. Expression of the chondrocyte hypertrophy marker type × collagen was also examined.

Results: Expression and constitutive phosphorylation of LKB1 were observed in normal and low grade OA human knee articular chondrocytes. However, both expression and phosphorylation of LKB1 were markedly decreased in OA chondrocytes beyond grade III, which correlated with decreased expression and phosphorylation of AMPKa. Treatment of articular chondrocytes with IL-1b and TNFa induced de-phosphorylation of LKB1 and AMPKa. Importantly, knockdown of LKB1 and CaMKKb in articular chondrocytes attenuated phosphorylation of AMPKa, and resulted in significant enhancement of MMP-3 release and nitric oxide (NO) generation induced by IL-1b and TNFa. In addition, type × collagen protein expression induced by TNFa was markedly enhanced in chondrocytes with knockdown of LKB1 or CaMKKb.

Conclusions: Human knee OA articular chondrocytes with grade III and beyond exhibit markedly decreased LKB1 phosphorylation that correlates with decreased AMPK phosphorylation. Knockdown of LKB1, as well as CaMKKb, by RNAi enhanced chondrocyte hypertrophy and pro-catabolic responses of articular chondrocytes to inflammatory cytokines, and was closely linked with decreased AMPK activation defined to regulate the pro-catabolic responses. These findings identify therapeutic potential of activation of the LKB1-AMPK and CaMKKb-AMPK pathways in order to inhibit the progression of OA.

S100A8 Enhances Osteoclastic Bone Resorption in Experimental Antigen-Induced Arthritis. Lilyanne C. Grevers[3], Teun J. de Vries[1], Vincent Everts[1], Annet W. Sloetjes[3], Thomas Vogl[2], Johannes Roth[2], Wim B. van den Berg[3] and Peter L. van Lent[3]. [1]Department of Oral Cell Biology, ACTA, UVA and VU University Amsterdam, Amsterdam, The Netherlands, [2]Institute of Experimental Dermatology, University of Münster, Muenster, Germany, [3]Radboud University Nijmegen, Medical Centre, Nijmegen, The Netherlands

Background: Rheumatoid Arthritis (RA) is characterized by bone destruction in the joints caused by enhanced formation and activity of osteoclasts. In RA, local inflammatory mediators produce many factors that stimulate osteoclastogenesis. The "alarmins" S100A8 and S100A9 are the most up-regulated proteins present in RA synovial fluid and significantly correlate with joint destruction. The aim of the present study was to investigate the role of S100A8 on osteoclastic bone resorption in murine antigen-induced arthritis (AIA).

Methods: Bone destruction was analyzed 7 and 21 days after AIA induction in knee joints of S100A9−/− mice, which also lack S100A8 expression, and wild type controls. Bone marrow precursors from S100A9−/− and wild type mice were differentiated into osteoclasts in-vitro. Additionally, osteoclast precursors were stimulated with recombinant S100A8 (rS100A8) during osteoclastogenesis. Receptor involvement was investigated using an anti-RAGE blocking antibody or TLR4−/− osteoclast precursors. In-vitro experiments were analyzed for the formation of TRACP-positive multinucleated cells ($TRACP^+$ MNCs), actin ring formation by immunolocalization, mRNA expression levels of osteoclast markers, and resorption pit formation on bone.

Results: Bone erosions were significantly suppressed in S100A9−/−mice 7 and 21 days after AIA induction. In-vitro, bone marrow-derived precursors from S100A9−/− mice developed normally into functional osteoclasts. Stimulation of osteoclast differentiation with rS100A8 resulted in increased numbers of predominantly smaller sized $TRACP^+$ MNCs (3–5 nuclei per cell), as compared to unstimulated controls. mRNA expression of DC-STAMP, an important cell-cell fusion factor was moderately down-regulated (ddCt = −1.39), which might explain the smaller size of the osteoclasts. The expression of TRACP, cathepsin K and calcitonin receptor was not changed. Furthermore, actin ring formation, essential for the bone resorptive capacity of osteoclasts, was enhanced and bone resorption levels were significantly increased in S100A8 stimulated osteoclasts (50% versus 35% in unstimulated controls, $P<0.03$) The stimulatory effects of S100A8 on osteoclast maturation and function could not be inhibited by RAGE blockade, whereas the increased osteoclast numbers, actin ring formation and resorption pit formation were completely abrogated using TLR4−/− osteoclasts.

Conclusion: This study demonstrates that S100A8 stimulates osteoclast formation and activity and indicates that both S100A8 and TLR4 are important factors in mediating osteoclastic bone destruction in experimental arthritis.

Serum Biomarkers Predict Progressive Structural Damage in the BeSt Study. Yijing Shen[1], Linda Dirven[4], Guy Cavet[1], Michael Centola[5], B. A. C. Dijkmans[2], Lyndal K. Hesterberg[1], Thomas Huizinga[4], Willem F. Lems[6] and Cornelia F. Allaart[3]. [1]Crescendo Bioscience, Inc., [2]JBI, Amsterdam, The Netherlands, [3]Leiden Univ Med Ctr, Leiden, The Netherlands, [4]Leiden University Medical Center, [5]Oklahoma Med Research Foundation, Oklahoma City, OK, [6]VU University Medical Center

Background: The ability to predict progressive structural damage has the potential to improve disease management and outcomes in rheumatoid arthritis (RA) patients. Blood-based biomarkers measuring the current rate of joint destructive damage could identify patients at risk for accelerated bone and cartilage damage. We aim to identify serum biomarkers for progressive structural damage, to build and evaluate predictive models to estimate the current rate of structural damage, and to compare the performance of serum biomarkers to that of conventional measures, including DAS, CCP, CRP, and RF status.

Methods: We examined 90 individual candidate biomarkers in longitu-

dinal serum samples (baseline and year 1) with imaging results and clinical data from 160 patients followed in the BeSt trial, a 5-year blinded study comparing four different treatment arms (sequential monotherapy, step-up combination, combination therapy with prednisone, and combination therapy with infliximab) in aggressive early RA. The concentrations of individual biomarkers were assessed for their association with change in total Van der Heijde-modified Sharp Scores (mSS) at 2 years. Statistical models using combinations of serum biomarkers were built to predict the rate of change of total mSS. Good disease control may influence the computation of mSS rate of change; hence additional analyses incorporating therapy change information into the biomarker model were also performed. Various models built by conventional measures were compared to the serum biomarker model. Performance of the models was evaluated by the Pearson correlation coefficient between actual and predicted rates of change and by the area under the ROC curve (AUC) in cross-validated test sets. Mean mSS rate of change in the test sets was used to dichotomize patients into high and low groups for AUC calculation.

Results: Candidate serum biomarkers predicted damage better at Year 1 than at baseline, probably because baseline samples were collected before therapy took effect. We identified serum biomarker combinations (cor = 0.60, AUC = 0.75) that predicted change in mSS from Year 1 to Year 2 and were superior to DAS28ESR (cor = 0.33, AUC = 0.61), CRP (0.38, AUC=0.67), DAS28ESR with CCP (cor = 0.22, AUC = 0.61), or DAS28ESR with RF (cor = 0.37, AUC = 0.62) in predicting radiographic progression. In total, 35 individual biomarkers were associated with joint damage progression with false discovery rate (FDR) <0.1, 18 at FDR<0.05. Incorporating therapy information into the biomarker model didn't change model performance.

Conclusion: The best performing models included markers of bone and cartilage destruction, pro-inflammatory cytokines and acute phase proteins. Combinations of biomarkers were able to predict radiographic outcomes despite therapy changes and good control of disease activity. Serum biomarker-based indices have the potential to improve prediction of structural damage progression over standard clinical measures of disease activity in RA patients.

Strontium Ranelate Inhibits Key Factors Affecting Bone Remodelling in Human Osteoarthritic Subchondral Bone Osteoblasts. Johanne Martel-Pelletier[2], Steeve Kwan Tat[3], Anne-Christine Goulet[3], Judith Caron[1], Daniel Lajeunesse[4] and Jean-Pierre Pelletier[4]. [1]ArthroLab Inc., Montreal, [2]CR-CHUM, Notre-Dame Hospital, Montreal, QC, Canada, [3]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, [4]University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, Canada

Background: In osteoarthritis (OA) the progression of cartilage degeneration has been associated with the remodelling of the subchondral bone. Human OA subchondral bone osteoblasts were shown to have an abnormal phenotype and altered metabolism leading to an abnormal resorptive process. Bone resorption is suggested to occur, at least in part, through the increased levels of two proteolytic enzymes, MMP-2 and MMP-9, and RANKL, which are mainly produced by osteoblasts. In this study, we investigated in human OA subchondral bone osteoblasts the modulatory effect of strontium ranelate (SrRan) on key factors that affect the bone remodelling process.

Methods: Osteoblasts were cultured in a medium containing 0.1, 1 and 2 mM of SrRan during 18h for mRNA determination and 72h for protein determination. The effect of SrRan was evaluated on the expression (PCR) of MMP-2, MMP-9, OPG, RANKL (total), RANKL-1, and RANKL-3, on the production of OPG (ELISA) and membranous RANKL (flow cytometry). After incubation of osteoblasts with pre-osteoclasts (differentiated human peripheral blood mononuclear cells), the resorbed surface was measured using a sub-micron synthetic calcium phosphate thin film.

Results: The expression (mRNA) levels of MMP-2 and MMP-9 were significantly decreased by SrRan at 1 mM ($p\leq0.005$, $p\leq0.024$, respectively) and 2 mM ($p\leq0.003$, $p\leq0.007$) for MMP-2 and also at 0.1 mM ($p\leq0.05$) for MMP-9. Both the expression ($p\leq0.003$) and synthesis ($p\leq0.002$) of OPG were significantly increased with SrRan at 1 and 2 mM. RANKL (total) as well as the isoforms RANKL-1 and RANKL-3 were increased by SrRan at the higher concentrations tested. Of note, it is known that the different RANKL isoforms differentially regulate RANKL membranous localization: RANKL-3, in contrast to RANKL-1, prevents it. This is reflected by the significant ($p\leq0.02$) reduction in the level of membranous RANKL by SrRan at 2 mM. In addition, osteoblasts treated with SrRan induced a significantly ($p\leq0.002$) decreased resorbed surface compared to the control cells.

Conclusion: This study provides new and interesting data on the mode of action of SrRan on the metabolism of human OA subchondral bone osteoblasts. The data suggest that this drug may exert a positive effect on OA pathophysiology by inhibiting, in subchondral bone osteoblasts, the synthesis of key factors leading to bone resorption, a feature often associated with OA and recognized as a marker of this disease progression.

Introduction: Synovial membrane mesenchymal stem cells (MSCs) have been demonstrated to be a good source of cells for the study of cartilage tissue engineering. Multiple stem cells markers have been found by flow cytometry and immunofluorescence in MSCs from human synovial membrane pools. In this study we analyzed the chondrogenic potential of subpopulations of MSCs derived from human synovial membranes enriched for CD73, CD106 and CD271 markers.

Material and Methods: Subpopulations of human synovial membrane MSCs enriched for CD73, CD106 and CD271 markers were isolated using a cytometry sorter and characterized by flow cytometry for MSC markers. The expression of Sox9, Nanog and Runx2 genes by these cells was measured by reverse transcriptase-polymerase chain reaction. The chondrogenesis of each subpopulation was assessed by culturing the cells in a defined medium to produce spontaneous spheroid formation and differentiation towards chondrocyte-like cells. The examination of the spheroids by histological and immunohistochemical analyses for collagen type II (COL2), aggrecan, collagen type I (COL1), metalloprotease 13 (MMP13) and collagen type $\times$ (COLX) levels were performed to assess their chondrogenesis capacity. The adipogenesis and osteogenesis potential of each subpopulation was determined using commercial media; the resulting cells were stained with oil red O or red alizarin to test the degree of differentiation.

Results: The subpopulations had different profiles of cells positive for the MSC markers CD44, CD69, CD73, CD90 and CD105 and showed different expression levels of the genes Sox9, Nanog, Runx2 involved in chondrogenesis, undifferentiation and osteoblastogenesis, respectively. Immunohistochemical analysis demonstrated that COL1, COL2, COLX, MMP13 and aggrecan were expressed in the spheroids as soon as 14 days of culture. The $CD271^+$ subpopulation expressed the highest levels of COL2 staining compared to the other subpopulations. CD105 and Runx2 were shown by immunohistochemistry and genetic analysis to have significantly higher expression CD271+ subpopulation than the other subpopulations.

Conclusions: Spheroids formed from CD271-enriched and CD73-enriched MSCs from normal human synovial membranes mimic the native cartilage extracellular matrix more closely than $CD106^+$ MSCs and are

possible candidates for use in cartilage tissue engineering. Both cell types have potential for promoting the differentiation of MSCs into chondrocytes, presenting new possibilities for achieving intrinsic cartilage repair.

TGF-β-Induced CD4+CD25+Foxp3+ Regulatory T Cells Suppress Bone Erosion in Collagen-Induced Arthritis through Restraining the Osteoclastogenesis. NIng Kong[3], Ziyan Yang[2], Julie Wang[3], Ryan Park[3], Grant Dagliyan[3], Peter S. Conti[3], Hejian Zou[1] and Song Guo Zheng[3]. [1]Fudan University Medical School, [2]UCLA Department of Biomed, [3]USC Keck School of Medicine

Background: It is well-known that osteoclasts are responsible for the bone destruction in rheumatoid arthritis (RA) and collagen induced arthritis (CIA). Previous study has demonstrated that activated natural CD4+CD25+ regulatory T cells (nTregs) can inhibit osteoclastogenesis and CIA in a factor receptor activator of NF-kB ligand (RANKL) dependent pathway by blocking osteoclast differentiation from osteoclast precursors (OCP). Since we and other groups have identified that TGF-β-induced CD4+CD25+Foxp3+ regulatory T cells (iTregs) have the similar phenotypic and functional characteristics as nTregs, here we try to learn if iTregs also have the suppressive capacity on osteoclastogenesis and CIA.

Methods: In vitro, osteoclasts were induced from bone-marrow cells with RANKL and macrophage colony-stimulating factor (M-CSF). Naive CD4+ cells were isolated from splenocytes of normal DBA1/J mice and stimulated with anti-CD3/CD28 coated beads with IL-2 (Tcon) or IL-2+TGF-β (iTregs) for five days. On day 0, Tcon and iTregs were added to cultures for the induction of osteoclasts formation at different ratios in the presence of anti-CD3 monoclonal antibody. Osteoclast formation was determined by staining with tartrate-resistant acid phosphatase (TRAP), identified and counted by microscopes. In vivo, 3×106 iTregs were adaptively transferred to DBA1/J mice on d14 after immunization with CFA and bovine CII. The prevalence and severity of CIA mice were monitored every other day. After four-week transfer, mice accepted CT scanner on joints. The histological analysis of joints was performed and joints were stained for the identification of osteoclasts.

Results: Addition of 10% of iTregs almost completely suppressed osteoclast formation in cultures compared with addition of similar doses of Tcon cells. Addition of anti-TGF-β or anti-IL-10 antibody to cultures cannot abolish the suppressive activities and cell-contact was required for the suppressive effect. In addition, CIA mice received iTregs have a significant lower prevalence and clinic scores than mice received Tcon cells or no cells. Of note, CT scanner showed that the joints of CIA mice received iTregs had much less bone erosion than other two groups. Accordingly, histological analysis revealed that the joints in CIA mice received iTregs had much less osteoclasts than that in mice received Tcon cells or CIA models.

Conclusions: iTregs can inhibit osteoclastogenesis in vitro and in vivo, and eventually suppress bone erosion in CIA diseases. This study implicates that manipulation of iTregs may have a therapeutic effect on rheumatoid arthritis and other autoimmune diseases.

The Calcitonin Receptor Is Localized to Specific Phenotypes of Cartilage Chondrocytes *In Situ*. Pingping Chen-An, Yadong Li, Bodil C. Sondergaard, Toni Silvestra-Segovia, Per Qvist, Morten A. Karsdal and Anne C. Bay-Jensen. Cartilage Biology and Biomarkers, Denmark

Background: Arthritis is associated with excessive cartilage loss. Salmon calcitonin is reported to have chondro-protective effect on degenerative joint disease. We have recently shown that the calcitonin receptor (CTR) was expressed by primary chondrocytes; however it was also evident that not all chondrocytes expresses the CTR. Articular cartilage can be divided into different zonal layer, which encumbers different chondrocyte phenotypes; the superficial layer–discoid chondrocytes, the upper zone–spherical chondrocytes, mid zone–resting chondrocytes, deep zone–hypertrophic chondrocytes, calcified cartilage and subchondral bone. We therefore investigated, which of these chondrocytes express the CTR *in situ*.

Methods: Full-depth articular cartilage tissue was isolated from the tibia plateau of 20 different patients undergoing total knee replacement. The tissue was fixed, decalcified and embedded in paraffin. Sections of 5 μm were cut, blocked for unspecific binding and stained for the calcitonin receptor using the monoclonal antibody MAb 31/01-1H10 (Welcome receptor, Australia). Dako envision+ system was used for visualization of the antibody binding. Adjacent sections were stained with proteoglycans using safranin O and fast green staining. Sections were evaluated by Mankin score and specific arthritic features were identified in the cartilage. Anotations on positive staining were made of these features. Statistics were performed by Fishers' exact test.

Results: All sections had some degree of pathological features ranging from Mankin score 4 to 10. No or limited immune-reactivity was observed in the discoid chondrocytes of the superficial zone and spherical chondrocytes of the upper zone. In contrast when the superficial zone was lost a fraction of the spherical chondrocytes, namely those with clonal activity, displayed the receptor. At no time did we observe the CTR in the mid zone. Furthermore, we found the receptor to be present in a portion of hypertrophic chondrocytes of the deep zone. These observed distributions were significant ($p<0.05$). Furthermore, strong proteoglycan staining (intense red staining) was seen in the CTR positive anotations. Since we only observed immune-reactivity in cells with high metabolic activity, assessed by proteoglycan staining and general morphology, and did not observe any staining in the mid zone chondrocytes, it might indicated that the expression of the CTR is related to chondrocytes with high metabolic activity.

Conclusions: We here report that human articular cartilage chondrocytes do express the CTR *in situ*, and that this expression is associated with chondrocytes with high metabolic activity. The presence of the CTR suggests that chondrocytes are target for treatment with salmon calcitonin. These data support previous data that identifies the expression of CTR in primary osteoarthritic chondrocytes.

The Enhanced Expression of Suppressor of Cytokine Signaling (SOCS)-3 in Human Pathological Chondrocytes Impairs the TLR4 and IGF-1 Signaling in These Cells. Fons A. J. van de Loo, Miranda B. Bennink, Onno J. Arntz, Henk M. van Beuningen, Peter M. van der Kraan, Sharon S. Veenbergen and Wim B. van den Berg. Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands

Introduction: Osteoarthritis (OA), a degenerative joint disease, and Rheumatoid arthritis (RA), an inflammatory joint disease, are both characterized by progressive loss of the articular cartilage matrix due to an imbalance between matrix synthesis and degradation. Loss in the chondrocytes ability to respond to growth factor stimulation may be a key factor contributing to the development of OA and RA. We recently found that enforced expression of SOCS3 caused IGF-1 resistance in chondrocytes, thereby preventing upregulation of matrix proteoglycan synthesis. This study is designed to determine the expression of SOCS3 in human pathological chondrocytes and unravel the biological/functional consequences.

Methods: Chondrocytes were isolated from cartilage of patients undergoing surgical joint replacement. The mRNA and protein levels of SOCS1 and SOCS3 were measured by qPCR and westernblotting. Levels of SOCS3 were compared to a human immortalized chondrocyte cell-line (G6), mesenchymal-stem cells differentiated chondrocytes, and primary chondrocytes isolated from healthy bovine cartilage or from a SLE patient. The regulation of SOCS1 and 3 expression was studied in OA chondrocytes by incubation with different cytokines and TLR agonists. To determine the functional consequences the cytokine and TLR ligand induced nitric-oxide production and IGF-1-stimulated proteoglycan (PG) synthesis was studied.

Results: The SOCS3 mRNA expression in articular chondrocytes and cartilage was markedly upregulated (32-fold) in 21/24 OA, 5/5 RA patients, 3/3 trauma patients tested, as compared to the G6 cell-line, stem cell-differentiated chondrocytes, and chondrocytes derived from a SLE-patient. Exposure of the mesenchymal stem cell-derived chondrocytes with conditioned media of OA synovial explants upregulated SOCS3 to the same extent as seen in the OA chondrocytes. Exposure of OA chondrocytes to different cytokines (IL-1β, IL-17, IL-18) and TLR ligands (LPS, Pam2Cys, Poly(I:C), FK156, MDP could not further upregulate SOCS3 expression. In contrast, SOCS1 expression was markedly lower (20-fold) in comparison to SOCS3 in OA chondrocytes and could be upregulated to the level of SOCS3 using

IL-1β, IFNg, IL-17, Pam2Cys, Poly(I:C), and especially with the combination of IFNg and Poly(I:C). SOCS3 expression in OA chondrocytes was confirmed at the protein level. This means that the SOCS3 and SOCS1 genes are independently regulated and that SOCS3 has reached the maximal expression level. In the OA chondrocytes, the TLR4 ligand LPS was unable to induce NO production and IGF-1 failed to stimulate PG synthesis. Forced expression of SOCS3 in bovine cartilage-derived chondrocytes blocked the LPS (NO) and IGF-1 (PG-synthesis) response in these cells.

Conclusion: We found increased SOCS3 but not SOCS1 expression in human pathological chondrocytes. SOCS3 could block TLR4 and IGF-1 activation in chondrocytes. This suggests that SOCS3 modifies normal chondrocyte function and this could play a major role in the development of cartilage pathology seen in osteoarthritis and rheumatoid arthritis patients.

The HCO_3^-/Cl^- Anion Exchanger SLC4A2 Regulates pH and Actin Organization within Osteoclasts. Fabienne Coury[1], Andrew K. Stewart[3], Sebastien Stephens[2], Lynn Neff[2], William C. Horne[2], Seth L. Alper[3], Roland Baron[2] and Antonios O. Aliprantis[1]. [1]Department of Immunology and Infectious Diseases, Harvard School of Public Health, and Department of Medicine, Harvard Medical School, Boston, MA, [2]Department of Oral Medicine Infection and Immunity, Harvard Dental School, [3]Division of Nephrology, Beth Israel Deaconess Medical Center

Overactivation of bone resorption by osteoclasts occurs in numerous rheumatic diseases such as osteoporosis and rheumatoid arthritis. To resorb bone, osteoclasts secrete acid into a resorption lacuna between their apical ruffled membrane and the bone surface. This process is facilitated by reorganization of their actin cytoskeleton to form a sealing zone, which, like a gasket, seals off the resorption lacuna to prevent acid leakage. To prevent cytoplasmic alkalinization during lacunar acid secretion, electroneutral exchange of bicarbonate for chloride occurs through an anion exchanger, Solute carrier family 4, anion exchanger, member 2 (SLC4A2, AE2). We recently showed that in the absence of Slc4a2, mice develop osteopetrosis due to impaired osteoclast function. Accordingly, SLC4A2-deficient osteoclasts are unable to secrete acid and resorb bone. Here, we show that SLC4A2 may serve an additional and previously unrecognized function in the osteoclast: the regulation of actin dynamics and podosome organization. In vitro, SLC4A2 deficient osteoclasts display a delay in actin belt formation. The actin belts ultimately formed by SLC4A2-null osteoclasts are thicker and made up almost completely of punctuate, large podosomes lacking the diffuse actin cloud characteristic of wild-type belts. Furthermore, the average podosome life span is significantly longer in the actin belts of null osteoclasts, while actin polymerization is increased. Interestingly, while SLC4A2 was not required for microtubule assembly, we show it is required to recruit c-Src to the actin belt. c-Src is a major intracellular mediator of osteoclast activation, coordinates organization of the actin belt and is required for osteoclast function in vivo. We also show that SLC4A2 is exclusively expressed at the basolateral membrane of mouse osteoclasts. In addition, in its absence, osteoclasts are unable to exchange Cl^- for HCO_3^- and display intracellular alkalinization. Taken together, our results indicate that SLC4A2 regulates two cell biological processes required for mature osteoclasts to efficiently resorb bone: reorganization of the actin cytoskeleton and acid secretion. Whether the effect of SLC4A2 deficiency on the osteoclast cytoskeleton represents a direct function for this molecule in actin organization or an indirect effect of intracellular alkalinization is currently under investigation. Inhibitors designed to block SLC4A2 as a treatment for diseases characterized by excessive bone remodeling may need to take into account the binary function of this molecule in the osteoclast.

WNT3A Signals Simultaneously through Multiple Pathways in Human Articular Chondrocytes, Resulting in Distinct Outcomes. Giovanna Nalesso[2], Costantino Pitzalis[1] and Francesco Dell'Accio[2]. [1]William Harvey Research Institute, Barts and the London Queen Mary School of Medicine and Dentistry, Bromley Kent, United Kingdom, [2]William Harvey Research Institute, Barts and the London Queen Mary School of Medicine and Dentistry

Background: Disruption of Wnt signalling leads to osteoarthritis. Wnts signal through β Catenin/TCF or through non canonical pathways involving Ca++/CamKII, PKC, PKA, and the planar cell polarity pathway. Individual Wnt ligands are known to signal through different pathways depending of the cellular context. Canonical and non canonical signalling are active in cartilage and may play distinct roles in osteoarthritis. The purpose of the study was to systematically dissect WNT3A signalling in chondrocytes and understand the mechanisms through which disruption of this signalling leads to cartilage breakdown.

Methods: Articular chondrocytes were isolated from preserved cartilage of patients undergoing knee arthroplasty for osteoarthritis. Mouse cartilage explants were obtained from the femoral head of adult mice. The activation of the canonical and calcium dependent pathways upon Wnt3a stimulation was evaluated by the SUPER8TOPFlash, CREB, and NF-AT reporter assays, calcium mobilization assay, Western blotting for β catenin or p-CAMK2, and Axin-2 mRNA expression.

Results: Wnt3a induced the simultaneous activation of the canonical and CaMKII-dependent pathways. More importantly, using a systematic strategy of stimulation of Wnt3a and blockade of individual pathways, we have been able to demonstrate reciprocal inhibition of the two pathways and to separate specific downstream effects. We have built a model that, through such reciprocal inhibition, explains why excessive Wnt3A stimulation or blockade leads to cartilage destruction through different mechanisms.

Conclusions:

- Wnt3A signals simultaneously through the canonical and CamKII dependent pathways in cartilage
- The β catenin and the CamKII-dependent pathways are reciprocally inhibitory and have distinct outcomes.

ACR Poster Session C

Cell-Cell Adhesion, Cell Trafficking and Angiogenesis

Wednesday, November 10, 2010, 9:00 AM–6:00 PM

1504

A Novel Role for Inducible Fucosyltransferase2 as a Regulator of Angiogenesis. Mohammad A. Amin[1], Jeffrey H. Ruth[2], Pei-suen Tsou[2], Phillip L. Campbell[2], Hubert Marotte[2], SolHee Lee[2], Sivakumar Nallasivam[2], Steven E. Domino[2] and Alisa E. Koch[3]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, [3]Unversity of Michigan, Ann Arbor, MI

Purpose: Fucosyltransferases (Futs) are involved in the synthesis of fucosylated glycans and blood group antigens. A number of studies have shown the role of some Futs in angiogenesis and inflammation. The importance of angiogenesis is well established in diseases such as rheumatoid arthritis (RA). This is a novel study which demonstrates that Fut2, heretofore not known to regulate angiogenesis, is cytokine inducible in human dermal microvascular endothelial cells (HMVECs) and plays an essential role in inflammatory angiogenesis.

Methods: We performed reverse transcriptase polymerase chain reaction (RT-PCR) and quantitative PCR to determine Fut2 mRNA expression in HMVECs after stimulation with interleukin-1β (IL-1β). To determine the role of signaling molecules in Fut2 mRNA expression, we stimulated HMVECs with IL-1β in the presence or absence of chemical signaling inhibitors and collected RNA to examine the role of signaling molecules in Fut2 expression. We harvested endothelial cells (ECs) from Fut2 null and wild type (wt) mice and performed Matrigel tube formation assays *in vitro*. We also used Matrigel plug and the inflammatory sponge granuloma angiogenesis assays *in vivo* to elucidate the significance of Fut2 in angiogenesis by employing Fut2 null and wt mice. To evaluate the mechanism by which Fut2 contributes to angiogenesis, we stimulated Fut2 null and wt mouse ECs with IL-1β, and performed enzyme linked immunosorbent (ELISA) assays to determine if Fut2 deficient ECs produced lower amounts of angiogenic factors than their wt counterparts.

Results: IL-1β enhanced Fut2 mRNA expression in HMVECs compared to nonstimulated cells with a maximum increase at 60 minutes. Phosphatidylinositol 3 kinase and p38 were critical in HMVEC IL-1β stimulated Fut2 mRNA expression. Fut2 null ECs exhibited a significant 2 fold decrease in tube formation compared to wt ECs, indicating that Fut2 may be an important factor in angiogenesis *in vitro*. To determine whether Fut2 contributed to angiogenesis *in vivo*, we performed mouse Matrigel plug and inflammatory sponge granuloma angiogenesis assays using Fut2 null and wt mice. Fut2 null

mice were deficient in angiogenesis in both the Matrigel plug and the sponge granuloma compared to wt mice ($p<0.05$). To determine the mechanism of impaired angiogenesis in the absence of Fut2, ECs harvested from Fut2 null and wt mice were stimulated with IL-1β. Vascular endothelial growth factor (VEGF) was less in Fut2 null ECs at both the mRNA and protein levels, suggesting a novel role for Fut2 as regulator of angiogenesis.

Conclusions: These data suggest an intriguing role for Fut2 as regulator of angiogenesis. Fut2 may be a potential therapeutic target controlling production of angiogenic factors such as VEGF in angiogenesis-dependent diseases such as RA.

CD86 Is Involved in the Intercellular Contacts between IL15 Activated Natural Killer Cells and THP-1 Cells That Result in TNF Production. Amalia Lamana, Belen Diaz-Sanchez, gips. Ortiz, Santos Castañeda, Rosario Garcia-Vicuña and Isidoro Gonzalez-Alvaro. Rheumatology Department. HU La Princesa. IIS Princesa, Madrid, Spain

Background: We have previously described that the interaction between NK cells activated with interleukin 15 (IL15) and macrophages leads to persistent TNF production and may be relevant in the perpetuation of rheumatoid arthritis in a subset of patients (1). Abatacept, an effective drug for controlling this disorder, inhibits the costimulatory signal induced by the interaction of CD28 expressed on T cells with CD80 and CD86 expressed on macrophages.

Aim: To study the pattern of CD28 expression on NK cells and its potential implication in the interactions that result in TNF secretion in cultures of NK and THP-1 cells.

Methods: We studied by flow cytometry the expression of CD16, CD28 and CD56 on different NK lineage tumor cell lines (NKL, NK3.3 and YT Indy obtained from ATCC) and on NK cells from peripheral blood (PB) of 33 healthy donors (HD). In addition, PB lymphocytes (PBL) were stimulated or not with IL15 (50 ng/ml) for 16 h. Resting and activated cells were washed twice with medium and co-cultured with THP-1 cells (10 PBL by each THP-1 cell) in the presence or absence of CTLA4-Ig, anti CD86 and anti CD80 (as a control since THP-1 cells do not express this molecule) blocking monoclonal antibodies (mAb). After 24 hours, supernatants were harvested and TNF production was measured by ELISA. In some conditions, cells were separated by a permeable support (transwell) that allowed the passage of soluble mediators but not cells. Furthermore, we performed experiments with PBL depleted in CD28 or CD16 positive cells.

Results: NKL and YT Indy tumoral cell lines expressed CD28. NK cells from HD could be classified according on their pattern of CD16 and CD56 expression as: group 1 (GR1) is CD56dim CD16high; group 2 (GR2) is CD56dim CD16negative; and group 3 (GR3) is CD56 high CD16low/negative. The most abundant population was GR1 (median 60% of NK; interquartile range [IQR] 48–75%) where cells lack CD28. The median percentage of NK subpopulation with GR2 profile was 17% (IQR 12–34%). A subset of GR2 NK cells, ranging from 5 to 50%, expressed CD28. The GR3 subpopulation represented about 5% of PB NK cells and did not express CD28. Supernatants from PBL and THP-1 cells showed TNF production that increased ($80+/-15\%$; $p<0.001$) when PBL were pre-treated with IL15 and was abrogated when the two cellular types were separated by transwells. Interestingly, the presence of anti-CD86 mAb in the culture medium decreased TNF production ($-50+/-30\%$; $p=0.02$) mainly when PBL were pre-activated with IL15. CTLA4-Ig decreased TNF production only in a subpopulation of HD. On the other hand, IL15 did not increase the CD28 expression on NK cells and the depletion of CD28 positive cells did not impair TNF production, whereas depletion of CD16 positive cells abrogated its production.

Conclusions: In this study we have described that blockade of CD86 decreases the production of TNF in a model that is mediated by IL15-activated NK cells. Although we have detected a subpopulation of NK cells expressing CD28, this subset do not seem to be involved in the model. More studies are needed to determine the CD86 ligand on CD16+ NK cells since in a subset of donors CTLA4-Ig was also able to decrease TNF production.

Characterization of CCR7 and Its Ligands CCL19 and CCL21 in Rheumatoid Arthritis. Sarah R. Pickens[5], Michael V. Volin[1], Richard M. Pope[4], Arthur M. Mandelin[2] and Shiva Shahrara[3]. [1]Midwestern University, [2]Northwestern University, Chicago, IL, [3]Northwestern Univ Feinberg, Chicago, IL, [4]Northwestern Univ Med School, Chicago, IL, [5]Northwestern University, Chicago, IL

Introduction: The aims of this study were to characterize the expression of CCR7 and its ligands CCL19 and CCL21 in rheumatoid arthritis (RA) synovial tissue (ST) and synovial fluid (SF) and to demonstrate the role of CCL19 and CCL21 in RA pathogenesis.

Methods: Immunohistochemistry was employed to determine expression patterns of CCR7, CCL19 and CCL21 in RA and NL STs. CCL19 and CCL21 expression levels were also determined in normal (NL), osteoarthritis (OA) and RA ST, as well as in SF from OA, juvenile idiopathic arthritis (JIA), psoriatic arthritis (PsA) and RA patients using ELISA. CCL19 and CCL21 mRNA levels were quantified in NL and RA peripheral blood (PB) monocytes and macrophages, as well as in RA SF macrophages by real-time RT-PCR. Next, we identified proinflammatory factors that modulate expression of CCL19 and CCL21 in PB differentiated macrophages using real-time RT-PCR. Finally, production of proinflammatory factors was examined in CCL19 and CCL21 activated macrophages and RA ST fibroblasts employing ELISA.

Results: We found that ST lining and endothelial cells positively stained for CCR7 and that the immunostaining was 2 fold higher in RA compared to NL STs. Consistently, CCL19 and CCL21 expression was significantly increased in RA ST lining (1.3 and 3 fold respectively) and endothelial cells (1.5 and 2 fold respectively) compared to NL ST. Levels of CCL21 were generally higher in RA and OA STs compared to CCL19. However, NL ST had similar levels of CCL19 and CCL21. Further, CCL19 and CCL21 levels were elevated in RA (2.5 and 1.5 fold respectively) and PsA SFs (2 and 1.6 fold respectively) compared to OA SFs. Interestingly, CCL19 levels were significantly increased in RA SF macrophages compared to RA and NL PB macrophages, while CCL21 expression was upregulated in RA SF and PB macrophages compared to the same cells in NL PB. Next, we showed that CCL19 expression levels were greatly induced by LPS (70 fold) and IL-1β (6.5 fold) activation of macrophages compared to untreated cells. However, only RA SF stimulation (2.5 fold) upregulated levels of CCL21 in macrophages compared to untreated cells. Additionally we found that CCL19 and CCL21 were capable of inducing the production of VEGF and Ang-1 from RA ST fibroblasts and secretion of IL-8 and Ang-1 from macrophages.

Conclusion: Our results suggest that CCR7 and its ligands CCL19 and CCL21 are elevated in RA ST lining and endothelium, and ligation of CCR7 may play an important role in mediating angiogenesis in RA synovium.

Chemerin Levels Are Increased in Rheumatoid Arthritis Patients Who Smoke, Correlate with Disease Activity, and Decrease after Adalimumab Treatment. Marieke Herenius[2], Cristina Lebre[3], Ana Oliveira[3], Carla Wijbrandts[3], Daniëlle Gerlag[3] and Paul P. Tak[1]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, Utrecht, The Netherlands, [3]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands

Background: Chemerin is a recently discovered chemokine that modulates chemotaxis and activation of dendritic cells and macrophages. The expression of chemerin in rheumatoid synovial tissue strongly suggests involvement of chemerin in the migration/accumulation of dendritic cells and macrophages in the inflamed joint. Furthermore, we have recently shown in synovial biopsy explant cultures that chemerin levels are upgulated by TNF-a and that chemerin can induce TNF-a. Elevated chemerin levels have also been related to dyslipidemia and hypertension in obesity, thereby linking it to the metabolic syndrome.

Objective: To explore the role of chemerin in rheumatoid arthritis (RA) in relationship to known cardiovascular risk factors and to evaluate the effects of anti-TNF treatment on serum levels of chemerin.

Methods: 49 patients with active RA (disease activity score evaluated in 28 joints (DAS28)) ≥ 3.2) were started on adalimumab therapy (40 mg subcutaneously every other week). Blood was drawn from patients while fasting at baseline and 16 weeks after the initiation of therapy. Chemerin

levels were measured by ELISA. Known risk factors for cardiovascular disease were determined at baseline.

Results: Baseline chemerin levels correlated with DAS28 and ESR ($r=0.38$, $p=0.007$ and $r=0.40$, $p=0.005$, respectively). Of interest, we found chemerin levels to be significantly higher in current smokers (n=9, median 162ng/ ml, IQR 159–168 ng/ml) than non-smokers (n=33, median 143 ng/ml, IQR 130–169 ng/ml, $p=0.03$). Baseline chemerin levels were not related to sex, age, BMI, serum lipid levels (TC, HDL, LDL, TG, Apo A-I, Apo B, Lp(a))or cardiovascular events in the medical history. After 16 weeks of adalimumab treatment there was a significant reduction of DAS28, ESR, CRP ($p<0.001$, $p<0.001$, and $p<0.001$, respectively) associated with a reduction of serum levels of chemerin from 152 ng/ml (±34 ng/ml) to 141 ng/ml (±29 ng/ml) ($p=0.025$).

Conclusions: Levels of chemerin are related to disease activity and reduce after adalimumab treatment. Interestingly, smoking might increase levels of chemerin, a potent chemoattractant for dendritic cells and macrophages, promoting clinical signs and symptoms of RA and perhaps also the metabolic syndrome.

Contribution of NR4A2 Gene Expression in Modulation of Thrombospondin-1 in Human Joint Disease. Jason P. McMorrow[3], Ursula Fearon[3], Douglas J. Veale[1], Oliver M. FitzGerald[2] and Evelyn P. Murphy[3]. [1]St Vincents Univ Hospital, Dublin, Ireland, [2]University College Dublin, Ranelagh Dublin, Ireland, [3]University College Dublin, Dublin, Ireland

Background: During joint inflammation perpetuation of angiogenesis leads the reorganisation and increase in blood vessel number. During early stages of disease an angiogenic switch occurs which shuts off angiogenic inhibitors such as Thrombospondin-1 (TSP-1) and leads to increased production of pro-angiogenic mediators. The NR4A subfamily of orphan nuclear receptors have recently emerged as novel transcriptional regulators of angiogenic growth factor and cytokine action in inflammatory diseases. The aim of this study was to examine the levels of the TSP-1 in human serum, expression of TSP-1 in synovial tissue and to monitor the effects of anti-TNFα therapy on both systemic and local TSP-1 levels.

Methods: TSP-1, VEGF, NR4A, and IL-8 mRNA levels were determined in using real-time PCR. TSP-1 protein levels were quantified in synovial tissue (ST) by immunohistochemistry (IHC) in a cohort of patients (n=10) pre and post anti-TNF therapy. TSP-1 serum levels were measured by ELISA in healthy volunteers (n=5) and 2 cohorts of patients (n=12; n=15) receiving anti-TNFα treatment. TSP-1 promoter activity was monitored by luciferase reporter assays.

Results: TSP-1 protein levels were measured in patient serum at baseline (n=12) and compared to levels in healthy volunteers (n=5). A significant decrease in TSP-1 expression was observed in patients with active disease ($p<0.007$). Following anti-TNFα treatment, TSP-1 serum levels were restored (n=15; $p<0.047$). TSP-1 and NR4A2 expression and localisation was measured in the ST of patients (n=10) receiving anti-TNFα therapy. Our findings demonstrate that low expression levels of TSP-1 in inflamed tissue in the lining layer and subling endothelial cells. TSP-1 expression was highly cell associated. High levels of NR4A2 were quantified in all patient tissue. Post-treatment, NR4A2 levels are significantly reduced, while TSP-1 protein levels are enhanced demonstrating a significant diffuse pattern of expression.

Using primary synoviocyte cells (n=9), analysis revealed negligible levels of TSP-1 mRNA, high levels of NR4A1–3 and IL-8 transcripts in low passage cells. In high passage cells, reciprocal levels of TSP-1, NR4A and IL-8 expression were observed. Stable NR4A2 expression in normal synoviocyte cells resulted in decreased TSP-1 mRNA and protein levels. To determine whether NR4A effects on TSP-1 expression occurred at the transcriptional level, we evaluated transactivation of the hTSP-1 (2872 bp) promoter using a series of promoter deletions cotransfected with NR4A2. NR4A2 reduced TSP-1 promoter activity by approx. 50%. Within the promoter deletions we identified a repressor region. Deletion of this promoter region resulted in NR4A2 activity transformed from a repressor to transcriptional activator of TSP-1 expression.

Conclusion: These data reveal that moderate expression of TSP-1 in human inflammatory joint disease can be significantly enhanced during anti-TNF treatment and identifies a novel role for NR4A2 as a transcriptional repressor of TSP-1 expression in human synovial tissue.

Role of the Metalloproteinase ADAM-8 in the Regulation of the Inflammatory Response. PSGL-1 Shedding by ADAM-8 in Human Neutrophils. Maria Jesus Dominguez-Luis[4], Ana Urzainqui-Mayayo[1], Ada Maria Herrera-Garcia[4], Ana Diaz-Martin[5], Maria Teresa Arce-Franco[5], Faustino Mollinedo[2], Francisco Sanchez-Madrid[1] and Federico Diaz-Gonzalez[3]. [1]Immunology Service, Hospital de La Princesa, Madrid, Spain, [2]Instituto Superior del Cancer, Salamanca, Spain, [3]Rheumatology Service, Hospital Universitario de Canarias, La Laguna, Tenerife, Spain, [4]Rheumatology Service, Hospital Universitario de Canarias, La Laguna, Spain, [5]Rheumatology Service, Hospital Universitario de Canarias, Spain

ADAM (A disintegrin and metalloproteinase domain) proteins are a family of transmembrane proteases with heterogeneous functions and expression profile. One of its members, ADAM-8 is constitutively present at both cell surface and intracellular granules levels in human neutrophil, and it has been implicated in the L-selectin shedding. However, the potential role of this metalloproteinase in the regulation of other "sheddable" proteins involved in the initial phase of the inflammatory response such as PSGL (P-selectin glycoprotein ligand)-1, had not been investigated.

Objective: To study the capability of ADAM-8 to process the ectodomain of PSGL-1 in human neutrophils.

Methods: In this study have been used human peripheral blood neutrophils from healthy donors, HL-60 cells (human promyelocytic leucemia cells) and CEM (T-lymphoblastic leucemia cell line). The association PSGL-1/ ADAM-8 was studied by co-immunoprecipitation assays in HL60 cells. The membrane and intracellular expression of these two proteins in neutrophils was assessed by flow cytometry and confocal immunofluorescence microscopy. Supernatant concentration of PSGL-1 was determined by ELISA. Native and catalytically inactive ADAM-8 was expressed in CEM line (not possess endogenous ADAM-8) by nucleofection. PSGL-1 function was evaluated in a flow chamber by the dynamic behavior of CEM cells preincubated with termolisyn-activated recombinant ADAM-8 over a P-selectin-coated surface.

Results: Both confocal microscopy studies and co-immunoprecipitation assays showed the association ADAM-8/PSGL-1 in human neutrophils and HL60, respectively. Pull-down assays established that the binding capacity of ADAM-8 to PSGL-1 was lost if cytoplasmic tail of PSGL-1 was truncated before amino acid 18. Incubation of human neutrophils with thermolysin-activated recombinant soluble ADAM-8 resulted in PSGL-1 shedding assessed by ELISA respect to cells incubated with inactive soluble ADAM-8 (t-student, $p<0.05$). In addition, CEM cells transfected with native ADAM-8 showed a reduction in PSGL-1 surface expression (by flow cytometry) and a decrease in the number of cells that roll on recombinant P-selectin (in flow chamber) respect to cells transfected with a catalytic-inactive ADAM-8 (t-student, $p<0.05$).

Conclusions: Both the membrane and soluble form of ADAM-8 are able to regulate the PSGL-1 and L-selectin surface expression in human neutrophils. All these data support a potential relevant role for ADAM-8 in the recruintment of neutrophils into tissues during the inflammatory response.

***In Vitro* Hypoxia-Induced Mitochondrial Genome Mutagenesis and Dysfunction.** Monika Biniecka[2], Edward Fox[1], Chin T. Ng[2], Wei Gao[2], Ursula Fearon[2], Douglas Veale[2] and Jacintha O'Sullivan[2]. [1]Department of Pathology, University of Washington, Seattle, WA, [2]Translation Research Group, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Co. Dublin, Ireland

Background: Hypoxia is characterized by an inadequate supply of molecular oxygen and has been associated with increases in reactive oxygen species (ROS) production. O_2 sensing and ROS source in response to hypoxia is though to be mediated by Electron Transport Chain, hence mitochondrial genome is highly susceptible to attack by oxygen radicals. Oxidative stress is postulated as a primary source of mitochondrial DNA mutations (mtDNA)

and clonally expanded mitochondrial mutagenesis has been detected in patients with rheumatoid arthritis. In this study we examine whether *in vitro* hypoxia induces mitochondrial dysfunction resulting in mitochondrial genome mutagenesis and we examine the role of HIF-1α and NF-kB in mediating these events.

Method: K4 cells (immortalised human synoviocyte cells) were exposed to normoxia (21%) or hypoxia (1%). Levels of mtDNA point mutations were quantitatively evaluated using Random Mutation Capture assay. Intracellular ROS production and mitochondrial membrane potential (MMP) were measured using fluorescent molecular probes. Markers of oxidative DNA damage (8-oxo-dG) and lipid peroxidation (4-HNE) were determined in cell culture supernatants by ELISA. Protein expression of HIF-1α and NF-kB were assessed by Western blots. The effect of antioxidant treatment on mitochondrial mutagenesis and dysfunction were examined by culturing cells under normoxic (21%) and hypoxic (1%) conditions in the presence or absence of manganese superoxide dismutase (MnSOD) or N-Acetyl Cysteine (NAC) or a hydroxylase inhibitor dimethyloxalylglycine (DMOG).

Results: Hypoxia significantly increases the level of mitochondrial DNA point mutations ($p<0.05$), ROS production ($p<0.05$) and MMP ($p<0.01$) in comparison to normoxia. Treatment with of MnSOD, NAC and DMOG significantly reduced hypoxia-induced mtDNA mutagenesis, intracellular ROS production and attenuated MMP hyperpolarization (all $p<0.05$). Levels of 8-oxo-dG and 4-HNE were significantly higher in K4 supernatants exposed to hypoxia ($p<0.0002$ and $p<0.005$ respectively) than to normoxia and cell stimulation with MnSOD, NAC and DMOG suppressed hypoxic secretion of these oxidative stress markers (all $p<0.002$). MnSOD, NAC and DMOG stabilized HIF-1α protein accumulation under hypoxia. There was no difference in the levels of NF-kB protein expression between all oxygen and antioxidant treatment groups.

Conclusion: Hypoxia drives mitochondrial dysfunction manifested by ROS overexpression and altered MMP. Hypoxia-induced mtDNA mutations are a consequence of elevated oxidative damage indicating ROS as a primary source of mitochondrial mutagenesis. Early detected oxidative stress and mitochondrial genome instability are transient and can be rescue after treatment with MnSOD, NAC and DMOG. Hypoxic HIF-1α activation after antioxidants and hydroxylase inhibitor treatment may contribute to gene expression that prevents mtDNA damage following oxidative stress thus HIF-1α antagonizes hypoxia-induced mitochondrial mutagenesis.

Allograft Inflammatory Factor-1 Facilitates the Migration of Fibroblasts and Has a Correlation with the Pathogensis of Skin Fibrosis in a Murine Model of a Murine Model of Sclerodermatous GVHD. Aihiro Yamamoto[1], Eishi Ashihara[2], Yoko Nakagawa[2], Hiroshi Obayashi[3], Takahiro Seno[1], Masatoshi Kadoya[1], Masahide Hamaguchi[1], Hidetaka Ishino[1], Masataka Kohno[1], Taira Maekawa[2] and Yutaka Kawahito[1]. [1]Department of Inflammation and Immunology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine, [2]Department of Transfusion Medicine and Cell Therapy, Kyoto University Hospital, [3]Institute of Bio-Response Informatics

Allograft inflammatory factor (AIF)-1 is an IFN-γ-inducible, Ca^{2+}-binding EF-hand protein that is encoded within the HLA class III genomic region in the direct vicinity of TNF-α. AIF-1 has been identified in chronic rejection of rat cardiac allografts and is thought to be involved in the immune response. We previously showed that AIF-1 was strongly expressed in synovial tissues in rheumatoid arthritis and that rAIF-1 increased the IL-6 production of synoviocytes and peripheral blood mononuclear cells. Recently, the expression of AIF-1 has been reported in systemic sclerosis (SSc) tissues, whose clinical features and histopathology are similar to those of chronic graft-vs-host disease (GVHD). To clarify the pathomechanism of fibrosis, we underwent bone marrow transplantation and made sclerodermatous (Scl) GVHD mice. We examined the expression and function of AIF in Scl GVHD mice on day 21 after BMT. We demonstrated that immunoreactive AIF-1 and IL-6 were significantly expressed in infiltrating mononuclear cells and fibroblasts in thickened skin of Scl GVHD mice compared with control. The immunohistochemical findings were confirmed by Western blot analysis. Wound healing assay also revealed that rAIF-1 increased the migration of normal human dermal fibroblasts (NHDF) directly, but cell growth assay didn't showed that rAIF-1 increased the proliferation of them. These findings suggest that AIF-1, which can induce the migration of fibroblasts and the production of IL-6 in affected skin tissues, is an important molecule promoting fibrosis in GVHD. Although the biological function of AIF-1 has not been completely elucidated, AIF-1 can induce IL-6 secretion on mononuclear cells and fibroblast chemotaxis. AIF-1 may accordingly provide an attractive new target for antifibrotic therapy in SSc as well as Scl GVHD.

Bach1 Regulates Heme Oxygenase-1 Expression of Human Monocytes in Response to LPS: Implication in Behcet's Disease. Mitsuhiro Takeno, Takuya Miyazaki, Yohei Kirino, Sei Samukawa, Maasa Hama and Yoshiaki Ishigatsubo. Yokohama City University Graduate School of Medicine

Background: Heme oxygenase (HO)-1 is an inducible anti-inflammatory protein which regulates innate immune functions and involved in pathogenesis of various rheumatic diseases. We have found that increased TLR4 expression is associated with defective HO-1 expression in leukocytes from Behcet's disease patients, leading to an augmentation of inflammatory responses. However, effects of lipopolysaccharide (LPS), a TLR4 ligand, on HO-1 expression have been controversial in monocytic cells: both enhancing and reducing effects have been reported. We here investigated the regulatory roles of the transcriptional repressor Bach1 and the activator Nrf2 in HO-1 expression of human monocytes in response to LPS.

Methods: Peripheral blood mononuclear cells (PBMC) were isolated from healthy donors. Expressions of HO-1, Bach1, and Nrf2 were semiquantitiatively analyzed by immunoblotting at the protein level nd real-time PCR techniques at the mRNA level, respectively. Transcriptional activity of HO-1 gene was determined by luciferase assay. The binding of Bach1, and Nrf2 to Maf-recognition elements (MARE) was determined by chromatin immunoprecipitation assays.

Results: Immunoblotting studies showed that freshly isolated peripheral monocytes expressed substantial amounts of HO-1, along with nuclear Nrf2 and cytoplasmic Bach1. In contrast, HO-1, Nrf2 and Bach1 proteins were little expressed in unstimulated human myelogenous leukemic cell lines such as U937. In response to LPS, HO-1 was reduced in primary monocytes, but upregulated in U937 cells. The differences were associated with distinct kinetics of Nrf2 and Bach1. Immunoblottting studies in cytoplasmic and nuclear fractions, and chromatin immunoprecipitation assays revealed that, in peripheral monocytes, Nrf2 predominantly bound to MARE, the upstream enhancer lesions of HO-1 gene, while LPS promoted nuclear translocation of Bach1 and preferential bindings of Bach1 to MARE. On the other hand, Bach1 was highly bound to MARE in U937 cells under a resting condition, whereas treatment with LPS reversed the biding proportions of the two proteins. Thus, HO-1 expression level is regulated by the binding proportion of Nrf2 and Bach1 to MARE. Furthermore, the LPS-mediated HO-1 reduction was abrogated by Bach1 siRNA.

Conclusions: The present study demonstrates that LPS suppresses HO-1 expression through nuclear translocation of Bach1 in human peripheral monocytes and suggests that Bach1 is a possible therapeutic target in inflammatory diseases including Behcet's disease.

BMS-582949 Is a Dual Action p38 Kinase Inhibitor Well Suited To Avoid Resistance Mechanisms That Increase p38 Activation in Cells. Gary Schieven[1], Rosemary Zhang[2], Sidney Pitt[2], Ding-Ren Shen[2], Jian Cao[2], John Sack[2], Arthur Doweyko[2] and Petra Ross-MacDonald[2]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]Bristol-Myers Squibb

Purpose: Multiple p38 kinase inhibitors (p38i) have been reported to show tachyphylaxis (only transient benefit) in clinical studies of RA, suggesting the induction of resistance mechanisms. By contrast, BMS-582949 has demonstrated clinical efficacy in a PhIIa RA study without tachyphylaxis. Potential kinase resistance pathways in cells and the effect of BMS-582949 on such pathways were investigated to better understand the mechanism by which BMS-582949 avoids tachyphylaxis.

Methods: The phosphorylation of p38 in the cells was measured with phosphospecific antibodies to measure effects on p38 activation. Cells were

treated with p38i alone or in combination with LPS to provide an inflammatory stimulus, and changes in gene expression were measured utilizing microarrays.

Results: BMS-582949 was found to inhibit p38 activation in cells, as measured by phosphorylation of p38. Furthermore, BMS-582949 treatment of cells in which p38 had been activated by LPS rapidly reversed p38 activation as shown by loss of phosphorylation of p38. BMS-582949 is therefore a dual action p38 kinase inhibitor, inhibiting both p38 kinase activity and p38 activation in cells. By contrast, SCIO-469, a p38i that was reported to show tachyphylaxis, did not inhibit p38 activation in cells. In gene expression analysis of cells treated with p38i, all changes observed for p38 pathway components were consistent with cellular feedback to drive p38 activation more strongly. Treatment of either hepatocytes or monocytes with p38i alone resulted in up to 80% increased MKK6 expression, and treatment of monocytes with p38i plus LPS (compared to LPS alone) resulted in increased expression of several upstream activating kinases and p38a itself, while decreasing expression of MKP-1 which dephosphorylates and deactivates p38. X-ray crystallography revealed that BMS-582949 binding to p38a results in a conformational change of the activation loop which is phosphorylated by upstream kinases, whereas SCIO-469 had little effect. BMS-582949 may therefore inhibit phosphorylation of p38 by upstream MKK by inducing a less accessible conformation of the activation loop.

Conclusions: BMS-582949 acts as a dual action kinase inhibitor in cells, inhibiting both p38 kinase activity and activation of p38. Treatment of cells with a variety of p38 inhibitors resulted in changes expected to drive cellular p38 activation more strongly. Increasing activation of p38 may be a resistance pathway by which cells can overwhelm effects of p38 inhibitors that only inhibit p38 kinase after it is activated. By blocking activation of p38 kinase, BMS-582949 appears to be well suited to resist such cellular responses that would drive p38 activation more strongly.

1514

Both Insulin Receptor and Nampt Activity Are Implicated in Visfatin/ Nampt Induced PGE2 Synthesis in Articular Chondrocytes. Marjolaine Gosset[4], Francis Berenbaum[2], Colette Salvat[4], Alain Sautet[1], Martin Holzenberger[3] and Claire Jacques[4]. [1]Faculty of Medicine P&M Curie, Paris, France, [2]Faculty of Medicine P&M Curie, UR4 Paris Universitas, Paris, France, [3]Inserm U893, Paris, France, [4]UR4 Paris Universitas, Paris, France

Purpose: We recently reported on visfatin expression in articular chondrocytes and its role in prostaglandin (PG)E2 release in cartilage. However, the signaling pathways of visfatin remain unclear. Visfatin was first reported as a protein that binds to the insulin receptor (IR). More recently, a nicotinamide phosphoribosyltransferase (NAMPT) enzymatic activity involved in nicotinamide mononucleotide (NMN) production, a precursor of the cofactor NAD+, has been demonstrated. The aim of this study was to decipher the signaling pathways implicated in visfatin induced PGE2 release in chondrocytes.

Methods: IR expression from OA human chondrocytes and immature murine articular chondrocytes (iMACs) were assessed using real-time RT-PCR, immunoblotting and immunocytofluorescence. A highly specific monoclonal antibody raised against IR was used. Phosphorylation of IR and AKT was analyzed using Western Blot. IR tyrosine kinase activity was inhibited by using HNMPA-(AM)3 and a siRNA strategy was used to investigate the role of IR in visfatin induced PGE2 release. The role of IGF-1 Receptor (IGF-1R) in visfatin signaling was assessed using primary chondrocytes from IGF-1R knockout mice (IGF-1R−/−) and iMACs treated with an IGF-1R blocking antibody. NAMPT activity was inhibted using APO 866. PGE2 was measured by EIA.

Results: (1) Visfatin is known to bind to, and to activate IR in various cell types. However, IR is not considered to be usually present on chondrocytes. We therefore tested the implication of IGF-1R, a close homologue to IR, in visfatin signaling. When stimulated with 5μg/ml visfatin, IGF-1R−/− chondrocytes unexpectedly exhibited higher PGE2 release than IGF1R+/+ controls (228±4 compared to 86±29 pg/ml, $p<0.05$), ruling out a direct role of IGF-1R in the visfatin effect. Moreover, visfatin (5μg/ml – 24h) induced PGE2 release in iMACs treated with 2 and 5μg/ml IGF-1R blocking antibody compared to control cells (respectively a 1.3 and a 1.9 fold, $p<0.05$ – visfatin treated cells released 110±16 pg/ml PGE2, n= 3). (2) IR was expressed in cultured human chondrocytes from healthy (n=3) and OA patients (n=7) and in iMACs (n=3). (3) Insulin (100nM - 24h) did not trigger PGE2 release in iMACs (control: 118±68 pg/ml and insulin-stimulated cells: 130±79 pg/ml, n=3, NS). (4) Dose-responses of insulin from 0 to 1μM was performed in term of phosphorylation of IR and Akt. Moreover, insulin (100nM) from 0 to 60min triggered IR and Akt phosphorylation. (5) Blocking IR activity using HNMPA-(AM)3 (100nM-24h pre-treatment) inhibited visfatin (5μg/ml-24 h) induced PGE2 release (54% decrease, n=3, $p<0.05$). Moreover, blocking IR expression by siRNA inhibited visfatin-induced PGE2 release (5μg/ml visfatin: 3576±265 pg/ml versus visfatin + IR siRNA1: 1864±515 pg/ml and visfatin + IR siRNA2: 930±216 pg/ml corresponding to a 48% and 74% decrease respectively, n=2, $p<0.05$). (6) Inhibition of the NAMPT activity of visfatin using APO866 from 0 to 1μM gradually induced a decrease in PGE2 release up to 32% (visfatin treated cells released 95±30 pg/ml PGE2, n=3, $p<0.05$).

Conclusions: In chondrocytes, visfatin exerts pro-inflammatory events by both activation of its cognate receptor and Nampt activity.

1515

Comparison of IL-17F and IL-17A Effects and Signaling in Human Rheumatoid Arthritis Synoviocytes. Arnaud Hot, Saloua Zrioual, Anne Tournadre, Vanina Lenief and Pierre Miossec. Immunogenomics and Inflammation Research Unit and Department of Immunology and Rheumatology, Hospital Edouard Herriot, Lyon, France

Objective: IL-17A is implicated in rheumatoid arthritis (RA) pathogenesis; however the contribution of IL-17F remains to be clarified. Using microarrays and gene specific expression assays, we compared the effects IL-17A versus IL-17F on gene expression and signaling in human RA synoviocytes.

Methods: IL-17A and IL-17F expression was studied in OA and RA synovium by immuno-histochemistry. The comparison between IL-17A and IL-17F stimulatory effect on RA synoviocytes was assessed at the protein level by ELISA and at the mRNA level by microarrays (Affimetrix U133 +2) and real-time RT-PCR. IL-17RA and IL-17RC inhibition was achieved by small interfering RNA (siRNA). Western blotting, qRT-PCR, and DNA binding assay were used to evaluate mitogen-activated protein kinase (MAPK), activator protein 1 (AP-1) and nuclear factor kappa B (NF-κB) expression and activation. TNFRII expression was studied by real-time RT-PCR and immunofluorescence, and neutralizing antibody was used to analyse its contribution to CCL20 secretion.

Results: IL-17A and IL-17F were detected in plasma cell like cells in RA but not OA synovium. In microarrays, IL-17A and IL-17F alone had very similar but not identical regulatory effects, IL-17F being less active. Indeed, IL-17A was more potent to induce IL-6 or IL-8 secretion than IL-17F, which was inactive alone. Both cytokines induced a rather similar expression pattern in the presence of TNF-α. Based on a cooperation index, 130 and 203 genes were synergistically induced by IL-17A or IL-17F plus TNF-α, respectively. Among these, the new target genes CXCR4, LPL and IL-32 were validated by real-time RT-PCR. Virtually all IL17A and IL-17F inducible genes were dependent on NF-κB activation, whereas a minor number was modulated by p38. IL-17A induced activation of all three MAPK (ERK, p38 and JNK) and downstream transcription factors AP-1 and p65 NF-κB. IL-17F was less potent but induced activation of p50 NF-κB. IL-17A and less IL-17F induced TRAF 6 but not MyD88. Inhibition of either IL-17RA or IL-17RC expression via siRNA led to near complete abrogation of IL-6 expression mediated by IL-17A and the combination of IL-17F and TNF-α. IL-17A and IL-17F upregulated TNFRII expression, but had no effects on TNFRI, IL17RA or IL17RC. TNFRII blockade inhibited the synergistic induction of CCL20 by IL-17A or IL-17F and TNFα.

Conclusion: IL-17A and IL-17F are both expressed in RA synovium. In the presence of TNFα, they induced very similar but not identical pattern expression pattern in RA synoviocytes. The enhanced expression of TNFRII contributes to the synergistic effect of IL-17A and F with TNF-α. Targeting IL-17F could be a promising treatment of RA.

Disclosure: A. Hot: None; **S. Zrioual:** None; **A. Tournadre:** None; **V. Lenief:** None; **P. Miossec:** None.

1516

Down-Regulation of Pyrin Promotes Up-Regulation of the Anti-Apoptotic Gene, *BCL2*, Via the Signal Transducer, gp130, and Leads to the Activation of the PI3K/Akt Pathway. Geryl M. Wood[4], James Balow, Jr[3], Hong-Wei Sun[2], Ivona Aksentijevich[3], Jae Jin-Chae[3], Nitza Shoham[1] and Daniel L. Kastner[3]. [1]Allergy Immunology Laboratory, Meir Hospital, Kfar-Saba, Israel, [2]Biodata Mining and Discovery, Office of Science and Technology, National Institutes of Health, NIAMS, [3]Laboratory of Clinical Investigation, National Institutes of Health, NIAMS, [4]Laboratory of Clinical Investigation, National Institutes of Health, NIAMS, Bethesda, MD

Purpose: Familial Mediterranean fever (FMF) is a periodic fever syndrome characterized by episodes of self-limited fever and localized inflammation. The gene causing FMF, *MEFV*, encodes a protein, pyrin, which is expressed in myeloid cells and in the myeloid leukemia cell line, THP.1. Identification of several pyrin-interacting proteins has led to the conclusion that pyrin participates in at least three cellular pathways that are connected to inflammation: cell death, cytokine secretion and cytoskeletal signaling.

Methods: RNA interference (RNAi) technique was employed to compare gene expression profiles between the human myeloid leukemia cell line, THP.1, expressing endogenous pyrin (scrambled control, SC) and cells in which the gene had been knocked down (si*MEFV*). Affymetrix cDNA microarray analysis was used to identify potential novel pyrin-dependent pathways. Western blot and qRT-PCR analysis was used for validation. Flow cytometry and kinase inhibition assays were used to study functionality and mechanism.

Results: Among our differentially expressed genes, we identified two up regulated genes involved in cell survival, *BCL2* and *gp130*. Consistent with these findings, pyrin truncated mice show impaired macrophage apoptosis after IL4/LPS stimulation, independent of IL1b. Western blot and qRT-PCR analyses using independent samples, confirmed the THP.1 microarray data. Western blots comparing BCL2 expression in PBMCs from healthy controls and FMF patients revealed a significantly higher level of BCL2 in FMF patients than controls. These data were in agreement with the Bcl2 expression found in CD11b+ cells from knock-in mice expressing human mutations. The influence of pyrin knockdown on apoptosis was explored. Inducing apoptosis after staurosporine stimulation showed 1.8-fold less apoptosis in si*MEFV* cells compared to SC. To examine the involvement of *gp130* in siMEFV up-regulation of BCL2, we co-transfected siRNA for *gp130* and *MEFV*. We demonstrate reduction in BCL2 after the addition of siRNA for *gp130* compared to si*MEFV* alone. Since the PI3K/Akt survival pathway is activated thru gp130 signaling, we investigated this pathway as a possible mechanism of action. Western blot detection showed no difference in expression of PI3K phosphorylation between SC and siMEFV, in contrast to Akt, which revealed increased levels of phosphorylation in siMEFV treated cells compared to SC. Also, the PI3k/Akt inhibitor LY294002 was able to reduce BCL2 up-regulation by siMEFV with further reduction evident when Akt IV, a specific Akt inhibitor was employed.

Conclusion: These data support the hypothesis that knocking down pyrin in myeloid cells inhibits apoptosis in part via the gp130 receptor, which activates the PI3k/Akt pathway and leads to an increase in *BCL2* expression. It suggests that in some cases, the human mutations may function like the knockdown system.

Effect of the PEG Component of Certolizumab Pegol on Calcium Flux in Cellular Systems. Gianluca Fossati[2] and Andrew Nesbitt[1]. [1]New Medicines, UCB, Slough, Berkshire, United Kingdom, [2]New Medicines, UCB, Slough, UK

Background: Certolizumab pegol (the only PEGylated Fab′ anti-TNF [CZP]) has a very low incidence of injection site pain (ISP) in all clinical studies. It has been hypothesized that this could be due to inhibition of mast cell degranulation by the PEG component of CZP.[1] Mast cells (from human peripheral blood monocytes) could be involved in mediating ISP as they are present at high numbers in the skin and can rapidly secrete many inflammatory mediators in preformed granules. Changes in Ca^{2+} flux from intracellular stores or by influx from outside the cell are primary indicators of cell activation and when mast cells degranulate, this is preceded by a calcium flux into the cell. PEG has been shown to bind metal ions (in particular calcium ions)[2] and, therefore, the aim of this study was to determine if PEG could inhibit calcium flux in a cellular system.

Methods: Peripheral blood monocytes, positively isolated using MACS beads, were incubated for 30 min with the fluorophore Fluo-4 which changes its fluorescence emission when it chelates calcium. Calcium flux was measured using flow cytometry by detecting the Fluo-4 emission at 515–535 nm. Ionomycin was added at 2 μg/mL and the emission measured over a 4-min period relative to background, which was assessed for 1 min prior to ionomycin addition. The effect of a range of concentrations of the 40 kDa PEG component of CZP on calcium flux induced by ionomycin was assessed. In addition, the effect of PEG on an ionomycin-induced calcium flux in cultured mast cells was determined by a similar method except that the flux was measured using a fluorimeter.

Results: Ionomycin caused a dramatic flux of calcium in the monocytes. PEG caused a dose-dependent inhibition of calcium flux in these cells over a range of concentrations from a minimum of 40 mg/mL. This is a physiological concentration of PEG as the equivalent local concentration of PEG which is injected into patients is 88.9 mg/mL. The IC_{50} for inhibition of the calcium flux caused by PEG was around 10 mg/mL. The maximum inhibition observed was 84.2% obtained at 40 mg/mL, with the effect titrating out around 1 mg/mL. In mast cells the IC_{50} was around 11 mg/mL.

Conclusion: The PEG component of CZP inhibits calcium flux in monocytes and mast cells at a concentration relevant at the site of injection. This inhibition of calcium flux could, therefore, explain the low levels of ISP observed with CZP in the clinic. This effect would only be observed at the site of injection as systemic concentrations of the drug are below the levels where an effect is seen.

Expression of the Wnt Inhibitor sFRP-1 in Synovial Fibroblasts Is Regulated by the Histone Methyltransferase EZH2. Michelle Trenkmann[1], Matthias Brock[3], Renate E. Gay[2], Christoph Kolling[5], Rudolf Speich[4], Beat A. Michel[2], Steffen Gay[2] and Lars C. Huber[3]. [1]Center of Experimental Rheumatology, University Hospital Zurich/Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Center of Experimental Rheumatology, University Hospital Zurich/Zurich Center of Integrative Human Physiology (ZIHP), Switzerland, [3]Center of Experimental Rheumatology, University Hospital Zurich/Zurich Center of Integrative Human Physiology (ZIHP), Switzerland/Department of Internal Medicine, University Hospital, Zurich, Switzerland, [4]Department of Internal Medicine, University Hospital Zurich, Switzerland, [5]Schulthess Clinic, Zurich, Switzerland

Background: Methylation of histone 3 lysine 27 (H3K27) by the histone methyltransferase EZH2 is associated with silencing of affected gene promoters. We have previously reported that EZH2 expression is increased in rheumatoid arthritis synovial fibroblasts (RASF) compared to osteoarthritis (OA) SF and further induced by TNF-α. Here we identified secreted frizzled-related protein (sFRP)-1, an inhibitor of the Wnt signalling pathway, as a specific target gene of EZH2 in SF.

Methods: RASF (n=5) were transfected with a vector containing the EZH2 coding sequence or an siRNA targeting EZH2. After 72h and 96h, cells were analyzed for SFRP1 expression at mRNA (by quantitative real-time PCR) and protein levels (by ELISA). Constitutive and TNF-α stimulated expression of SFRP1 was measured in OASF and RASF for both mRNA and protein. To investigate the level of histone methylation within the *SFRP1* gene promoter in RASF (n=10) and OASF (n=7), chromatin immunoprecipitation (ChIP) was performed by using antibodies specific for H3, H3K4me3 and H3K27me3.

Results: Overexpression of EZH2 in RASF resulted in a reduction of SFRP1 mRNA (15±17%, p=0.086 after 72h; 18±9%, p<0.05 after 96h, respectively). Secretion of sFRP-1 protein decreased from 689±216 pg/ml to 507±56 pg/ml (p=0.11) after 72h and from 1095±101 pg/ml to 836±150 pg/ml (p<0.05) after 96h. Conversely, silencing of EZH2 in RASF led to an increase of SFRP1 mRNA level by 15±12% (p<0.05) after 72h and of 15±35% (p=0.38) after 96h.

The constitutive expression of SFRP1 mRNA was strongly reduced in RASF by 86% as compared to OASF (delta Ct RASF: 7.1±2 (n=15), OASF: 4.5±1.7 (n=12), p<0.005). These findings could be confirmed on the protein

level by ELISA (566±354 pg/ml for RASF, 1285±845 pg/ml for OASF, $p<0.01$) and Western blot (n=10 and 7). Stimulation with TNF-α significantly reduced SFRP1 mRNA after 24h and 48h in RASF (by 56±13% and 85±6%, $p\leq0.0001$, n=6) and OASF (by 48±14% and 82±7%, $p\leq0.0001$, n=7). ChIP analysis revealed that the promoter of SFRP1 is trimethylated at H3K27 in SF (H3K27me3/H3 ratio RASF: 0.45±0.36, OASF: 0.22±0.08, p=0.12). Conversely, the H3K4me3/H3 ratio, which is a mark of active gene transcription, was reduced in RASF (0.31±0.27) compared to OASF (0.66±0.32, $p<0.05$). The mRNA expression of SFRP1 correlated positively with occupation of the activating H3K4me3 ($R^2=0.71$, $p<0.0001$) and negatively with occupation of the repressing H3K27me3 mark ($R^2=0.4$, $p<0.01$) in its promoter.

Conclusion: Our data strongly indicate that EZH2 regulates the expression of the Wnt inhibitor sFRP-1 in SF. We show that the levels of sFRP-1 are constitutively decreased in RASF and further reduced by stimulation with TNF-α. Wnt signalling has been shown to be activated in RASF and to contribute to the invasive and aggressive behaviour of these cells. We provide here the first evidence that this aberrant Wnt activation appears to be, at least in part, due to an epigenetic dysregulation of its inhibitor sFRP-1.

Fms-Like Tyrosine Kinase 3 Ligand (Flt3L) Levels Are Elevated in Arthritis: Role of Flt3L in Regulating Monocyte Migratory Pattern in RA. Inês Ramos[2], Ana Oliveira[3], Geurt Schilders[3], Saïda Aarrass[3], Cristina Lebre[3] and Paul P. Tak[1]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Division of Clinical Immunology and Rheumatology, Academic Medical Center/University of Amsterdam, Amsterdam, The Netherlands, [3]Division of Clinical Immunology and Rheumatology, Academic Medical Center/University of Amsterdam, Amsterdam, The Netherlands

Background: Fms-like tyrosine kinase 3 ligand (Flt3L) is a potent endogenous growth factor for myeloid (m)DC and plasmacytoid (p)DC. Its administration to mice and humans leads to dramatic increases of various DC subsets while Flt3L−/− mice show reduced DC numbers. Flt3L and its receptor have been poorly studied in the setting of autoimmune diseases in general and in experimental arthritis in particular. Since in rheumatoid arthritis (RA), circulating blood DC subsets numbers are reduced and enriched in synovial fluid (SF) and synovial tissue (ST), we investigated whether Flt3L can contribute to local accumulation of DC in these compartments by inducing migration of cells from the peripheral blood (PB).

Methods: Patients with active RA, psoriatic arthritis (PsA), other forms of spondyloarthritis (SpA), osteoarthritis (OA), gout and healthy donors (HD) were included in this study. Soluble (s)Flt3L levels in SF and serum were determined using a commercially available ELISA. Expression of membrane-bound (m)Flt3L, Flt3L receptor (CD135) and chemokine receptors in PB mononuclear cells (PBMC) and SFMC were assessed by FACS. Immunohistochemical analysis was performed to detect Flt3L and CD135 RA synovial tissue. Monocytes from HD were isolated and cultured for 24h with recombinant Flt3L and chemokine receptor expression was assessed by FACS.

Results: The levels of Flt3L in RA, PsA, and SpA, OA and gout SF were significantly higher compared to paired serum. In addition, Flt3L levels were significantly higher in RA, PsA and SpA SFs compared to gout SF. In PB monocytes, B cells and mDC the expression of mFlt3L in RA was higher compared to HD. Flt3L receptor expression was confined to monocytes and mDC and higher in RA SF compared to PB. Immunohistochemistry and immunofluorescence data showed the presence of Flt3L and Flt3L receptor in RA ST. Interestingly, Flt3L increased the expression of the chemokine receptors CCR1, CCR2 and CCR5 by monocytes in vitro.

Conclusion: The increased levels of Flt3L in RA SF could contribute to the specific accumulation of DC in the synovial compartment compared to PB in inflammatory joint disease. Flt3L-induced expression of CCR1, CCR2 and CCR5 by monocytes might be important for the increased recruitment of DCs as well as monocytes and lymphocytes into the inflamed compartment. Achieving a detailed understanding of Flt3L function(s) in RA may lead to the development of novel immunotherapies for immune-mediated inflammatory diseases.

Functional Expression of CD13/Aminopeptidase N by RA Synovial Cells In Vitro and In Vivo. Rachel Morgan, Judith Endres and David A. Fox. University of Michigan

Purpose: Aminopeptidase N (CD13, EC 3.4.11.2) is a metalloproteinase expressed on and secreted by myeloid cells and fibroblasts. Previously published data has documented increased CD13-related enzymatic activity in RA synovium compared to OA, and has proposed a role for CD13 as a T cell chemoattractant. The mechanisms whereby T cells become localized to the synovial lining and contribute to synovial inflammation and joint destruction remain incompletely understood. While CD13 has been identified on synovial fibroblasts (FLS), ELISA assay of CD13 in synovial fluid, serum or culture supernantants has not yet been reported. The purpose of this study was to critically examine CD13 expression and function in RA synovium.

Method: Novel monoclonal antibodies (mAb) were developed from splenocytes of mice immunized with an RA FLS line that had been treated with IL-17. Hybridoma supernatants were screened by flow cytometry to detect cell surface structures upregulated by IL-17 but not TNF. This approach yielded one mAb, termed 591.1D7.34, which was used to immunoaffinity purify a protein that was identified as CD13 by amino acid sequencing. 1D7 and another anti-CD13 mAb, WM15, were then used to create a sandwich ELISA for CD13. CD13 enzymatic activity was measured in parallel by cleavage of L-Leucine 7-amido-4-methyl coumarin hydrochloride (L-leu-AMC) to release the fluorescent molecule AMC.

Results: We detected substantial amounts of CD13 in synovial fluids and synovial fibroblast cell lysates, sera and culture supernatants by ELISA, with a significant ($p<0.0001$) increase in CD13 in RA synovial fluids (1191±121.6 ng/ml) when compared to OA (646.1±45.64 ng/ml). Similar to previously published data we also found a significant difference in CD13-type enzymatic activity between RA and OA synovial fluids (3402±239.6 nmoles of substrate cleaved per hour per ml of synovial fluid versus 2250±93.18 nM/hr, $p<0.0001$). This activity was depleted by 1D7 immunoprecipitation. Recombinant CD13 was chemotactic for T cells.

Conclusion: CD13 is released by synovial fibroblasts into the synovial fluid and its expression is upregulated on FLS by IL-17. These findings suggest a mechanism by which IL-17 may enhance synovial inflammation in RA independent of TNFα. We have shown that the CD13 protein is present in significant amounts and accounts for most of the L-leu-AMC cleavage activity in synovial fluids. These data support the concept of CD13 as a multifunctional pro-inflammatory mediator that can serve as a T cell chemoattractant in the RA joint.

Gottron's Papules Exhibit Accumulation of CD44 Variant 7 (CD44v7) and Its Binding Partner Osteopontin: A Unique Molecular Signature. Jessica Kim[1] and Victoria P. Werth[2]. [1]New York University School of Medicine, [2]University of Pennsylvania, Philadelphia, PA

We previously reported an abundance of chondroitin sulfate (CS) in dermis from dermatomyositis (DM) lesions (SID 2008). Because the CD44v7 variant has CS side-chains (Invest Ophthmol Vis Sci 48:1164, 2007) and can mediate autoimmunity in the gut (J Immunol 161:1069, 1998), we examined its distribution in CS-rich regions of DM skin. Surprisingly, CD44v7 was abundant in Gottron's papules, a hallmark lesion of DM overlying interphalangeal (IP) joints, but not in lesional or non-lesional dermis in other regions. Staining density of CD44v7 in Gottron's dermis was double that of healthy IP dermis ($p<0.0001$). Moreover, healthy IP dermis showed far more CD44v7 than did healthy non-IP dermis from the same volunteer, indicating location-specific induction, independent of DM. We hypothesized a role for mechanical stretching, because it induces CD44v7/v8 in non-dermal cells (Invest Ophthmol Vis Sci 48:1164, 2007). We found that confluent dermal fibroblasts cultured on membranes and stretched constantly for 6 hours showed a 62%±3% increase in CD44v7 mRNA levels relative to unstretched cells ($p<0.0001$). Interaction of CD44v7 with the cytokine-like molecule osteopontin has been implicated in chronic inflammation (JCI 107:1055, 2001). Here, we found 2.8-fold increased density of osteopontin staining in the dermal matrix of all DM skin compared to healthy controls ($p<0.05$), with no significant difference between Gottron's vs. non-Gottron's skin. IFN-γ stimulates osteopontin expression by monocytoid cells, and IFN-γ polymorphisms associate with myositis. Treatment of dermal fibroblasts with IFN-γ for 6 hours provoked a ~10-fold increase in OPN mRNA ($p<0.0001$).

Lastly, adhesion studies show that stretching of dermal fibroblast monolayers overnight in the presence of exogenous recombinant osteopontin results in a 2.3-fold increase in the binding of THP-1 human monocytes ($p<0.0001$). Overall, we propose that stretch-induced expression of CD44v7 over joints, in concert with IFNγ-induction of osteopontin, provides a unique molecular signature of Gottron's papules in DM and may contribute to their pathogenesis.

Identification of the NR4A Family of Orphan Nuclear Receptors as Mediators of Adenosine A2A Receptor Activation. Jason P. McMorrow[2], Evelyn P. Murphy[2] and Bruce N. Cronstein[1]. [1]New York Univ Med Ctr, New York, NY, [2]University College Dublin, Dublin, Ireland

Background: The effects of adenosine signalling on the regulation of inflammation suggest that targeting adenosine receptor activation/inactivation could have important therapeutic implications in wound healing and inflammatory disease. In recent studies we report that adenosine, acting at A2A receptors, plays an important role in bleomycin-induced dermal fibrosis, a model for scleroderma. Activation of A2A receptors on cultured human dermal fibroblasts directly stimulates collagen production. What remains to be elucidated are the cell-specific signal transduction events and the transcriptional mediators that act to promote adenosine receptor-mediated responses during these processes.

Aim: To establish cell-specific effects of a selective A2A receptor agonist, CGS-21680, on the expression of the NR4A family of transcription factors in the presence of signaling inhibitors and inflammatory stimuli.

Methods: THP-1 monocyte cells were differentiated to macrphages by stimulation with PMA (10 ng/mL) for 48 h. Normal human dermal fibroblasts (NHDF) and macrophage cells were treated for 1 hour with medium or the selective adenosine A2A receptor agonist, CGS-21680 (10-8-10-6 M), in the presence or absence of the A2A receptor antagonist, ZM241385 (10-6 M). In some experiments NHDF were pre-treated with the MEK inhibitor, U-0126 or the p38 inhibitor, SB202190 for 1 hour before treatment with CGS-21680. Protein and total RNA was harvested and NR4A levels measured by western analysis and real-time PCR.

Results: Treatment of human macrophage-derived THP-1 cells and dermal fibroblast NHDF cells with increasing concentrations of CGS-21680 robustly induces the expression of all three NR4A family members (NR4A1, 2 and 3) in a time dependent manner. The temporal effects of CGS-21680 on NR4A transcription are abolished in cells pre-treated with the A2A antagonist ZM-241385 (1 μM) and blocked by protein inhibitors directed against PKA and MEK1/2. In THP-1 cells, co-treatment with CGS-21680 and LPS or IL-4 resulted in significantly ($p<0.005$) enhanced NR4A1, 2 and 3 transcription. In contrast, minimal effects on NR4A expression are measured in cells co-treated with TNF-α or IL-1. Furthermore, in LPS- and IFN-γ-treated NHDF cells, CGS-21680 effects on NR4A1, 2 and 3 expression is significantly reduced while, in cells co-treated with TGF-β, levels remain unchanged.

Conclusion: This study identifies the NR4A family as novel transcriptional mediators downstream to adenosine A2A receptor activation. In addition, these data reveal that cytokine-specific effects on A2A receptor mediating signaling are cell-type dependent.

Increased Expression of Acid Sensing Ion Channel (ASIC) Mediated by ERK/MAPK Pathway in Mouse Anti-Type II Collagen Antibody-Induced Arthritis. Juyoun Kim[2], Keon Uk Park[2], Jinyeong Chae[3], Hyun-OK Kim[1] and Sang-Hyon Kim[2]. [1]Department of Rheumatology, College of Medicine and Institute of Health Science, Jinju, Korea, Republic of, [2]Keimyung University Dongsan Medical Center, Daegu, Kungsang Province, Korea, Republic of, [3]Keimyung University Dongsan Medical Center, Daegu, Kungsang, Korea, Republic of

Introduction: The collagen-induced knee joint inflammation (CIA) model produces sensitization of nociceptors innervating the knee joint, a substrate for primary hyperalgia; and sensitization of neurons in the dorsal horn, a substrate for secondary hyperalgia. Different acid-sensing ion channel (ASIC) isoforms have been identified and critical for development of secondary hyperalgesia in peripheral sensory neurons innervating skin and muscle. This study was aimed to investigate the ASIC expression in mouse anti-type II collagen antibody-induced arthritis (CIA) and its association with ERK expression.

Methods: Mice were divided into 2 groups; control, CIA. Histological and X-ray assessment of arthritis were done. Measurement of type II collagen specific antibodies, TNFα, IL-17, and IL-6 were done. Both mRNA and protein levels of ASIC1, ASIC2, and ASIC3 were evaluated. We examined ERK/MAPK expression and its activation in the knee joint with or without CIA.

Results: Histological and X-ray assessment revealed increased infiltration of inflammatory cells, synovial hyperplasia, and the destruction of the articular cartilage and bone in CIA group. ASIC1, ASIC2, and ASIC3 were markedly increased compared with those in control. The concentrations of anti-type II collagen antibody in CIA were significantly higher than those in control ($P<0.05$). Serum concentrations of TNF-α ($P<0.005$) and IL-6 ($P<0.05$) in CIA group were also increased. ERK pathway activation was noted by increased p-ERK expression.

Conclusion: Taken together, these results implicate that increased ASIC involved in the joint pain in mice anti-type II collagen antibody-induced arthritis. Activation of ERK pathway could be related to ASIC expression in arthritis.

Increased Levels of Soluble Programmed Death 1 (sPD-1) and Its Soluble Ligand (sPD-L1) in Early Rheumatoid Arthritis Are Associated with Disease Activity and Progression. Stinne R. Greisen[4], Tue K. Rasmussen[5], Kristian Stengaard-Pedersen[1], Merete L. Hetland[2], Kim Hørslev-Petersen[6], Malene Hvid[4] and Bent Deleuran[3]. [1]Arhus University Hospital, Aarhus, Denmark, [2]Copenhagen Univ Hosp Hvidovre, Hvidovre, Denmark, [3]Institute of Medical Microbiology and Immunology, University of Aarhus and 2Department of Rheumatology Aarhus University Hospital, 8000 Aarhus C, Denmark, [4]Institute of Medical Microbiology and Immunology, University of Aarhus, 8000 Aarhus C, Denmark, [5]Institute of Medical Microbiology and Immunology, University of Aarhus, 8000 Aarhus C, Denmark and Department of Dermato-Venerology, Aarhus University Hospital, 8000 Aarhus C, Denmark, [6]King Christian X Hospital for Rheumatic Disease, University of Southern Denmark, Graasten, Denmark

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease. Disturbance of the balance between immune modulatory and inflammatory factors results in joint inflammation progressing to destruction. The regulatory molecules Programmed Death 1 (PD-1) mainly expressed on activated T cells and its ligand (PD-L1), expressed by antigen presenting cells, are believed to negatively regulate T cell induced activation. They are both recently reported present in a soluble form, sPD-1 and sPD-L1.

Objective: To investigate the presence of sPD-1 and sPD-L1 in early RA patients and their correlation with core parameters for disease activity, radiographic progression as well as to the follicular CD4 T cells (TFH) cytokine IL-21 and dendritic cell associated cytokine IL-23.

Methods: In a longitudinal sample set of early RA patients ($n=40$, <6 months' disease) we measured plasma levels of sPD-L1 and sPD-1 by ELISA (R&D systems), at baseline (0 month) and after 9 months of treatment with methotrexate, and investigated for correlations with disease activity in 28 joints (DAS28), C-reactive protein (CRP), and total Sharp score (TSS). To remove heterophillic antibodies, heat aggregated goat IgG (25ug/ml) was added to buffers. Statistical correlations were assessed by Spearman's rho, and data are expressed as median with IQR in parenthesis. In a transverse sample set ($n=30$) of chronic RA patients (>8 years of disease) we measured sPD-1 and sPD-L1 in plasma.

Results: In patients with early RA, plasma levels of sPD-L1 and sPD-1 were both significantly higher at 0 months than after 9 months of treatment. Treatment reduced sPD-L1 from 29.9 ng/ml (10.5–85.3) to 16.8 ng/ml (4.8–35.2), $p<0.001$and sPD-1 from 421 pg/ml (40.0–2560.0) to 40.0 pg/ml (40.0–840.0), $p<0.05$. In chronic RA patients levels of sPD-1, but not sPD-L1 tended to be lower than in early RA patients. In early RA, the change in sPD-1 was associated with DAS28 at 9 months ($r2=0.401$, $p=0.021$), and TSS at 2 years ($r2=-0.468$, $p=0.02$). No association to CRP was observed. Plasma levels of sPD-1 as well as sPD-L1 at 0 months strongly correlated

with IgM-RF (PD-1: (r2=0.737, p<0.0001) and PD-L1: (r2=0.417, p=0.016)). PD-1 at 0 months additionally correlated with anti-CCP antibodies (r2=0.515, p=0.002). Interestingly, plasma levels of both IL-21 and IL-23 at 0 months correlated with plasma levels of sPD-1 and sPD-L1 at 0 months in early RA (all p<0.05).

Conclusion: The significantly elevated plasma levels of both sPD-1 and sPD-L1 in early RA patients, point to strong activation of antigen presenting cells and T cells in the initial phases of the disease. The fact that we observed association to core disease parameters as well as IgM-RF, anti-CCP antibodies and IL-21 and IL-23, further supports PD-1 pathways involvement in this central mechanism in RA. We believe that decrease in sPD-1 together with the unchanged presence of sPD-L1 in chronic patients compared with early RA supports a shift from T cells to antigen presenting cells as the predominant cell types, involved in perpetuating the inflammation in RA.

Lack of IL-17RA Signaling Prevents Autoimmune Inflammation of the Joint and Give Rise to a Th2-Like Phenotype in Collagen-Induced Arthritis. Anne-Marie Mus, Odilia Corneth, Patrick Asmawidjaja and Erik Lubberts, Erasmus MC. University Medical Center

Introduction: IL-17A plays an important role in collagen-induced arthritis (CIA). On the other hand, CIA developed normally in IL-17F deficient mice. This could be due to IL-17A that is still expressed in these mice. It has been shown that around 20% of the IL-17A deficient mice still develop marked collagen-induced arthritis with a somewhat lower severity that the control littermates. Spontaneous arthritis development in the IL-1Ra deficient mice could not be completely prevented in double IL-17A/IL-17F deficient mice. However, it is still not fully clear how important the role of the IL-17A and IL-17F signaling is in the development of autoimmune collagen-induced arthritis.

Objective: To examine the role of the IL-17RA signaling in the development of CIA.

Methods: Since the IL-17RA deficient (IL-17RA−/−) mice can not signal for IL-17A and IL-17F these mice were used in this study and were compared to control mice and the CIA resistant IL-23p19 deficient (IL-23p19−/−) mice. All mice were immunized intra-dermally with chicken type II collagen (CII) in CFA at days 0 and 21. The arthritis incidence and severity were scored macroscopically. In a set of experiments, mice were given a third CII/CFA injection at day 50. At days 20, 34, and 69 sera was collected for CII-specific IgG's measurements by ELISA. In addititon, at days 10 and 69, splenic $CD4^+$ T cells were isolated and intracellular flow cytometry of different cytokines was performed.

Results: CII-immunized control mice developed CIA from day 24 onwards with an incidence between 40–60%. As expected, the IL-23p19−/− mice did not develop CIA. Interestingly, the IL-17RA−/− mice were completely protected and did not develop CIA even after a third CII/CFA injection. In contrast to the low percentage of IL-17^+ $CD4^+$ T cells in the IL-23p19−/− mice, there was a significant increase in the percentage of these cells in the IL-17RA−/− group compared to the control group at day 69. No significant difference was found in the percentage of IFN-gamma$^+$ $CD4^+$ T cells between all three groups. Interestingly and in contrast to the IL-23p19 knockout mice, the IL-17RA deficient showed a Th2-like phenotype in splenic $CD4^+$ T cells at day 69. No difference was noted for FoxP3 expression in the splenic $CD4^+$ T cells between the three different mouse groups. Moreover, the CII-specific IgG2a levels in the sera of IL-17RA−/− was significantly lower compared to the control group at day 20 and lower although not statistically significant at day 69. At this latter time point, CII-specific IgG1 levels in the sera of IL-17RA−/− was increased although not statistically significant compared to the control.

Discussion: These data revealed a critical role for the IL-17RA signaling in the development of autoimmune inflammation of the joint. Moreover, these data show a Th2-like phenotype in IL-17RA−/− mice immunized with CII, suggesting that IL-17 receptor signaling is involved in the suppression of Th2 cytokines in autoimmune collagen arthritis.

Lower Expression of Fli-1 Leads to Decreased Inflammatory Cell Infiltration in the Kidneys from NZM2410 Mice. Sarah Williams[4], Emmanuel Reyes-Cortes[2], Eva Karam[3], Eiji Suzuki[3], Gary S. Gilkeson[1] and John Zhang[5]. [1]Med Univ of South Carolina, Charleston, SC, [2]Medical University of South Carolina, Charleston, SC, [3]Medical University of South Carolina, [4]Ralph H. Johnson VA Medical Center, Charleston, SC, [5]Ralph H. Johnson VA Medical Center and Medical University of South Carolina, Charleston, SC

Background and Purpose: Fli-1 expression levels, a member of the Ets family of transcription factors, are a mitigating factor in the development of nephritis in murine models of systemic lupus erythematosus (SLE). Lupus nephritis is a major cause of death in both models and human patients, and is characterized by immune complex formation and inflammatory cell infiltration. Overexpression of the Fli-1 protein in transgenic mice resulted in the development of a lupus-like disease with nephritis. Expression of Fli-1 in SLE patients and animal models of lupus is higher compared to normal controls. In this study, we examined the effects of reduced Fli-1 expression on inflammatory cell infiltration in conjunction with nephritis development in NZM2410 mice, an animal model of SLE.

Methods: We generated Fli-1 heterozygous knockout NZM2410 mice ($Fli1^{+/-}$; **Fli-1** homozygous knockout is embryonic lethal) and wild-type (WT) littermate ($Fli1^{+/+}$) mice for use as controls. The expression levels of monocyte chemotactic protein-1 (MCP-1) and Chemokine (C-C motif) ligand 5 (CCL5, also known as RANTES) in the kidneys from 18-week-old mice were analyzed by real-time PCR. Pathological scores of the kidneys from 34-week-old mice were assessed and the number of macrophages, neutrophils, T cells and B cells in the kidneys were stained with specific antibodies and counted in 10 random high power fields (HPF). These numbers were averaged and directly compared between WT and $Fli-1^{+/-}$ NZM2410 mice. The MCP-1 in serum was measured by ELISA.

Results: Since expression of CCL5 and MCP-1 were demonstrated to initiate inflammatory cell infiltration in the kidneys of lupus mice, we first examined the expression of MCP-1 and CCL5 in the kidneys from both $Fli-1^{+/-}$ and WT controls. Expression of MCP-1 and CCL5 in the kidneys from 18-week old $Fli-1^{+/-}$ NZM2410 mice was significantly decreased compared to that from WT littermates. $Fli-1^{+/-}$ NZM2410 mice also had significantly reduced renal pathology scores compared to those from WT littermates (WT mice: 6.846 ± 0.9635; $Fli-1^{+/-}$ mice: 3.882 ± 1.043, $p<0.05$). The number of macrophages, neutrophil granulocytes, T cells and B cells in the kidneys from $Fli-1^{+/-}$ NZM2410 mice decreased by 44 – 75% compared to WT littermate controls. The serum MCP-1 levels in Fli-1+/− NZM2410 mice were significantly lower at the age of 34 weeks compared with WT littermates (WT mice: 118.9 ± 17.7 pg/ml; $Fli-1^{+/-}$ mice: 67.7 ± 7.1 pg/ml, $p< 0.01$).

Conclusion: Our data indicate that lower expression of Fli-1 results in decreased expression of CCL5 and MCP-1 in the kidneys with significantly reduced infiltration of inflammatory cells, which leads to lower overall kidney pathological scores in NZM2410 mice. Therefore, Fli-1 plays an important role in the development of nephritis in NZM2410 mice.

Mechanisms and Clinical Relevance of TRAIL-Triggered Responses in Synovial Fibroblasts of Rheumatoid Arthritis Patients. Rachel Audo[4], Flavia Calmon Hamaty[5], Dominique Baeten[1], Bernard G. Combe[2], Michael Hahne[4] and Jacques Morel[3]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Department of Rheumatology. Teaching Hospital of Lapeyronie, Montpellier, France, [3]Department of Rheumatology. Teaching Hospital of Lapeyronie, Montpellier, France, [4]IGMM, UMR5535, CNRS, Montpellier, Montpellier, France, [5]IGMM, UMR5535, CNRS, Montpellier

Background: Studies in mice suggest a protective role for the TNF-related apoptosis-inducing ligand (TRAIL) in arthritis. We investigated the role of TRAIL in rheumatoid arthritis (RA) patients. We have shown that exposure to TRAIL induces apoptosis only in a portion of RA Fibroblast-Like Synoviocytes (FLS) and that in the surviving cells, TRAIL induced proliferation. In the present study, we compared FLS resistant and RAFLS-sensible to TRAIL-induced apoptosis including levels of the TRAIL receptors

(TRAIL-R) and clinical features of respective patient. Furthermore, we evaluated TRAIL levels in RA patients.

Method: FLS were extracted from synovial tissue of RA patients (n=30) and analyzed by FACS for expression of TRAIL-receptors. We obtained DAS28 within the 3 months of surgery for 13 patients. TRAIL-responses of FLS were analyzed by FACS for apoptosis and thymidine-incorporation for proliferation. TRAIL receptor activity was assessed by RNA silencing. HIC were performed to evaluate TRAIL level in synovial tissues from RA (n=7) and OA patients (n=4). ELISA was used to determine TRAIL-levels in synovial fluid of osteoarthritis (OA; n=20), spondylarthritis (SpA; n=20) and establish RA patients (n=30). Serum levels of TRAIL and its soluble decoy-receptor osteoprotegerin (OPG) were measured by ELISA in 72 patients fulfilling the ACR criteria (1987) with recent (<2 years) and active (>3 swollen joints) RA that were not treated or had a stable background treatment for at least 1 month (M0). 48 of the RA patients were followed up at 6 months (M6).

Results: Depending on the patient, we observed variability in RAFLS sensitivity to TRAIL-induced apoptosis. We therefore classified the cultures depending on their sensitivity (<10%; RAFLS-R, n=10 and >at 30%, RAFLS-S, n=11). Disease activity of RA patients inversely correlated with susceptibility of FLS to TRAIL-induced apoptosis (r=-0.688, p=0.0092, n=13). TRAIL-S cells expressed significantly lower levels of TRAIL-R1 (p=0.014) and silencing of TRAIL-R1 increased TRAIL-induced apoptosis in RA FLS (p<0.05; n=7). TRAIL levels were elevated in the arthritic joints of patients with established RA and synovial fluids displayed elevated TRAIL levels compare to those of OA and SpA patients (p<0.0001 and p=0,002 respectively). In early RA, patients in remission at M6 (DAS28<2.6) (n=14) had a lower ratio OPG/ TRAIL at baseline than patients without remission (n=34) (0.54 ± 0.25 and 0.94 ± 0.71 respectively, p=0.028), but high serum levels of TRAIL at M6 were associated with joint damages (p=0.0063).

Conclusion: Surprisingly, TRAIL-R1 seems to be a survival factor protecting RAFLS against TRAIL-induced apoptosis. Furthermore, we found a negative correlation between TRAIL sensitivity RAFLS in vitro and RA activity, suggesting that RAFLS develop resistance to TRAIL-induced apoptosis to escape TRAIL protective role. Indeed, in early RA patient, a low OPG/TRAIL ratio at baseline was associated with remission at 6 months but persistent TRAIL serum levels are associated with joint damage. These findings suggest a dual role for TRAIL in RA and resistance of RA FLS to TRAIL-induced apoptosis is associated with a disease promoting activity of TRAIL in RA.

Pro-Inflammatory Activity of SIRT1 in Monocytes. Fabienne Niederer[1], Caroline Ospelt[1], Fabia Brentano[1], Beat A. Michel[2], Christoph Kolling[4], Michael O. Hottiger[3], Renate E. Gay[2], Steffen Gay[2] and Diego Kyburz[2]. [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Switzerland, [3]Institute of Veterinary Biochemistry and Molecular Biology, University Zurich, Switzerland, [4]Schulthess Clinic, Zurich, Switzerland

Purpose: Sirtuins are a conserved family of NAD+ dependent histone deacetylases (HDAC) and mono-ADP-ribosyltransferases. The human sirtuins are critical regulators of many cellular processes, including cell survival and inflammation. Here we focused on the expression of SIRT1 in monocytes and tissues from patients with rheumatoid arthritis (RA) and osteoarthritis (OA) and assessed the function of SIRT1 in monocytes.

Methods: To study the expression of SIRT1 in RA and OA tissues, Western blot and immunohistochemistry were performed. Monocytes from peripheral blood were negatively isolated from healthy donors or RA patients using magnetic MicroBeads (MACS separation). Levels of SIRT1 mRNA were measured with SYBR green Real-time PCR. Healthy monocytes were stimulated (n=9) with the Toll-like receptor 4 (TLR4) ligand LPS (10 ng/ml) for 8 hours in the presence or absence of a SIRT1 inhibitor, EX-527 (9 uM). Moreover, freshly isolated monocytes (n=5) were transfected to overexpress a wild type or an enzymatically inactive mutant form of SIRT1 for 18 hours, following LPS-stimulation (10 ng/ml) for 8 hours. The levels of TNF-α protein were measured in the supernatants of stimulated monocytes by ELISA (BD Bioscience).

Results: Performing Western blot analysis of SIRT1 in RA and OA tissues, we found an upregulation of SIRT1 in whole RA tissues. Immunohistochemistry in synovial tissues showed the expression of SIRT1 in monocytes/macrophages. Consistently, levels of SIRT1 mRNA in monocytes from RA patients were expressed at dCt = 7.55 ± 0.31 and in healthy controls at dCt = 8.69 ± 0.72, p=0.12. Treatment of LPS-stimulated monocytes with the SIRT1 inhibitor EX-527 significantly reduced TNF-α production by 37 ± 17% (p<0.01). Monocytes transfected with a vector encoding an enzymatically inactive form of SIRT1 showed a prominent downregulation of TNF-α by 81 ± 21% (p=0.04) compared to wild type SIRT1 transfected cells.

Conclusion: SIRT1 is overexpressed in RA tissues and monocytes. The inhibition of SIRT1 activity significantly reduced the production of TNF-α in monocytes. Thus, SIRT1 appears to contribute to the characteristic inflammatory phenotype of synovial cells in rheumatoid arthritis.

Ras GTPase Homologues Make Redundant Contributions to RA FLS Activation and Broad Silencing of Ras Proteins Decreases Inflammation and Joint Destruction in Experimental Arthritis. Daphne de Launay[1], Jeroen Vreijling[1], Joana Abreu[1], Aleksander Grabiec[1], Marjolein van Maanen[2], Marjolein Sanders[2], Margriet Vervoordeldonk[2], Henrik Oerum[3], Kees Fluiter[1], Paul Peter Tak[1] and Kris Reedquist[1]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands, [2]Academic Medical Center, University of Amsterdam, The Netherlands, [3]Santaris Pharma A/S, Horsholm, Denmark

Changes in expression and activation of Ras proteins are thought to contribute to the pathologic phenotype of stromal fibroblast-like synoviocytes (FLS) in rheumatoid arthritis (RA). Here we examined the expression of each Ras protein in the synovial tissue of RA patients and disease controls, and the contributions of H-, K-, and N-Ras homologues to FLS activation in vitro and experimental arthritis in vivo.

Methods: Synovial Ras homolog expression was determined by immunohistochemistry and digital image analysis in patients with RA (n = 10), inflammatory osteoarthritis (n = 4) and reactive arthritis (n = 7). In a second cohort consisting of patients with RA (n = 20) and psoriatic arthritis (PsA) (n = 19), Ras homolog expression was monitored by immunohistochemistry and mRNA expression. Ras protein and mRNA expression was examined in RA and PsA FLS. The activation status of Ras homolgues in RA FLS following stimulation with TNF and IL-1 was determined by affinity precipitation and immunoblotting. RA FLS were transfected with active mutants of H-, K-, and N-Ras, and Ras protein expression was specifically or broadly silenced using locked nucleic acids (LNA), and effects on basal and IL-1-dependent cytokine and MMP-3 production assessed. The potential therapeutic effects of broad, pan-Ras silencing in murine collagen-induced arthritis (CIA) were examined using pan-Ras and control LNA (1 mg/kg, 3 times weekly ip, 8 mice per group).

Results: Similar levels of each Ras homolog were expressed in RA and disease control synovial tissue, although H-Ras protein and mRNA expression was significantly elevated in RA synovial tissue and FLS compared to PsA. Each Ras protein was also expressed in RA FLS and activated by TNF and IL-1. H-Ras, but not other Ras homolgues, was sufficient and required for spontaneous FLS MMP-3 production ($P < 0.05$), while multiple Ras proteins induced IL-6 and IL-8 induction, and each silencing of each Ras homolog suppressed IL-1-induced IL-6 production ($P < 0.05$). The three Ras homologues also redundantly activated overlapping sets of MAP kinase, NF-kappaB and PI3-kinase intracellular signalling pathway in FLS. In vivo, pan-Ras LNA, which significantly suppressed synovial expression of H- and N-Ras, decreased clinical severity of CIA in mice compared to control LNA ($p< 0.005$), as well as cartilage destruction ($P < 0.05$), bone erosion ($P < 0.05$), and the ratio of anti-collagen IgG2a/IgG1 auto-antibodies ($P < 0.01$).

Conclusions: Overlapping contributions of Ras homologues to global inflammatory parameters of RA FLS activation and pathology in CIA, suggesting a therapeutic potential in broadly, rather than specifically, targeting closely related Ras proteins may be effective in treating RA.

Resveratrol Inhibits TNF-α-Induced MMP-9 Expression through a mTOR Independent Pathway. Xiaoxia Zhu[2], Jianhua Qiu[1] and Hejian Zou[2]. [1]Department of Neurology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, [2]Department of Rheumatology, Huashan Hospital, Fudan University, Shanghai, China

Autoimmune diseases are characterized by progressive inflammation manifested with overexpression of matrix metalloproteinases (MMPs) and pro-inflammatory cytokines such as TNFα, IL-1β. Blockade of TNFα or IL-1β signaling has been successfully applied to clinical therapy of some autoimmune diseases such as rheumatoid arthritis. Resveratrol, a natural phytoalexin, has been shown to have anti-inflammation properties. However, the mechanism is not fully understood. Here, we investigated whether resveratrol attenuates TNFα-induced inflammation and potential mechanism in NIH/3T3 fibroblasts. Upregulation of MMP-9, MMP-13 and IL-1β were observed 6 hours or 24 hours after TNF-α treatment in NIH/3T3 fibroblasts examined by gel zymography and/or quantitative real-time PCR. Increase of phosphorylated Akt, mammalian target of rapamycin (mTOR) and S6 ribosomal protein (S6RP) were also detected in the cells. Nevertheless, Resveratrol suppressed TNFa induced upregulation of MMP-9, MMP-13, IL-1β. Resveratrol also inhibited phosphorylation of Akt, mTOR, S6RP induced by TNFa. However, Rapamycin, a special mTOR inhibitor, failed to attenuate overexpression of MMP-9 induced by TNFa. Our results indicate that resveratrol inhibits TNFα-induced inflammation via a mTOR-indepenent fashion. Resveratrol may be a potential therapeutic candidate for treatment of autoimmune diseases, although its mechanism remains to be further elucidated.

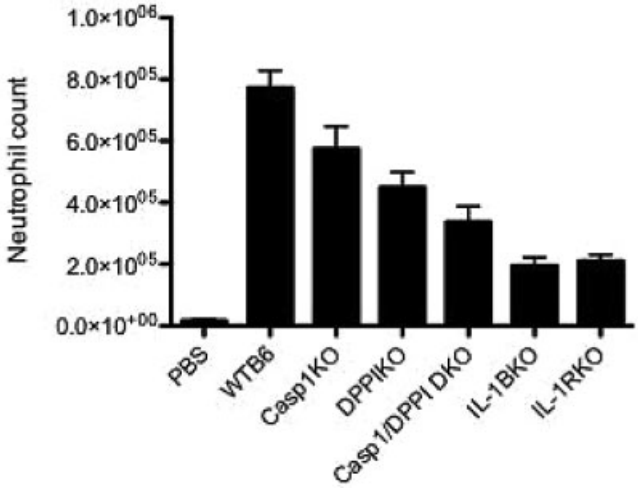
Role of Dipeptidyl Peptidase I (Cathepsin C) in the Maturation of IL-1β In Vivo. Hajime Kono[1], Zubin Patel[2], Tamiko Yanagida[1], Maki Takayama[1] and Kennth Rock[2]. [1]Teikyo University School of Medicine, [2]University of Massachusetts Medical School

Background: IL-1β plays a pivotal role in rheumatic diseases including crystal-induced arthritis, autoinflammatory diseases and rheumatoid arthritis. IL-1β is transcribed as a nonfunctional pro-protein that requires specific cleavage to be converted to a functionally active form. Caspase-1 was identified as an enzyme that plays a dominant role in the maturation of IL-1β. Recent advances revealed that the activity of Caspase-1 is controlled by the formation of supramolecular complex, the inflammasome. In Vitro studies using macrophages or monocytes showed that the maturation of IL-1β in response to monosodium urate, silica or cholesterol crystals totally depends on inflammasome activation. Although we and others showed that the acute neutrophilic inflammatinon to crystals almost entirely depends on IL-1β In Vivo, mice deficient in inflammasome components showed only a modest reduction in these responses. The results thus prompted us to explore the contribution of other enzymes that might generate IL-1β In Vivo. Neutrophil-derived serine proteases (cathepsin G, neutrophil elastase, and proteinase 3) are expressed specifically in mature neutrophils and are thought to play an important role in inflammation and reported to have activity to generate active IL-1β In Vitro. These serine proteases are transcribed as inactive zyomgens and require processing by lysozomal cysteine protease dipeptidyl peptidase I (DPPI, Cathepsin C) to become active. To investigate the role of neutrophil serine proteases in IL-1b dependent acute inflammation In Vivo, we generated the DPPI/Caspase-1 double deficient mice and analyzed the neutrophilic responses to crystals or dead cells.

Materials and Methods: DPPI/Caspase-1 double deficient mice were generated by mating the single deficient mice. Silica crystals (0.125 or 0.5mg) were injected intraperitoneally into these various mice as well as wild type control, IL-1β deficient and IL-1 receptor deficient mice. The neutrophil and monocyte numbers in the peritoneal lavage were quantified by flow cytometry after 4 or 14 hours of injection. One way ANOVA with Dunnett's multiple comparison test was used to compare the groups.

Results: Fourteen hours after injection of silica crystal, the mean total number of neutrophil in the peritoneal cavity were 1.9×10^{-6} (WT), 2.1×10^{-6} (Caspase-1 KO), 1.3×10^{-6} (DPPI KO), 1.0×10^{-6} (DPPI/Caspase-1 DKO), 0.4×10^{-6} (IL-1β KO), 0.3×10^{-6} (IL-1R KO) and 0.0×10^{-6} (PBS injected WT control). The 4 hour result of neutrophil recruitment in response to silica injection was shown in Figure 1.



Conclusion: The data indicate that DPPI plays a role in the crystal induced acute inflammatory responses in addition to Caspase-1. The residual response in DPPI+caspase I-double deficient mice indicates that that there must be additional proteases that contribute to IL-1β maturation In Vivo.

The Expression of the Anti-Apoptotic Transcription Factor NFkappaB-P65 Is Markedly Diminished in Chondrocytes of Murine Osteoarthritic Cartilage and in a Subset of Human Osteoarthritic Cartilage Samples. Fons A. J. van de Loo, Onno J. Arntz, Miranda B. Bennink, Esmeralda Blaney-Davidson, Peter M. van der Kraan and Wim B. van den Berg. Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands

Introduction: Chondrocytes play a central role in cartilage pathology as seen in rheumatoid arthritis (RA) and osteoarthritis (OA) patients by a deranged synthesis of extracellular matrix (ECM) components and the enhanced release of ECM destructive metalloproteinases (MMPs). Nuclear factor-kappaB (NF-kappaB) is an important transcription factor in the regulation of MMPs, but is also regarded as a survival factor in cells. We studied the regulation of NF-kappaB-P65 in chondrocytes in rheumatoid arthritis, osteoarthritis, mouse models of arthritis and osteoarthritis and the functional consequences of decreased level of NFkappaB-P65.

Methods: NF-kappaB-P65 was measured in primary chondrocytes of arthritic cartilage obtained from joint replacement surgery, and in cartilage of a spontaneous osteoarthritis mouse model (STR/ORT), streptococcal cell wall-, antigen-induced arthritis, and of young (14 weeks) and old (>12 months) mice by Western blotting, immunohistochemistry or RT-qPCR. To study the functional consequences of decreased level of NF-kappaB-P65 in chondrocytes the murine H4 chondrocyte-cell line was stably transduced with a lentivirus expressing a short-hairpin RNA against NF-kappaB-P65. To study the biological consequences, conditioned medium of OA synovium was added to the murine H4 chondrocyte cell line with the lowest NF-kappaB-P65 level.

Results: High NF-kappaB-P65 levels were detected by immunohistochemistry and Western blot in chondrocytes of RA patients, whereas in a subset of OA cartilage samples the levels were unexpected low (6 out of 12). In mouse models the level of NF-kappaB-P65 showed the same regulation. NF-kappaB-P65 levels in cartilage from murine arthritis models was increased up to 250% at day 2 after induction of streptococcal cell wall- or antigen-induced arthritis and at day 7 returned to the basal level of naive knee joints, whereas in STR/ORT mice levels were diminished more than 75% when joints became affected, as determined by immunohistochemistry. Levels of NF-kappaB-P65 in young and old mice were equal, but the older groups showed more variation, detected by immunohistochemistry. *In vitro*, we selected chondrocyte cell-lines with different levels of NF-kappaB-P65. By adding TNFalpha, cell death was only induced in the cells with low levels of NF-kappaB-P65, as detected by 7-AAD staining. A clear negative correlation between TNFalpha induced cell death and the levels of NF-kappaB-P65 in chondrocyte cell-lines was found. Adding conditioned me-

dium of synovial explants from different OA patients to the murine chondrocyte cell-line with the lowest NF-kappaB-P65 level, resulted in more than 60% chondrocyte death in 3 of the 5 conditioned medium samples tested which could be prevented by preincubation of these media with soluble-TNFR1 (Enbrel). TNFalpha was detected using a Luminex assay in the same samples that caused cell death.

Conclusions: This study clearly demonstrated that lower levels of NF-kappaB-P65 makes chondrocytes more vulnerable for TNFalpha, a cytokine which can be produced during OA, and that this anti-apoptotic transcription factor is downregulated in chondrocytes in murine OA and in 50% of OA patients.

TLR2 Mediates Acute Serum Amyloid A Induced Pro-Inflammatory Effects in Rheumatoid Arthritis. Mary Connolly[3], Ashwini Maratha[1], Sinead Nic an Ultaigh[3], Sinead Miggin[2], Ursula Fearon[3] and Douglas J. Veale[3]. [1]Institute of Immunology, National University of Ireland Maynooth, Maynooth, Ireland, [2]Institute of Immunology, National University of Ireland Maynooth, [3]Translational Research Group, Dublin Academic Medical Centre, St. Vincents University Hospital., Ireland

Introduction: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterised by progressive joint destruction. Serum amyloid A (A-SAA) is an acute phase protein with cytokine-like properties. Previously we have shown that A-SAA correlates with RA disease activity, is produced at high levels locally in the joint and promotes synovial tissue angiogenesis, migration and MMP production. Recently, A-SAA was identified as a ligand for Toll Like Receptor 2 (TLR2), however no study has examined a role for TLR2 in mediating A-SAA-induced inflammation in RA.

Objective: To examine A-SAA-induced inflammation *via* TLR2 in rheumatoid arthritis

Methods: A-SAA and TLR2 expression in synovial tissue (ST) was examined by immunohistochemistry. Human embryonic kidney (HEK) 293 cells overexpressing TLR2/TLR4 were transfected with the NF-κB luciferase reporter gene plasmid. After 24 hr, cells were stimulated with A-SAA (10 and 50μg/ml), the TLR2 ligand Pam_2CSK_4 or the TLR4 ligand LPS. After 8 hr, ligand-induced reporter gene activity was assessed. Primary fibroblasts (RASFCs) isolated from synovial biopsies obtained at arthroscopy and human microvascular endothelial cells (HMECs) were stimulated with A-SAA (10μg/ml) $\pm$ anti-TLR2 (OPN 301, 1μg/ml). IL-8 was measured by ELISA. Proliferation, invasion and ICAM expression were quantified by crystal violet assay, transwell invasion assays and flow cytometry. Migration and angiogenesis were examined using wound repair and tubule formation assays respectively.

Results: A-SAA and TLR2 expression were observed in the lining layer and perivascular regions of RA synovium. A-SAA induced a 12-fold increase in NF-kB reporter gene activity in HEK293-TLR2 cells ($p<0.05$), an effect greater than that observed with Pam_2CSK/Pam_3CSK. In contrast, A-SAA failed to induce NF-kB reporter gene activity in HEK-TLR4, confirming specificity for TLR2. A-SAA induced IL-8 expression in RASFCs from 2.58$\pm$1.51pg/ml to 3453.19$\pm$1715.33pg/ml, an effect inhibited in the presence of anti-TLR2, where IL-8 levels fell to 1461.15$\pm$819.04pg/ml. A-SAA induced HMEC proliferation by 60.9% ($p<0.001$) which was significantly reduced by 38.2% in the presence of anti-TLR2 ($p<0.05$), similar to RASFCs. A-SAA increased ICAM expression on HDECs and RASFCs by 65.4% and 64.3% respectively, which was dramatically inhibited by 59.8% and 38.8% in the presence of anti-TLR2 ($p<0.05$). Furthermore, A-SAA-induced invasion and wound repair were inhibited by anti-TLR2, with no effect on TNFα-induced events. Finally, A-SAA induced angiogenic tube formation by 31.7%, an effect that was inhibited in the presence of anti-TLR2 by 24.5%.

Conclusion: A-SAA mediates pro-inflammatory events in RA including chemokine induction, adhesion, migration and angiogenesis, *via* TLR2. TLR2 blockade may represent a therapeutic strategy for the treatment of arthritis.

TNF-a and Chemerin Cross-Talk in Rheumatoid Arthritis. M. C. Lebre[2], M. I. Ramos[2], C. Hofstra[3], H. van Eenennaam[3], S. Aarrass[2] and Paul P. Tak[1]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Division of Clinical Immunology & Rheumatology, Academic Medical Center/University of Amsterdam, Amsterdam, The Netherlands, [3]Merck Research Laboratories, Oss, The Netherlands

Background: Rheumatoid arthritis (RA) synovium is characterized by a dense infiltrate, consisting of macrophages, T and B cells, plasma cells and dendritic cells (DC). Inflammatory chemokines present in RA synovium may contribute to the accumulation of these immune cells. We have recently shown that plasmacytoid DC (pDC) are enriched in RA synovial tissue (ST) compared to $CD1c^+$ myeloid DC. In line with these observations, we have shown that chemerin (and its receptor chemR23) expression is upregulated in RA ST compared to non-RA arthritis patients. Moreover, in RA ST ChemR23 was specifically expressed by $CD68^+$ macrophages and pDC, while chemerin expression was confined to endothelial cells (CD31 and vWF positive).

Objective: To investigate the regulation of chemerin expression in an ex-vivo model of human RA.

Methods: Arthroscopic synovial tissue biopsies were obtained from patients with active RA and cultured in medium or in the presence of recombinant (r)-TNF-a or r-chemerin. After 6 days, cell-free supernatants were harvested and the levels of TNF-a or chemerin were analyzed by Luminex or ELISA, respectively. When indicated, anti-chemerin or anti-ChemR23 neutralizing antibodies were added to TNF-a-stimulated cultures.

Summary of the Results: RA synovial biopsies released chemerin spontaneously. Interestingly, TNF-a stimulation induced significantly higher levels of chemerin compared to medium control. In addition, RA synovial biopsies released TNF-a spontaneously and addition of chemerin to the cultures strongly induced TNF-a release, suggesting a vicious cycle. Of importance, spontaneous and TNF-a-induced chemerin could be blocked by the addition of neutralizing antibodies against chemerin or against ChemR23. Moreover, spontaneous TNF-a could also be blocked by the addition of neutralizing antibodies against chemerin.

Conclusion: These findings suggest that elevated levels of chemerin in RA synovial tissue might regulate local TNF-a release and vice-versa in a positive feedback loop. The reciprocal interplay between chemerin and TNF-a is novel and might represent an attractive candidate for future drug development by blocking the chemerin/ChemR23 system to disrupt disease perpetuation.

Toll-Like Receptor 4 Signalling Is Specifically TAK1-Independent in Synovial Fibroblasts. Fons A. J. van de Loo[1], Ben T. van den Brand[1], Shahla Abdollahi-Roodsaz[1], Onno J. Arntz[1], Michael Kracht[2], Jeroen Geurts[1] and Wim B. van den Berg[1]. [1]Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, [2]Rudolf-Buchheim-Institute of Pharmacology, University of Giessen, Hannover, Germany

Introduction: Activated synovial fibroblasts are key players in the pathogenesis of rheumatoid arthritis (RA) by driving inflammation and joint destruction. Numerous molecules including cytokines and toll-like receptor (TLR) ligands induce pro-inflammatory signalling and gene expression through a hierarchical network of kinases. Upstream mitogen-activated protein kinase kinase kinases (MAP3Ks) represent an attractive target for RA treatment. In this study we sought to determine the role of the MAP3K transforming growth factor-β activated kinase1 (TAK1) in cytokine and TLR-mediated signalling.

Methods: TAK1 activity was inhibited using either a small molecule inhibitor or lentivirallyoverexpressed kinase-inactive TAK1-K63W mutant in murine embryonic and human dermal and synovial fibroblasts. Fibroblasts were stimulated with IL-1, TNF, TLR2 or TLR4 agonists and responses were evaluated using transcriptional reporters and analysis of gene expression of collagenases (MMP3,13), cytokines (IL-1β,-6) and chemokines (IL-8, MCP-1).

Results: TAK1 inhibition abrogated cytokine- and TLR-induced activation of NF-κB and *Saa3*-promoter reporters in murine and human dermal fibroblasts. In synovial fibroblasts, TAK1 crucially regulated IL-1 and

TNF-mediated NF-κB, but not *Saa3*-promoter activation.Furthermore, TAK1 was required for inducible mRNA expression of IL-1β, IL-6, IL-8, MMP3 and MMP13, but not MCP-1, in response to IL-1, TNF and TLR2 agonist. Unexpectedly, TLR4-induced NF-κB activation and gene expression was fully TAK1-independent.

Conclusion: In general, TAK1 plays a prominent role in regulation of IL-1- and TNF mediated signalling in fibroblasts. Interestingly, TLR4 signalling is specifically TAK1-independent in synovial fibroblasts. Consequently, therapeutic TAK1 inhibition in arthropaties may not dampen the damage-associated molecular pattern-mediated TLR4 activation of synovial fibroblasts.

Tyrosine Kinase Inhibitors Reduce NMDA Receptor NR1 Expression, Nuclear Translocation and Thermal Hyperalgesia/CentralSensitization in a Rat Arthritis Model. Terry A. McNearney[5], Ying Lu[5], Zaiming Ye[2], Liping Zhang[3], Giulio Taglialatela[5], Todd Pappas[1], Wen-Ru Zhang[5] and Karin N. Westlund[4]. [1]Asuragen, Inc, Austin, TX, [2]MD Anderson Medical Center, Houston, TX, [3]University of Kentucky, Lexington, TX, [4]University of Kentucky, Lexington, KY, [5]University of Texas Medical Branch, Galveston, TX

Objective: This study was designed determine if the central changes of the spinal cord in response to a peripheral inflammatory knee joint arthritis in rats are mediated by non-receptor tyrosine kinase.

Methods: *S*pinal microdialysis administration of non-receptor tyrosine kinase inhibitors was used to measure their impact on secondary thermal hyperalgesia upon application of noxious radiant heat to the ipsilateral footpad in a kaolin and carrageenan (k/c)-induced knee arthritis model. NMDA NR1 cellular expression and nuclear localization by immunocytochemistry and Western blot analysis of the lumbar spinal cord were also measured. Statistics: Student's t-tests and one-way ANOVA Newman Keuls Multiple Comparison tests. A p value <0.05 was considered significant.

Results: Tyrosine kinase inhibitors genistein and lavendustin A, (but not lavendustin B or diadzein) effectively reduced 1) the development of secondary hyperalgesia, 2) the increases in glutamate NMDA receptor subunit NR1 expression in spinal cord that normally ensue 4 hours after intra-articular k/c-induced knee joint inflammation and 3) nuclear translocation of NR1. Genistein or staurosporin also inhibited the upregulation and shift of NMDA NR1 protein staining to the nuclear membrane and nucleus that is notable within 4 hours after treatment of neuroblastoma (SH-SY5Y) cell cultures with glutamate. Nuclear translocation of the NMDA NR1 subunit was also evident with activation of human primary and clonal synoviocytes. Nucleotide sequencing from clonal synoviocyte cDNA confirmed a putative nuclear localization sequence, similar to sequences derived from neuronal cells.

Conclusion: Tyrosine phosphorylation is necessary for spinal cord responses to peripheral inflammation including centrally mediated nociceptive sensitization producing secondary hyperalgesia. Tyrosine phosphorylation is required for NMDA receptor mediated NR1 subunit nuclear translocation, upregulation and perhaps other long term plastic changes. These studies implicate NR1 in direct interactions with the nucleus suggesting a role for NR1 as a fast intracellular mediator.

An Evaluation of Prescription Insurance Coverage Inconsistencies—Prior Authorization Does Not Mean Approval. Dawn C. Crate[2] and Daniel A. Albert[1]. [1]Dartmouth-Hitchcock Med Ctr, Lebanon, NH, [2]Dartmouth-Hitchcock Medical Center

Purpose: To evaluate the medication prior authorization process for rheumatology prescriptions.

Method: Cases were acquired through the prescription insurance coverage prior authorization process in the Rheumatology Section between March 1, 2010 and June 18, 2010. Each case was charted in a table to reflect the length of time it took to receive the outcomes including:

specific medication prior authorization
patient diagnosis
diagnosis as on or off label (using FDA standards)
whether the insurance company requested a peer to peer or step therapy (alternate medication)
number of times insurance company was contacted before outcome was given
outcome and reason for outcome

Results: The Dartmouth-Hitchcock Rheumatology Clinic referred 65 patients for insurance carrier prior authorization between March 1, 2010 and June 18, 2010. This population represents 16% of the total number of patients seen in clinic during that timeframe. The prescription prior authorization process averaged to two hours per patient from initial referral to completion. Time spent per request ranged from twenty minutes to three hours, 100% of the cases needed more than one phone call to determine the outcome,62.5% of the total cases required a peer to peer (medical provider required to contact an insurance company physician), 75% of the cases were approved. Out of the 75% approved, 12.5% were found to not need a prior authorization, 50% of the cases that were approved were denied once the claim was submitted through billing. These cases are now in an appeal process. 37% of the cases were for off label use and out of those 50% were approved then denied when the claim was submitted. Categories of problems include:

1) FDA approved medications not covered
2) Insurance company representative conveyed incorrect information about coverage
3) Approval given then subsequently withdrawn (denied)
4) Medication denied then approved without appeal
5) Insurance company confused about their own appeal process
6) Pharmacy told patient prior approval needed when it wasn't and vice versa.

Conclusion: There is no consistent prescription prior authorization process within the insurance company industry. The lack of standardization creates problems such as an approval is initially granted and then upon review the approved medication coverage is denied. Insurance carriers also may initially approve a medication but then require reauthorization at the time of renewal. Patients are frequently required by the insurance company to trial one or more medications before approval will be given for the prescribed treatment plan.

The current lack of process amongst the insurance company industry for prescription medication prior authorization is time consuming, inefficient and costly for physicians, clinic staff, patients and insurance carriers.

Arthritis Prevalence and Access to Care in Indigenous People: Results of a Population-Based Study. Allen J. Lehman[1], Matthew H. Liang[3], Linda Li[2], John M. Esdaile[2], Catherine L. Backman[5], Phyllis Jorgensen[4], Kim Roberts[4], Linda Lavender[4] and Diane Lacaille[2]. [1]Arthritis Research Centre of Canada, Vancouver, BC, Canada, [2]Arthritis Research Centre of Canada; University of British Columbia, [3]Harvard, Boston, MA, [4]Kwakiutl District Council Health Centre, [5]University of British Columbia, Vancouver, BC, Canada

Purpose: North American Indigenous people are believed to have a high prevalence of arthritis yet limited research has examined the burden of arthritis and access to care. Our objectives were to: 1) identify the prevalence of chronic pain in peripheral joints, neck or back with functional limitations; 2) identify the prevalence of reported diagnoses of arthritis; and, 3) evaluate access to care for arthritis, in three on-reserve Indigenous populations.

Methods: A household survey of all adults living in three on-reserve communities was performed using a community case-finding strategy. Band Council support was provided and public forums were held to obtain community feedback prior to survey. Surveys were administered face-to-face by three trained interviewers residing in the community. The interview administered to each community member asked about chronic pain in the joint, neck, and back, and related functional limitations. Those indicating functional limitations secondary to arthritis/joint problems were then asked

about their access to health care services and barriers to care. Descriptive analyses were conducted.

Results: Of 536 residents of these communities, 402 (75%) completed the initial interview. Participants' mean age was 46 yrs (range=19–93), 52% were female, 61% were married and 23% were never married. Thirty-percent (n=119/402) reported a physician or health professional diagnosis of arthritis (excluding fibromyalgia), with 79 identifying specific type(s), including rheumatoid arthritis (n = 27), hip osteoarthritis (OA; n = 24), knee OA (n = 33), hand OA (n = 25), neck/back arthritis (n = 15), or other (n = 12). In comparison, non-age adjusted prevalence estimates reported in national surveys using the same question was 19% for off-reserve Indigenous People and 16% for non-Indigenous people. Chronic joint, neck, or back pain and functional limitations were reported by 41% (166/402). Of these 166 individuals, 140 reported at least one health care professional visit for their problem: family doctor = 75%; physical therapist = 28%; occupational therapist = 20%; rheumatologist = 16%; traditional healer = 15%; dietician = 13%; counsellor or psychologist = 7%. Assistive devices were used by 39%, and 70% used medications in the past 12 mos. Difficulties obtaining care in the past 12 mos were reported by 28% (n=47/166), such as long wait lists (n = 20), difficult access to rheumatologists (n = 19), poor transportation availability and/or high costs (n =16), lack of awareness of health care professional to see (n = 12), high treatment costs (n = 11), and perceived inadequate or culturally inappropriate health care (n = 10).

Conclusions: The burden of arthritis was high in the three Indigenous communities evaluated. The prevalence of reporting a diagnosis of arthritis exceeded that reported in national surveys for off-reserve Indigenous People and non-Indigenous people; and a large proportion (41%) reported chronic joint, neck or back pain with functional limitations. Along with suboptimal access to care, these findings suggest the need for further research to determine the specific types of arthritis and to identify solutions for improving health equity and access to care.

Aspirin vs. Low Molecular Weight Heparin for Prophylaxis Against Venous Thromboembolism after Total Knee or Hip Replacement in Lower Risk Individuals: A Cost-Utility Analysis. John T. Schousboe[1] and Gregory A. Brown[2]. [1]Park Nicollet Institute, Minneapolis, St Louis Park, MN, [2]Park Nicollet Institute, Minneapolis, MN

Introduction: Venous thromboembolism (VTE) is common following total joint replacement (TJA) surgery, but there is substantial disagreement as to the best way to prevent VTE events. The American Academy of Orthopedic Surgeons guideline recommends aspirin after TJA for patients at average or lower risk of VTE or at high risk of bleeding. The American College of Chest Physicians guideline recommends stronger anticoagulants (adjusted dose warfarin, low molecular weight heparin, or fondiparinux) for VTE prophylaxis after TJA, and specifically recommends against aspirin. Our objective was to estimate the lifetime incremental costs per quality adjusted life year gained for 10 days of low molecular weight heparin (LMWH) vs. aspirin 160 mg daily following joint replacement surgery.

Methods: A Markov cohort model allowing 6 transient events following TJA (deep vein thrombosis, pulmonary embolism, operative site hemorrhage, non-operative site major hemorrhage, intracranial hemorrhage, and thrombocytopenia), and 5 chronic health states (healthy post TJA, post TJA VTE without post-phlebitic syndrome, post TJA VTE with post-phlebitic syndrome, post intracranial hemorrhage, prosthetic joint infection). Costs and loss of quality of life associated with each event and chronic health state were derived from the medical literature. The absolute risks of VTE and bleeding events on LWMH following TJA were derived from a pooled analysis of clinical trials, and the relative risks of VTE and major bleeding on aspirin vs. LMWH were derived from literature estimates of each drug vs placebo. LMWH and aspirin were compared for four sets of individuals; those without any additional risks for VTE (non-obese, no personal or family history of VTE), obese individuals but without additional risk factors, and those with a family history of VTE.

Results: The costs (2008 U.S. $) per QALY gained for LMWH compared to aspirin prophylaxis post TJA for those age 55 to 85 are as follows:

	Scenario		
Age	No Added VTE Risks	Obese (BMI >30 mg/kg^2)	Family History of VTE
55	Aspirin Dominant	$35,762	$1,850
65	$635,488	$31,644	LMWH Dominant
75	$326,842	$31,819	LMWH Dominant
85	$246,044	$27,310	LMWH Dominant

Results were highly sensitive to the relative risks of VTE and major bleeding events on aspirin vs LMWH, modestly sensitive to the risks of and quality of life loss associated with post-phlebitic syndrome.

Conclusion: Aspirin may be a cost-effective reasonable choice for VTE prophylaxis following TJA for those individuals with no additional risk factors for VTE events, based on currently available data. For those with one or more additional VTE risk factor, LMWH is preferred over aspirin. A randomized controlled trial of aspirin vs LMWH post TJA might clarify the relative risks and benefits of these two strategies.

Assessment of the Incremental Cost of Osteoporosis-Related Fractures among Women in a Large U.S. Managed Care Population. Hema Viswanathan[1], Jeffrey White[6], Sally W. Wade[5], Jingbo Yu[3], Jeffrey R. Curtis[4], Bradley Stolshek[2], Claire Merinar[2], Joel Kallich[2], Akhila Balasubramanian[2] and John Adams[2]. [1]Amgen Inc., Thousand Oaks, CA, [2]Amgen Inc., [3]HealthCore, Inc., [4]University of Alabama - Brimingham, Birmingham, AL, [5]Wade Outcomes Research and Consulting, [6]WellPoint, Inc.

Purpose: While incremental or attributable costs of osteoporosis (OP)-related fractures have been reported, data on the economic impact of OP-related fractures in commercial health plan populations are limited. The objective of this study was to quantify the incremental cost of OP-related fractures among women in a large U.S. managed care plan between 2004 and 2008.

Methods: Female patients were identified from a large, commercially-insured population with integrated pharmacy and medical claims. Patients were included if they were age 45 to 64 years, had an OP medication claim between 1/1/2005 and 4/30/2008 (first claim defines index date), and had continuous coverage for 12 months pre-index. Patients were excluded if they had: pre-index Paget's disease or malignant neoplasm, were in a skilled nursing facility, on combination therapy at index, or had a fracture ≤ 6 months post-index. Clinically-diagnosed and coded fractures were identified using published claims criteria; total direct costs were assessed in the 6 months pre- and post-fracture event date. Event dates were assigned to patients with no fracture; propensity score weighting was used to increase comparability of fracture and non-fracture patients. A generalized linear model was used to compare differences in 6 months pre-/post-event cost for patients with fracture and those without fracture. Covariates included demographics, prior fractures, comorbidities, and other potential confounders. Generalized estimating equations methods were used to account for repeated measures.

Results: The study population included 47,650 women (N = 2,461 with fracture) with a mean (± SD) age of 56.4 ± 4.7 years. Mean unadjusted total costs showed minor variation in the 6 months pre-event vs post-event for non-fracture patients. Mean pre-/post-event cost differences were substantially larger for patients with vertebral, hip, or other fractures (Table).

Table. Unadjusted Mean Total Direct Costs Per Patient

	Mean Total Direct Costs Per Patient (95% Confidence Interval) for Patients With:			
	Vertebral Fracture	Hip Fracture	Other Fracture	No Fracture
Number of Patients	214	138	2,109	45,189
6 Months Pre-Event	$12,888 ($8,381, $17,395)	$7,766 ($5,542, $9,989)	$5,195 ($4,751, $5,640)	$3,207 ($3,136, $3,278)
6 Months Post-Event	$27,303 ($21,088, $33,517)	$23,935 ($19,133, $28,737)	$12,218 ($11,185, $13,250)	$3,226 ($3,159, $3,292)
Post-Event Minus Pre-Event (Difference)	$14,415 ($7,559 $21,271)	$16,169 ($11,484, $20,855)	$7,023 ($6,011, $8,034)	$19 ($56, $94)

After adjusting for covariates, OP-related fractures were associated with an estimated $9,512 (95% CI: $8,364, $10,660, $p < 0.0001$) per patient in

additional direct health care costs across all fracture types during the 6 months immediately after the fracture.

Conclusion: On average, women with an OP-related fracture incurred nearly $10,000 in additional health care costs in the 6 months post-fracture compared with patients with no fracture. Efforts to reduce fracture risk may ultimately lower associated direct health care costs.

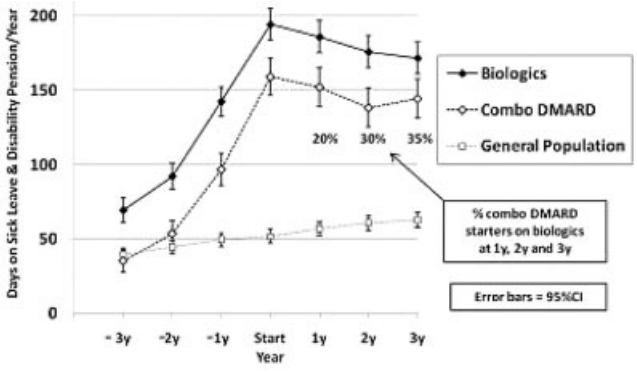
Bending the Cost Curve in Early RA: Sick Leave and Disability Pension before and after Initiation of Biologics or DMARD Combination Therapy. Martin Neovius[1], Julia F. Simard[1], Johan Askling[2] and ARTIS Study Group[3]. [1]Karolinska Institute, Stockholm, Sweden, [2]Karolinska Institute, [3]Sweden

Background: Biologic treatment is effective but expensive. Increased work force participation arguably holds the greatest potential for offsetting some of the treatment cost. It has been speculated that treatment may improve productivity in patients with RA, and early RA in particular, but long-term work ability development in this patient segment in relation to intensified anti-rheumatic treatment is not well-described.

Objective: To estimate the sick leave and disability pension trajectory over seven years in patients with early RA before and after treatment initiation with biologics or combo-DMARDs.

Methods: Patients aged 16–59 years old and a disease duration of less than five years when initiating treatment with biologics or combo-DMARDs (n=860/547; mean age 45y/46y; 76%/73% women; median RA duration 2.2y/1.2y) in 2000–2004 were identified in the Swedish Rheumatology Quality Register. For each RA case, five age-, sex-, education-, and county-matched general population comparators were sampled. Sick leave and disability pension data from 1997 to 2007 were retrieved from national registers.

Results: During the year of treatment initiation, patients selected for biologic therapy had a mean 194 (136+59) days of sick leave and disability pension registered, compared to 159 (133+26) days in patients starting combo-DMARDs, and 52 (20+32) days in matched general population comparators. A rapid increase in annual days of sick leave and disability pension was observed before start of intensive anti-rheumatic therapy, but thereafter the number of days/year decreased for patients who had either initiated biologics or combo-DMARDs. However, the gap compared to the general population remained wide and three years after treatment start patients in the treatment groups had a mean of near or above 150 days of sick leave and disability pension registered annually.



Conclusion: Using seven years of real world data in patients with less than five years RA duration, rapidly increasing productivity losses were observed before initiation of intensive drug treatment. Treatment initiation was associated with a breakpoint in and small reversal of this development, but a large unmet need remained in these patients compared to general population comparators.

Differences in Clinical and Economic Profiles of Rheumatoid Arthritis Patients Using Frequently Dosed Subcutaneous or Less Frequently Dosed Intravenous Biologic Therapy. Chureen T. Carter[1], O. Tunceli[3], Susan C. Bolge[2], Leigh Denny[2], C. Fang[3] and Joseph Singer[3]. [1]Centocor Ortho Biotech Services, LLC, Horsham, PA, [2]Centocor Ortho Biotech Services, LLC, [3]HealthCore, Inc.

Background: Adalimumab (ADA) and etanercept (ETA) are subcutaneously (SC) administered biologics with frequent recommended dosing of every other week or weekly in rheumatoid arthritis (RA), respectively. Abatacept (ABA) and infliximab (IFX) are intravenously (IV) administered biologics with less frequent recommended dosing during the maintenance period of every 4 or 8 weeks, respectively. Due to differences in dosing and routes of administration among therapies, the selection of appropriate treatment becomes multi-factorial. Patient characteristics may influence treatment selection. The purpose of this analysis was to describe the baseline clinical and economic profiles associated with frequently dosed SC and less frequently dosed IV biologic therapies (BIO) initiated in RA patients.

Methods: Commercially-insured patients aged ≥ 18 years at index, with ≥ 2 pre-index ICD-9 diagnosis codes for RA (714.xx), and who had initiated SC (ADA, ETA) or IV (ABA, IFX) BIO between 1/1/2004-10/31/2009 were identified from the HealthCore Integrated Research database. Patients had continuous enrollment 6 months pre-index and 12 months post-index, and did not receive any biologics pre-index. Patients were required to have 1 prescription of SC or IV BIO at index and on or after the 365th follow-up day. Patients with selected inflammatory conditions were excluded. Baseline demographic and clinical characteristics, as well as, pre-index healthcare costs were evaluated by index BIO administration route.

Results: A total of 2,931 RA patients receiving BIO were identified [1,902 initiated SC (ADA n=621, ETA n=1,281) and 1,029 patients initiated IV (ABA n=91, IFX n=938)]. Patients were mostly female in both groups (SC=76%, IV=74%). Patients initiating IV BIO were significantly older than SC patients (59 ± 14 years vs. 50 ± 12 years, $p<0.0001$, respectively). Chronic conditions such as ischemic heart disease, myocardial infarction, hypertension, and chronic obstructive pulmonary disease were significantly more common among IV users ($p<0.0001$ for all comparisons). Patients initiating IV BIO had higher mean pre-index all cause ($1,749 vs. $1,409; $p<0.0001$) and mean pre-index RA-related costs ($1,361 vs. $968; $p<0.0001$) compared to patients initiating SC BIO.

Conclusions: Patient profiles were different for frequently dosed SC and less frequently dosed IV biologic users. Patients receiving IV therapies were generally older, had more selected chronic conditions, and had higher RA-related baseline costs compared to patients receiving SC therapies. Future research of clinical and economic outcomes during treatment with SC or IV biologics in RA should adjust for the different patient types at baseline.

DXA Screening and Use of Osteoporosis Medications in Two Large Regional Healthcare Systems. Amy Warriner[5], Ryan C. Outman[4], Jeffrey R. Curtis[5], Adrian Feldstein[1], Harry Glauber[3], Junling Ren[2], Douglas Roblin[2], Ana Rosales[1], Robert Unitan[3] and Kenneth G. Saag[7]. [1]Kaiser Permanente Center for Health Research, Portland, OR, [2]Kaiser Permanente Center for Health Research, Atlanta, GA, [3]Kaiser Permanente Northwest, [4]Univ of Alabama at Birmingham, Birmingham, AL, [5]Univ of Alabama at Birmingham, Birmingham, AL

Statement of Purpose: To compare the effect of a patient panel-support tool (PST) vs. standard of care on dual energy x-ray absorptiometry (DXA) screening in two large healthcare systems. Despite U.S. guideline recommendations for all women 65 years and older to have a screening bone density scan with central DXA, less than one-third of eligible U.S. women have undergone DXA testing.

Methods: We evaluated DXA receipt and use of prescription osteoporosis medications among women aged 65–90 in two large healthcare systems. Women were eligible for inclusion in the analysis if they had at least 24 months of enrollment at Kaiser Permanente Georgia (KPGA) or Northwest (KPNW). Primary outcomes included a DXA scan in the past 5 years and use of osteoporosis medications in the past year. The analysis included data

obtained in 6 month intervals from January 2005 through July 2009. From this data, we examined the effect of a PST (KPNW) vs. standard of care (KPGA). The PST uses EMR data to graphically display "care gaps" for each patient, based on current evidence. Through this mechanism, primary care physicians within the KPNW system are alerted to order a DXA in patients without a DXA in the previous 5 years (start date February 26, 2007).

Summary of Results: The number of women undergoing screening DXA increased significantly in the KPNW group with the proportion increasing from 25.3% in January 2005 to 58.7% in July 2009 (Risk Difference {RD} 33.3%, 95% CI 32.5 – 34.1%). This differs from KPGA, in which minimal change in DXA scan use occurred between January 2005 and July 2009, 43.1% and 45.3%, respectively (RD 2.2%, 95% CI 0.6–3.9%). The majority of the increased DXA use was seen following the implementation of the PST, Figure 1.

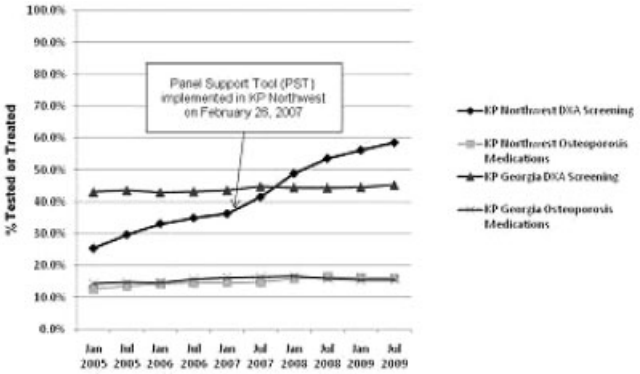

Figure 1. Percentage of women aged 65–90 receiving DXA screening or prescription of osteoporosis medications in 2005–2009 in KP Northwest and KP Georgia.

However, the number of women taking an osteoporosis medication did not increase significantly over the 5 year period in either region, +3.4% in KPNW and +1.3% in KPGA.

Conclusions: Among older women, DXA testing increased incrementally over the past 3 years in the KPNW healthcare system, following the implementation of a PST. However, despite the increased screening, the use of osteoporosis-specific medications for fracture risk reduction did not increase significantly. In a similar healthplan that did not implement such a program, the rates of DXA testing remained relatively flat. Further randomized studies are needed to confirm effectiveness of methods to improve appropriate DXA utilization.

Erectile Dysfunction Is Associated with Gout in the Campaign Against Cancer and Heart Disease (CLUE II). Janet W. Maynard, Mara A. McAdams, Alan N. Baer, Judith Hoffman-Bolton, Allan C. Gelber and Josef Coresh. Johns Hopkins

Purpose: Erectile dysfunction (ED) is related to a variety of chronic medical conditions, including hypertension, obesity, and cardiovascular disease. We sought to identify whether gout was associated with ED independent of risk factors for cardiovascular disease in a community-based setting.

Methods: The CLUE II cohort consists of individuals, aged 13 to 87 years, who resided within or surrounding Washington County, Maryland. All participants received follow-up questionnaires (1996, 1998, 2000, 2003, and 2007). At baseline in 1989, participants were asked to self-report gender, race, age, and height. On the 2007 follow-up questionnaire, participants self-reported weight and a physician or health professional diagnosis of gout, ED, diabetes, and hypertension. This study was restricted to CLUE II participants who responded to the 2007 questionnaire (7,142) and were male. We assessed whether having gout was associated with ED. The distributions of variables among the men with gout versus those who did not have gout were compared using chi-squared or t-tests, as appropriate. We assessed the relationship between gout and ED with odds ratios from logistic regression.

Results: Of the 2,605 male participants responding to the 2007 questionnaire, 256 (9.8%) had gout and 779 (29.9%) had ED. A significantly greater proportion of participants with gout had ED (102, 39.8%) compared to participants without gout (677, 28.8%), $p<0.001$. The mean age of participants with gout was significantly greater than those without gout (68.7±11.3 years vs. 65.0 ±12.3 years, $p<0.001$). A significantly greater proportion of participants with gout were obese (BMI ≥ 30 kg/m^2) (47.9%) compared to those without gout (32.1%), $p<0.001$. Similarly, a significantly greater portion of participants with gout were hypertensive (72.0%) compared to those without gout (47.8%), $p<0.001$. A greater proportion of gout participants were diabetic (15.2%) than participants without gout (8.6%), $p<0.001$. There was a statistically significant association between gout and ED, even after adjustment for age (Table). However, this association was not observed after adjustment for hypertension, obesity, and diabetes.

Table. Association between Gout and Erectile Dysfunction.

	ED and Gout OR (95% CI)
Model 1: Unadjusted	**1.64 (1.25, 2.13)**
Model 2: Age	**1.38 (1.05, 1.83)**
Model 3: Model 2 + hypertension	1.24 (0.94, 1.64)
Model 4: Model 3 + obesity	1.19 (0.90, 1.59)
Model 5: Model 4 + diabetes	1.15 (0.85, 1.53)

Significant values ($p<0.05$) are **bold**.
Abbreviations: OR (odds ratio), CI (confidence interval)

Conclusion: In a community-based cohort we found that men with gout are more likely to have ED than men without gout, even after adjustment for age. However, this relationship may be mediated by obesity, diabetes, and hypertension, which are known risk factors for ED. Potential causal mechanisms need to be investigated, but even in their absence, the association suggests that physicians should explore this common treatable condition with their gout patients.

Floor and Ceiling Effects and Choice of Physical Function Instruments. Eswar Krishnan[3], Bharathi Lingala[4], Bonnie Bruce[1] and James F. Fries[2]. [1]Stanford Dept of Medicine, Palo Alto, CA, [2]Stanford Univ Medical Ctr, Palo Alto, CA, [3]Stanford University, Palo Alto, CA, [4]Stanford University

Background: The spectrum of physical function ranges from high-level nursing home to long-distance runner, and improvement anywhere along this continuum represents an improvement in health. Yet, our measurement tools, from the SF-36 and the HAQ to the IRT-based new PROMIS tools, do not contain floor items sufficiently basic to assess low levels of function nor sufficiently difficult ceiling items to test function above the average. In many populations more than half may be beneath the floor or above the ceiling. As a result, instrument performance might suffer at population extremes, leading to much larger sample size requirements. We sought to estimate the size of this effect and to suggest remedies

Methods: We initially performed a simulation study that estimated the sample size requirements of an IRT-calibrated 8 item questionnaire at 3 separate settings: general population, and populations where physical function was 1 standard deviation worse and 1 standard deviation better than general population. Based on the results we performed a prospective observational study of 451 patients with RA (rheumatid arthritis). Mean 12-month score changes (Δ) in Physical function short form (PF10), PF-10 improved using IRT techniques, and PROMIS PF short form were measured and used to compute sample size needed for a 2.5% change with 80% power at a p value of 0.05.

Results: Whereas 50 patients were needed for detecting a change at 80% among those with physical function worse than general population (typical of patient populations) the corresponding sample size needs in the general population setting was 140. In samples of individuals with physical function 1 standard deviation superior to general population,(positive health), the sample size need was 325. In the empirical study the median sample size needs for those with no measurable disability at baseline (HAQ-DI =0), and those at progressively higher baseline disability categories (0.01<HAQ-DI≤1.50; and HAQ-DI ≥1.6) the median estimated sample sizes were 146, 228 and 284 respectively.

Conclusion: Our data document the profound deterioration in instrument performance when the function of the study population does not match the coverage range of the items used. We did not have sufficient items addressing the floors of physical function to enable precise estimation of change, even in the PROMIS PF 154 item bank. Traditional power calculations in such instances will over-estimate power, and power should be separated estimated in upper, middle, and higher ranges of severity as well as overall. The immediate need is extension of item bank content toward the extremes and validation of new items against populations with matching levels of impairment. This can lead to development of new short-forms appropriate to the population studied. The extended item banks become large in size, and this in turn argues for early transition to a Computerized Adaptive Testing (CAT) environment to reduce questionnaire burden while extending sensitive measurement across the range.

Fragility Fractures in Brazilian Community-Dwelling Elderly: Prevalence and Risk Factors. Jaqueline B. Lopes, Camille P. Figueiredo, Liliam Takayama, Valeria F. Caparbo and Rosa M. R. Pereira. Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo

Purpose: Estimate the prevalence of fragility fractures and investigate factors associated with this condition in Brazilian community-dwelling elderly.

Methods: 1075 elderly subjects (659 women/416 men) from São Paulo, Brazil were evaluated using specific questionnaire including risk factors for osteoporotic fractures. Fragility fractures were defined as those resulting of a fall from standing height or less after 50 years of age at sites characteristic of bone fragility. Traumatic fractures and those occurring at the face, skull, ankle, elbow and finger were not considered. Anthropometric data was obtained by physical examination and body mass index (BMI) was calculated. Bone mineral density (BMD) was measured by DXA in hip and lumbar spine. Laboratory tests were also determined.

Results: The prevalence of fragility fractures was of 11.9% (127) and the main fracture sites were forearm (50.4%), humerus (19.7%), femur (11.2%) and ribs (8.7%). Women had higher prevalence (15.3%; 95%CI 12.6–18.1) than men (6.5%; 95%CI 4.1–8.9) (P<0.001). In women, the main factors associated with fractures were Caucasian race (OR=1.7; 95%CI 1.1–2.8; P=0.027), BMI (OR=0.9; 95%CI 0.89–0.98; P=0.002) and femoral neck T-score (OR=0.7; 95%CI 0.5–0.9; P<0.001). After adjustment for these significant variables, the logistic-regression analyses revealed that Caucasian race (OR=1.7, 95%CI 1.03–2.7 P=0.038) and femoral neck T-score (OR=0.7, 95%CI 0.51–0.86; P=0.002) remains a significant factor for fragility fractures in women. In men, the main factors associated with fragility fractures were current smoking (OR=3.2; 95% CI 1.4–7.6; P=0.007), diabetes mellitus (OR=3.1; 95%CI 1.3–7.1; P=0.008), chronic faller (OR=2.9; 95%CI 1.1–7.6; P=0.033) and femoral neck T-score (OR=0.4, 95%CI 0.2–0.6; P<0.001). The logistic-regression analyses revealed that current smoking (OR=2.5, 95% CI 1.2–6.2; P=0.048), diabetes mellitus (OR=4.5; 95%CI 1.8–11.1; P=0.001) and femoral neck T-score (OR=0.4, 95%CI 0.2–0.6; P<0.001) were independent factors in predicting fragility fractures in men.

Conclusions: Our results suggest that fragility fractures are common in Brazilian community-dwelling elderly, and a low hip BMD was an important risk factor for this condition in both genders. In men, diabetes and smoking are also related to this complication. The identification of these factors may improve the prediction of fracture risk and enhance the evaluation of patients with osteoporosis.

Higher Serum Urate Levels Correlate with Increased Prevalence of Comorbidities in the US General Population: NHANES 1999–2008. Yanyan Zhu[1], Bhavik Pandya[2] and Hyon Choi[1]. [1]Boston University of School of Medicine, Boston, MA, [2]Takeda Pharmaceuticals International, Inc, Deerfield, IL

Objective: To estimate the prevalence of major comorbidities according to individuals' serum urate (sUA) levels based on a recent, nationally representative sample of US men and women regardless of whether or not they had gout.

Methods: Using the National Health and Nutrition Examination Survey (NHANES) 1999–2008 data from 24,693 participants (11,816 men and 12,877 women) aged 20 years and older, we determined the prevalence of major comorbidities according to individuals' sUA levels, including hypertension, diabetes, myocardial infarction, heart failure, stroke, renal impairment, and obesity, regardless of whether or not they had gout. Obesity was defined as body mass index ≥30 kg/m^2. Comorbidities were defined based on an affirmative answer to a question asking if a physician or other health professional had diagnosed the corresponding condition.

Results: The prevalence of major comorbidities correlated with an increase in sUA levels. Among individuals with sUA levels ≥10 mg/dL, 66% had hypertension, 32% diabetes, 23% history of myocardial infarction, 33% history of heart failure, 12% history of stroke, 18% renal impairment, and 65% obesity (Table).

Table. Prevalence of Comorbidities According to sUA Level Categories in NHANES 1999–2008

	Prevalence, % (95% Confidence Interval) Serum Urate Levels (mg/dL)						
Cormorbidities	**<4.0**	**4.0–5.9**	**6.0–6.9**	**7.0–7.9**	**8.0–8.9**	**9.0–9.9**	**≥10.0**
Hypertension	16.9 (14.9–18.8)	26.6 (25.4–27.7)	34.4 (32.2–36.5)	41.4 (38.6–44.1)	50.0 (44.2–55.7)	67.2 (59.3–75.2)	66.0 (52.6–79.4)
Renal Impairment	1.3 (0.8–1.8)	1.8 (1.5–2.0)	2.4 (1.8–2.9)	2.3 (1.6–2.9)	5.1 (3.8–6.5)	9.2 (3.0–15.5)	17.7 (8.9–26.6)
Diabetes	6.1 (5.1–7.2)	7.2 (6.6–7.8)	8.1 (7.1–9.0)	8.4 (6.8–10.1)	11.6 (8.4–14.9)	23.4 (14.8–31.9)	32.4 (19.4–45.4)
Myocardial Infarction	1.7 (1–2.4	2.8 (2.5–3.2)	3.8 (2.9–4.7)	5.9 (4.6–7.1)	7.8 (5.9–9.7)	16.1 (9.6–22.5)	23.1 (14.3–31.9)
Heart Failure	1.0 (0.6–1.4)	1.7 (1.4–2.0)	2.5 (2.0–3.1)	4.4 (3.3–5.5)	6.4 (4.5–8.2)	13.4 (7.8–18.9)	32.9 (20.2–45.6)
Stroke	1.8 (1.2–2.4)	2.5 (2.1–2.9)	2.4 (2.0–2.9)	4.4 (3.2–5.6)	4.6 (2.8–6.4)	11.8 (7.3–16.4)	11.7 (5.0–18.4)
Obesity	16.9 (15.2–18.6)	29.2 (27.9–30.5)	41.2 (38.9–43.5)	46.3 (43.3–49.4)	52.9 (48.7–57.0)	56.6 (48.1–65.2)	65.3 (53.6–77)

Conclusions: These findings from the latest nationally representative sample of US adults indicate that the prevalence of comorbidities proportionally increases with increasing levels of serum urate.

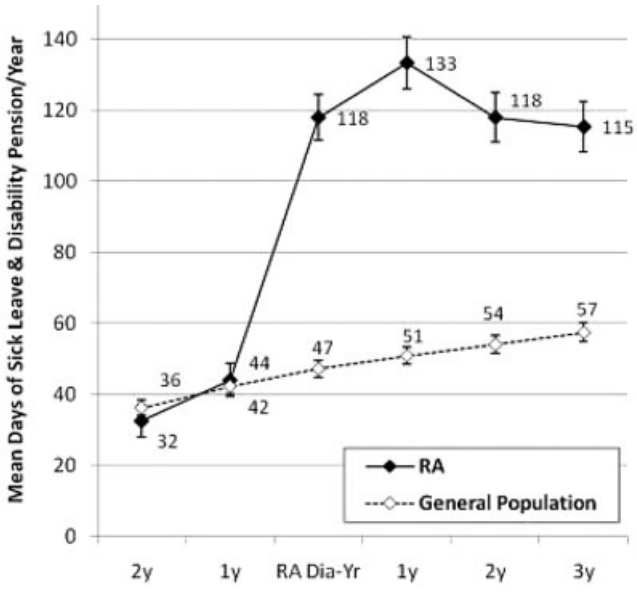
How Large Are the Productivity Losses in Contemporary Patients with RA, and How Soon in Relation to Diagnosis Do They Develop? A Six-Year Nationwide Cohort Study. Martin Neovius[1], Julia F. Simard[1], Johan Askling[2] and ARTIS Study Group[3]. [1]Karolinska Institute, Stockholm, Sweden, [2]Karolinska Institute, [3]Sweden

Background: Marked changes in the therapeutic approaches to early RA have taken place the last decade. Whether the increasing treatment intensity and number of treatment options have led to improvements in work ability is unclear. Furthermore, nationwide assessments of the societal burden due to reduced work ability in contemporary patients with RA are lacking.

Objective: To estimate the sick leave and disability pension trajectory in patients diagnosed with early RA 1999–2007, and productivity losses in prevalent patients with RA in 2007.

Methods: Patients of working age diagnosed with early RA in 1999–2007 were identified in the Swedish Rheumatology Quality Register (early RA cohort: n=3,084; mean age 46y; 73% women). Additionally, prevalent patients on Jan 1, 2008, were identified in the National Patient Register and the Swedish Rheumatology Quality Register (prevalent RA cohort: n=25,934; mean age 52y; 73% women). For each patient with RA, five age-, sex-, education-, county-, and time period-matched general population comparators were sampled. Sick leave and disability pension days were retrieved from national registers for 1997 to 2007.

Results: In the early RA cohort, sick leave and disability pension increased from a mean 44 to 118 days/year (mean difference 74, 95%CI 69–79) from the year before to the year of RA diagnosis. A further increase to 133 days/year (mean difference 15, 95%CI 11–20) was observed the following year, followed by a rebound to 118 and 115 days/year the subsequent two years. During the three years following RA diagnosis, sick leave halved from a mean 103 to 51 days/year while disability pension doubled from 30 to 64 days/year.



In the prevalent RA cohort, patients had a mean 158 (31+126) days of sick leave and disability pension compared to 71 (15+56) in comparators in 2007 (mean difference 87, 95%CI 84–90). Large variations existed across age, sex and education level, but RA cases had consistently greater productivity losses. The annual costs associated with sick leave and disability pension were $24,000 per patient with $13,000 attributable to RA.

Conclusion: Despite better drugs and improved treatment strategies, data from contemporary patients with early and established RA indicate large unmet needs.

Incidental Capture of Chikungunya Associated Chronic Rheumatism along with Other Rheumatic Musculoskeletal Disorders in a Rural Community in South India: A BJD India WHO COPCORD (Community Oriented Program for Control of Rheumatic Diseases) Project.

Ashish J. Mathew[3], Vinay Goyal[2], Elizabeth George[2], Dany Varughese[2], Jacob Antony[2] and Arvind Chopra[1]. [1]BJD India Co-ordinator, Pune, India, [2]The Trivandrum COPCORD Study Group, [3]The Trivandrum COPCORD Study Group, Medical College Hospital and Health Action by People, Trivandrum, India.

Background: Chikungunya (CHIKV) is a predominantly self limiting, severely painful, febrile, arboviral, musculoskeletal illness. Although post CHIKV chronic rheumatism is reported in <10% cases, prospective community data is sparse. In 2007, Kerala (a south Indian state) witnessed an unprecedented CHIKV epidemic. We present the burden of chronic rheumatic musculoskeletal disorders (RMSD) following the epidemic, captured inadvertently during a rural community survey (25 miles from Trivandrum, the state capital) in 2008.

Method: An updated COPCORD Bhigwan (India) model (Chopra. J Rheumatol 2009; 36:614-22) questionnaires were used in a house-house survey to identify painful RMSD (last seven days) in a randomized population of 5133 adults. Respondents recorded pain sites on a human mannequin. Rheumatology physicians evaluated all cases. Diagnosis was clinical but often guided by the ACR criteria. We relied on typical narration, records and serology to classify CHIKV. A validated modified Indian Health Assessment Questionnaire (HAQ) - (Chopra. J Rheumatol 2000; 27:1365-72) was used to evaluate functional disability. Moderate and severe grades were considered significant.

Results: Painful RMSD, the predominant self-reported ailment, was present in 30% of the community (Mean age of 53.24±15.3 years, 72% women). Common pain sites were knees (83.5%), elbows (36%), low back (31.1%) and shoulders (29.5%). Cases were broadly classified as ill-defined aches (28%), soft tissue rheumatism (21%), degenerative joint disease (20%), post-infectious arthropathy (19%), inflammatory arthritis (4%) and miscellaneous (8%). The crude point prevalence rates of RMSD are shown below.

Table 1. Crude prevalence rates of RMSD in each group

Diagnoses	Prevalence (%)	95% CI (%)
Soft tissue rheumatism	**10.13**	**9.3–10.96**
• Periarthritis shoulder	2.16	1.83–2.49
• Plantar fasciitis	1.56	1.28–1.84
• Fibromyalgia	1.29	1.03–1.55
Degenerative arthropathy	**9.72**	**8.91–10.53**
• Knee OA	5.77	5.23–6.31
• Nodular OA	1.85	1.54–2.16
Infection related arthropathy	**9.16**	**8.37–9.95**
• Post CHIK polyarthralgias	5.73	5.2–6.26
• Post CHIK reactive arthritis	2.45	2.1–2.8
• Post CHIK tenosynovitis	0.95	0.73–1.17
Inflammatory arthritis	**1.79**	**1.43–2.15**
• Rheumatoid arthritis	0.51	0.35–0.67
• SSA	0.58	0.41–0.75

CHIKV related RMSD was classified in 14% cases, of which 283 (Mean age: 45.64±11.37 years, 76% women) were naive for RMSD prior to the epidemic. Polyarticular onset (OR −4.35; 95% CI 2.77–6.83), wrist pain at onset (OR −4.23; 95% CI 2.62–6.45) and female sex (OR −2.747; 95% CI 1.76–4.28) were predictors of chronic rheumatism in this group. Similar to Bhigwan COPCORD the prevalence of RA and SSA was conspicuous. Significant HAQDI was scored by 17% respondents. Difficulty in the HAQ items of walking, squatting and sitting cross-legged corresponded with the dominant pain sites in knees and lower back. In the age group 25–54 years, 9% had ceased work due to RMSD.

Conclusion: Though ill defined rheumatism remained the dominant category in this rural community, a wide spectrum of RMSD was observed. Such has been the conclusion of several COPCORD surveys. In the current study, CHIKV enhanced the community burden of RMSD. A long term follow up is warranted to study the future impact.

Mortality Outcomes amongst Patients with Rheumatiod Arthritis with and without Joint Surgery: A Comparative Study.

Courtney A. Shourt[1], Cynthia S. Crowson[2], Sherine E. Gabriel[3] and Eric L. Matteson[4]. [1]Department of Medicine, Mayo Clinic College of Medicine, [2]Division of Biostatistics, Department of Health Sciences Research, Mayo Clinic College of Medicine, [3]Division of Epidemiology, Department of Health Science Research, and Division of Rheumatology, Mayo Clinic College of Medicine, [4]Division of Rheumatology, Mayo Clinic College of Medicine

Objective: To examine the association between joint surgery and mortality in patients with rheumatoid arthritis (RA).

Methods: A retrospective medical record review was performed of all cases of adult onset RA incident from a defined geographic population base who fulfilled criteria for RA in 1980–2007. The arthritis related surgeries included in the study were primary total joint arthroplasty (TJA), joint reconstructive procedures (JRP), soft tissue procedures (STP) and revision arthroplasty. Cox models with time-dependent covariates for surgery occurring during follow-up were used to examine the influence of surgery on mortality.

Results: The study included 814 RA patients (mean age: 56 years; 68% female) with mean follow-up of 9.6 years, during which 204 died. A total of 190 patients underwent ≥1 surgical procedures involving joints during follow-up. The presence of any joint surgery was significantly associated with mortality (hazard ratio [HR]: 1.4; 95 % confidence interval [CI]:1.01, 1.96; $p = 0.04$) compared to patients not requiring joint surgery. This association was more pronounced among patients with JRP (HR: 2.77; 95% CI: 1.85, 4.14; $p < 0.001$). Following additional adjustment for risk factors known to be associated with mortality in RA patients (age, sex, calendar year, body mass index, smoking, rheumatoid factor positivity, severe extra-articular manifestations, comorbidities [cardiovascular disease, renal disease, liver disease, dementia, cancer, alcohol abuse] and use of glucocorticoids), the mortality risk associated with any joint surgery was somewhat attenuated

(HR: 1.37; 95% CI: 0.96, 1.97; p=0.08), but the association with JRP persisted (HR: 2.86; 95% CI: 1.89; 4.33; p<0.001).

Conclusion: Overall, there were significant differences in survivorship in patients with RA undergoing joint surgeries compared to patients who did not require joint surgery, especially among patients with JRP. This association persisted following adjustment for known risk factors for mortality possibly indicating a higher disease burden in these patients.

Disclosure: C. A. Shourt: None; **C. S. Crowson:** None; **S. E. Gabriel:** None; **E. L. Matteson:** None.

1551

Oral Tobacco Use Is Significantly Associated with Rheumatic Musculoskeletal (RMSK) Pain: Result of a WHO ILAR COPCORD (Community Oriented Program for Control of Rheumatic Diseases) Rural Population Study in India. Arvind Chopra[1], Sarika Chaturvedi[4], Manjit Saluja[2], Vaijayanti Lagoo Joshi[2] and Sanjiv Sarmukadam[3]. [1]Center for Rheumatic Diseases, Pune, India, [2]Center for Rheumatic Diseases, [3]Center for Rheumatic Diseses, [4]FRCH, Pune, India

Tobacco is a risk factor for RA and osteoporosis but its role in RMSK pain is not reported. Oral tobacco is a popular custom in India with alleged benefits of enabling work (or? bearing pain) in a socioeconomically challenged scenario.

We reported significant oral tobacco use in patients with RMSK pain from 4000 village Bhigwan (South Pune) COPCORD survey (Chopral.J Rheumatol 2002; 29: 614). In 2004, we completed 8000 urban population COPCORD survey in Pune (West India) and though there were urban rural differences (Joshi, Chopra. J Rheumatol 2009; 36: 614), oral tobacco use remained significant (OR 1.78, 95% CI 1.30, 2.4: not published). In 2008, we completed another 4775 non-random population ((90% response, 95% Hindu Maharashtarian ethnic) survey in village Ralegan Sidhi (East Pune) using Bhigwan model. Surveys were cross sectional and populatons matched well with Indian census 2001.Phase I Ralegan data analysis results are presented.

Methods: The methodology of COPCORD Bhigwan has been published (see above ref). The screening question was "Have you suffered from pain/swelling/stiffness in the joints or musculoskeletal soft tissues within the last seven days (considered current) or sometime in the past (last 3 months)?" Respondents marked pain sites on a human mannequin. All evaluations were carried out free of cost. Data was entered in MS Excel format and analyzed using statistical package(SPSS). 11 of the 19 variables from phase 1 database were selected in a step wise procedure for logistic regression analysis; RMSK (past or current) was the dependent variable. Variables discarded in the final run were *marital status, *literacy (read and write), alcohol use, *combined farm and house work, *vehicle accident, *sprain, *fracture and *sprain/fracture; *found significant in univariate analysis.

Results: 1513 population (32%) reported RMSK pain; women preponderant(2:1). In 85% cases, pain lasted > 4 weeks at multiple sites (>3). 37% men and 32% women used oral tobacco (rubbed tobacco powder on teeth and gums at least twice daily) and recalled several years of prior use. 49.8% cases recorded tobacco use (p<0.05). Table shows OR.

Risk factor	Odds ratio	95% Confidence Interval	
		Lower limit	Upper limit
Age	Coefficient = 0.0351, Coeff/SE = 14.8		
Sex (female)	1.54	1.27	1.87
Diet (Non-vegetarian)	0.741	0.643	0.855
Religion (Hindu)	1.70	1.20	2.41
Attended school	0.704	0.601	0.825
Oral Tobacco Use (past/current)	1.28	1.09	1.49
Farming	1.20	1.01	1.41
Household work	2.01	1.66	2.43
Intense Labour	1.40	1.20	1.64
Accident, any type	4.55	3.60	5.75
Agriculture related trauma	1.59	0.947	2.67

Increasing age, female gender, oral tobacco use, working in farms, house hold work, intense labor (as perceived by the subject) and accident of any type were significantly associated with RMSK pain. Non- vegetarian diet and school education (irrespective of years) seems to provide protection. Additional work in the fields besides house hold chores did not increase the risk.

Conclusion: In this rural COPCORD, oral tobacco use was a significant risk factor for RMSK pain. This validates our earlier conclusion from previous urban and rural COPCORD in the Pune region. Not surprisingly, history of accident trauma was a significant risk factor in the current report. Tobacco and trauma have important preventive bearing in public health, more so in developing economies.

Osteoporosis Medication Adherence and Fracture Risk among Women in a Large U.S. Health Plan. Hema Viswanathan[1], Sally W. Wade[5], Jeffrey R. Curtis[4], Jingbo Yu[3], Jeffrey White[6], Bradley Stolshek[2], Claire Merinar[2], Akhila Balasubramanian[2], Joel Kallich[2] and John Adams[2]. [1]Amgen Inc., Thousand Oaks, CA, [2]Amgen Inc., [3]HealthCore, Inc., [4]University of Alabama at Birmingham, [5]Wade Outcomes Research and Consulting, [6]WellPoint, Inc.

Purpose: Osteoporosis (OP) poses a significant economic and clinical burden. Low adherence may mitigate treatment efficacy, including fracture risk reduction. This study examined the association between OP medication adherence during the first year on therapy and subsequent fracture risk using recent data from a commercially insured population.

Methods: Female patients were identified from a large, commercially insured U.S. population with integrated pharmacy and medical claims. Patients were included if they were ≥ age 45, new to OP therapy (no OP medication claims in prior year) with first (index) OP medication claim between 1/1/2005 and 4/30/2008, and had continuous coverage for ≥ 12 months pre- and post-index. Patients were excluded if they had: pre-index Paget's disease or malignant neoplasm, or were in a skilled nursing facility, or on multiple OP medications at index. Clinically-diagnosed and coded fractures were identified using published claims criteria. Patients who had a fracture in the first year on therapy were excluded. This ensured that the time periods for assessing exposure (medication) and outcome (fracture) did not overlap. Logistic regression was used to assess the association between the medication possession ratio (MPR: < 0.5, 0.5 to 0.8, > 0.8) during the 12 months post-index and fracture risk thereafter in bisphosphonate users. Covariates included baseline demographic and clinical characteristics including comorbidities and prior fracture.

Results: The analysis included 35,958 patients who were new to OP therapy, had a mean age (± SD) of 59.4 ± 9.2 years (range: 45 to 102 years), and had a mean post-index follow up of 834.3 days. At index, 99.6% of patients used a bisphosphonate. Over 12 months post-index, the mean MPR was 0.57 (95% CI: 0.57, 0.58). Mean 12-month MPR was lower among patients with fracture (N = 1,006) compared with those without fracture (N = 34,952; 0.54 vs 0.57, respectively; $p < 0.001$). Patients were clustered at the upper and lower ends of the MPR range. In multivariate modeling, bisphosphonate users with a MPR > 0.8 (N = 12,318) over 12 months had a 18% lower risk of subsequent fracture compared with those with a MPR < 0.5 (N = 13,878), even after controlling for demographic characteristics, insurance type, prior fracture, select comorbidities, and other potential confounders ($p = 0.007$; Table).

Table. Adjusted Fracture Risk by Level of Adherence Among Female Bisphosphonate Users*

Medication Possession Ratio (MPR)	Number of Patients	Odds Ratio for Fracture	95% Confidence Interval	*p*-value
<0.5	13,878	Reference	NA	NA
0.5 to 0.8	5,233	0.805	0.668, 0.971	0.023
>0.8	12,318	0.822	0.713, 0.947	0.007

* Adjusted for demographic characteristics, insurance type, prior fracture, select comorbidities, and other potential confounders

Conclusion: In this study, female patients in a large, commercial health plan had a mean 12-month MPR of 0.57 for OP medications. Women with low adherence (MPR < 0.5) experienced an increased fracture risk even after controlling for a large number of fracture-related covariates.

Patient Age, Ethnicity and Wait Times Determine the Likelihood of Non-Attendance at a First Specialist Rheumatology Assessment. Valerie Milne[2], Robin Kearns[1] and Andrew A. Harrison[2]. [1]University of Auckland, New Zealand, New Zealand, [2]University of Otago, Wellington, New Zealand, New Zealand

Purpose: Failure to attend first specialist assessment in rheumatology clinics not only results in lost opportunities for early diagnosis and treatment with DMARDs but also wastes health resources. Long wait times and deprivation have been linked with non-attendance at outpatient appointments [1,2]. This study aims to identify factors that predict non-attendance at rheumatology FSA with a view to optimising use of resources and patient outcomes.

Method: Administrative data for 1,953 new referrals over a 2-year period were collected from a public rheumatology unit that provides rheumatology services for three New Zealand health boards. Bivariate odds ratios were generated to test the association between attendance and geographic, demographic and clinic referral variables. Variables that were significant at the 0.05 level were included in linear regression models that tested their association with wait times.

Results: Referral appointments were completed for 87 percent of patients. Of the uncompleted referrals, 6 percent cancelled in advance and 7 percent failed to attend without prior warning. Patient age ($p<0.001$) and ethnicity ($p=0.002$) predicted failure to attend. New Zealand Maori (OR 0.74, CI –0.97) and Pacific Island (OR 0.72, CI 0.54–0.95) patients were less likely to attend their FSA than New Zealand Europeans, and patients in the 20–29 age group were less likely to attend than 40–49 year olds (OR 0.55 CI 0.41–0.74). Gender was not a significant factor in attendance.

Likelihood of failing to attend was also associated with longer wait times ($p=<0.002$). However, although age and ethnicity affected attendance, wait times were independent of these factors, with referral location and clinic location being significant predictors of long wait times ($p<=0.001$). Patients referred from locations near to the hub of the rheumatology service had shorter mean wait times than those living further away. Patients referred from the health board providing the service were significantly more likely to have a shorter wait to the FSA than patients from within the other two health boards (OR 0.56 CI 95% O.51–0.61 and OR 0.40 CI 0.34–0.47).

Conclusion: In this study age, ethnicity, wait times and location of services were important predictors of non-attendance at FSA. Attendance rates could potentially be improved by focussing clerical resources on at-risk demographic groups and by restructuring the clinical service to reduce wait times and geographic barriers. This could result in more efficient use of clinic resources and more timely intervention in inflammatory arthritis.

Predictors of Vitamin D Deficiency among Veterans. Joshua Baker[3], Alexis Ogdie[3], Li yun Zhang[2], Jan Dinella[4], H. Ralph Schumacher[5] and Sally W. Pullman-Mooar[1]. [1]Philadelphia, PA, [2]Second Hospital of Shanxi Medical University, China, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Pennsylvania, [5]VA Medical Center - 151K, Philadelphia, PA

Introduction: Due to a number of factors, vitamin D deficiency is increasingly recognized as highly prevalent in many populations and of increasing concern among rheumatologists due to its noted effects on bone, immunity, and cardiovascular health. It remains unclear which patients are highest risk for vitamin D deficiency.

Methods: 4076 patients with vitamin D levels performed at our VA Medical Center were extracted within a 24-month period, between 2007 and 2008, from the electronic medical record. Diagnosis codes and other demographic data were also extracted. A predictive model was created using multivariable logistic regression analysis with vitamin D deficiency (<20 ng/mL) as the outcome.

Results: Patients with vitamin D deficiency were more likely to be younger, black, female, had higher pain scores on VAS scales, and had a greater number of diagnoses including diabetes, obesity, stroke, and renal disease. The lowest levels of vitamin D were founds in patients with CKD, diabetes, degenerative disc disease, and stroke. The 7 patients with calcium pyrophosphate deposition disease (CPPD) had the lowest levels of vitamin D of all diagnoses evaluated. In multivariable logistic regression, the strongest independent predictors of deficiency were younger age, black race, winter month, elevated systolic blood pressure, obesity, and a history of stroke, renal disease, and diabetes. Interestingly, patients with osteoporosis, RA, and SLE had significantly increased levels of vitamin D compared to other groups, possibly secondary to supplementation practices within those groups. These findings were similar when a cutoff of <30 ng/mL was used (not shown).

Conclusions: Our results suggest that, among veterans, increased attention should be paid to the risk of vitamin D deficiency in patients who are black, obese, and have multiple co-morbidities, including a history of hypertension, renal disease, stroke, and diabetes. Further study in patients with CPPD disease is indicated. Our limitations include indication bias and lack of data on supplementation.

Projecting the Effects of a 5-Point Reduction in Body Mass Index on Knee or Hip Osteoarthritis and Health-Related Quality of Life in a Closed Population to 2031: A Microsimulation Study. Eric C. Sayre[1], Jacek A. Kopec[4], Behnam Sharif[4], William M. Flanagan[3], Philippe Fines[3], Mushfiqur Rahman[5], Michal Abrahamowicz[2], David Buckeridge[2], Sam Harper[2], John Lynch[7], Douglas Manuel[6], Jillian Oderkirk[3] and Michael Wolfson[6]. [1]Arthritis Research Centre of Canada, Vancouver, BC, Canada, [2]McGill University, Canada, [3]Statistics Canada, Canada, [4]University of British Columbia, Canada, [5]University of British Columbia, Canada [6]University of Ottawa, Canada, [7]University of South Australia, Canada

Purpose: Body mass index (BMI) is a risk factor for knee or hip osteoarthritis (OA). Obesity (BMI>=30) increased from 10 to 15% in Canada between 1990 and 2000. BMI reduction is expected to reduce OA and improve health-related quality of life (HRQoL). The purpose of this study is to project in a national cohort the effect of a risk-targeted 5-point reduction in BMI on OA and HRQoL between 2001 and 2031.

Method: We used the Population Health Model (POHEM) platform to develop a stochastic continuous-time microsimulation model of physician-diagnosed OA. Incidence rates were calibrated to agree with administrative data for British Columbia, Canada. Projected upward trends in BMI under the base case (no intervention), the effect of obesity on OA incidence and the impact of OA on HRQoL were modeled using Canadian national surveys and

hospital data. The effect of BMI on OA was fit categorically: underweight (<18.5), normal (<25.0), overweight (<30.0) and obese (>=30.0). A closed population weighted for 2001 Canada that reflected projected mortality was followed in POHEM to 2031, aged 20+. BMI was reduced by 0 or 5 points in 2001 in persons with BMI>=25. Outcomes included OA prevalence and incidence (per 1000 person years), average Health Utilities Index Mark 3 (HUI), and health-adjusted life years (HALE). Monte Carlo error was estimated via subsamples. HRQoL models included BMI only indirectly through rates of OA.

Results: There were 22,483,400 in-scope subjects in the simulated population in 2001, 14,317,129 in 2031. Average age in 2001 is 45.89 (95% Monte Carlo CI=45.79, 45.99), in 2031 is 67.43 (67.37, 67.50). In 2001, average BMI is 25.55 (25.53, 25.58), OA incidence 7.42 (7.35, 7.49), OA prevalence 12.23% (12.00, 12.46), average HUI 0.874 (0.872, 0.875), proportion obese 14.99% (14.77, 15.20) and proportion overweight 33.66% (33.38, 33.94).

Under the base case, in 2031, average BMI is 27.79 (27.75, 27.82), OA incidence 21.03 (20.89, 21.16), OA prevalence 33.11% (32.98, 33.25), average HUI 0.752 (0.750, 0.753), proportion obese 26.82% (26.6, 27.04) and proportion overweight 37.15% (36.97, 37.33), with the rest normal or underweight. HALE for 20 year-olds is 27.06 (26.92, 27.21), for 40 year-olds 24.71 (24.61, 24.80) and for 60 year-olds 16.94 (16.81, 17.07).

With a 5-point targeted reduction in BMI, in 2031, average BMI is 25.56 (25.53, 25.58), OA incidence 19.29 (19.16, 19.42), OA prevalence 30.69% (30.55, 30.82), average HUI 0.756 (0.754, 0.758), proportion obese 11.57% (11.4, 11.74) and proportion overweight 38.19% (38.01, 38.36). HALE for 20 year-olds is 27.14 (26.99, 27.28), for 40 year-olds 24.81 (24.72, 24.91) and for 60 year-olds 17.00 (16.87, 17.12).

Conclusion: Reducing at-risk BMI by 5 points in 2001 would lead to a moderate reduction in OA (1.74 incidence and 2.42% prevalence) by 2031, but only very small improvements in HRQoL attributable to rates of OA. (Lowering BMI will have additional direct benefits on HRQoL.) Monte Carlo error was small, but future studies should incorporate additional error such as around parameter estimates. Future studies should vary BMI reduction and the target group, and simulate open populations including births and immigration.

Racial Differences in Gout Risk and Uric Acid Levels in Both Men and Women in the Atherosclerosis Risk in Communities (ARIC) Study. Janet W. Maynard, Mara A. McAdams, Alan N. Baer, Allan C. Gelber and Josef Coresh. Johns Hopkins

Purpose: Gout is a common form of inflammatory arthritis; yet, few studies have evaluated the relationship between race and gout in both women and men. We evaluated the association of race with gout and uric acid levels in the Atherosclerosis Risk in Communities (ARIC) Study, a large population-based and racially-diverse cohort.

Methods: ARIC is a population-based cohort study of 15,792 individuals (55% women) recruited in 1987–1989. Our study population consisted of African-American and Caucasian men and women with and without gout. A participant was considered to have gout if 1 or more of the following criteria were met: a) gout was self-reported, b) surveillance of hospital discharge summaries revealed an ICD-9 code for gout (274.0, 274.1, 274.8, or 274.9), or c) the participant reported use of a medication taken primarily to treat gout (allopurinol, colchicine, or probenecid) at any study visit. The distributions of baseline variables among the men with gout versus those without gout were compared using chi-squared or t-tests, as appropriate. We stratified by gender and used multivariate logistic regression to model the association of race and prevalent gout. The multivariate models included baseline age, BMI, protein, organ meat, shellfish, and alcohol intake, hypertension, antihypertensive medication use, income, education, tobacco use, diabetes, and renal function. Lastly, we generated a multivariate model with the previously mentioned confounders and uric acid.

Results: 399 women (4.6%) and 702 men (9.9%) had gout in the ARIC cohort. In both men and women, a significantly higher proportion of African-Americans had gout ($p<0.001$). After stratifying by gender, the mean serum uric acid level was higher in African-Americans compared to Caucasians ($p<0.001$ in women and men). The mean difference in uric acid levels for African-Americans versus Caucasians was 0.57 mg/dL (0.50, 0.64) in women and 0.31 mg/dL (0.22, 0.40) in men. African-American race was associated with an increased risk of gout even after adjusting for known confounders in both men and women (Table). However, after further adjustment for uric acid levels at baseline, the effect was not statistically significant.

Table. Association of Race with Gout in the Atherosclerosis Risk in Communities (ARIC) Study.

	Caucasians	African-Americans
Women		
Gout cases, n (%)	203 (3.4)	196 (7.4)
Uric acid level (mg/dL) (mean ± SD)	5.3 ± 1.4	5.9 ± 1.5
Age-adjusted OR (95% CI)	1.00 (Ref)	2.42 (1.97, 2.96)
Multivariate OR (95% CI)	1.00 (Ref)	1.57 (1.17, 2.10)
Multivariate Model including uric acid OR (95% CI)	1.00 (Ref)	1.34 (0.99, 1.80)
Men		
Gout cases, n (%)	490 (9.0)	212 (13.0)
Uric acid level (mg/dL) (mean ± SD)	6.7 ± 1.3	7.0 ± 1.6
Age-adjusted OR (95% CI)	1.00 (Ref)	1.55 (1.31, 1.85)
Multivariate OR (95% CI)	1.00 (Ref)	1.42 (1.12, 1.79)
Multivariate Model including uric acid OR (95% CI)	1.00 (Ref)	0.99 (0.77, 1.27)

Key: OR=odds ratio; CI=confidence interval

Conclusions: African-American race is associated with a greater than 50% increase risk of gout in both men and women, even after adjustment for known confounders. This suggests that above and beyond differential prevalence of medical comorbidities, including hypertension, race increases gout risk. This increased gout risk may be mediated by higher uric acid levels in African-Americans compared to Caucasians.

Racial/Ethnic and Sex Differences in Somatosensory Abnormalities in Subjects with or at High Risk of Knee Osteoarthritis: Preliminary Analysis of the Multicenter Osteoarthritis (MOST) Study. Jasvinder Singh[2], Niu Jingbo[5], Laura Freylaw[9], Joachim Scholz[6], Lars Arendt-Nielsen[1], Cora E. Lewis[8], Clifford Woolf[6], Larry Bradley[8], David T. Felson[4], Michael C. Nevitt[7], Irina Tolstykh[7] and Tuhina Neogi[3]. [1]Aalborg University, Aalborg, Denmark, [2]Birmingham VA Medical Center and University of Alabama, Birmingham, Minneapolis, MN, [3]Boston Univ Schl of Med, Boston, MA, [4]Boston University School of Medicine, Boston, MA, [5]Boston University School of Medicine, [6]Childrens Hospital and Harvard School of Medicine, [7]UCSF, San Francisco, CA, [8]University of Alabama, Birmingham, [9]University of Iowa

Objective: There may be racial/ethnic and sex differences in the pain experience of knee OA, which may be reflected in differences in somatosensory evaluations. Our objective was to assess differences in somatosensory findings between Caucasians and African-Americans (AA), and between men and women.

Methods: MOST is a cohort study of persons aged 50–79 years of age, with or at high risk of knee OA. At the 60-month clinic visit, participants underwent knee radiography, answered pain questionnaires, and had the following somatosensory assessments: static allodynia using a 26g monofilament, and hyperalgesia using a pin. Temporal summation (TS), an augmented pain response to repetitive mechanical stimuli thought to reflect central sensitization, was also assessed. These assessments were carried out separately over each patella and wrist. An abnormal response to 26g or pinprick was defined as the participant experiencing pain or a non-response on 3 out of 4 trials, respectively. TS was defined as being present when, after touching the skin with a 60g monofilament repeatedly at a frequency of 1Hz for 30 seconds, the subject reported increased pain or new pain at the site being tested. Univariate and multivariate-adjusted prevalences (age, BMI, clinic and race and sex, as applicable) of the somatosensory tests were obtained for each site and summated as being present overall at any site, stratified by race/ethnicity and gender.

Results: Of the 770 with somatosensory data, there were 652 Caucasians (438 women, 214 men) and 118 AAs (73 women, 45 men). Mean age, BMI and K-L grade was similar for all groups (Table 1).

Table 1. Clinical and demographic characteristics of study cohort

		University of Alabama (n = 371)			University of Iowa (n = 399)	
All subjects	White men (N = 125)	White women (N = 128)	Black men (N = 45)	Black women (N = 73)	White men (N = 89)	White women (N = 310)
Age, mean (SD), year	65.9 (8.3)	68.1 (7.2)	62.8 (7.0)	65.2 (8.0)	71.2 (7.9)	68.1 (7.9)
BMI, mean (SD), kg/m^2	30.8 (5.3)	28.5 (5.4)	31.3 (6.0)	32.6 (5.8)	30.3 (5.8)	30.2 (6.3)
K-L grade N (%)						
0–1	68 (54%)	57 (45%)	21 (47%)	26 (36%)	43 (48%)	159 (52%)
2	14 (11%)	28 (22%)	6 (13%)	15 (21%)	16 (18%)	68 (22%)
3–4	43 (34%)	43 (34%)	18 (40%)	32 (44%)	30 (34%)	82 (27%)

Adjusted prevalence of static allodynia with 26g was higher in African-American women and almost achieved statistical significance (p=0.06) (Table 2). Adjusted prevalences of the pin-prick and temporal summation somatosensory evaluations were not significantly different among the sex and racial groups.

Table 2. Age, BMI- and clinic-adjusted prevalence rates (95% CI) of pain and Temporal summation (*any site,* person-based)

	White men		White women		Black men		Black women		
	Prev (%)	95% CI	Prev (%)	95% CI	Prev (%)	95% CI	Prev (%)	95% CI	p-value
26 g[a]	3.3	1.6	5.2	3, 7	4.9	−3, 12	14.4	6.23	0.06
Pinprick	6.6	3, 10	7.5	5, 10	9.6	−1, 20	9	1, 17	0.91
Temporal summation	62.7	56, 69	57.7	53, 62	66.5	54, 79	64.6	54, 75	0.45

[a] Model was adjusted for sex, race, BMI and clinic site; additional adjustment for age not done since model became unstable and age was not significant for this test.
P-value is from an Analysis of variance

Adjustment for presence/absence of osteoarthritis did not impact the results for the pinprick and temporal summation tests; however this model did not converge for static allodynia for 26g.

Conclusions: African-Americans and women had greater prevalence of somatosensory abnormalities compared with Caucasians and men, but most of these differences were not statistically significant. This preliminary study is the first to demonstrate racial/ethnic difference in response to the 26g von Frey hair stimulus in patients with knee OA. Further exploration regarding factors that may contribute to such differences is warranted.

Relationship between Physical Activity and Health-Related Utility in Knee Osteoarthritis Patients. Larry Manheim[2], Jing Song[2], Rowland W. Chang[1] and Dorothy D. Dunlop[3]. [1]Northwestern Univ, Chicago, IL, [2]Northwestern University, [3]Northwestern University Medical School, Chicago, IL

Purpose: Cost Effectiveness analysis relies on health utility measurement to evaluate the relative effectiveness of many interventions. We examine the relationship between health-related utility and physical activity levels in persons with Knee Osteoarthritis (KOA), to address the following questions: 1) do individuals who meet Center for Disease Control (CDC) recommended levels of physical activity have higher levels of health-related utility? 2) is it necessary to meet CDC guidelines to have higher utility levels or is utility positively related to physical activity at more modest levels of physical activity?

Methods: This study uses baseline data from 143 subjects with radiographic knee OA (KL grade ≥2) enrolled in the IMPAACT study, a randomized controlled trial to evaluate a tailored physical activity intervention. The SF-36 health-related quality of life measure was used to derive the SF6-D utility measure over the follow-up period (3, 6 and 12 months) which yields values between zero (death) and one (perfect health). Baseline physical activity was assessed by accelerometers worn over one week. Each person completed a set of baseline questionnaires, used to measure subject demographics, comorbidities (based on reported medication use), BMI, disability level, and level of pain. The relationship of physical activity to subsequent health utility over one year was assessed using multiple regression with general estimating equations (GEE) multiple regression.

Results: Health-related utility was significantly higher for persons who met CDC guidelines (≥ 150 minutes of moderate/vigorous activity per week in bouts lasting more than 10 minutes), relative to those who were inactive. However, only 11% of individuals meet guidelines and 40% of the sample had no bouts of moderate/vigorous activity. We therefore asked whether higher levels of any intensity activity (as measured by accelerometer counts) were positively associated with higher utility. We found that even moving above the lowest quartile of accelerometer counts to the next quartile was associated with a significant increase in utility of.051 points (p=.025), after controlling for K-L grade, pain, number of comorbidities present, level of disability, and demographics. Among these other factors only level of pain remains a significant predictor of utility level when all variables are included in the regression.

Table. Partial Association of Physical Activity with Utility after controlling for Disease Severity, Pain, Comorbidities, Disability, Intervention, Demographics

Level of Physical Activity	Average Utility (Adjusted)	Partial Coefficient (Adjusted)	Significance Level
Lowest Quartile	0.765	reference group	
Lower Middle Quartile	0.816	+.051	p = .025
Higher Middle Quartile	0.838	+.073	p = .001
Highest Quartile	0.845	+.080	p = .003

Conclusion: Higher levels of physical activity at baseline were related to higher subsequent levels of health-related utility in KOA. This result holds for those meeting CDC guidelines. Importantly even persons not meeting guidelines but doing some activity had better utility that persons in the bottom activity quartile (largely inactive) Thus, even modest increases in physical activity levels may provide a significant improvement in health utility.

Reporting of the Recruitment Process in Randomized Clinical Trials of Biological Agents for the Treatment of Rheumatoid Arthritis. Ismail Simsek and Yusuf Yazici. NYU Hospital for Joint Diseases

Purpose: Before using the results of a randomized controlled trial (RCT) for treating an individual patient, a clinician must determine whether the patient differs from those who participated in the trial in a meaningful way. Therefore it is important to evaluate how the RCT sample was assembled from the general patient population. The trial recruitment process can be described with qualitative and quantitative data, both of which can contribute important information about the generalizability/external validity. The adequacy of reporting in RCTs has received increased attention and culminated in the publication of guidelines such as CONSORT. We tried to assess the adequacy of reporting of the recruitment process and quantify the levels of RA patients participating in RCTs of biological agents.

Methods: PubMed was searched for all reports of RCTs involving etanercept, infliximab, adalimumab, golimumab, certolizumab, abatacept and rituximab in RA patients in the English language published before 12/31/2009. Extension studies, interim analysis, and secondary analysis of previously published data were excluded as were phase I and phase II trials. Data recorded were: (1) eligibility fraction (proportion eligible of those screened), (2) enrolment fraction (proportion randomized of those eligible), (3) recruitment fraction (proportion of potential participants actually randomized), and (4) number of patients needed to be screened (NNS) in order to randomize one participant.

Results: A total of 45 RCTs were identified. Seventeen (37%) reported the number of patients who were evaluated by the investigators for eligibility, 14 (31%) reported the number eligible for participation, and all reported the actual number recruited. Only 9 (20%) of the RCTs reported recruitment process completely. Of the studies that reported quantitative recruitment information, the median eligibility fraction was 81% (IQR 71% to 91%), and the median enrolment fraction was 99% (IQR 82.25% to 100%). The median NNS was 1.23 (IQR 1.16 to 1.42), with most trials reportedly recruiting every patient screened for eligibility. We found no associations between provision of sufficient recruitment data and funding source, publication year, and the journal where the article was published.

Conclusions: A substantial majority of RCTs did not provide sufficient information about the patient recruitment process which makes assessments of external validity difficult. Furthermore, the rate of reporting of the recruitment process in this study was found to be lower as compared to similar studies conducted in different specialties or disease settings. Our finding of low NNS levels also suggests that once screened for eligibility patients are likely to be randomized. However, this finding needs to be treated with caution as it may actually present inadequate reporting of the eligible population

Rheumatologists Practise Evidence Based Medicine, an Observational Study. Stephen Hall[1], Adam Moreton[4], Kathryn A. Gibson[2], Barry A. Kane[2], Vivek Thakkar[2], J. Hanrahan[1], Evange Romas[1], Timothy Godfrey[1], Marie Feletar[1], Alexander Stockman[1], Jennifer Harmer[1], Rani Axtens[1], Peter Ryan[1], Andrew Gibson[1], Christopher Mack[1], Robert J. Moots[3] and Geraldine Hassett[2]. [1]Department of Medicine, Cabrini Health, Melbourne, Australia, [2]Rheumatology Department, Liverpool Hospital, Sydney Australia, [3]School of Clinical Sciences, University of Liverpool, Liverpool United Kingdom, Liverpool, United Kingdom, [4]School of Clinical Sciences, University of Liverpool, Liverpool United Kingdom

Background: Evidence-based medicine (EBM) is used to inform treatment guidelines and in decision-making about funding for medicines and procedures. The extent to which evidence exists and EBM is employed in clinical rheumatology practice is unclear.

Objectives: To assess the extent to which rheumatologists in office practice follow EBM in their treatment recommendations.

Methods: The medical records of 190 patients attending rheumatology clinics with participating physicians (Liverpool Hospital, Sydney, Australia, private practices in Melbourne, Australia and University Hospital Aintree, Liverpool, UK) on or after 2nd July 2007 were reviewed and interventions were identified for each diagnosis made. A standardized search protocol was utilized to identify randomized controlled trials (RCT) in Medline (1950– present) and EMBASE (1980–present) supporting these interventions. In addition the Cochrane Database of Systematic Reviews was searched. Where there was no RCT evidence to support a treatment recommendation a subsequent adjudication process was undertaken to assess if the recommendation was supported by expert opinion.

Results: A total of 332 interventions were recommended. This generated 251 literature searches. Approximately 50% of interventions in clinical rheumatology were supported by EBM. The adjudication process supported 64% of non EBM based recommendations. Only 20% of interventions were neither supported by EBM or at adjudication. This occurred more often for soft tissue and non-inflammatory conditions compared to inflammatory conditions and osteoporosis. Adherence to EBM was similar in the private and public sector in Australia and across the public sectors of Australia and the United Kingdom.

Conclusion: Approximately 50% of rheumatology practice is supported by RCT data. Where RCT data does not exist, expert opinion supports 64 % of the recommended interventions, thus only 20% of all interventions in rheumatology office practice lack evidence. The extent to which evidence exists varies across the rheumatic diseases. There is no difference in the rate of EBM across the public and private sectors of rheumatology.

Screening and Treatment of Glucocorticoid Induced Osteoporosis in a Large U.S. National Pharmacy Database. Ryan C. Outman[2], Nathan J. Markward[1], Mona Khalid[1], Ronald E. Aubert[1], Jeffrey R. Curtis[2], Robert S. Epstein[1], Felix W. Frueh[1], Eric J. Stanek[1], Amy Steinkellner[1], Amy H. Warriner[2] and Kenneth G. Saag[2]. [1]Medco Health Solutions, Inc., [2]Univ of Alabama at Birmingham, Birmingham, AL

Statement of Purpose: Despite a significant associated fracture risk, previous population-based studies document low screening and treatment rates for individuals with glucocorticoid(GC)-induced osteoporosis (GIOP). Using data from a national pharmacy benefit manager, we evaluated the influence of physician specialty on the rates and predictors of bone mineral density (BMD) measurement and anti-osteoporotic prescriptions among patients who received 90 or more days of GC therapy between January 2004 and December 2006.

Methods: Using integrated medical and pharmacy data, we identified GC users and the physician that most frequently prescribed the GC prescriptions. In the 12 months following the 90 days of GC exposure, we also identified the presence of BMD tests and prescription medications commonly used to prevent or treat GIOP, including GIOP-specific therapies and hormone replacement therapy. BMD tests and GIOP prescription medications did not have to be ordered by the GC prescribing physician in order to be credited as having been done. Multivariable logistic regression was employed to examine the influence of physician specialty on BMD testing and GIOP prescribing patterns.

Summary of Results: 106,310 chronic GC users treated by 53,766 physicians were identified during the data extraction process and followed for 12 months after satisfying the 90-day exposure threshold. The mean age of the sample was 61 (SD = 18) years, and 59% were female. In the 12 months prior to satisfying the 90-day exposure threshold, GC-associated conditions and their relative frequencies included rheumatoid arthritis (6%), systemic lupus erythematosus (<1%), chronic obstructive pulmonary disease (5%), asthma (3%), and inflammatory bowel disease (<1%).

During the 12 month follow-up period, overall rates of BMD testing and any GIOP prescription medication were 4.6% and 23.5%, respectively. GIOP prescription medication use was 11.4% among women < 50, 32.3% among women 50–70, and 42.1% among women >70. BMD testing and GIOP medication use were significantly greater among women ≥ 50 (6.4 and 36.8%) compared to men (3.5% and 14.7%, $p < 0.001$) and women <50 (3.6% and 11.4%, $p < 0.001$).

After adjusting for patient age, gender, and GC-related baseline covariates, BMD testing was found to differ significantly by specialty of GC prescriber (internal medicine referent): endocrinology [OR = 1.61 (1.28–2.03)], gastroenterology [OR = 1.52 (1.27–1.81)], nephrology [OR = 1.78 (1.48–2.15)], and rheumatology [OR = 1.38 (1.26–1.51)]. GIOP medication use also differed by specialty (internal medicine referent): other [OR = 0.78 (0.75, 0.82)]; endocrinology [OR = 0.73 (0.64, 0.85)], gastroenterology [OR = 1.15 (1.05, 1.27)], nephrology [OR = 1.37 (1.23, 1.51)], pulmonology [OR = 1.34 (1.25, 1.45)], and rheumatology [OR = 1.59 (1.52, 1.67)].

Conclusions: Among high-risk individuals, both BMD screening and GIOP treatment rates remain low even through 2007, particularly for pre-menopausal women and men of all ages. Significant practice pattern variations among specialties persist. Developing interventions to improve GIOP management remains a high priority.

Self-Management Strategies in Overweight/Obese Canadians with Arthritis. Sasha R. Bernatsky[1], Corneliu Rusu[2], Siobahn O'Donnell[2], Gillian A. Hawker[5], Crystal Mackay[4], Louise McRae[2], Mayilee Canizar[4] and Elizabeth M. Badley[3]. [1]McGill UHC/RVH, Montreal, QC, Canada, [2]PHAC, [3]University of Toronto, Toronto, ON, Canada, [4]University of Toronto, [5]Women's College Hospital, Toronto, ON, Canada

Purpose: To estimate the prevalence of being overweight/obese, among Canadians with arthritis, and to describe the arthritis self-management strategies among these individuals.

Methods: The 2009 Survey on Living with Chronic Diseases in Canada (SLCDC) was developed by the Public Health Agency of Canada in collaboration with Statistics Canada, to provide information on how arthritis affects Canadians, and how it is managed. A nationally representative sample of 4,565 Canadians age ≥20 years, who reported having been diagnosed with arthritis by a health professional in the 2008 Canadian Community Health Survey (CCHS) were interviewed. Data from the 2009 SLCDC, was linked with data from the 2008 CCHS to analyze self-management strategies (including exercise, weight control/loss, classes, community based programs) among overweight (BMI=25.0–29.9) or obese (BMI>30) Canadians with arthritis.

Results: The over-all response rate for the SLCDC survey was 78%. Within the SLCDC sample with arthritis(N= 4,565), the majority were female(63.2%), aged 45+(88.6%), reported post-secondary education(68.7%) and were unable to report type of arthritis(42.4%).

Almost a third (27.4%) of the 4,565 was obese, with an additional 39.9% overweight. The overweight/obese individuals were mostly (59.5%) female and aged >45(89.7%). Regardless of weight category, about 75% had accessed a health professional in the past year, to manage their arthritis. Just under half (49.5%) of the overweight/obese individuals reported being told by a health professional to exercise, and a similar number (45.5%) were told to control/lose weight. A slightly smaller percentage of the overweight/obese versus under/normal weight individuals (60.9% versus 67.1%, respectively) reported engaging in exercise to manage their arthritis symptoms. About 68% of overweight/obese individuals reported using weight control/loss to manage their arthritis symptoms.

In univariate analyses of overweight/obese individuals, we found no correlation between engaging in any arthritis self-management strategies and any of the following factors: age, income, marital status, region of residence, and time since diagnosis. Factors independently associated with not engaging in arthritis self-management strategies included: male sex; not having a

medical doctor; not taking medications; no reported recommendation by a health professional to exercise, control/lose weight or use assistive devices; the presence of co-morbidities; worse self-reported health; and less disability in activities of daily living.

Correlates of NOT engaging in ANY self-management activities, for overweight/obese (BMI>25) individuals with arthritis (N = 273)

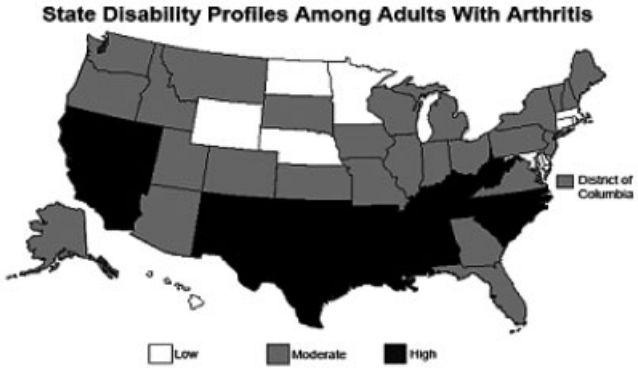
State-Specific ICF Disability Profiles among US Adults with Arthritis. Jennifer M. Hootman[3], Kristina A. Theis[1], Julie Bolen[2] and Charles G. Helmick[1]. [1]CDC, Atlanta, GA, [2]CDC, [3]Centers for Disease Control, Kennesaw, GA

Background: Population level estimates of arthritis-related disability are needed to define the burden, identify target populations for intervention, and monitor effectiveness of public health programs. The International Classification of Function (ICF) is a standard framework used to describe health and disability and may be useful for population surveillance.

Methods: Data were from the 2009 Behavioral Risk Factor Surveillance System, an annual telephone health survey conducted in all 50 states and the District of Columbia (DC; n = 424,592 adults). Arthritis (ARTH) was defined as a 'yes' response to "Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?". Three outcome measures, based on ICF domains, were created: 1) impairment = severe pain (PAIN), 2) limitation = activity limitation (AL), and 3) restriction = social participation restriction (SPR). PAIN was defined as 7 or higher on a 0–10 point scale. AL was defined as a limitation in usual activities due to arthritis. SPR was defined with a question asking about the extent that arthritis interfered with social activities such as shopping, going to movies or social gatherings. Respondents reporting "A lot" (versus "A little/Not at all") were defined as having SPR. State-specific prevalence estimates (%) and 95% confidence intervals (CI) among adults with arthritis were calculated for each of the ICF domains by state using statistical weights to account for the complex sample design. An overall state disability profile for each state was created using tertiles for each ICF domain. States in the highest tertile for all 3 ICF domains were classified as HIGH disability profile states and states in the lowest tertile for all 3 ICF domains were classified as LOW. All others were classified as MOD.

Results: Median prevalence for all 50 states/DC for each ICF domain were: PAIN = 23.9% (CI 22.3 – 26.2: state range 17.4% AK to 38.3% MS), AL = 44.6% (CI 43.5 – 46.1: state range 35.5% HI to 56.6% TN), and SPR = 14.8% (CI 14.0 – 15.9: state range 10.8% HI to 28.7% TN). Ten states (19.6%) were classified as having a LOW, 27 states (52.9%) were classified as MOD, and 14 states (27.5%: AL, AR, CA, KY, LA, MS, NV, NM, NC, OK, SC, TN, TX, WV) were classified as having a HIGH disability profile (figure). Tennessee, had the worst disability profile of all states/DC, ranking 50th in PAIN (35.7%), 51st in AL (53.6%) and 51st in SPR (14.8%). An estimated 14.5 million US adults with arthritis live in states with HIGH arthritis-related disability profiles.



Conclusions: These data identify states with poor disability profiles which may be high priority targets for widespread dissemination of evidence-based public health interventions that improve pain and function among adults with arthritis.

Disclosure: J. M. Hootman: None; **K. A. Theis:** None; **J. Bolen:** None; **C. G. Helmick:** None.

Statistical Methods Analyzing Count Data with Excessive Zeros in Arthritis Research. Bin Zhang[3], Jingbo Niu[5], Yanyan Zhu[6], Tuhina Neogi[2], Ling Xu[1], David T. Felson[7], Michael P. LaValley[8] and Yuqing Zhang[4]. [1]Beijing, China, [2]Boston Univ Schl of Med, Boston, MA, [3]Boston Univ Schl of Medicine, Boston, MA, [4]Boston Univ School of Medicine, Boston, MA, [5]Boston University, Boston, MA, [6]Boston University, [7]Boston University School of Medicine, Boston, MA, [8]BU School of Public Health, Boston, MA

Background: Arthritis research data are often collected in multiple joints within a person (i.e., number of hand joints with Radiographic Osteoarthritis (ROA)) or multiple sub-regions of a joint (i.e., number of sub-regions with cartilage loss in a knee). It is common that the outcome measures contain excessive zeros (zero-inflated data), e.g., the majority of the study subjects have zero count of hand joint ROA. When assessing the relationship between outcome measure of interest (e.g., number of hand joint ROA) with risk factors (e.g., obesity), commonly used statistical methods, including Poisson regression and generalized estimating equations (GEE) model, fail to account for the zero-inflated data, resulting in not only producing biased effect estimates but also creating artificial association between disease outcomes and their risk factors.

Methods: We use zero-inflated models, mixture models that have two parts: one part deals with the excessive zeros and the other part with a usual random variable (RV) such as a negative binomial (NB), to analyze zero-inflated data. We simulated 1000 zero-inflated negative binomial RV Y, where Y=0 with proba-

bility only related to predictor x3, otherwise Y has NB distribution associated with predictors x1 and x2. We used 3 statistical models: the GEE model, the Zero-inflated Poisson regression model (ZIP), and the zero-inflated NB regression model (ZINB) to analyze the simulated data. We applied the same three models to examine the relation of body mass index (BMI) to the prevalence of ROA among participants in the Beijing Osteoarthritis Study.

Results: As shown in Table 1, the effect estimates (i.e., $\beta 1$, $\beta 2$, $\beta 3$) obtained from ZINB model is closer to true values than those from either GEE or ZIP model. Furthermore, GEE model generated a false association between X3 and Y, whereas no such an association was found using ZIP or ZINB models. Among participants of the BOA study, 70.8% of subjects had no ROA in any hand joints. The prevalence ratio or hand OA (PR) is significantly associate with BMI, per 5 unit BMI increase PR=1.2 (95% CI:1.12–1.28, P<0.001) from GEE model and 1.12 (95% CI: 1.03–1.22, P<0.01) from ZIP model, and no significant associate found, PR=1.10 (95% CI: 0.95–1.27, P=0.2) from ZINB model, adjusting for age and sex. A goodness-of-fit test suggests that the ZINB model should be used instead of the ZIP or Poisson regression models. Thus, the positive association between BMI and hand ROA obtained from GEE model may be false due to ignoring the zero-inflated phenomenon.

Table 1. Simulation Results

	$\beta 1$	$\beta 2$	$\beta 3$ (when Y is NB)	$\beta 3^*$ (when Y=0)
True Values	0.8	0.5	0	5
GEE	0.77 (0.73, 0.82)	0.39 (0.35, 0.44)	−0.73 (−0.77, −0.69)	Can not be estimated
ZIP	0.75 (0.71, 0.80)	0.44 (0.39, 0.49)	0.01 (−0.06, 0.07)	4.45 (3.74, 5.25)
ZINB	0.78 (0.70, 0.85)	0.47 (0.40, 0.54)	−0.01 (−0.11, 0.10)	5.01 (4.10, 5.92)

Conclusion: We demonstrated the superiority of zero-inflated models analyzing count data with excessive zeros. We show that zero-inflated models are important not only to discover the unbiased associations between outcomes and their risk factors but also to avoid introducing false association when there is none.

The Association of Race with Gout: A Broadly Representative Inpatient Survey. Allan C. Gelber[1], Janet W. Maynard[2] and Carlton Haywood, Jr[2]. [1]Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD

Purpose: Gout is a leading cause of inflammatory arthritis. Established risk factors for gout include age, gender, hypertension and obesity. Relatively few studies have examined the association of race with gout status. We sought to determine, in a large, nationally representative survey of inpatient hospital stays, whether race was independently related to gout risk.

Method: We examined the 2004 Nationwide Inpatient Sample. In that calendar year, 37 states contributed data to the survey. For each hospital stay, one primary and 14 secondary ICD-9 diagnoses were recorded, as well as race, age, gender, socioeconomic status (SES) measures of health insurance and median household income for ZIP code. Hospital size and teaching status were recorded. We ascertained all hospital stays with a primary or secondary diagnosis of gout. The presence of co-morbid hypertension, obesity, acute and chronic renal insufficiency and sickle cell disease was identified. Our analyses were restricted to the 26 states that used race as a demographic code, and to patients aged 18–65 years. Using logistic regression, we examined the independent association of race with prevalent gout, with adjustment for demographic variables, co-morbidity profile, SES and hospital characteristics.

Results: A total of 2,332,974 hospital stays met the inclusion criteria. There were 18,851 (0.8%) hospitalizations in which a discharge diagnosis of gout was recorded. Overall, the study population was 62% female, 22.3% black and 77.7% white. Mean age was 43 years. In the dataset, 20% were receiving Medicaid, 29% had a household income <$36,000, 7% were diagnosed with obesity, 29% with hypertension, 2% with acute and 1.5% with chronic renal failure. These admissions were comprised of 47% urban teaching hospitals; 44% in the South, 26% in Northeast. Compared to the white patients, the risk of gout among the black patients in the survey is as follows:

Model	OR	95% CI
Race, unadjusted	1.44	1.40–1.49
Race, age-adjusted	1.71	1.66–1.76
Race, gender-adjusted	1.46	1.41–1.51
Race, hypertension-adjusted	1.14	1.11–1.18
Race, obesity-adjusted	1.43	1.39–1.48
Race, age, gender, hypertension, obesity	1.51	1.46–1.56
Race, age, gender, co-morbidity, SES, hospital profile-adjusted	1.51	1.45–1.56

Conclusion: In a broadly representative 2004 sample of US hospitalizations, black race was associated with a 50% increase in risk for coexistent gout. Clinicians evaluating hospitalized adult patients who manifest joint pain and swelling, ought to consider the greater burden of gout among the black segment of the American population.

The Clinical and Economic Burden of Corticosteroid Adverse Events (AEs): A Systematic Literature Review. Evelyn F. Sarnes[2] and Maria E. Watson[1]. [1]GlaxoSmithKline, Research Triangle Park, NC, [2]Xcenda, Palm Harbor, FL

Background: Systemic corticosteroids are an important and commonly used therapy; however, their use must be balanced against a set of side effects. This study evaluated the clinical and economic burden of systemic corticosteroid AEs in a wide variety of patient populations. A secondary objective was to consider the clinical and economic impact of reducing daily corticosteroid doses.

Methods: A systematic review of 2007–2009 studies retrieved by a predefined search strategy in Medline, EMBASE, and Cochrane Library, as well as AHRQ, NICE, and NHS HEED (free text) was performed to supplement an existing literature review. Relevant articles (observational and intervention studies) evaluated incidence/relative risk of AEs following corticosteroid use or the relationship between dose/duration and AEs. Case studies, studies in infants, and studies with inhaled corticosteroids were excluded. Titles/abstracts of retrieved articles were screened for eligibility. A secondary search, based on citations from other systematic reviews and including pre-2007 articles, was conducted to obtain data on psychiatric conditions, infections, and peptic ulcers. Information about dose-response relationships was combined with cost data from the literature to estimate the cost implications of a dose reduction for two corticosteroid AEs.

Results: A total of 323 articles were evaluated from the primary search; 27 were included. Excluded articles did not focus on corticosteroid AEs (n=70), were case studies (n=50), evaluated corticosteroid efficacy (n=38), or evaluated therapy to alleviate corticosteroid AEs (n=13). The secondary search added 20 studies. Overall, 25 were retrospective in design, 13 were conducted in the US and 21 in Europe. The AEs for which the literature contained the greatest number of reports were psychiatric events (18 reports), infections (15), gastrointestinal (GI) conditions (14), and fracture (11). Common AEs (>30% incidence) with a greater number of reports were sleep disturbances, lipodystrophy, adrenal suppression, and hypertension. The incidence of fracture varied by location: wrist fracture, Colles' fracture, and lower limb fracture were generally low (incidence 3–5%). Vertebral fractures were more common (range, 21–30%). Severe GI AEs were less frequent (ulcers, 1–5%; bleeding, 3–5%). Despite wide variability in study design, population, daily dose, conditions treated, and treatment duration, most AEs (fracture, myocardial infarction (MI), weight gain, infections, glaucoma, and psychiatric events) demonstrated a dose-response pattern with increasing daily dose. Studies of fractures and MIs demonstrated the clearest dose-response relationship. As such, reducing daily dose requirements may reduce AE clinical and economic burden. For example, dose reduction from 7.5–15 mg/day to <7.5 mg/day may avoid 96 fractures per 10,000 elderly patients at $18,358 per fracture and a reduction from >10 mg/day to ≤10 mg/day avoid 19 MIs per 10,000 patients at $26,472 per MI (US $ 2009).

Conclusions: The clinical and economic burden of corticosteroid AEs is substantial; lowering the daily dose requirements may lower the incidence of many AEs.

The Cost-Effectiveness of Corticosteroid Injection of the Carpal Tunnel. Suzanne L. DeLea[1], Janet L. Poole[1], Natalia Chavez-Chiang[2], Wilmer L. Sibbitt[3] and Arthur D. Bankhurst[4]. [1]University of New Mexico, Albuquerque, NM, [2]University of New Mexico, [3]University of New Mexico HSC, Albuquerque, NM, [4]University of NM Med Ctr, Albuquerque, NM

Objective: Corticosteroid injection is a useful and low-cost therapy for carpal tunnel syndrome.This randomized controlled study addressed whether two different low-cost injection techniques affected the outcomes and cost-effectiveness of carpal tunnel injections.

Design: Prospective, randomized, controlled, single-blinded interventional trial.

Setting: Hospital outpatient musculoskeletal clinic.

Patients: 64 subjects with symptomatic carpal tunnel syndrome.

Interventions: 64 wrists with carpal tunnel syndrome were randomized to palpation-guided anatomic carpal tunnel injection with 80 mg triamcinolone acetonide by: 1) a conventional technique, or 2) injection by a mechanical syringe, the RPD (the reciprocating procedure device) syringe. A one-needle, two-syringe technique with hydrodissection by 1% lidocaine was used.

Main Outcome Measurements: Baseline pain by 10 cm Visual Analogue Pain Scale (10 cm VAS), procedural pain, pain at outcome (2 weeks and 6 months), responders, therapeutic duration, reinjection rates, total cost/patient/year, and cost/responder/year were determined.

Results: Both methods reduced pains cores by greater than 50% from baseline at 2 weeks ($p<0.001$). Relative to the conventional method, the mechanical syringe resulted in 62% greater reduction in injection pain ($p<0.02$), a 68% increase in responder rate ($p<0.02$), 50% reduction in non-responder rate ($p<0.02$), 57% increase in therapeutic duration ($p<0.001$), a 25% increase in time to next procedure, a 36% ($43 US) reduction in cost/patient/yr for a patient treated in a physician office ($p<0.001$), and a 34% reduction ($33 US) in cost/patient/year for a hospital outpatient ($p<0.001$) as well as reduced cost/responder/year ($p<0.001$).

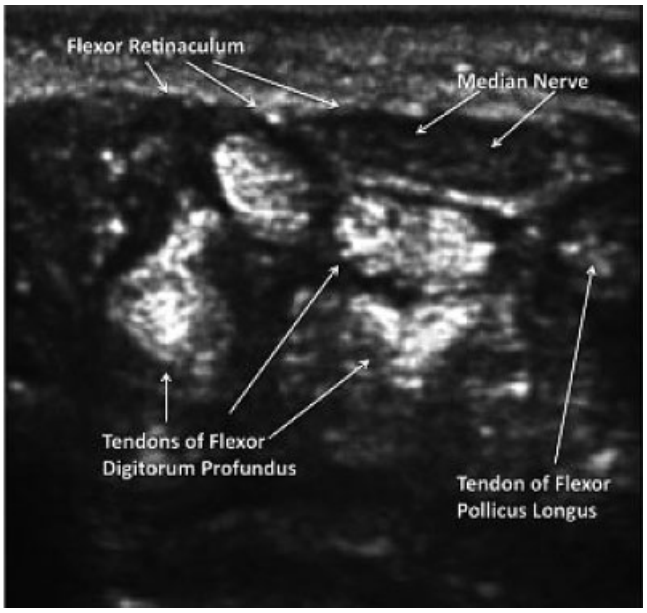

Figure 1.

Figure 2.

Figure 3.

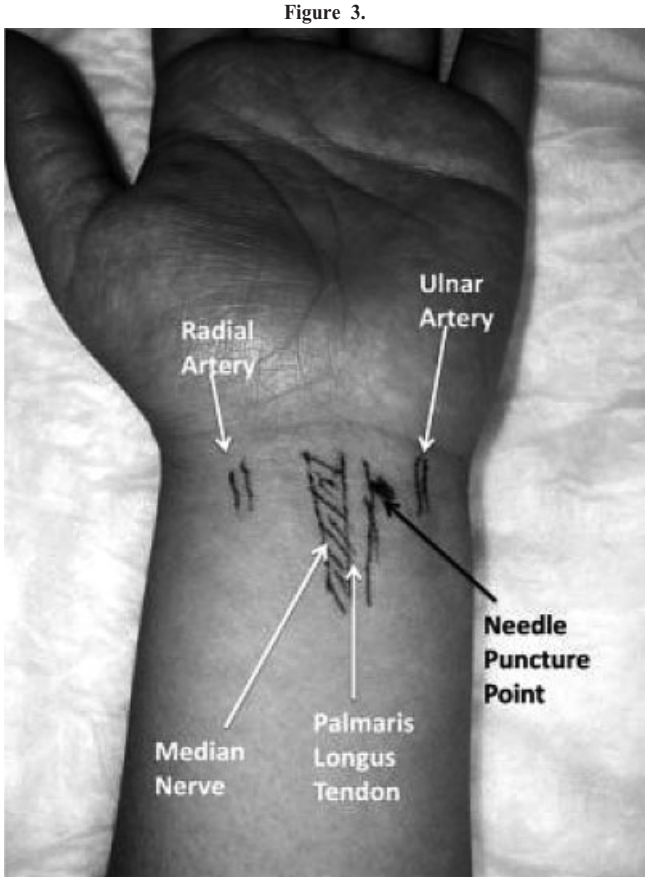

Figure 4.

Conclusion: Cost-effectiveness and outcomes of corticosteroid injection for carpal tunnel syndrome can be significantly improved by using low-cost alterations in technique.

The Prevalence and Characteristics of Fluorosis Causing Skeletal Deformities in Rural Tanzania. Helen G. Jarvis[2], Peta S. Heslop[2], John Kissima[1] and Richard Walker[3]. [1]Hai District Hospital, Kilimanjaro Region, Tanzania, East Africa, [2]Newcastle upon Tyne NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, [3]Northumbria Healthcare NHS Foundation Trust, Tyne & Wear, United Kingdom

Introduction: Excessive ingestion of fluoride affects bone during growth causing a condition known as skeletal fluorosis (SF). This process can distort the congruence of joints, particularly weight bearing joints, leading to bone and joint pain. Previous small case series have reported rheumatological deformities in areas with high fluoride concentrations in the drinking water. Due to the harmful effects of excessive fluoride to teeth and bone the WHO (2004) recommended that fluoride levels in drinking water be < 1.5 mg/L. The area of Tanzania where the study was based had reported levels of fluoride as high as 35 mg/L in the ground water.

A survey was carried out to estimate the prevalence of SF in a Northern Tanzania village and the study was designed to focus on identifying those with deformity and disability due to SF.

Methods: Using census information a door to door survey was conducted to identify cases of SF. Based on literature review and expert opinion, a diagnosis of severe SF was made if the following were identified on clinical examination: abnormal coronal tibio-femoral angle, sabre tibia or juvenile kyphosis/scoliosis with no alternative cause. Cases were then examined for other clinical manifestations, and disability/pain levels were estimated using a 4 point Likert scale. Social & educational exclusion were also assessed as part of the estimate of disease burden.

Results: A population of 1435 were studied 762 (53%) Female & 673 (47%) Male, of whom 1135 (79%) were under 30 years of age. We identified 56 cases (22 (39%) female & 34 (61%) male) of severe SF (aged 2 – 30 yrs). This gives a crude prevalence of 3.9% of severe deforming disease.

52 (93%) had evidence of coronal tibio-femoral joint deformities - 45 valgus & 7 varus. Sabre tibia was identified in 18 (32%) and juvenile scoliosis/kyphosis in 3 (5%) of the cases. Combinations of the above diagnostic criteria were common with 2 cases having all 3 conditions.

Pain was reported in 37 (66%) cases using the ascending 4 point Likert severity scale. 25 (45%) reported moderate to severe pain & 36 (64%) reported limitation of normal activities. 97% had knee and lower limb pain with only 32% of those reporting pain in other skeletal sites.

17 (30%) felt their school attendance had been affected & 5 (9%) felt they were treated differently by their peers due to their SF.

Financial constraints meant only those with the worst deformities were referred for corrective surgery. 11 children have been operated on to date.

Conclusion: In this area with very high levels of fluoride in the ground water, SF is a common condition. The prevalence of nearly 4% in this village represents only the most severe end of the spectrum, being an estimate of the disability and burden that this condition causes in a community ingesting excessive amounts of fluoride. It appears that only the under 30's in the population have been affected by severe SF, most likely due to the time of construction of the deep wells in the area, which carry higher fluoride levels than surface water. Severe SF also seems to be more common in males than females, possibly due to hormonal effects. The study group is currently investigating why, despite endemic exposure, only a minority appear to develop severe deforming disease.

Thiazide and Loop Diuretics Are Associated with Incident Gout in the Atherosclerosis Risk in Communities (ARIC) Study. Mara A. McAdams[4], Janet W. Maynard[2], Allan C. Gelber[1], Alan N. Baer[3] and Josef Coresh[4]. [1]Baltimore, MD, [2]Johns Hopkins Univ, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD, [4]Johns Hopkins, Bloomberg School of Public Health

Background: While there is a clear association between diuretic use and the development of gout, it is unclear whether both thiazide and loop diuretics are associated with an increased incidence of gout. We quantified the association between incident gout and diuretic use, type of diuretic.

Methods: ARIC is a prospective population-based cohort study of 15,792 individuals recruited in 1987–1989 from four US communities. It consists of 1 baseline visit (visit 1) and 3 follow-up visits administered 3 years apart. At ARIC visit 4, participants were asked, "Has a doctor ever told you that you had gout?" Participants were excluded if they did not attend visit 4 or had gout prior to visit 1. At baseline, blood pressure values were measured. Participants were asked to bring all medications that they had taken in the past 2 weeks to the baseline visit. Medication data, including diuretic use and class, were obtained by trained interviewers reviewing prescription bottles. Hypertension (HTN) was defined by the report of a medication to treat HTN or a blood pressure measurement $> 140/90$ mm Hg.

We examined whether baseline diuretic use was associated with incident gout over 9 years of follow-up. We used logistic regression to calculate the odds of incident gout associated with diuretic use in the whole population and the subset with baseline HTN. All models were adjusted for age, sex, race, HTN and baseline body mass index, estimated glomerular filtration rate, diabetes, and protein and alcohol intake. The models for loop diuretics were also adjusted for CHF diagnosis.

Results: There were 10,872 participants who met the study criteria; 1,643 (15%) took a diuretic, 3,248 (30%) had HTN at baseline and 43% of the HTN patients were taking a diuretic. The study population was 57% female and 22% African-American. There were 286 gout cases. Per 1000 participants, the cumulative incidence of gout was 28 overall, 61 among those who reported diuretic use in the 2 weeks prior to the baseline visit, 21 for those not exposed to a diuretic, and 51 for those with HTN. Baseline use of any diuretic, including thiazide and loop diuretics, was associated with an approximately 2-fold increased risk of incident gout, after adjustment for confounders. Among the participants with HTN, the risk of gout was increased approximately 1.5-fold compared to non-diuretic users. Results were similar by sex and race, except for the association of loop diuretics (African-America, Adjusted OR=0.76, not significant) and (White, Adjusted OR= 3.6, p-value< 0.001).

Table. Odds of gout by diuretic use and class

Participants using diuretics (n=1,549) vs. participants not using diuretics, n=10,872 with 286 incident gout cases

	Any diuretic use	Thiazide	Loop
Gout	94	44	16
No Gout	1,549	799	158
Unadjusted OR	2.87 (2.23, 3.69)	2.24 (1.61, 3.11)	3.91 (2.30, 6.62)
Age adjusted OR	2.85 (2.21, 3.68)	2.21 (1.59, 3.08)	3.86 (2.28, 6.55)
Fully adjusted OR	2.26 (1.70, 3.00)	1.93 (1.35, 2.74)	2.14 (1.11, 4.14)

Participants with hypertension using diuretics (n=1,299) vs. participants not using diuretics, n=3,248 with 165 incident gout cases

	Any diuretic use	Thiazide	Loop
Gout	86	43	11
No gout	1,299	693	95
Unadjusted OR	1.50 (1.09, 2.05)	1.22 (0.85, 1.74)	2.25 (1.18, 4.28)
Age adjusted OR	1.50 (1.10, 2.06)	1.22 (0.85, 1.74)	2.27 (1.19, 4.33)
Fully adjusted OR	1.49 (1.06, 2.10)	1.44 (0.99, 2.10)	1.29 (0.57, 2.93)

Note: OR refers to odds ratios and we presented 95% Confidence Intervals. We did not calculate odds ratios for the exposure to thiazide diuretics because there was only one exposed case.

Conclusion: Our results suggest that diuretic use is associated with incident gout. Thiazide and loop diuretics were associated with twice the risk of gout. This study supports the previously reported association of diuretic use with gout and suggests that this association occurs with both loop and thiazide diuretics in a population based multi-ethnic sample reporting gout incidence.

Trends in Orthopedic Surgery Utilization among Patients with Rheumatoid Arthritis: A Focus on Surgery Type and Gender. Courtney A. Shourt[1], Cynthia S. Crowson[2], Sherine E. Gabriel[3] and Eric L. Matteson[4]. [1]Department of Medicine, Mayo Clinic College of Medicine, [2]Division of Biostatistics, Department of Health Science Research, Mayo Clinic College of Medicine, [3]Division of Epidemiology, Department of Health Science Research, and Division of Rheumatology, Mayo Clinic College of Medicine, [4]Division of Rheumatology, and Division of Epidemiology, Mayo Clinic College of Medicine

Objective: To describe current trends in arthritis related orthopedic surgery utilization amongst a population based cohort of patients with rheumatoid arthritis (RA).

Methods: A retrospective medical record review was performed of all incident cases of adult onset RA from a defined geographic population base who fulfilled criteria for RA in 1980–2007. Orthopedic surgeries occurring after the incidence date were recorded, including primary total joint arthroplasty (TJA), joint reconstructive procedures (JRP), soft tissue procedures (STP) and revision arthroplasty, classified according to joint involved (hip, knee, wrist, shoulder, elbow, hand, ankle, foot, cervical spine and temporomandibular). Cumulative incidence of surgery was estimated using Kaplan-

Meier methods. Time trends and gender differences were examined using Cox models.

Results: The study included 814 RA patients (mean age: 56 years; 68% female; mean follow-up 9.6 years). A total of 190 patients underwent ≥1 surgical procedures involving joints during follow-up. The cumulative incidence of any joint procedure at 10 years for 1980–1994 was 30.4% compared to 21.9% for 1995–2007 (p=0.08). The cumulative incidence of all joint surgeries was lower in the 1995–2007 cohort compared to the 1980–1994 cohort, with the greatest reduction in soft tissue procedures (synovectomies, tendon repairs, tendon transfers, meniscus repair, ligament release, cartilage repair), which decreased from 13.4% in 1980–1994 to 7.3% in 1995–2007 at 10 years after RA incidence (p=0.018). Knee surgeries were less common in patients diagnosed in 1995–2007 compared to those diagnosed in 1980–1994 (hazard ratio [HR]: 0.56; p=0.045), as were hand surgeries (HR: 0.45; p=0.059), but there was no change in hip surgeries (p=0.68). There were more surgeries preformed (across all surgery types) amongst female patients with a cumulative incidence of 29.4% at 10 years compared to 23.5% for men during the same time period (p=0.057).

Conclusion: The rates of arthritis related surgery continue to decrease for patients more recently diagnosed with RA, especially soft tissue procedures and knee surgeries. This trend is particularly noticeable in women. This decrease in rates may reflect improved treatments or secular trends in disease expression or changes in practice patterns.

Understanding Billing Data: A Survey of Billing Process and Codes Used by Family Physicians for Rheumatological Conditions. Diane Lacaille, Jack Chang and Pamela Rogers. Arthritis Research Centre of Canada, Vancouver, BC, Canada

Objectives: Administrative data are increasingly used for research purposes. Accuracy of diagnostic codes used in billing data is a common concern, especially for data from family physicians (FPs). The objectives of our study were: 1) To understand the process used by FPs from different practice settings for billing and assigning diagnostic codes; 2) To identify the specific diagnostic codes commonly used by FPs for various rheumatologic diseases.

Methods: A sample of 343 FPs were randomly selected from the list of all FPs in the province, while ensuring a representative distribution of gender, time since graduation, and geographic location (health authority). FPs with specialized practices, in fully administrative roles, or not in active practice were excluded. Self-administered surveys were sent by fax. Reminders were sent to non-responders twice, at two week intervals. The survey elicited information about their practice setting, the process they used for billing and for assigning diagnostic codes, as well as information about their choice of diagnostic codes for selected rheumatologic conditions. Descriptive analysis was performed.

Results: Of the 343 FPs invited to participate, 74(5%) were ineligible, and 130 (48%) participated. The sample included 79% in full-time practice, 61% in urban areas, 67% with > 20 years since graduation and 37% who used electronic medical records (EMR). Results indicated that 67% of FPs select the diagnostic code themselves, 15% use EMR to assign the diagnostic code, and 10% have their MOAs assign the code. When coding themselves, 76% of FPs reported using a specific code for each type of arthritis, while 24% reported using the same code for all arthritis. Of those, commonly used codes included 781 (MSK symptom) [41%], 715 (OA) [22%], 716 (unspecified arthritis) [16%] and 714 (RA) [13%]. When patients present with multiple complaints, 46% of FPs reported submitting the code for the complaint which took the most time. When asked which code they used for specific types of arthritis, FPs provided the correct code for RA in 83% of respondents, OA (76%), Gout (83%), AS (63%), PsA (14%) with 23% using the code for psoriasis, SLE (13%). Subgroup analysis showed that practice setting (rural vs urban), but not other practice characteristics, influenced use of diagnostic codes. FPs in rural settings were more likely to use specific codes for each type of arthritis [86% vs 65% of urban FPs], and to select accurate codes (RA: 93% vs. 75%, rural vs. urban resp., OA: 85% vs. 69%, Gout: 83% vs. 60%, p<0.05).

Conclusion: Most FPs selected the diagnostic code themselves, use specific codes for each arthritis, and use the code for the complaint which took the most time. Selection of the accurate code for specific types of arthritis occurred in greater than 70% of respondents for OA, RA, and gout, but was inadequate for PsA and SLE. However, the use of a single code for all types of arthritis by nearly a quarter of FPs, with some using OA and RA, as well as misclassifications when specific codes were used, may lead to false positive cases of OA and RA. Further research is needed to validate diagnostic codes used by FPs in order to fully understand the impact of coding errors on estimates of prevalence.

Urate-Lowering Therapy in Chronic Gout Results in Clinically Important Improvements in Health-Related Quality of Life—SF-36 Is Responsive to Change in Chronic Gout. Puja Khanna[2], Fernando Perez-Ruiz[1], Paul Maranian[2] and Dinesh Khanna[2]. [1]Hospital de Cruces, [2]UCLA

Purpose: SF-36 is a validated outcome measure to assess generic health-related quality of life (HRQOL) in patients with gout. We assessed HRQOL in patients with gout in an academic outpatient rheumatology setting.

Methods: SF-36 was administered at baseline, then at yearly intervals. Patients who had a gout flare within the past 1 month were excluded. We assessed statistical significance and the minimal clinically important differences (MCID) at the first and second year. Statistical significance was evaluated using paired t-test for changed scores of the SF-36 scales. MCID for SF-36 scales and summary scores was defined as improvement of ≥5 points and ≥2.5 points at 12 months, respectively. We assessed responsiveness to change (effect size) and interpreted it based on Cohen's criteria: 0.20–0.49 as small, 0.50–0.79 as moderate, and >=0.80 as large, and the predictors for improvement in the SF-36 scales and summary scores. We assessed improvement (defined as >=MCID) in 8 SF-36 scales and 2 summary scales. Independent variables included age, tophi (presence/absence), comorbidities (presence/absence), baseline joint involvement, baseline serum urate levels, change in serum urate level and number of flares from baseline to 12 months.

Results: Of 99 subjects, 96 were male, mean age was 57.1 years, disease dur was 8.2 years, 47% had associated comorbidities, 40% had tophi, and 64% had evidence of radiographic damage. Data was available for 77 patients at 1 year and 36 patients at 2 years. Patients were treated with urate lowering therapy (ULT) including allopurinol (N=64), benzbromarone (N=4), or combination therapy (N=1); only 7 patients were on oral colchicine. Baseline mean (SD) serum urate level was 8.9 (1.36) mg/dl and mean numbers of flares were 4.7 (4.5) over the last year. Patients with presence of tophi, polyarticular disease, and radiographic damage had lower SF-36 scores compared to patients without it. Urate-lowering therapies were associated with reduction in serum uric acid to 5.46 (1.1), (-3.44 (1.73); p< 0.001) and number of flares (-4.00 (4.32); p<0.001) over 12 months; and associated with a statistically significant and clinically meaningful improvement in the SF-36 scales and summary scores at 12 months (Table). Reduction in flares independently predicted improvements in SF-36 scales (bodily pain, physical functioning, and role physical) at 1 year after adjusting for the covariates (p values= 0.001–0.06). Improvement in SF-36 scores was maintained at 2 years.

SF-36	Baseline Mean (SD)	1-Year Mean (SD)	Effect Size#	% achieving MCID
Physical function	43.39 (11)	48.44 (8.33)*	0.48	34
Role Physical	43.68 (11.41)	49.44 (10.41)*	0.50	36
Bodily Pain	39.91 (11.23)	52.12 (10.77)*	1.09	69
General Health	43.04 (8.92)	47.12 (9)*	0.49	38
Vitality	50.74 (12.24)	54.97 (11.2)*	0.31	41
Social functioning	45.5 (11.89)	51.18 (8.82)*	0.40	53
Role emotional	48.98 (11.04)	51.69 (8.69)	0.20	22
Mental health	49.73 (11.92)	52.91 (10.51)	0.21	30
SF-36 PCS	40.37 (9.45)	48.48 (8.89)*	0.91	70
SF-36 MCS	52.16 (10.8)	54.15 (9.3)	0.08	38

* p<0.001

Conclusion: In this real-life observational cohort, appropriate gout specific-therapy was associated with statistical and clinically meaningful improvements in the number of flares and HRQOL at 1 year then maintained at 2 years. SF-36 is responsive to change with treatment in gout over time. Our data shows that SF-36 is responsive to change in chronic gout.

1573

Validation of Diagnostic Codes for Subtrochanteric, Diaphyseal, and Typical Hip Fractures Using Administrative Claims Data. Pongthorn Narongroeknawin, Nivedita M. Patkar, Bita Shakoory, Archana Jain, Jeffrey R. Curtis, Elizabeth Delzell, Philip H. Lander, Robert Lopez-Ben, Michael J. Pitt, Monika M. Safford, David A. Volgas and Kenneth G. Saag. Univ of Alabama at Birmingham, Birmingham, AL

Background: As part of developing administrative claims-based algorithms for identifying subtrochanteric and diaphyseal fractures of the femur (SFF and DFF), we assessed the accuracy of hospital and physician diagnosis codes for these fractures. Algorithms that combined hospital discharge with surgeon's diagnosis codes to identify cases of these fractures yielded relatively high positive predictive values (PPV) and will be useful in future population-based observational studies.

Methods: Candidates for study inclusion were all patients with an ICD-9 diagnosis code for femoral fracture, at a University hospital from 01/2004 to 12/2008. Individuals with hospital discharge diagnosis for open femoral fracture and distal end femoral fractures were excluded because these fractures are usually caused by major trauma and not associated with longer term bisphosphonates use.

Based on the clinical history, radiology report, operative note, and discharge summary accounting for the fracture admission, patients were assigned to one of the following classifications: (1) SFF, defined as fracture at the region between the lesser trochanter and a point 5 centimeters distal; (2) DFF, defined as fracture at the region between subtrochanteric and supracondylar areas; or (3) "typical" hip fracture, other than SFF and DFF. We classified suspected SFF and DFF cases according to several alternative algorithms based on ICD-9 diagnosis codes, with the goal of identifying the algorithm that maximized PPV.

Result: We identified 137 persons with a suspected SFF and randomly selected 50 persons each with a suspected DFF or typical hip fracture. The PPV of case algorithms, which were varied based on the position and source of the diagnosis codes on medical claims, ranged from 69–89% for SFF, from 89–98% for DFF, and from 85–98% for typical hip fracture.

In a subgroup analysis, the PPVs of the various algorithms for SFF and typical hip fracture among patients age > 55 years and among patients without major trauma ICD-9 codes were the same as those in the primary analysis. In contrast, the PPVs of algorithms for DFF were lower for these subgroups than those in primary analysis. However, the number of confirmed DFF cases in these subgroups was small.

Conclusions: Administrative claims data-based algorithms that combined hospital discharge with surgeon's diagnosis codes to identify cases of SFF, DFF, and typical hip fracture yielded high PPVs. These claims algorithms will be useful in future population-based observational studies to evaluate the association between osteoporosis medications and subtrochanteric and diaphyseal fractures.

Table 1. Characteristic of Validation Sample

	All patients (n=235)	Subtrochanteric fracture[1] (n = 137)	Diaphyseal fracture[2] (n = 55)	Typical hip fracture[3] (n = 60)
Age (Mean ± SD)	48 ± 21	45 ± 20	41 ± 20	57 ± 23
Female (%)	36	32	38	43
Presence of major trauma code[4] (%)	71	81	87	53

Vitamin C Supplementation and Serum Uric Acid: A Meta-Analysis of Randomized Controlled Trials. Stephen P. Juraschek, Edgar R. Miller and Allan C. Gelber. Johns Hopkins Medical Institutions, Baltimore, MD

Background: Vitamin C is an essential micronutrient with uricosuric properties. Observational studies demonstrate an inverse association between levels of dietary or plasma vitamin C and serum uric acid (SUA). Thus far, clinical trials of vitamin C report inconsistent effects on SUA. The purpose of this meta-analysis was to determine the pooled effect of vitamin C on SUA culled from prior reports.

Methods: We conducted a meta-analysis of randomized controlled trials of vitamin C supplementation on SUA. A total of 1,988 publications, identified in MEDLINE, EMBASE, and CENTRAL databases, were subjected to the following inclusion criteria: (1) randomized controlled trials conducted on human subjects; (2) end-trial serum uric acid means and variance were reported; (3) oral vitamin C supplementation and a concurrent control group; and, (4) trial duration of at least one week. Trials that enrolled children or patients on dialysis or where vitamin C supplements were combined with other uricosuric agents were excluded. SUA effects were pooled by random-effects models and weighted by inverse variance.

Summary of Results: Thirteen trials met our eligibility criteria, totaling 545 participants. The median dose of vitamin C was 500 mg/d, trial size ranged from 8 to 184 participants, and median study duration was 30 days. Eight trials examined vitamin C as the only active intervention, whereas 5 trials administered vitamin C together with other vitamins, minerals or pharmacologic agents. The aggregate weighted effect of the 13 trials showed a SUA reduction of −0.33 mg/dL (95% CI: −0.66, 0.00; $P = 0.05$). Trials with a mean pretreatment SUA level above 4.85 mg/dL, the median value for these 13 trials, had a significantly greater SUA reduction in comparison to trials with mean pretreatment values ≤4.85 mg/dL ($P = 0.02$ in subgroup comparision). Notably, the pooled effects of trials with larger doses of vitamin C and those with vitamin C as the sole intervention showed greater significant reductions in SUA levels (Table).

Table. Vitamin C supplementation effects on serum uric acid - overall and subgroup analyses.

		Serum Uric Acid (mg/dL)	
	n	mean (95% CI)	P-value
All Trials (N = 13)	545	−0.33 (−0.66, 0.00)	0.05
Subgroup: Pretreatment Serum Uric Acid			
Trials with mean UA≤4.85 mg/dL (N=5†)	204	0.15 (−0.09, 0.39)	0.23
Trials with mean UA>4.85 mg/dL (N=5†)	252	−0.83 (−1.62, −0.04)	0.04
Subgroup: Vitamin C Dose			
Trials with dose <500 mg/d (N = 6)	203	0.09 (−0.17, 0.34)	0.52
Trials with dose ≥500 mg/d (N = 8*)	369*	−0.56 (−1.01, −0.11)	0.01
Subgroup: Intervention			
Only Vitamin C (N = 9*)	372*	−0.52 (−0.93, −0.10)	0.02
Vitamin C and other agents (N = 5)	200	0.12 (−0.15, 0.39)	0.38

N = Number of trials; n = Number of trial participants.
† Total number does not equal 13 since 3 trials did not report mean pretreatment SUA.
* One trial consisted of two distinct vitamin C intervention groups.

Conclusions: In this meta-analysis, vitamin C supplementation lowered SUA. Greater reductions in SUA occurred in trials that used high doses of vitamin C and in trials with subjects with higher pretreatment SUA levels. These data support consideration of vitamin C supplementation as a uricosuric agent in the prevention and control of gout.

What Kinds of Advice Do Health Food Store Employees and Pharmacists Provide to Consumers with Acute Low Back Pain? Jaya K. Rao[2], Dio Kavalieratos[1], Mary Roth[1], Morris Weinberger[1] and Timothy Carey[1]. [1]Chapel Hill, NC, [2]UNC Eshelman School of Pharmacy, Chapel Hill, NC

Background: Approximately 80% of adults experience at least 1 episode of acute low back pain (ALBP) during their lives. ALBP symptoms typically resolve in 4–6 weeks. Evidence-based guidelines recommend that physicians treat patients with ALBP conservatively with nonsteroidal anti-inflammatory drugs, avoid ordering imaging studies, and encourage usual activities as tolerated. Given that patients often use self-care strategies to treat pain, we examined the advice that health food store (HFS) employees and retail pharmacists provide for ALBP symptoms.

Methods: The study protocol was approved by the University of North Carolina Institutional Review Board. The actor, a 22 year-old Caucasian white male, visited 10 retail pharmacies and 10 HFSs in North Carolina during October 2009. He interacted with the HFS employees and pharmacists using the following standardized script: 1) his symptoms began 2 days ago and he was able to see a primary care physician (PCP) earlier that day; 2) the PCP followed ALBP guidelines and recommended ibuprofen every 6 hours; and 3) he was dissatisfied with the PCP's recommendations. He asked for general treatment recommendations, and specifically asked whether he needed to see a physician or other practitioner. He documented the recommendations on a data collection form following each encounter. We calculated the total monthly costs for each product recommended and examined whether the products had underlying evidence as a treatment for ALBP or potential side effects or interactions with prescribed medicines.

Results: Of the 6 pharmacists who recommended continuing ibuprofen, 2 reinforced a regular dosing schedule. Another 3 recommended changing to naproxen and 1 stated that the physician should have prescribed a muscle relaxant. Seven pharmacists suggested a physician visit but varied with respect to time frame; 4 recommended a visit if the symptoms lasted more than 2–3 days while 3 recommended a visit if the symptoms were not resolved within 1–2 weeks. Although 4 pharmacists said that imaging studies were not necessary, 3 recommended a radiographic study (1 specifically suggesting an MRI). Of the 10 HFS employees, 4 suggested continuing the ibuprofen; notably, 1 recommended increasing the dose to 800 mg every 6 hours. Nine HFS employees recommended various supplements and topical remedies with a total monthly cost ranging from $2 to $331. The recommendations included products that are safe but have no evidence to support their use for ALBP (e.g., glucosamine) and several that have known side effects (e.g., magnesium citrate) or could interact adversely with prescription medications (e.g., bromelain extract). Only 2 HFS employees suggested a physician visit, with one recommending having an MRI performed.

Conclusions: Pharmacists may inadvertently raise expectations regarding ALBP evaluation and symptom resolution while HFS employees may encourage consumers to purchase expensive products with no proven benefit for ALBP management. These results should be confirmed in a broader sample of pharmacists and HFS employees.

Who Falls? A Decade of Experience at a Musculoskeletal Specialty Hospital. Lisa A. Mandl[1], Michael Parks[2], Patricia Quinlan[2], Tina Bailey[2], Jacklyn Katz[2] and Steven Magid[2]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery

Summary: This study evaluates in-patients who fell at a musculoskeletal specialty hospital with no emergency room or trauma unit. Almost all admissions were for elective orthopedic procedures, a small percentage for non-critically ill rheumatic disease patients.

Methods: Retrospective review of all in-patient falls from 2000–2009. Falls were identified from the hospital's falls reporting database and ICD-9 discharge codes.

Results: There were a total of 868 in-patient falls in patients 18 years and over. The fall rate was 0.9 % of admissions, and 2.0 falls/1000 inpatient days. There were no significant trends in fall rate over time. Average age was 68 years, (range 18–93), 57.7 % were women. Among patients who fell, 97 (11.5%) had a lower extremity procedure, 156 (18.5%) had a spine procedure, 124 (14.7%) had a total hip replacement (THR), 322 (38.2%) had a total knee replacement (TKR) and 77 (8.9%) were admitted for other procedures or medical reasons. Twenty-six falls were second or third falls in the same patient during the same admission. Of the 842 first fall during an admission, 384 (45.1 %) involved using the bathroom and 145 (17.5 %) were in patients with a known history of previous falls. 110 first falls (13.1 %) resulted in injuries, of which 28 (3.3%) were serious, as defined by return to the operating room, transfer to a higher level of care, dislocation, fracture or intra-cranial bleed. Neither falls nor serious falls were significantly associated with day of the week or time of day. Patients with serious falls were more likely to fall earlier in their stay, (post-operative day 2.3 vs. 4.1; P-value 0.003) and have had a total hip replacement (p-value= 0.001). There was no significant association of serious falls with body mass index, age, gender, location in the hospital, day of the week or previous history of falling.

Discussion: Falls are avoidable events which can have devastating consequences. Most fall studies in the literature involve sick medical in-patients. Much less is known about falls in patients healthy enough for elective orthopedic surgery, or in non-critically ill rheumatology patients. This large series identifies bathroom related activities as high risk times for falling in these patients. Almost one fifth of patients were known to have fallen previously. This suggests the need for more effective fall prevention strategies in known high risk patients. The largest percentage of falls were in TKR patients, though serious falls were more common in THR patients. This is important, as the rates of both TKR and THR are projected to increase dramatically over the next two decades. THR patients are at higher risk for serious falls, and should be monitored closely, especially during the first 3 post operative days. These data can inform the creation of interventions to prevent falls and their consequences in this patient population.

***BLK* Confers a Risk for Renal Involvement in Japanese Patients with Systemic Lupus Erythematosus.** Kenichi Shimane[2], Yuta Kochi[5], Ryo Yamada[5], Yukinori Okada[1], Akari Suzuki[5], Keiko Myouzen[5], Tetsuya Horita[3], Tomonori Ishii[7], Michito Hirakata[4], Hirofumi Amano[6], Michiaki Kubo[1], Yusuke Nakamura[1], Naoyuki Kamatani[1] and Kazuhiko Yamamoto[8]. [1]CGM, RIKEN, Yokohama, Japan, [2]Department of Allergy and Rheumatology, Graduate School of Medicine, the University of Tokyo, Tokyo, Japan, [3]Hokkaido University Graduate School of Medicine, Sapporo, Japan, [4]Keio University School of Medicine, Tokyo, Japan, [5]Laboratory for Autoimmune Diseases, Center for Genomic Medicine, Institute of Physical Chemical Research (CGM, RIKEN), Tokyo, Japan, [6]School of Medicine, Juntendo University, Tokyo, Japan, [7]Tohoku University Graduate School of Medicine, Sendai, Japan, [8]Univ Tokyo Gr Schl of Med, Tokyo, Japan

Objectives: To find out whether 4 confirmed susceptibility genes to systemic lupus erythematosus (SLE), *BLK*, *STAT4*, *IRF5* and *TNFAIP3*, confer genetic predisposition to specific sub-phenotypes of SLE.

Methods: Our SLE case-control cohort consisted of 606 patients (mean age 43.4 years, 90.6% women) and 934 unrelated controls (mean age 52.6 years, 25.0% women), and they were all Japanese. We selected four single nucleotide polymorphisms (SNPs), rs13277113 (*BLK*), rs7574865 (*STAT4*), rs41298401 (*IRF5*) and rs2230926 (*TNFAIP3*), which are established genetic risk factors for SLE shared between Caucasian and Asian populations. We genotyped the SNPs using TaqMan assays. The difference of the genotype frequency was tested with the Chochran-Armitage trend test, using PLINK.

Results: We found a significant association of rs13277113 (*BLK*) with renal involvement (OR 1.48, 95%CI 1.14–1.93, p=0.0034) and a moderate association of rs41298401 (*IRF5*) with lupus anticoagulant (LAC) positivity

(OR 1.89, 95%CI 1.09–3.26, p=0.022). A stratified analysis between *BLK* and renal involvement by the morphologic classification (according to World Health Organization morphologic classification of lupus nephritis) indicated that rs13277113 (*BLK*) was more significantly associated with patients with class III and IV (OR 1.70, 95%CI 1.17–2.46, p=0.0057) than those with class I, II and V (OR 1.20, 95%CI 0.78–1.84, p=0.41), suggesting that BLK may be particularly involved in the progression of proliferative glomerulonephritis.

Conclusion: We demonstrated that polymorphisms in *BLK* and *IRF5* genes are associated with renal involvement and LAC positivity, respectively, in Japanese SLE patients. This suggests that disease susceptibility genes would effect on SLE sub-phenotype.

Background: The HapMap International project has provided an extensive catalogue of the common human genetic variation. It made possible the design of genome-wide association studies, which have radically contributed to the dissection of the genetic basis of SLE and multiple susceptibility variants have been identified. The 1000 genomes project, although not completed yet, is providing a deep source of newly identified variants that are ready to be used. In the present work, we have fine mapped four SLE-associated genes and imputed a handful of SNPs using these data, revealing novel potentially functional variants.

Methods: Fine mapping of BLK, ATG5, PXK and SCUBE1 was performed in the European multicenter collection "BIOLUPUS". Individuals with <90% of European ancestry identified by using PCA and STRUCTURE were removed as well as duplicated or related samples. Publicly available reference haplotypes and fine-scale recombination maps were downloaded from the 1000 genomes project (release August 2009) and HapMap phase 3 (CEU+TSI) for chromosomes 3, 6, 8 and 22. We combine these two reference panels and imputed the missing SNPs in our study data set by IMPUTEv2. Only SNPs for which the probabilities of each imputed genotype was >90% and the missing rate was <5% were included. A total of 299 SNPs in PXK, 60 SNPs in ATG5, 66 SNPs in BLK and 115 SNPs in SCUBE1 were tested for association in 1256 cases and 1576 controls, adjusting by the country of origin using GENABELv1.4–4 and PLINKv7. Multiple testing was corrected by genomic control and false discovery rate methods. The minimum set of SNPs explaining the association was calculated by multivariate logistic regression. Any SNP belonging to this set was typed, if it was an imputed SNP. A set of selected regions for each gene was re-sequenced in a number of individuals. Functional studies including expression and splicing analysis were performed.

Results: The only gene with genome-wide significance of association was BLK ($P = 6.5\times10^{-7}$ for the strongest SNP). The previously associated variants rs13277113 ($P = 1.58\times10^{-6}$) and rs2736340 ($P = 1.82\times10^{-6}$) ranked 2nd and 4th respectively. Conditional analysis suggested three independent groups of SNPs: one located in the promoter region (including rs13277113), another one in intron 1 and a third group of low frequency variants (MAF < 0.01) in the 3'UTR region.

In ATG5, the association was explained by two independent SNPs in the surroundings of exon 5. In PXK, a long haplotype of highly correlated SNPs in LD with the previously associated variant rs6445975 was delimited to the end of the gene. Association analysis with the levels of expression of these three genes is presented.

None of the SNPs in SCUBE1 reached significance after correction for multiple testing. Extremely high heterogeneity in the distribution of haplotypes and patterns of LD were observed among different countries.

Conclusions: We not only replicated the association of BLK, ATG5 and PXK but also present an extensive mapping of these genes. We narrowed down the associated regions and performed functional studies in order to understand the role of potentially causal variants on gene function.

Background: Sjögren's syndrome (SS) is a clinically heterogeneous autoimmune disease characterized by exocrine gland dysfunction and involves both innate and adaptive immune responses. A complex genetic architecture has been hypothesized, however, genetic studies to date have been primarily limited to candidate genes approaches. We used high-density genotyping arrays to perform a genome-wide association (GWA) scan in an unbiased manner to identify SS susceptibility loci.

Methods: We have established the Sjogrens Genetics Network (SGENE) to assemble samples (currently >4000 subjects) for large-scale genetic studies. We used the Illumina OMNI1-Quad arrays containing >1.1×10E6 variants in a discovery cohort of 272 European-derived primary SS cases and 387 healthy controls. Stringent quality control criteria, adjustments for population stratification, and standard GWA statistical methodologies were used to compare allele frequencies between cases and controls. A total of ~774,000 single nucleotide polymorphisms (SNPs) were tested for association to SS in our final GWA dataset. For replication, we used a DNA pooling approach in an independent collection of cases and controls of European-decent, also genotyped using the OMNI1-Quad arrays. Weighted Z scores were used to determine meta p-values for combined discovery and replication data.

Results: The most significant region associated with risk of disease was the major histocompatibility complex (MHC) with 45 SNPs exceeding a genome-wide significance threshold of 5×10E-8, all of which replicated in our independent pooled samples. Within the MHC, peak significance was observed at HLA-DRA for rs9268832 (p=1.65×10E-10, odds ratio 2.3, CI: 1.8–3.0). Analysis in the replication cohort for rs9268832 resulted in p=1.61×10E-4, and an overall combined p=2.56×10E-13. Additional results across the extended MHC support association with multiple loci throughout this region. Evidence for novel genetic associations outside of the MHC were also observed. For example, association of SS with rs13282959 in both the discovery and replication cohorts was identified (meta p=1.93×10E-6). This SNP is located in a region of high regulatory potential near the musculin (MSC) gene. MSC is a multi-functional transcription factor involved in signaling pathways following B cell receptor activation. We specifically evaluated our data for evidence of association with ~30 loci previously established in systemic lupus erythematosus (SLE), a closely

related autoimmune disease. Association of IRF5 and TNIP1 was observed in both our discovery and replication cohorts. Support for other associated genes in both SLE and SS was observed for BANK1, PRDM1, JAZF1, STAT4, and IL12B.

Conclusions: This study represents the most comprehensive assessment of the genetic contribution to SS performed to date. We have identified and replicated numerous loci associated with disease, some of which have been previously associated with SLE and other related autoimmune diseases. Further characterization of these effects are warranted to precisely define causal variants and determine functional consequences that contribute to disease pathogenesis.

An Immune Signature Based on Ex Vivo Responsiveness of Peripheral Blood Cells Is Associated with Radiographic Joint Damage in Rheumatoid Arthritis. John M. Davis III, Keith L. Knutson, Michael A. Strausbauch, Cynthia S. Crowson, Terry M. Therneau, Eric L. Matteson and Sherine E. Gabriel. Mayo Clinic, Rochester, MN

Purpose: In rheumatoid arthritis (RA), joint damage may occur even in patients with minimal disease activity. Thus, new techniques for determining the potential for future immune-mediated joint injury may facilitate targeting high-risk patients for aggressive therapy. The objective was to identify immune signatures of RA damage by broadly assessing ex vivo cytokine release by PBMC in response to stimulation.

Methods: We studied patients with early RA of <3 yrs duration, positive for rheumatoid factor or anti-citrullinated peptide antibodies. Radiography of the hands, wrists and feet was performed, and modified van der Heijde-Sharp (vdH-S) scores were determined. To establish immune signatures, we measured the release of 17 cytokines from PBMC in response to a panel of stimuli or in media alone using multiplexed immunoassays. The stimulation panel included anti-CD3/anti-CD28, CpG oligonucleotides (CpG), combined cytomegalovirus and Epstein Barr virus lysates (CMV/EBV), heat shock protein 60 (HSP60), phorbol myristate acetate with ionomycin (PMA/ionomycin), phytohemagglutinin (PHA), and combined Staphylococcal enterotoxins A and B (SEA/SEB). Mixed effects models were used to normalize the cytokine data and adjust for assay effects. Gradient boosting models (GBM) were used to predict the vdH-S score using all of the 136 stimulated cytokine concentrations and thereby derive a multi-cytokine prediction score (scale 0–100). Logistic regression models were used to determine the association of the GBM prediction score with the vdH-S score, dichotomized at the median, adjusting for clinical covariates.

Results: The study included 59 patients (median age: 54 yrs; 59% female; RA duration: 12.4 mo); 49 (84%) and 19 (24%) were taking methotrexate and biologics, respectively. The median vdH-S score was 18 units (interquartile range: 7, 37). In the GBM analysis, the production of the following cytokines (by descending relative influence for each stimulant) was associated with the vdH-S score, including: IL-12, IL-1β, and GM-CSF with CMV/EBV; IL-12, IL-10 and IL-4 with PMA/ionomycin; IL-6, IFN-g, and GM-CSF with anti-CD3/anti-CD28; IL-5, IL-12, and IL-10 with SEA/SEB; IL-12 with HSP60; IL-2, IL-4, and MCP-1 with CpG; GM-CSF and IL-5 with PHA; and finally, IL-7 and IL-8 in media alone; this model strongly correlated with the vdH-S score (Spearman correlation: 0.87). Cytokine production was generally increased with high vdH-S scores although GM-CSF, IL-2, IL-4 and MCP-1 were decreased under various stimulations. The multi-cytokine prediction score (per 10 units) was strongly associated with the presence of higher joint damage (vdH-S score $\geq$18 units) with an odds ratio of 1.28 (95% confidence interval: 1.11, 1.46; $p<0.001$) independent of covariates, including the use of methotrexate, biologics, and prednisone.

Conclusions: A PBMC-based immune signature, reflecting aberrant responsiveness of the peripheral innate and adaptive immune systems, is strongly associated with extent of radiographic joint damage in patients with early RA. Further studies are necessary to understand the biological implications of the findings and to define their clinical applicability.

An Immune Signature Based on the Ex Vivo Responsiveness of Peripheral Blood Cells for Monitoring Disease Activity in Rheumatoid Arthritis. John M. Davis III, Keith L. Knutson, Michael A. Strausbauch, Cynthia S. Crowson, Terry M. Therneau, Eric L. Matteson and Sherine E. Gabriel. Mayo Clinic, Rochester, MN

Purpose: New techniques with enhanced capacity to detect systemic immune dysregulation are needed to enable tighter control of rheumatoid arthritis (RA). The objective was to identify an "immune signature" for predicting the level of disease activity in patients with RA by broadly assessing ex vivo cytokine release by PBMC in response to stimulation.

Methods: We conducted a correlative study of patients with early RA in an academic rheumatology practice. Data were collected for patient reported outcomes (PROs), including pain, morning stiffness, disability, and quality of life, using validated instruments. To establish immune signatures, we measured the release of 17 cytokines by PBMC in response to a panel of stimuli or in media alone using multiplexed immunoassays. The stimulant panel included anti-CD3/anti-CD28, CpG oligonucleotides (CpG), combined cytomegalovirus and Epstein Barr virus lysates (CMV/EBV), heat shock protein 60, phorbol myristate acetate with ionomycin (PMA/ionomycin), phytohemagglutinin, and combined Staphylococcal enterotoxins A and B. Mixed effects models were used to normalize the log-transformed cytokine data and adjust for assay effects. Factor analysis was used to combine multiple PROs into a single composite outcome. Gradient boosting models (GBM) were used to predict the PRO composite outcome using all of the 136 stimulated cytokine concentrations and thereby derive a multi-cytokine prediction score. Linear regression models were used to determine the associations of the score with validated disease activity measures, including the Disease Activity Score in 28 joints (DAS28), adjusting for clinical covariates.

Results: The study included 98 patients (63% female; mean age 56 yrs; mean RA duration 2.9 mo) with a total of 136 visits. In the factor analysis, pain levels influenced the PRO composite outcome most heavily. Among patients with high PRO composite scores, we observed that the release of T cell-derived cytokines, including IFN-γ, MIP-1β, IL-4, IL-5, IL-10, and IL-17, was significantly decreased. In contrast, we observed that the release of several innate cell-derived cytokines, including IL-1β, IL-6, and TNF-α, was significantly increased in these patients. In the GBM analysis, the most influential cytokines were MIP-1β, IL-7, IL-5, IFN-γ, and IL-13, and the most influential stimuli were CMV/EBV, CpG, PMA/ionomycin, and anti-CD3/anti-CD28. The multi-cytokine prediction score was confirmed to be associated with the PROs used to train the score and also with established disease activity measures, demonstrating evidence of criterion validity. The score (0 – 100) was strongly associated with the DAS28 (β coefficient: 0.25 per 10 units; standard error: 0.063; $p=0.0002$), independent of clinical covariates, including the use of methotrexate, biologics, and prednisone.

Conclusions: A PBMC-based immune signature, reflecting aberrant responsiveness of the innate and adaptive immune systems, is able to quantify the clinical activity of RA. If validated and standardized in future studies, this approach could enable more sensitive monitoring of RA activity, facilitating strategies of tight control and improved patient outcomes.

Analysis of the Association of CDA (Cytidin Deaminase) (K27Q), TNF-α (-308G>A) and PTPN22 R620W Genetic Polymorphisms with Auto-Antibody Seropositive RA and the Response to B Cell Depletion. Barbara Tolusso[3], Fabio Di Pietro[7], Francesca Bobbio Pallavicini[4], Viviana Ravagnani[1], Maurizio Benucci[5], Edoardo Podesta'[2], Fabiola Atzeni[6], Valerio Napolioni[7], F. Carpi[7], Giusy Peluso[3], Francesca Faustini[3], Elisa Gremese[3], G. Biasi[1], Marianela Manfredi[5], Pier Carlo Sarzi Puttini[6], Bruno Lagana'[2], Carlomaurizio Montecucco[4] and Gianfranco Ferraccioli[3]. [1]Department of Clinical and Experimental Medicine, Section of Rheumatology & Internal Medicine, University of Verona, Verona, Italy, [2]Division of Clinical Immunology and Rheumatology, S. Andrea University Hospital, "Sapienza" University of Rome, II School of Medicine, Rome, Italy, [3]Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy, [4]Division of Rheumatology, University of Pavia, IRCCS S. Matteo Foundation, Pavia, Italy, [5]Rheumatology Unit, Department of Internal Medicine, Ospedale di S. Giovanni di Dio, Florence, Italy, [6]Rheumatology Unit, University Hospital L. Sacco, Milan, Italy, [7]School of Biosciences and Biotechnology, University of Camerino, Camerino (MC), Italy

Objective: To evaluate the genetic relationship between the two functional polymorphism of CDA (22G>A) and TNF-α (-308G>A) gene, and PTPN22 R620W respectively, in Rheumatoid Arthritis (RA) and their possible association with B cell depletion therapy.

Methods: One hundred and twenty three (82% female) RA patients who did not respond to previous DMARDs and/or TNFα blockers were enrolled in a multicenter italian study to evaluate the efficacy of RTX therapy. All RA were seropositive for at least one (RF-IgG,RF-IgA,RF-IgM,MCVA,ACPA) autoantibody. 181 healthy subjects living in the same geographical area entered in the study as a control group. DNA from patients and controls was genotyped for the PTPN22 R620W, TNFα-308 G/A and CDA K27Q polymorphisms by RLFP methods. The EULAR response criteria were used to assess the disease activity (DAS 44 ≤ 2.4: good response) at 6 months follow-up. Exact HWE tests were performed for each SNP independently among cases and controls. Logistic regression models (SAS V9.1.3) were used to assess the effects of each of the 4 SNPs on RA with adjusting for sex and age at disease onset. Multifactor dimensionality reduction (MDR,) was used to verify our interaction results. Models are evaluated on the testing balanced accuracy statistic (TBA), the cross-validation consistency (CVC) and the statistical significance of the model. These data were also analyzed using the G-MDR (V0.7) software package, an algorithm that includes adjustment for covariates (sex and age).

Results: All SNPs were in HWE except CDAK27Q (p=0.000011). Considering the TNFα −308A SNP, we showed an increased frequency of the allele A (19.8%) in the RA cohort compared to controls (9.1%; OR (95% CIs): 2.23 (1.40–3.60). The analysis of the CDA K27Q SNP showed a significant increased frequency of the genotype Q*/Q* (40.2%) and a decreased frequency of the genotype K*/Q* (31.2%) in RA patients compared to controls (Q*/Q*: 29.9%; OR: 1.58 (1.02–2.44); K*/Q*: 42.3%; OR: 0.62 (0.40–0.96). We found no difference in genotype distribution nor in allele frequencies of PTPN22 R620W between RA patients and controls. Based on the multilocus MDR approach, CDA K27Q SNP was the strongest risk factor for RA, with an average prediction accuracy of 57.9% (p=0.008). When we allowed for two genes in the analysis, the TNFα −308 G/A was identified in addition to CDA K27Q SNP and predicted disease status correctly 58.9% of the time (p=0.002); the prediction accuracy reached the value of 59.6% considering also the contribution of the PTPN22 R620W (p=0.001). Instead, the G-MDR method that includes sex and age in the analysis, showed that TNFα −308 G/A was the strongest risk factor for RA, with an average prediction accuracy of 57.6% (p<0.0001). No association was seen between PTPN22 R620W, TNFα-308 G/A and CDA K27Q polymorphisms and EULAR good response to RTX after 6th months FU.

Conclusions: Aggressive-progressive RA prone to receive RTX associates to −308 allele*A of the TNFα gene which is linked to high TNFalpha synthesis and to the QQ CDA genotype which is linked to a lower inhibition of the GM-CSF synthesis.

Purpose: *PPP2CA* encodes the most highly expressed catalytic subunit α of protein phosphatase 2A (PP2A), which comprises a family of serine/threonine protein phosphatase with various important roles in regulation of NF-κB, MAPK and WNT signaling pathways, as well as cell growth and division. Abnormal expression of PP2A in T cells from SLE patients results in the decreased production of IL-2, suggesting the involvement of PP2A in the abnormal immune regulation in SLE patients (JCI, 115, 3193, 2005). Here we examined the association of *PPP2CA* variants with SLE.

Methods: We genotyped a panel of 18 SNPs spanning a 32kb region from *PPP2CA* promoter to 3.2kb downstream (including 1 at promoter, 15 at intron and 2 at downstream) in six populations: African-Americans and Gullahs (AA&Gullah) (1,651 cases, 1,962 controls), Asians (1,272 cases, 1,270 controls), European Americans (EA) (3,980 cases, 3,546 controls), Hispanic and Native Americans (Hisp&NA) (1,508 cases, 812 controls) using Illumina iSelect system. Additionally, ~400 ancestry informative markers were used to control population admixture and to eliminate genetic outliers. Chi-square and Mantel-Haenszel test were performed to compare the allelic difference and conduct the trans-ethnic meta-analysis.

Results: Multiple SNPs of *PPP2CA* showed significant association with SLE in Asians, EA and Hisp&NA but not in AA&Gullah. Two SNPs (rs7704116 at intron 2 and rs10491322 at the 3′ downstream) showed consistently strong association with SLE across Asian, EA and Hisp&NA, which were in almost complete linkage disequilibrium (LD) (r^2 = 0.98–0.99) with each other in each population. Of note, rs7704116 showed the strongest association signal with SLE in Asians and Hisp&NA and the smallest *P* value after Meta-analysis of genotype data in Asian, EA, Hisp&NA and AA&Gullah populations ($p_{Meta} = 3.8 \times 10^{-7}$, OR = 1.21[1.12–1.30]) (Table 1). One 32kb haplotype block spanning from promoter to 3′UTR downstream of *PPP2CA* was constructed based on the genotyping data of 18 SNPs in Asian, EA, Hisp&NA and AA&Gullah populations, which led to the identification of a common risk haplotype (GGCAAAAC-GAAAAAAAAG) strongly associated with SLE ($p_{Meta} = 2.3 \times 10^{-7}$, OR= 1.28 [1.13–1.31]) (Table 1).

Table 1. Associations of rs7704116 and common risk haplotype with SLE in multiple ethnic groups

SNP/Haplotype	Position	Population	Number of subjects Cases	Controls	MA	MAF Cases	Controls	*P* value	OR (95% CI)	Meta-analysis *P* value	OR (95% CI)
rs7704116	Intron 2	Asian	1272	1270	A	0.07	0.04	8.1×10^{-5}	1.64 [1.28–2.11]	3.8×10^{-7}	1.21 [1.12–1.30]
		European	3971	3536	A	0.08	0.07	5.8×10^{-4}	1.24 [1.1–1.4]		
		Hisp&NA	1507	810	A	0.19	0.15	3.4×10^{-3}	1.28 [1.08–1.5]		
		AA&Gullah	1651	1962	A	0.13	0.13	0.68	1.03 [0.9–1.18]		
			Haplotype frequencies								
GGCAAAACGAAAAAAAAG	–	Asian	1272	1270	–	0.06	0.04	2×10^{-4}	1.59 [1.2–2.0]	2.3×10^{-7}	1.28 [1.13–1.31]
		European	3971	3536		0.09	0.08	0.001	1.22 [1.1–1.4]		
		Hisp&NA	1507	810		0.23	0.18	0.02	1.29 [1.1–1.5]		
		AA&Gullah	1651	1962		0.12	0.12	0.48	1.05 [0.9–1.2]		

Conclusions: This study provides evidence that *PPP2CA* represents a novel locus predisposing to SLE susceptibility in Asian, European, Hispanic and Native American populations. The common risk haplotype shared in these populations is likely to carry one or more underlying causal variant(s) that increase risk for the development of SLE.

[1]Arthritis and Immunology Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Arthritis and Immunology Program, Oklahoma Medical Research Foundation, Oklahoma City, OK; University of Oklahoma Health Sciences Center, Oklahoma City, OK; US Department of Veterans Affairs Medical Center, Oklahoma City, OK, [3]Center for Genomics and Oncological Research, Granada, Spain, [4]Cincinnati Children's Hospital Medical Center and US Department of Veterans Affairs Medical Center, Cincinnati, OH, [5]Imperial College London, Hammersmith Hospital, London, United Kingdom, [6]Medical University of South Carolina, Charleston, SC, [7]University of Alabama, Birmingham, AL, [8]University of California, Los Angeles, CA, [9]University of Chicago, Chicago, IL, [10]University of Southern California, Los Angeles, CA, [11]Wake Forest University Baptist Medical Center, NC, [12]Wake Forest University Health Sciences, NC

Objectives: Our previous study identified the G allele of an X-linked *TLR7* SNP (rs3853839, located at 3'UTR) associated with increased expression levels of *TLR7* and SLE susceptibility in 9,274 Eastern Asians ($p = 6.5\times10^{-10}$) that had a stronger male effect. In this study, we sought to further characterize and localize SLE-associated SNPs of *TLR7* and its functionally related gene *TLR8* (17-kb downstream of rs3853839) in non-Asian populations.

Methods: A total of 47 SNPs, spanning the ~55kb genomic region of *TLR7-TLR8*, were genotyped on a customized Illumina array in a collection of case-control samples including European Americans (EA, 3930 cases vs. 3477 controls), African Americans & Gullahs (AA&Gullah, 1674 cases vs. 1915 controls), and Hispanics & Native Americans (Hisp&NA, 1479 cases vs. 800 controls). Additionally, ~400 ancestry informative markers were genotyped to control population stratification and remove genetic outliers for analysis. Association analysis of each SNP was performed using PLINK and conditional analysis was conducted to distinguish independent signals from associated SNPs. We used Q statistic to test the heterogeneity of OR between males and females, and Mantel-Haenszel test to generate a trans-ethnic meta-analysis *P* value.

Results: Significant associations of SNPs ($P < 0.05$) with SLE in each ethnic group were observed at *TLR7* region after Bonferroni correction, including 3 SNPs in EA, 1 SNP in AA&Gullah and 1 SNP in Hisp&NA. The following conditional analysis revealed the previously identified *TLR7* 3'UTR SNP (rs3853839) as the only independent variant across all 3 populations, exhibiting the strongest association ($P = 1.5\times10^{-6}$ in EA, 1.4×10^{-3} in AA&Gullah and 2.8×10^{-6} in Hisp&NA, Table 1). Trans-ethnic meta-analysis yielded a *P* with genome-wide significance ($P = 1.05\times10^{-12}$, OR = 1.26), confirming our previous finding in Eastern Asians. However, unlike the Asian sample where both sexes showed association, the evidence for this SNP conferring risk to SLE was only observed in female non-Asian datasets.

Table 1. Association of rs3853839 with SLE in multiple ethnic groups

Ethnicity	Panels	Sex	Case/ Control	G Allele Frequency Case	Control	*P*	OR (95% CI)
Eastern Asian	Combined	M	358/1550	0.89	0.77	1.3×10^{-6}	2.33 (1.64–3.30)
		F	3976/3390	0.80	0.77	1.2×10^{-7}	1.24 (1.14–1.34)
		All	4334/4940	0.81	0.77	**6.5×10^{-10}**	**1.27 (1.17–1.36)**
European American	Replication	M	338/1137	0.198	0.201	0.9	0.99 (0.73–1.34)
		F	3592/2340	0.203	0.165	3.9×10^{-7}	1.28 (1.17–1.41)
		All	3930/3477	0.202	0.172	**1.5×10^{-6}**	**1.25 (1.14–1.37)**
AA&Gulah	Replication	M	131/573	0.214	0.157	0.1	1.46 (0.91–2.35)
		F	1543/1342	0.196	0.166	4.1×10^{-3}	1.22 (1.07–1.40)
		All	1674/1915	0.196	0.165	**1.4×10^{4}**	**1.23 (1.08–1.41)**
Hsp&NA	Replication	M	114/73	0.421	0.479	0.43	0.79 (0.44–1.43)
		F	1365/727	0.446	0.366	6.3×10^{-7}	1.40 (1.23–1.60)
		All	1479/800	0.445	0.371	**2.8×10^{-6}**	**1.36 (1.20–1.55)**

Conclusion: We replicated the association between rs3853839 and SLE with genome-wide significance in EA, AA&Gullah, and Hisp&NA populations, showing *TLR7* as a common risk locus for SLE in multiple ethnic groups.

Background: Systemic lupus erythematosus (SLE) is a complex autoimmune disease with varied and potentially severe clinical manifestations affecting multiple organs. Prevalence of this disease varies between genders and among age-groups and ethnicities. SLE affects women nine times greater than men and is more common in non-Caucasians than in Caucasians. Recent studies indicate that genetic variants in the region of tumor necrosis factor alpha-induced protein 3 (*TNFAIP3*) are associated with SLE in subjects of European and Asian ancestry. *TNFAIP3* encodes a zinc-finger protein called A20, a critical regulator of inflammatory signaling pathways. To further characterize and localize the effect of *TNFAIP3*, we genotyped and imputed single-nucleotide polymorphisms (SNPs) within and flanking *TNFAIP3* in multiple populations: European, African-American, Asian including Korean, Hispanic enriched for Amerindian-European admixture, and Gullah populations.

Methods: Using a custom designed SNP panel for the Illumina iSelect system, we genotyped 127 SNPs in and around *TNFAIP3* and 343 ancestry-informative markers (AIMs) in a total of 8922 SLE unrelated cases and 8077 controls. Then, using HapMap Phase III and 1000 Genomes Project data we imputed a minimum of 274 additional SNPs for each of the populations (the number varied based on linkage disequilibrium structure). We converted the posterior probabilities to the most likely genotypes with a threshold of 0.8 and removed imputed SNPs with less than 90% average certainty of the most probable genotypes. We assessed single marker association to SLE using logistic regression with sex, global and local ancestry adjustments under additive, dominant, and recessive models.

Results: Association analysis identified risk haplotypes in Europeans and Asians likely to harbor a causal variant. Further haplotype comparisons across populations revealed a variant that likely explains the majority of the genetic association between SLE and *TNFAIP3* identified in our study populations with $P=1.96 \times 10E-8$, OR=1.69, 95% CI=1.41–2.04 in Europeans, $P=3.30 \times 10E-9$, OR= 2.26, 95% CI=1.73–2.97 in Asians, and $P=1.24 \times 10E-9$, OR=2.53, 95% CI=1.88–3.41 in Koreans alone. No significant association was found in other populations.

Conclusion: These results support genetic association with SLE in the region of *TNFAIP3*, unique to Europeans and Asians and further demonstrate the complexity of identifying associations across different populations. Sequencing and functional studies are necessary to validate this variant and determine the contribution of *TNFAIP3* to SLE.

Background: The transcription factor NF-kB is an important factor in inflammation and the immune response. Unrestrained NF-kB response has previously been associated with autoimmune disease, sepsis, and some cancers. It is therefore not surprising that NF-kB signaling is tightly regulated within the cell through a pathway of protein-protein interaction and post-translational protein modification. One key component of this pathway is the *TNFAIP3* complex consisting of *TNFAIP3*, *TNIP1*, *TNIP2*, *TAX1BP1*, *ITCH*, and *RNF11*. This complex, along with the ubiquitin-conjugating enzyme *UBE2L3*, deactivates NF-kB pathway proteins through deubiquitation of K63 polyubiquitin chains and subsequently targets those proteins for degradation via K48 ubiquitination. Recent GWAS have revealed that genetic variants in the *TNFAIP3*, *TNIP1*, and *UBE2L3* regions are associated with systemic lupus erythematosus (SLE) in subjects of European and Asian ancestry. SLE is an autoimmune disease characterized by loss of tolerance to self-antigens and dysregulated interferon responses. To further characterize and localize the effect of the *TNFAIP3* regulatory complex, we genotyped and imputed single-nucleotide polymorphisms (SNPs) within and flanking *TNIP1* on 5q33, *TNIP2* on 4p16, *UBE2L3* on 22q11, *TAX1BP1* on 7p15 in multiple populations: African-Americans (1,569 cases/1,893 controls), Asians (1,328 cases/1,348 controls), Europeans (4,248 cases/3,818 controls), Gullah (155 cases/131 controls), and Hispanics enriched for Amerindian-European admixture (1,622 cases/887 controls).

Methods: Using the Illumina iSelect system, we genotyped a total of 231 SNPs in and around those loci and 343 ancestry-informative markers (AIMs). We then imputed untyped SNPs at those loci using HapMap Phase III and 1000 Genomes Project data. We converted the posterior probabilities to the most likely genotypes with a threshold of 0.8 and removed imputed SNPs with less than 90% average certainty of the most probable genotypes. We assessed single marker association to SLE using logistic regression with sex and global ancestry adjustments under additive, dominant, and recessive genetic models.

Results: We observed strong associations between SLE and multiple SNPs within *TNIP1* in Europeans, Hispanics, African-Americans, and Asians ($P_{combined}=5 \times 10E-8$) with the strongest signal at rs7708392 ($P_{combined}=2.53 \times 10E-19$). We also identified strong associations within *UBE2L3* in Europeans, Asians, African-Americans and Hispanics with the most significant association at rs7444 ($P_{combined}=1.25 \times 10E-14$).

Conclusions: These results establish that variants within *TNIP1* and *UBE2L3* contribute to differential risk of SLE in multiple populations. Further functional studies will be required to determine the precise variant(s) influencing SLE risk.

Association Study of the *ILAK1* Gene with Susceptibility to Systemic Lupus Erythematosus and Systemic Sclerosis. Yuko Ota[3], Yasushi Kawaguchi[1], Manabu Kawamoto[2], Kae Takagi[2], Akiko Tochimoto[2], Yasuhiro Katsumata[2], Takahisa Gono[2], Sayumi Baba[2], Yuko Okamoto[2] and Hisashi Yamanaka[4]. [1]Tokyo Women's Medical Univ, Tokyo, Japan, [2]Tokyo Women's Medical Univ, [3]Tokyo Women's Medical University, Tokyo, Japan, [4]Tokyo Womens Med Univ, Shinjuku-ku, Tokyo, Japan

We explored whether single nucleotide polymorphisms (SNPs) in the *Interleukin-1 receptor associated kinase-1*(*IRAK1)* gene contribute to systemic lupus erythematosus (SLE) and systemic sclerosis (SSc) susceptibility in the Japanese population. Two hundred forty-four patients with SLE, 180 patients with SSc and 268 healthy controls (HC) were enrolled in this study. Four SNPs (rs2239673, rs763737, rs7061789, and rs5945174) in the *IRAK1* gene were determined by allelic discrimination with the use of a specific TaqMan probe and PCR restriction fragment length polymorphism (PCR-RFLP). Association measured using either $\chi 2$ or Fisher's exact test at the allelic and genotypic levels. Because *IRAK1* is located on chromosome Xq28, cases and controls were stratified by gender and measured for each stratum.

In patients with SLE, the most common clinical manifestations in this study were nephritis (45%), cytopenia (32%), and neuropsychiatric manifestations (30%). The prevalence of butterfly rash was 17%, arthritis was 25%, serositis was 7%, and antiphospholipid antibody syndrome was 5%.

Both alleles and genotypes of all of the four SNPs in *IRAK1* gene showed strong associations with SLE in female cohort ($P < 0.0002$; odds ratio = 1.9), although there were no associations between alleles and genotypes in the SNPs with whole SLE and in male cohort. In SLE, there were significant correlations between the allele of each SNP and nephritis. There were also significant differences in the frequencies of genotype of the SNPs between patients with butterfly rash or cytopenia and HC. In the frequency of genotype of rs5945174, there was a significant difference between patients with nephritis and HC. In patients with SSc, there were no association in the alleles and genotypes of the four SNPs in the *ILAK1* gene.

In haplotype analyses, GGGG haplotype (defined as "G" at rs2239673, "G" at rs763737, "G" at rs5945174, "G" at rs7061789) was associated with susceptibility to Japanese patients with both SLE and SSc. The p value for association reached to $10^{-8}$and 10^{-2} respectively.In this study, we confirmed the association between an SNP in the *IRAK1* gene and susceptibility to SLE in female Japanese population. Several autoimmune disorders, including multiple sclerosis, rheumatoid arthritis, SLE and SSc are more common in women than men. Several mechanisms have been proposed as explanations for this gender bias. IRAK1, an X chromosome gene may have a critical role in the pathogenesis of SLE and SSc.

Combining Genetic and Environmental Risk Factors To Model RA Susceptibility. Lori B. Chibnik[3], Bo Ding[7], Brendan T. Keenan[4], Katherine P. Liao[2], Karen H. Costenbader[1], Lars Klareskog[6], Lars Alfredsson[7] and Elizabeth W. Karlson[5]. [1]Brigham & Women, Boston, MA, [2]Brigham & Women's Hosp, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham and Women's Hospital, [5]Brigham and Womens Hosp, Boston, MA, [6]Karolinska University Hospital, Stockholm, Sweden, [7]Karolinska University Hospital

Background: Cumulative genetic risk scores (GRSs) have shown promise in modeling rheumatoid arthritis (RA) susceptibility. In addition, many gene-environment interactions (GEIs) have been significant factors in RA risk. We combine a GRS and GEIs to develop the best model for RA risk.

Methods: We studied models of RA risk in two cohorts, the U.S. Nurses' Health Studies (NHS) and the Swedish Epidemiologic Investigation of RA (EIRA). We created a weighted GRS using 31 non-HLA single nucleotide polymorphisms at validated RA risk loci, where the weight for each risk allele is the log of the odds ratio based on published GWAS or meta-analysis. In addition, we genotyped HLA-DRB1 locus with subjects coded as having 0, 1 or 2 copies of shared epitope (SE) alleles. Based on previously found significant interactions, we included two additional polymorphisms, GSTT1-null and HMOX1. Smoking was the main environmental factor for GEI (dichotomized as $\leq$ 10 pack-years vs. $>$ 10 pack-years). Parallel analyses were performed among (1) 371 Caucasian seropositive (CCP+ and/or RF+) cases and 551 controls from NHS and (2) 987 Caucasian ACPA positive cases and 958 controls from EIRA to develop the best model in each dataset. We began with a base model including year of birth and smoking (plus sex and region of Sweden in EIRA). Hierarchical models adding the most significant factors were compared to the previous and base models using pseudo R^2 for parsimony and area under the ROC curve (AUC) and the Integrated Discrimination Improvement (IDI, which quantifies the overall improvement in sensitivity and specificity) for discrimination.

Results: The mean (SD) age of diagnosis of RA was 57 (10) in NHS and 50 (12) in EIRA. For NHS, the base model produced an AUC of 0.578. Adding the GRS and HLA to the model increased the AUC to 0.669. The IDI between the 2 models was 0.07 (0.05–0.08), indicating a significant improvement (null IDI = 0). Our best performing model contained the GRS and GEIs between smoking and HLA, GSTT1-null and HMOX1 and had an AUC of 0.700 and IDI of 0.10 (0.07–0.12) compared to the base model and 0.03 (0.02–0.04) as compared to the model with GRS and HLA. For EIRA, the base model produced an AUC of 0.630. Adding the GRS and HLA to the model increased the AUC to 0.733. The IDI between the 2 models was 0.11

(0.10–0.13). Adding the GEIs between smoking and HLA did not significantly improve the model (AUC = 0.734, IDI = 0.001 [−0.003–0.003]), compared to the model with GRS, clinical factors and HLA. Inclusion of other covariates did not improve the models in either cohort.

Conclusion: Inclusion of GEIs significantly improves the discriminative ability of models predicting RA risk in NHS but not EIRA. These conflicting results emphasize the importance of developing models separately in different populations. However, further work to discover genetic, environmental and GEI factors is needed before these models are used in clinical settings.

Table. Summary Measures for Selected Models in the US Nurses' Health Study and Swedish Epidemiologic Investigation in RA

	NHS[1]			EIRA[2]		
Model	AUC[3]	IDI[4] (95% CI) compared to Base	IDI[4] (95% CI) compared to Base+GR5+ HLA-SE	AUC[3]	IDI[4] (95% CI) compared to Base	IDI[4] (95% CI) compared to Base+GRS+ HLA-SE

Contribution of *VpreB1* Gene Copy Number Variation to the Risk of Rheumatoid Arthritis. Seung-Cheol Shim[2], Mi-Kyoung Lim[2], Dong-Hyuk Sheen[2] and Yeun-Jun Chung[1]. [1]Catholic University, Seoul, Korea, Republic of, [2]Eulji University, Daejeon, Korea, Republic of

Background: Copy number variation (CNV), especially in the genomic loci harboring dosage-sensitive genes, has been reported to affect susceptibility to diverse autoimmune diseases. In human, a copy number loss of 22q11.2, a region harboring pre-B cell receptor gene (*VpreB1*), has been suggested to be associated with chronic autoimmune arthritis. Recently, mice lacking surrogate light chain encoded by λ5 and *VpreB1* has been reported to harbor high levels of autoantibodies, and showed evidence of escape of pre-B cells expressing prototypic autoantibody heavy chains from negative selection, leading to mature autoantibody secreting $CD21^{-}CD23^{-}$ B cells in their serum.

Objective: To investigate whether CNV of the *VpreB1* associates with susceptibility to rheumatoid arthritis (RA), and whether RA patients have a significantly higher frequency of $CD21^{-}CD23^{-}$ B cells in the peripheral blood than healthy controls.

Methods: We evaluated the copy numbers of the *VpreB1* in an independent cohort of 229 cases and 233 controls using genomic quantitative real-time PCR. We also performed fluorescence in-situ hybridization analysis targeting *VpreB1* locus (22q11.22) and diploid control locus of the same chromosome arm (22q13.1). Next, we explored the frequency of B cell subsets in the peripheral blood from RA patients and controls, and further characterized $CD21^{-}CD23^{-}$ B cells using FACS.

Results: The median gene dose of *VpreB1* in the study population was two. The proportion of the individuals with <2 copy of *VpreB1* was significantly higher in RA patients than in controls (10.9% *vs* 0.9%, $p<0.0001$), while that of the individuals with >2 copy was lower in RA patients (1.7% in RA *vs* 18.9% in controls, $p<0.0001$).

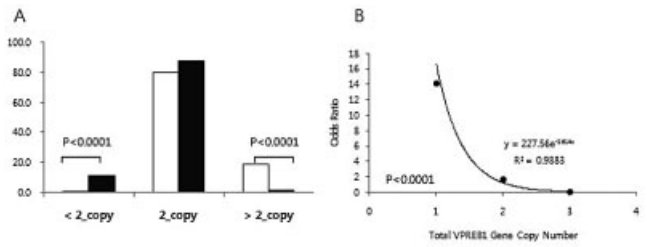

Figure 1.

VpreB1 copy number < 2 was associated with an increased risk of RA in which the odds ratio (OR) was 11.5 (95% CI 2.7–49.3). The OR for RA in individuals with >2 copies was significantly lower than that with 2 copies (OR=0.1, 95% CI 0.03–0.3). We also found that the proportion of $CD21^{+}CD23^{+}$ cells was significantly lower in RA patients than in controls (26.2% *vs* 34.9%, $p=0.005$), while that of $CD21^{-}CD23^{-}$ cells was significantly higher in RA (11.9% in RA *vs* 5.7% in controls, $p=0.002$).

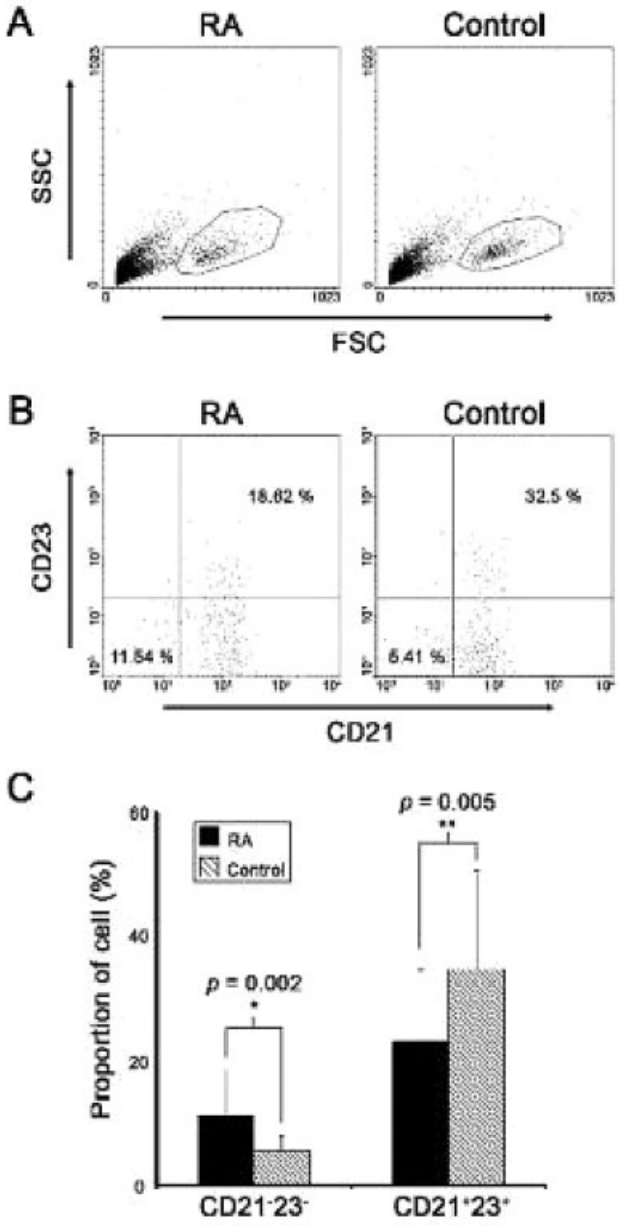

Figure 2.

The majority (73%) of $CD21^{-}CD23^{-}$ B cells were $CD38^{-}CD27^{+}$, a phenotype compatible with switch memory B cells.

Conclusions: This study provides evidence that low copy number of the *VpreB1* is a RA susceptibility genetic variant which could be involved in B cell dysregulation in this disease. These findings could help understanding the pathogenesis of RA and other autoimmune disorders in which aberrant B cell regulation plays an essential role.

Early Disease Onset Is Predicted by a Higher Genetic Risk for Lupus and Is Associated with a More Severe Phenotype in Lupus Patients. Ryan Webb[3], Jennifer A. Kelly[3], Emily C. Somers[7], Travis Hughes[3], Kenneth M. Kaufman[4], Elena Sanchez[3], Swapan K. Nath[3], Gail Bruner[3], Marta E. Alarcon-Riquelme[5], Gary S. Gilkeson[2], Diane L. Kamen[2], Bruce C. Richardson[6], John B. Harley[1] and Amr H. Sawalha[8]. [1]Cincinnati Children's Hospital Medical Center, VAMC, Oklahoma City, OK, [2]Med Univ of South Carolina, Charleston, SC, [3]Oklahoma Medical Research Foundation, [4]Oklahoma Medical Research Foundation, University of Oklahoma, US Department of Veterans Affairs Medical Center, [5]Oklahoma Medical Research Foundation, Uppsala University, Uppsala, Sweden, [6]University of Michigan, Ann Arbor, MI, [7]University of Michigan, [8]University of Oklahoma, US Department of Veterans Affairs Medical Center, Oklahoma Medical Research Foundation, Oklahoma City, OK

Purpose: Systemic lupus erythematosus (SLE) is a chronic, multi-organ, autoimmune disease that affects people of all ages and ethnicities. Herein, we explore the relationship between the age at disease onset and many of its diverse manifestations. We further determine the relationship between age of disease onset and genetic risk in SLE patients.

Methods: We explore the relationship between the age at disease onset and SLE manifestations in a multi-ethnic cohort of 1,317 patients. SLE patients were genotyped across 19 confirmed genetic susceptibility loci for SLE. Logistic regression was used to determine the relationships between the number of risk alleles present and age of disease onset.

Results: Childhood-onset SLE had higher odds of proteinuria, malar rash, anti-dsDNA antibody, hemolytic anemia, arthritis, and leukopenia (odds ratios = 3.03, 2.13, 2.08, 2.50, 1.89, 1.53, respectively, and p-values <0.0001, 0.0004, 0.0005, 0.0024, 0.011, and 0.045, respectively). In females, the odds of having cellular casts were 2.18 times higher in childhood-onset versus adult-onset SLE ($p=0.0027$). With age of onset ≥ 50, the odds of having proteinuria, cellular casts, anti-nRNP antibody, anti-Sm antibody, anti-dsDNA antibody, and seizures were reduced. Instead, late adult-onset SLE patients have higher odds of developing photosensitivity compared with early adult-onset patients (onset ≥ 18 and <50 yrs). Importantly, each SLE-susceptibility risk allele carried within the genome of SLE patients increased the odds of having a childhood-onset disease in an ethnicity-specific manner: each risk allele increased risk by an average of 48% in Gullah, and 25% in African-Americans, but this was not significant in Hispanic and European-American lupus patients.

Conclusions: We report and quantify for the first time the genetic contribution towards predicting early-onset disease in SLE patients. Furthermore, we report a more severe SLE phenotype in patients with an early-onset disease in a large multiethnic cohort, independent of gender, race, and disease duration.

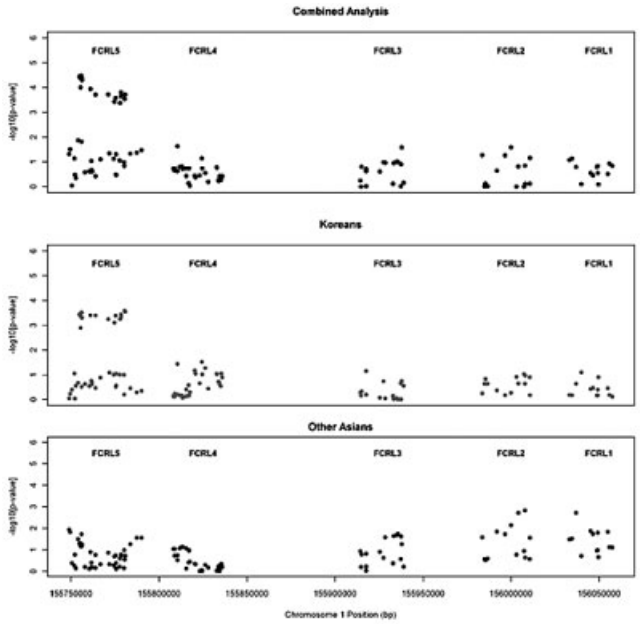
Background: The FCRL gene cluster in humans on chromosome 1q23.1 encodes 5 proteins that share a common ancestor with the classical Ig-binding Fc receptors. Each of the FCRL1–5 gene products are expressed by B cells but vary in their distribution on different subpopulations while FCRL3 is also found on NK and T cell subsets. Despite the similarity to the classical FCR, no definitive data demonstrate binding of Ig but very recent studies suggest binding of MHC and MHC-like molecules. A functional promoter variant in the FCRL3 locus has been inconsistently associated with SLE.

Methods: We have performed a large case-control association study (n= (cases:controls) 3938:3491/1527:1811/961:336/1265:1260 European-American (EA)/African-American (AA)/Hispanic (Hisp)/Asian) with 123 SNPs that span 5 FCRL genes (FCRL1–5) on chrm 1q23.1. SNPs were selected from variants identified in a re-sequencing project and were genotyped on a custom iSelect array (Illumina) as part of a large SLEGEN consortium experiment. Logistic regression models were used to test for association adjusting for population structure through principal components analysis and gender.

Results: In the Korean population (cases=640; controls=740), we detected association within the FCRL5 gene with strongest association at rs1571967 (intronic SNP)($p=3.6\times10\text{-}4$, OR=0.61[0.47–0.80]). This SNP was replicated in an independent collection of Asian case/control samples from North America (n=625/520) (combined $p=3.6\times10^{-5}$, OR=0.66 [0.54–0.80]).



We also observed independent association at 2 non-synonymous SNPs in the FCRL5 gene in the Asian population (peak association at rs6679793, combined $p=2.0\times10^{-4}$, OR=0.69 [57–0.84]). No evidence of association within FCRL3 (including the previously associated −169 promoter SNP, rs7528684) was observed. No significant associations ($p<0.005$) were detected in the FCRL1–5 genes in the EA, AA and Hisp populations.

Conclusions: Together, these results demonstrate an association in the FCRL5 gene with SLE in Asians. FCRL5 is known to bind a viral MHC class I-like molecule and is likely to be involved in regulating innate immunity. The identification of non-synonymous SNPs in FCRL5 that associate with SLE in Asian populations provides the opportunity to explore the impact of genetic variation in regulating immune responses in autoimmunity.

European Genetic Ancestry Protects Against the Development of Renal Disease in Systemic Lupus Erythematosus. Ilana B. Richman[7], Kimberly E. Taylor[7], Sharon A. Chung[6], Laura Trupin[7], Michelle A. Petri[4], Edward H. Yelin[6], Robert R. Graham[3], Annette T. Lee[1], Timothy W. Behrens[2], Peter K. Gregersen[5], Michael F. Seldin[9] and Lindsey A. Criswell[8]. [1]Feinstein Insititute Med Rsch, Manhasset, NY, [2]Genentech Inc, South San Francisco, CA, [3]Immunology Biomarkers Group, Genentech, South San Francisco, [4]Johns Hopkins University School of Medicine, Timonium, MD, [5]N Shore Univ Hosp Rsch Ctr, Manhasset, NY, [6]Rosalind Russell Medical Research Center for Arthritis, Division of Rheumatology, University of California, San Francisco, San Francisco, CA, [7]Rosalind Russell Medical Research Center for Arthritis, Division of Rheumatology, University of California, San Francisco, [8]UCSF-Box 0500, San Francisco, CA, [9]University of California, Davis

Background: African Americans, Asians, and Hispanics with systemic lupus erythematosus (SLE) are at greater risk of developing renal disease than Caucasians. The extent to which genetic or environmental factors contribute to these disparities remains uncertain. We hypothesized that in a multiethnic SLE case series, European genetic ancestry would be protective against the development of renal disease. We further hypothesized that any protective effect of ancestry may be partially attributable to variation in specific genes associated with renal disease in SLE.

Methods: This was a cross-sectional study of 1,910 adults with SLE enrolled in two SLE case collections. Clinical data and confirmation of SLE diagnosis were obtained by chart review. Self-reported socioeconomic data were available for a subset of participants. All participants were genotyped for a set of 116 single nucleotide polymorphisms (SNPs) informative for continental ancestry. A subset of participants was also genotyped for 80 SNPs in 14 candidate genes for renal disease in SLE and had HLA typing available. Continental ancestry was estimated for each participant using the program STRUCTURE, assuming 5 populations. We used logistic regression to test the association between European ancestry and renal disease, adjusting for disease duration and sex. Subsequent analyses assessed whether also adjusting for other continental ancestries, educational attainment, or SNPs in genes associated with renal disease in SLE attenuated the relationship between European ancestry and renal disease.

Results: Genetic ancestry estimation for 1910 SLE cases demonstrated that participants had on average 62.4% European, 15.8% African, 11.5% East Asian, 6.5% Amerindian, and 3.8% South Asian ancestry. Among participants, 34.4% (n=656) had a history of renal disease. After adjustment for ancestry, SNPs in *IRF5* (rs4728142), *BLK* (rs2736340), *STAT4* (rs3024912), *ITGAM* (rs9937837)and *HLA-DRB1*0301* and *DRB1*1501* were associated with renal disease in SLE ($p<0.05$). In multivariable logistic regression, a 10% increase in European ancestry was associated with a 15% reduction in the odds of having renal disease after adjustment for disease duration and sex (OR 0.85, 95% CI 0.82–0.87, p=1.9e-30). Adjusting for other genetic ancestries, educational attainment, or SNPs associated with renal disease did not substantively alter this relationship (Table).

Table. Association between European Ancestry and Renal Disease among SLE Cases

Model	N	OR for 10% ↑ in Euro Ancestry	95% CI	p-value
European ancestry + disease duration, sex (Model 1)	1820	0.85	0.82–0.87	1.9e–30
Model 1 + other genetic ancestries	1820	0.82	0.77–0.87	3.1e–13
Model 1 + educational attainment	1129	0.83	0.80–0.86	5.5e–24
Model 1 + *IRF5* (rs4728142), *BLK* (rs2736340), *STAT4* (rs3024912), *HLA DRB1*0301, *1501,* other genetic ancestries†	753	0.82	0.69–0.98	0.032

† Only SNPs with $p < 0.05$ in multivariable models were retained in the final model

Conclusions: European ancestry is protective against the development of renal disease in SLE, an effect independent of other genetic ancestries, common risk alleles, and socioeconomic status.

Fine Mapping and Expression Studies Point to KIF5A as the Gene Responsible for Association of the 12q13 Locus with Rheumatoid Arthritis. Annie McClure, Steve Eyre, Wendy Thomson, Jane Worthington and Anne Barton. The University of Manchester, Manchester, United Kingdom

Background: A region on chromosome 12q13 was shown to have modest association with rheumatoid arthritis (RA) in the Wellcome Trust genome-wide association study (GWAS) of seven common diseases. Two parallel studies have since confirmed this as a RA susceptibility locus in UK and US populations (rs1678542 $P=1.3\times10^{-7}$ and $P=5.4\times10^{-6}$, respectively) and the same SNP has also been associated with type 1 diabetes (T1D). Variants mapping to nearby genes have also been associated with T1D and multiple sclerosis. The associated variant, rs1678542, is located in intron 15 of *KIF5A*. KIF5A is a microtubule motor protein involved in the transport of neurofilaments and expression was reported to be confined to neurons. However other ubiquitous kinesin family members have been shown to be involved in cell motility and intracellular transport of HLA-class II molecules.

Objectives: The aim of the current study was to investigate the 12q13 region further to identify the most likely RA susceptibility gene in the region.

Methods: A region of ~400kb surrounding the associated variant on 12q13 was selected for fine mapping. Tag SNPs were chosen to capture all the known variation across the region ($r2 > 0.8$). Any SNPs showing larger effect sizes than rs1678542 were then genotyped in a larger, independent validation cohort of 3633 RA cases and 2908 controls.

To investigate the expression of KIF5A, RNA was extracted from the blood of 52 RA patients and cDNA was synthesised. Whole blood RNA samples were selected to represent the range of possible genotypes at rs1678542 (major allele homozygous n=20, heterozygous n=19, minor allele homozygous n=13). KIF5A is known to be expressed in the brain so RNA was extracted from mouse brain to act as a positive control. Primers were designed to amplify KIF5A in human and mouse transcriptomes. The expression of two housekeeping genes (GAPDH and ACTIN) was also measured in order to normalise KIF5A expression. QRT-PCR was carried out using the ABI 7500.

Results: In a fine-mapping cohort of 1,000 RA cases and 1,000 controls, 5 tag SNPs were identified that exhibited greater effect sizes than rs1678542. These 5 SNPs and rs1678542 were then genotyped in the larger validation cohort. Only rs1678542 remained significantly associated (p=0.004, OR 0.90 95%, CI 0.84–0.97). QRT-PCR of KIF5A confirmed its expression in whole blood. Correlation of expression with genotype at rs1678542 by linear regression showed a significant trend in expression by genotype (1×10^{-3}). Individuals homozygote for the protective major allele had reduced KIF5A expression when compared to individuals who were heterozygote or homozygote for the minor allele at rs1678542.

Conclusion: After fine mapping of the region, association remains strongest with the original SNP identified in the WTCCC GWAS mapping to the KIF5A gene. The demonstration of expression of KIF5A in whole blood improves its potential for involvement in RA pathogenesis. Furthermore we present the first evidence of a correlation between KIF5A expression and genotype at a SNP associated with RA. The next step will be to validate this correlation using allele specific expression.

Purpose: Genetic association of the IL2/IL21 region at 4q27 has been previously reported in lupus and a number of autoimmune and inflammatory diseases. Herein, using a very large cohort of lupus patients and controls, we localize this genetic effect to the IL21 gene.

Methods: We genotyped 45 tag SNPs across the IL2/IL21 locus in two independent lupus cohorts. We studied a European-derived cohort consisting of 4,248 lupus patients and 3,818 healthy controls, and an African-American cohort of 1,569 patients and 1,893 healthy controls. Genetic association between the genotyped markers was determined, and pair-wise conditional analysis was performed to localize the genetic effect in the IL2/IL21 locus in lupus.

Results: We establish and confirm the genetic association between IL2/IL21 and lupus in two independent lupus cohorts. Using conditional analysis and utilizing trans-ethnicity genotyping, we localize the genetic effect for the first time in this locus to two SNPs; rs6835457 located in the 3'UTR flanking region of IL21 (Pmeta=2.51E-06), and rs907715 located within IL21 (Pmeta=1.74E-06).

Conclusion: Our data identify IL21 as a lupus susceptibility gene within the IL2/IL21 linkage disequilibrium block. This localization might be relevant to other autoimmune and inflammatory disease with a reported association in the IL2/IL21 genetic locus.

Background: NMNAT2, one of the three Nicotinamide mononucleotide adenylyl transferases, is a central enzyme of the NAD biosynthesis pathway mainly expressed in Golgi-complex with a known function of delaying axon degeneration. In this study, we sought to replicate a putative association at rs2022013 in *NMNAT2* from the SLEGEN genome-wide association study (GWAS) conducted in women of European ancestry (Harley et at, 2008) not yet exceeding the stringent threshold for genome-wide significance (typically $P<5\times10^{-8}$).

Methods: A total of 24 SNPs, spanning the genomic region of *NMNAT2*, were genotyped on a customized Illumina array. Additionally, ~400 ancestry informative markers were used to control population admixture and to eliminate genetic outliers. The association of *NMNAT2* SNPs with SLE was tested in a collection of 15,424 case-control samples consisting of European Americans (EA), African Americans and Gullahs (AA&Gullah), Asians and Hispanic and Native Americans (Hisp&NA). We performed Chi-square test to compare the allelic difference between cases and controls, likelihood ratio test to distinguish independent signals from associated SNPs, and Mantel-Haenszel test to conduct the trans-ethnic meta-analysis.

Result: Among the 16 association signals observed in EA (3477 vs. 3470 case-control samples independent of SLEGEN GWAS), we replicated the association of rs2022013 ($P=9.5\times10^{-7}$, OR=0.84) and identified 4 independent SLE-associated SNPs located in intron 1 of *NMNAT2* (long isoform) with the strongest signal at rs12146097 ($P=1.6\times10^{-9}$, OR=1.34). Allelic association detected in EA was partially extended to Hisp&NA (5 SNPs with allelic *P* from 0.018 to 7.8×10^{-4}, 1508 vs. 812) but not to AA&Gullah (1680 vs. 1953). Rs607332 (within intron 6) exhibited the strongest signal in AA&Gullah ($P=0.0013$, OR=0.9) and Hisp&NA ($P=2.9\times10^{-4}$, OR=0.8) but had no association in EA, which indicated specific associations of *NMNAT2* SNPs in various populations. No SNP showed significant association with SLE in Asians (1272 vs. 1270). The most significant meta-analysis *P* value of 4 ethnic groups was detected at rs12146097 ($P=1.25\times10^{-9}$, OR=1.29).

Conclusion: We provided independent evidence that *NMNAT2* predisposes to susceptibility to SLE with genome-wide significance. Trans-ethnic fine mapping showed *NMNAT2* SNPs had different association patterns among multiple ethnic groups. Our data suggested the novel role of NAD biosynthesis in the pathogenesis of SLE.

Gene-Interactions Influence Methotrexate Efficacy in Rheumatoid Arthritis: Analysis of 62 SNPs Panel in a Monocentric Cohort of Rheumatoid Arthritis Affected Patients. Thomas Barnetche[1], Caroline Rooryck-Thambo[4], Christophe Hubert[3], Christophe Richez[2], Benoit Arveiler[4] and Thierry Schaeverbeke[2]. [1]Bordeaux University Hospital, Rheumatology Department, Bordeaux, France, [2]Bordeaux University Hospital, Rheumatology Department, [3]Genomics-Transcriptomics Facility, Bordeaux, [4]Human Genetics Laboratory EA4137, University Victor Segalen Bordeaux 2

Purpose: Methotrexate (MTX) is one of the most widely used disease-modifying antirheumatic drugs (DMARDs) for the treatment of rheumatoid arthritis. No single genetic marker allows predicting response to the treatment. Here, we aimed to establish gene-gene epistatic interactions to predict MTX response therapy. SNPs were selected in proteins and enzymes that step in folate, purine and adenosine pathways, and also in several transporters that participate to MTX cellular absorption and elimination.

Method: A sample of 222 RA affected patients treated with low dose of MTX (7,5mg to 25mg with oral, intra-muscular or subcutaneous administration) was included in a monocentric study. Efficacy to MTX was assessed using EULAR response criteria and/or physician's assessment. A panel of 62 SNPs was analyzed for each patient. Univariate analysis in genotypes and allele frequencies was performed. Then gene-gene interactions were studied using Multifactor Dimensionality Reduction (MDR). MDR is considered as a non-parametric approach to detect non-linear interactions between binary variables that influence a binary outcome. This method reduces the dimensionality of genotypes predictors from N-dimensions to one dimension in pooling multilocus genotypes into high-risk and low risks MTX response groups. The robustness and significance of the model were tested through cross validation consistency (CVC, 10-fold).

Results: The MDR method highlights that MTX response (about 67% in this sample) is related with epistatic interactions among variants in ABCC3 (ATP-binding cassette, sub-family C) efflux transporter (rs739921 [C/G], rs4148412[C/T]), ABCC5 efflux transporter (rs4148575 [C/T]) and adenosine monophosphate deaminase 1 (rs2268699 [A/C]). Testing accuracy was 0.635 and CVC was 10/10. Carriers of a predisposing genotype combination were 22.14-fold more likely to respond to MTX than those without (CI95%: 9.76–50.21; $p<0.0001$). Sensitivity was 73%, specificity was 89% and accuracy was 78%. Univariate analysis revealed independent association for only two of these four SNPs: rs4148412[C/T] (ABCC3) and rs2268699 [A/C] (AMPD1) ($p<0.05$).

Conclusion: These data indicate that epistatic interactions in MTX pharmacology pathway influence the treatment response. Further studies are needed to confirm the role of genetic variants in ABCC transporters in MTX response, and to determine the exact functional impact of this genetic model.

Genome-Wide Association Study for Rheumatoid Arthritis in the Korean Population Points to Population-Specific Candidate Loci as Well as Overlap with European Susceptibility Loci. Jan Freudenberg[2], Hye-Soon Lee[4], H. D. Shin[7], B. D. Han[5], Y. M. Kang[6], S. C. Shim[1], Y. K. Sung[4], CB Choi[4], Annette Lee[3], Peter K. Gregersen[2] and S. C. Bae[4]. [1]Eulji University Hospital, [2]Feinstein Institute for Medical Research, Manhasset, NY, [3]Feinstein Institute for Medical Research, [4]Hanyang University Hospital for Rheumatic Diseases, [5]Korea National Institute of Health, [6]Kyungpook National University School of Medicine, [7]Sogang University

We have carried out a genome-wide association study (GWAS) in Korean individuals in order to identify susceptibility loci for Rheumatoid Arthritis (RA). We generated high quality genotypes for 441398 SNPs in 801 cases of RA and 757 controls. Genome-wide significance (P<5*e-08) was attained by markers from the MHC-region and from the *PADI4* gene. We then selected and analyzed 79 markers from 46 loci for replication in an independent sample of 718 cases and 719 controls. The combined analysis of genotypes from both stages did not reveal any additional loci with genome-wide significance. However, the replication data showed nominal association signals (P<5*e-02) for markers from 11 out of the 46 replicated loci, greatly exceeding random expectation. Genes that were most significant in the replication stage and in the combined analysis include the known European RA loci *BLK*, *AFF3* and *CCL21*. Thus, in addition to the previously associated *STAT4* alleles, variants at these three loci may contribute to RA not only among Europeans, but also among Asians. In addition, we observed replication signals near the genes *PTPN2, FLI1*, *ARHGEF3, LCP2*, *GPR137B*, *TRHDE*, and *CGA1*. Based on the excess of small P-values in the replication stage, we estimate that more than half of these loci are genuine RA susceptibility genes. Finally, we systematically analyzed the presence of association signals in Koreans at established European RA loci. This showed a significant enrichment of European RA loci among Korean RA loci.

Genome-Wide Copy-Number-Variation Study in Chinese Han Population Identifies Deletion of LCE3C_LCE3B as Susceptibility Factor for Rheumatoid Arthritis. Xiaolan Lu[2], Jianping Guo[3], Ru Li[3], Xia Liu[3], Zuowei Wu[4], Jinxia Shi[3], Xinyu Wu[3], Yingni Li[3], Yi Zhao[3], Chun Li[3], Sisi Pan[3], Lei Zhu[3], Jing He[3], Xu Liu[3], Wenjun Chen[1], Baoli Zhu[4] and Zhanguo Li[3]. [1]Beijing Institute of Genomics, Chinese Academy of Sciences, [2]Department of Rheumatology and Immunology, People's Hospital Peking University, Beijing, China, [3]Department of Rheumatology and Immunology, People's Hospital Peking University, [4]Institute of Microbiology, Chinese Academy of Sciences

Objective: To identify susceptibility genes concerning copy number variations (CNVs) in rheumatoid arthritis (RA) and to determine whether the RA risk CNVs are specifically associated with certain subsets of RA.

Methods: We first conducted a genome-wide CNV analyses by array comparative genomic hybridization (aCGH), and further characterized the association between the CNV of the late cornified envelope (LCE) genes, LCE3C_LCE3B and RA in a case-control cohort (518 RA patients and 507 controls). All samples were directly genotyped for the presence or absence of LCE3C_LCE3B alleles by PCR. The cases were classified based on their HLA–DRB1 genotypes, anti-citrullinated protein antibodies (ACPAs) and rheumatoid factor (RF) status, as well as clinical features.

Results: In aCGH study, we identified LCE3C_LCE3B as a candidate risk factor for RA (Log2 ratio = 1.50 ± 0.92). In replication study, we further demonstrated that the deletion of LCE3C_LCE3B was associated with RA (allele analysis: p = 3.03×10-3; OR 1.30, 95%CI 1.09–1.56; genotype analysis: p = 2.02×10-3; OR 1.58, 95%CI 1.02–2.45), with the specificities in anti-cyclic citrullinated peptide antibody (anti-CCP) positive (p = 0.03; OR 1.40, 95%CI 1.01–1.94), RF negative (p = 0.04; OR 1.78, 95%CI 1.04–3.06), anti-keratin antibody (AKA) negative (p = 6.68×10-3; OR 1.51, 95%CI 1.01–2.26), and rheumatoid nodules (RNs) negative subsets (p = 0.01; OR 1.52, 95%CI 1.08–2.13).

Conclusion: Our study demonstrated that LCE3C_LCE3B-del was a novel susceptibility factor for RA in Chinese Han population, and the LCE3C_LCE3B-del association with RA was significantly relevant to HLA–DRB1 shared epitope (SE), anti-CCP, RF and AKA status.

Human Genetic, The Netherlands, [10]University Medical Centre Groningen, Dept. of Epidemiology, [11]University Medical Centre Utrecht, Dept. Medical Genetics, The Netherlands

Objective: Genome-wide association studies (GWASs) carried out in rheumatoid arthritis (RA) have led to the discovery of several genetic associations with this disease. Still, the current associated genetic variations can explain only part of the genetic risk involved in RA, and it is well recognised that these GWASs are likely underpowered to detect all common disease variants. Therefore, we explored the genomic regions showing low-significance associations in previous GWASs of RA.

Methods: To reduce the false-positive signal fraction, we exploited pathway analysis to prioritise regions containing genes most likely to be implicated in RA. We hypothesised that true disease genes would be in a similar pathway. Therefore, genes from similar pathways but located in different regions were prioritised for replication using Prioritizer software. 384 genetic variants selected from previous RA GWASs were tested in a Spanish case/control discovery cohort comprising 376 RA patients and 478 healthy controls for replication. Statistically significant associations were further validated in replication cohorts from Spain and Netherlands, up to a total of 1,818 RA patients and 2,498 controls.

Results: We detected a novel genetic association between RA and the MSRA gene (rs10903323, $P = 2.91\times10^{-5}$, OR = 1.51) in the Spanish combined population. This association was further tested in our independent Dutch replication cohort. Combined analysis showed an overall association of MSRA with RA ($P = 2.19\times10^{-4}$, OR = 1.28).

Conclusion: Novel association in the MSRA gene related to oxidative stress is described herein and support a major role for this process in RA.

1600

Identification of Genetic Markers of Rheumatoid Arthritis Severity by Genome-Wide Association Studies. Sebastien Viatte[1], Darren Plant[2], John Bowes[2], Deborah Symmons[2], Jane Worthington[2] and Anne Barton[1]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, The University of Manchester

Introduction: The largest genetic risk to develop rheumatoid arthritis (RA) arises from a group of alleles of the HLA DRB1 locus ("shared epitope"). Recent genome wide and candidate gene association studies have identified over 30 confirmed single nucleotide polymorphisms (SNPs) predisposing to disease (susceptibility loci). However, the genetic variants identified so far do not predict clinical outcomes, such as erosions, disability or response to treatment, well. We therefore sought to identify genetic markers of outcome of disease severity, in patients with recent-onset inflammatory polyarthritis (IP).

Methods: The Norfolk arthritis register (NOAR) is a primary care-based inception cohort of subjects with inflammatory polyarthritis recruited at symptom onset and followed prospectively. Demographic and clinical data

are recorded at inclusion and at yearly assessments thereafter. Serologic status (anti citrullinated protein antibodies (ACPA)) is determined at study entry. A subset of 372 patients was genotyped for 370,404 single nucleotide polymorphisms (SNPs) by genome-wide array (Illumina). The association of SNP markers with clinical and radiological markers of disease severity was investigated using the presence of erosions by 5 years as the primary outcome measure. Adjustment for the presence of ACPA, a known marker of disease severity, and for receiving disease modifying anti-rheumatic medications was incorporated into the analysis.

Results: At baseline 84% of the 372 genotyped patients satisfied the 1987 ACR criteria for RA; and 62% carried at least one copy of an HLA-DRB1 allele known to confer susceptibility to RA. 48% were erosive by 5 years. Genome-wide association studies revealed a number of SNPs with evidence for association with erosions by year 5 of follow-up (p-values $< 5.9\times10^{-6}$ for SNPs mapping to SLC15A4 (chr. 12), XIRP2 (chr. 2) and HLA-DQ (chr. 6)) or with the extent of radiological damage quantified by the Larsen score (5 SNPs mapping to MTMR7, $p=4.4\times10^{-8}$). Logistic regression analysis within the genotyped NOAR dataset confirmed the known strong association between positivity for ACPA and erosions, and showed a weaker but independent association between HLA-DRB1 susceptibility alleles and erosions.

Discussion: We have found a set of SNPs with strong evidence for association with radiological damage by 5 years. Genotyping of these candidate SNPs is currently underway in an independent cohort. The identification of genetic predictors of severity at presentation could be used to predict which patients are likely to develop erosive disease, and it may be possible to target these patients for more aggressive treatment earlier in their disease course. If replicated, these genetic markers may improve the predictive value of ACPA in identifying patients likely to experience a severe disease course and pave the way for a more personalised approach to medicine.

Identification of KIAA Proteins in Immune Complex Proteome from Juvenile Idiopathic Arthritis and Systemic Lupus Erythematosus. Anil Chauhan[2], Brooke Gilliam[2], Catherine P. Riley[1], Jiri Adamec[1] and Terry L. Moore[3]. [1]Purdue University, [2]Saint Louis University, [3]St Louis University, St Louis, MO

Purpose: Biomarkers discovered by proteome analysis are not only useful for patient stratification but for monitoring therapeutic responses and understanding of disease pathogenesis. Biological fluids such as plasma although a good source of information, present a technical challenge due to at least ten orders of magnitude dynamic range of protein concentration. Protein and peptide immuno-affinity pre-fractionation coupled with mass spectometry (MS)-based proteomics have been used for biomarker discovery; however a prior knowledge of the disease association is required. Thus we wanted to develop a proteomic approach that is capable of identifying low abundance disease associated proteins as a possible biomarker candidate. We achieved this by combining receptor affinity for isolation of immune complexes (ICs) with downstream coupling to nano-LC/MS-MS.

Methods: Fifteen IC samples from juvenile idiopathic arthritis (JIA) and systemic lupus erythematosus (SLE) patients were purified using receptor affinity columns and then fractionated on a Criterion XT Bis Tris precast 4–20% polyacryamide gel. Thereafter, each sample protein lane was cut into 5 equal pieces. Tryptic peptides from these samples were then developed on a nanoLC-Chip system (1100 Series LC, Agilent) and separated on the on-chip C-18 reversed phase ZORBAX 300SB-C18 ($0.075\mu m \times 150$ mm; Agilent). The NanoLC-MS chromatograms were acquired in positive ion mode with a capillary voltage of 1850 V, an end plate offset of 500 V, dry gas at 300°C and 4 L/min. Spectra were acquired for 350–2000 m/z at a scan speed of 8,100 m/z/s with 0.15 s maximum accumulation time.

Results: We identified a total of 873 proteins from ICs purified from the fifteen samples. The ICs from the JIA patients showed more proteins associated with cell adhesion, proliferation, protein transport, and ATP biosynthetic process, while the SLE group with cytoskeleton organization, signal transduction, T cell activation, and intracellular and signaling cascade. A number of proteins that are known target of post translational modifications in autoimmune response were also identified. The common proteins present in these ICs were complement proteins, fibrinogen, apolipoprotein A-I, cartilage acidic protein, and S100 calcium-binding proteins. The SLE-ICs showed a large number of nuclear proteins such as zinc finger proteins including 652, 644, 133, and matrin type 5. In addition, ICs from JIA and SLE showed the presence of T cell receptor beta chains, suggesting an active role for T cells. KIAA proteins are proteins encoded by large cDNA identified by Kazusa cDNA project. They display multiple domains that suggset their involvement in interactions with other biological molecules. We observed two unique sets of KIAA proteins one associated to JIA and other with SLE. There are 2031 KIAA cDNA entries in HUGE database that are being characterized (http://www.jp/huge/ppi).

Conclusion: We show a successful approach to identify low abundance antigens from ICs.The IC proteome shows more proteins unique to individuals rather than disease group. The presence of KIAA proteins in the ICs suggest their role in disease pathogenesis and as a new potential biomarker group.

Major Histocompatibility Complex Associations with Thrombosis and Antiphospholipid Antibody Production in Systemic Lupus Erythematosus. Rachel Kaiser[4], Sharon A. Chung[4], Kimberly E. Taylor[5], Suzanne L. May[2], Patricia P. Ramsay[2], Hong L. Quach[2], Diana L. Quach[2], Julie A. Lane[1], Janelle A. Noble[1], Michael F. Seldin[3], Lisa Barcellos[2] and Lindsey A. Criswell[6]. [1]Children's Hospital Oakland Research Institute, [2]UC Berkeley, [3]UC Davis, [4]UCSF, San Francisco, CA, [5]UCSF, [6]UCSF-Box 0500, San Francisco, CA

Purpose: Thrombosis occurs at a younger age and at an increased frequency in systemic lupus erythematosus (SLE) compared to the general population. Known risk factors such as antiphospholipid antibodies (aPL) incompletely explain outcomes in this complex phenotype. The major histocompatibility complex (MHC) has the strongest association with SLE but associations with subphenotypes are less well-established due in part to linkage disequilibrium in the region. Prior studies in Caucasians suggest that *HLA-DRB1* allele frequencies differ between SLE patients with and without aPL, and that DR4 and DR7 may be associated with anticardiolipin autoantibodies (aCL). We investigated the association of *HLA-DRB1* and other MHC loci (independent of *HLA-DRB1)* with thrombosis and aPL production in SLE.

Methods: We genotyped 909 SLE cases of European descent for 2360 single nucleotide polymorphisms (SNPs) across 4.9 Mb of the MHC using the Illumina Combined MHC panel. These cases were also genotyped for *HLA-DRB1* and 384 ancestry informative markers. Thrombotic events (deep venous thrombosis, myocardial infarction, stroke, pulmonary embolism, retinal vein thrombosis, recurrent miscarriage) and aPL status (aCL IgG and IgM, lupus anticoagulant (LAC)) were obtained from medical record review. Associations with *HLA-DRB1* alleles were identified using a relative predispositional effects (RPE) method. SNPs associated with aPL and thrombosis were identified using forward selection with conditional logistic regression based on haplotypes implemented in WHAP.

Results: We genotyped 1974 SNPs and 640 SLE cases after stringent quality control criteria were applied and subjects with <90% northern European ancestry were removed. Five percent of the subjects were LAC positive, 33% were aCL positive, 35% were positive for at least one of these aPLs, and 24% experienced at least one thrombosis. *HLA-DRB1*0701* was associated with thrombosis in a global X^2 test and in a multivariate model adjusting for age, gender, smoking history, disease duration, nephritis history, aPL, Northern European ancestry and medications (including immunodmodulators and hydroxychloroquine) (OR 2.06, 95%C.I. 1.09–3.90, p=0.027). No *DRB1* associations were found with aPL (global χ^2 p>0.05). Conditional logistic regression identified associations independent of *HLA-DRB1* in or near the BAT3-MDC1-HCP5 region with thrombosis (OR=2.53, haplotype specific $p=1.35\times10^{-10}$) and in or near the BTNL2-HLA-E-HLA-B region with aPL (OR 4.50, haplotype specific $p=6.80\times10^{-5}$).

Conclusions: *HLA-DRB1*0701* is associated with thrombosis in SLE but no *HLA-DRB1* associations were found with aPL, possibly due to a lack of power to detect an association. We also identified several MHC associations with thrombosis and aPL independent of the *HLA-DRB1* locus. Interestingly, these associations were in Class I and III in addition to the previously associated Class II loci. Furthermore, these associations were different for the outcomes of thrombosis and aPL. Thrombosis risk in SLE may be explained in part by MHC genetic variation.

1603

MMEL1 and CDK6 Are Associated with ACPA Positive and RF Positive Rheumatoid Arthritis. Marthe Thoresen Mæhlen[1], Tore K. Kvien[3], Till Uhlig[2] and Benedicte A. Lie[4]. [1]Dept. of Rheumatology, Diakonhjemmet Hospital, 2. Institute of Immunology, Oslo University Hospital, Oslo, Oslo, Norway, [2]Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Institute of Immunology, Oslo University Hospital, Oslo, Norway

Background: Genes play an important role in the aetiology of rheumatoid arthritis (RA), and recent genome wide association studies have reported several new SNPs to be associated with RA. Some of these have been replicated. However, further studies are needed to establish whether these are true risk loci.

Objective: Investigate whether 11 candidate SNPs (in KIF5A, REL, CCL21, PRKCQ, STAT4, CTLA4, MMEL1, CDK6, TRAF1, OLIG3-TNFAIP3 (2 SNPs)) are associated with RA and autoantibody production in the Norwegian population.

Method: DNA from 950 Norwegian RA patients and 1130 Norwegian controls were genotyped with TaqMan assays (Applied Biosystems). All 11 SNPs had >98% genotyping success rate and all genotypes were in Hardy-Weinberg equilibrium. χ^2 tests were used to test for associations. For the SNPs that were not associated with RA, we calculated the power in our dataset to detect an association using *Power and Sample Size program, version PS 3.0.14*. These calculations were based on odds ratios and minor allele frequencies published in a recent meta-analysis (Stahl, E.A. *et al Nat. Genet,* 2010).

Results: The major allele of MMEL1 and minor allele of CDK6 were both significantly associated with RA (table). The associations were restricted to ACPA positive and RF positive RA. The minor allele of STAT 4 was significantly associated with ACPA positive RA only. None of these 3 SNPs were associated with ACPA negative or RF negative RA. The remaining eight SNPs showed no significant association with RA in our Norwegian cohort.

Gene	Patients	Minor allele	MAF case	MAF control	Allele test	OR 95% CI	P-value
MMEL1	ALL	C	0.298	0.334	T/C	1.18 (1.03–1.35)	0.01
MMEL1	ACPA +	C	0.276	0.334	T/C	1.30 (1.11–1.53)	0.001
MMEL1	RF +	C	0.251	0.334	T/C	1.45 (1.26–1.78)	>0.001
CDK6	ALL	G	0.262	0.227	G/C	1.20 (1.04–1.39)	0.01
CDK6	ACPA +	G	0.274	0.227	G/C	1.28 (1.09–1.52)	0.003
CDK6	RF+	G	0.278	0.227	G/C	1.31 (1.10–1.56)	0.003
STAT4	ALL	T	0.239	0.223	T/G	1.10 (0.95–1.27)	0.22
STAT4	ACPA+	T	0.253	0.223	T/G	1.18 (1.0–1.40)	0.05

Conclusion: We replicated the proposed associations between MMEL1 and CDK6 with RA. In addition we demonstrated that CDK6 and MMEL1 are associated to both ACPA positive and RF positive RA. Further we confirmed that STAT4 is associated with ACPA positive RA. We found no association with eight SNPs, however due to moderate to low risk in other populations, we may have had insufficient power to detect an association.

Multiple Expanded B-Cell Clones Are Already Present in Early Rheumatoid Arthritis: Results of a Comparison between Early and Longstanding Disease Using High Throughput Sequencing Technology. Marieke E. Doorenspleet[2], Stefano Alivernini[2], Marjolein J. de Hair[2], Paul L. Klarenbeek[2], Marieke M. Herenius[2], Marleen G. van de Sande[2], Barbera D. van Schaik[1], Rebecca E. Esveldt[2], Antoine H. van Kampen[1], Danielle M. Gerlag[2], Frank Baas[3], Paul P. Tak[2] and Niek de Vries[2]. [1]Dept. of Clinical Epidemiology, Biostatistics and Bioinformatics Academic Medical Center-University of Amsterdam, [2]Div. Clinical Immunology and Rheumatology Academic Medical Center-University of Amsterdam, Amsterdam, The Netherlands, [3]Laboratory for Genome Analysis Academic Medical Center-University of Amsterdam

Background: B-cells play an important role in the pathogenesis of rheumatoid arthritis (RA) but their exact role remains unclear. We previously found that expanded B-cell clones can be detected in inflamed synovial tissue (ST) of patients with longstanding RA. These clones were either absent or of very low frequency in peripheral blood (PB), suggesting local retention and/or proliferation in the synovium. Here we examined whether oligoclonal B-cell expansions can be detected in early stages of RA.

Objectives: Compare expanded B-cells in paired samples (ST and PB) during different stages of disease using novel high throughput sequencing technology.

Methods: We included 2 anti-CCP+ patients with active RA. Patient 1 (pt1) was DMARD naïve and had a disease duration less than 1 year. Patient 2 (pt2) had active disease despite methotrexate treatment and had a disease duration of more than 10 years (longstanding RA). mRNA was isolated from paired samples (ST biopsies from arthritic ankle/knee and PB, respectively). Linear amplification was performed with primers for all V(ariable)-families of the receptor heavy-chain. The amplified products contain the Complementarity Determining Region 3 (CDR3), which can be used as a 'fingerprint' for each clone. The samples were analyzed using a Genome Sequencer (454/Roche). The frequency of clones was determined by custom bioinformatics algorithms identifying the CDR3-region of each receptor (up to 1 million receptors at once). Clones with a frequency of ≥1% were arbitrarily considered as highly expanded.

Results: In the longstanding RA-patient 15 highly expanded B cell clones were detected in the ST. Of interest, we also detected 14 highly expanded clones in the ST of the early RA patient. In both patients the highest frequency observed was 7%, and none of the highly expanded clones had a clearly higher frequency than the other clones. The oligoclonal pattern observed was defined by distinctly different CDR3 sequences and use of different gene segments in both patients. In the PB samples of both patients only few expanded clones were found (5 and 6 highly expanded clones, respectively). However, most clones that were highly expanded in ST could also be detected in the PB of both patients, albeit at very low frequencies (less than 0,05% in both patients). In contrast, highly expanded clones from the PB were not at all found in ST. Comparing both patients, the highly expanded clones were all different.

Conclusion: This is the first analysis of B-cell clones in ST and PB samples comparing RA patients with different disease duration, using novel HTS technology. Our data suggest that oligoclonal B-cell expansions can already be detected in early stages of RA. This suggests that multiple epitopes might already be involved in so-called early RA.

New HLA-DRB1 Classifications in Association with Rheumatoid Arthritis for Global Application: Beyond the Conventional Shared Epitope Hypothesis. So-Young Bang[1], Hye-Soon Lee[1], Ji-Seon Lee[1], Eun-Mi Kim[1], Kyung Wha Lee[2] and Sang-Cheol Bae[1]. [1]Department of Rheumatology, Hanyang University Hospital for Rheumatic Disease, Korea, Republic of, [2]Hallym Institute for Genome Application, Hallym University Sacred Heart Hospital, Korea, Republic of

Objectives: The HLA-DRB1 shared epitope (SE) hypothesis does not wholly explain HLA contribution to rheumatoid arthritis (RA) susceptibility. Different classification systems have been proposed, but few have been validated in non-Caucasians. Here, we investigated the relevance of recent HLA-DRB1 allele classifications of RA susceptibility and protection in a large Asian cohort of RA patients and controls.

Methods: All 2,601 unrelated Korean subjects including 1,482 patients with RA and 1,119 unaffected controls were genotyped. Four-digit level HLA-DRB1 typing was performed by direct DNA sequence analysis. HLA-DRB1 alleles were grouped according to the Tezenas du Montcel and Mattey classification systems.

Results: Based on Tezenas du Montcel classification, S_2/S_{3P} genotype was associated with the greatest risk for RA, with an OR (95% CI) of 15.30 (4.79–48.93). We confirmed our previous finding that DRB1*0901 was the second significant risk allele for RA in the Korean population [OR 1.83 (1.53–2.19), $P = 4.37 \times 10^{-11}$]. The HLA-DRB1 alleles were reanalyzed according to our modified classification system including DRB1*0901 [S_4 (^{67}F^{70}RRRAE^{74})]. Interestingly, S_2/S_{3P} and S_4/S_{3P} genotypes were associated with the higher risk for RA compared with conventional classification. Additionally, the SE/D^{70+} genotype was associated with lower risk for RA, compared with the SE/D^{70-} genotype using the Mattey classification system.

RA risk for genotypes according to our modified HLA-DRB1 classification system*

Genotype	No. (%) of controls (n=1,119)	No. (%) of RA cases (n=1,482)	OR (95% CI)	*P*
S_2/S_3*	4 (0.36)	26 (1.75)	21.96 (6.82–70.73)	3.87×10^{-27}
S_4/S_3*	36 (3.22)	149 (10.05)	11.91 (7.59–18.68)	1.20×10^{-20}
S_3*/S_3*	3* (3.13)	190 (12.82)	11.90 (7.69–18.43)	1.20×10^{-28}
S_4/S_4	11 (0.98)	31 (2.09)	6.46 (2.91–14.35)	4.44×10^{-4}
S_3*/L	311 (27.79)	602 (40.62)	4.41 (3.47–5.60)	6.00×10^{-34}
S_2/L	11 (0.98)	20 (1.35)	2.61 (1.09–6.24)	0.03
S_4/L	148 (13.23)	203 (13.70)	2.59 (1.91–3.51)	9.82×10^{-10}
L/L	563 (50.31)	258 (17.41)	reference	—

*Logistic regression analysis adjusted for age and sex. All odds ratios (OR) 95% confidence intervals (95% CI), and P values were calculated by comparing each group with the reference group. DRB1 alleles were divided into three susceptible *0401). S_3* ("RRAA/" *0101, *0102, *0404, *0405, *0408, *0410, *0445, *1001, *1402 and *1406) and S_4 ("*10^{-10}RRRAE/*" *0901)] and low risk (L, others) alleles. S_2/S_2 and S_2/S_4 genotypes were not observed in Korean populations.

Conclusions: All susceptible alleles, except *0901, were classified as S_2 or S_{3p} using the Tezenas du Montcel criteria. We propose that an appropriate HLA classification system including DRB1*0901 is required in populations with DRB1*0901 as an RA susceptibility allele. An appropriate HLA-DRB1 model should aid in clarifying the roles of these alleles in RA.

Pre Analytical Effects of Serum Collection and Handling in Quantitative Immunoassays for Rheumatoid Arthritis. Ferhan Qureshi[3], William Manning[3], Scott Eastman[3], Wayne Hu[3], Michael Centola[6], Mary Turner[7], Craig W. Carson[5], Ana A. Kumar[4], Linda A. Zacharias[2], Claire Alexander[3], Doug Haney[3], Guy Cavet[3] and Lyndal K. Hesterberg[1]. [1]Crescendo Bioscience, Inc., South San Francisco, CA, [2]Crescendo Bioscience, Inc., Edmond, OK, [3]Crescendo Bioscience, Inc., [4]OK Arthritis Center, Edmond, OK, [5]Oklahoma Arthritis Ctr, Edmond, OK, [6]Oklahoma Med Research Foundation, Oklahoma City, OK, [7]Oklahoma Medical Research Foundation

Background: Pre-analytical variables related to serum processing and handling can have significant influences on the results obtained in quantitative protein immunoassays. Understanding the impact of these variables is critical for assay development, validation, and commercial testing. The effect of 2 routine serum collection methods (on the clot with ambient temperature shipping vs. centrifuged with cold chain shipping) and 2 serum handling variables (time before assay and freezing) were examined in a novel, validated, 12-biomarker RA disease activity test (DA Test) and up to 15 additional proteins being evaluated as predictors of structural damage progression in Rheumatoid Arthritis (RA).

Method: To evaluate serum collection variables, multiple matched sets of Becton Dickinson Serum Separator Transport Tubes (BD SST™) were drawn from 10 RA patients, with varying disease activity. One set of tubes from each individual was processed per manufacturer's instructions followed by overnight shipment in a temperature controlled (2–8°C) package ("Cold chain"). A matched tube from each individual was simultaneously shipped overnight at ambient temperature while remaining on the clot (e.g. not centrifuged; OTC). Upon arrival, the OTC tube was centrifuged and all samples were aliquoted for analysis in single-plex ELISAs and mutli-plex Meso Scale Discovery immunoassays.

To evaluate post-processing serum handling effects, matched aliquots of serum were held at multiple temperatures (−80°C, −20°C, 4°C and 25°C) for extended periods of time before assaying to generate a DA Test score which was then compared to the scores obtained in a baseline measurement. Additionally, multiple aliquots of serum (including both pools and individuals) were subjected to 3 successive freeze thaw cycles at −80°C prior to analysis by immunoassay.

Results: Significant differences in analyte concentrations were seen in >45% (13/27) of the analytes between the 2 collection methods. Twelve of thirteen biomarkers levels increased in the OTC samples, while one decreased. Of the 13 biomarkers with significant changes, 5 had poor correlation within the 10 RA patient samples ($R^2 < 0.7$) compared to the centrifuged, cold chain samples. The individual DA Test scores varied widely, (−16% to 126%), confirming the value of onsite centrifugation and cold chain shipping. The impact of serum storage (post-processing) at the various temperatures tested and multiple freeze thaw cycles on biomarker levels was minimal. Additional studies, to characterize combinations of multiple pre-analytical variables are currently being designed.

Conclusion: Serum collection, processing and handling methods have a significant impact on the measurable serum protein levels. These results illustrate the importance of characterizing pre-analytical variability to ensure test accuracy and for using robust serum processing and handling procedures for development, validation, and clinical testing with biomarker assays including the DA Score.

1607

Serum TNFα and IL-6 Concentrations in Systemic Lupus Erythematosus, Rheumatoid Arthritis and Controls Are Associated with Polymorphisms in *PTPN2*, *IRF5*, *INFG*, and *NOD2*. Joseph F. Solus[3], Young Hee Rho[3], Annette M. Oeser[4], Cecilia P. Chung[2], Chun Li[3], Jeffrey R. Smith[3] and C. Michael Stein[1]. [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University Medical Center, Baltimore, MD, [3]Vanderbilt University Medical Center, [4]VUMC 23rd Ave South Pierce, Nashville, TN

Purpose: Elevated serum concentrations of inflammatory mediators are characteristic of autoimmune inflammatory disease. Genetic variation contributes to the regulation of inflammation. We examined the hypothesis that indicators of inflammation in systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are associated with a subset of genetic polymorphisms previously implicated in the etiology and pathology of inflammatory autoimmune disease.

Method: Serum TNFα and IL-6 concentrations were measured by multiplex ELISA (Millipore Corp.) in patients with SLE (n=148) or RA (n=166) and in control subjects without inflammatory rheumatic disease (n=177). Candidate genes were chosen from publications reporting association with autoimmune or inflammatory disease. Genotypes for 345 SNP markers from 75 genes were determined using Golden Gate assay (Illumina Inc.). Association was calculated by linear regression of $\log_{10}$-transformed data using an additive genetic model.

Results: TNFα concentrations were higher in patients with SLE (median 4.8, IQR [3.1–7.9] pg/ml) and RA (5.5 [2.8–11.0] pg/ml) than controls (2.8 [2.1–3.9] pg/ml). IL-6 concentrations were higher in patients with SLE (5.7 [2.3–22.4] pg/ml) and RA (13.8 [4.4–43.0] pg/ml) than controls (2.9 [1.0–11.5] pg/ml), and were higher in RA than SLE (all $p<0.001$). Several genetic variants were associated with markers of inflammation. TNFα was associated with *IRF5*(rs10488631) in SLE ($p=0.01$) and controls ($p=0.001$) but not in RA, and with *IFNG*(rs2069727) in SLE ($p=0.007$) but not in RA and controls. TNFα was associated with *PTPN2*(rs2542151), *DRB1*(rs3021304) and *NOD2*(rs5743291) in RA ($p=0.001$, 0.001, 0.009), and in controls with *NOD2* ($p=0.01$), but not in SLE. The top rank order for associations with IL-6 were *TYK2*(rs280523) and *IL10*(rs1800890) in SLE ($p=0.005$ for each), *DRB1*(rs3021304) and *NOD2*(rs748855) in RA ($p=0.0005$, 0.001), and *MMP7*(rs12285347, rs17098318) in controls ($p=0.002$, 0.009). Several other associations for IL-6 were of nominal significance ($p<0.01$). The analysis of all samples as a single group revealed *PTPN2* as the top rank order association for both TNFα and IL-6 ($p<0.0001$, $p=0.0006$). A possible interaction between *PTPN2* and disease status was observed for TNFα ($p=0.03$) but not for IL-6 ($p=0.9$).

Conclusion: An *IRF5* polymorphism previously associated with susceptibility to lupus and other autoimmune disease was associated with serum TNFα concentrations in SLE patients and controls but not in RA, suggesting that the mechanism of regulation of TNFα through interferon regulatory factor 5 is retained in SLE but is disrupted or obscured by other factors in RA. An analogous situation may exist for regulation of TNFα and IL-6 in patients with RA or SLE and healthy controls through *PTPN2, NOD2,* and *IFNG*.

SLE-Associated Genetic Variants Influence Gene Expression in Patients. Hatice Bilgic[4], Thearith Koeuth[5], Joseph C. Wilson[5], Ward Ortmann[1], Michelle Petri[2], Peter Gregersen[3], Timothy Behrens[1] and Emily C. Baechler[5]. [1]Genentech, Inc., [2]Johns Hopkins School of Medicine, [3]The Feinstein Institute for Medical Research, [4]University of Minnesota, MN, [5]University of Minnesota

Background: SLE is a complex disorder which is likely to be affected by multiple biological pathways. Mapping the genetic influences of individual genes and or/pathways that contribute to disease may reduce complexity and increase the power to identify genetic risk factors that cause SLE. Recent genome-wide genetic association studies in SLE have identified numerous single nucleotide polymorphisms (SNPs) conferring risk to lupus. We hypothesized that some of these genetic variants will correlate with gene expression phenotypes in SLE. Uncovering these SNP/transcript associations may permit a better understanding of the genetic underpinnings of human SLE, and the identification of novel targets for therapy.

Methods: We studied 309 Caucasian SLE patients enrolled from the Hopkins Lupus Cohort via the Autoimmune Biomarkers Collaborative Network. Gene expression levels were quantified in peripheral blood cells of SLE patients with the Illumina WG-6 BeadChip expression arrays. Any gene that had a detection p-value >0.1 (not expressed) for $>95\%$ of samples was removed from analysis. For the remaining genes, the expression values in individual samples that had detection $p>0.1$ had were replaced with the minimum detectable ($p<0.1$) expression value for that gene. This resulted in 24,849 probes for further analyses. Type I interferon (IFN) gene signature scores were calculated from the expression of 70 IFN-inducible genes. DNA samples from the same subjects were genotyped on Illumina HumanHap 550K Genotyping BeadChip and subjected to standard data quality filters. We selected 34 SNPs previously shown to be associated with SLE and interrogated the correlation of genotype with gene expression using Pearson correlation and one-way ANOVA.

Results: In this discovery cohort, we identified putative cis-associations between blood cell gene expression levels and SNPs in or near 3 genes (BLK, KLK1, and UBE2L3) for which there is a priori evidence of genetic association with disease. Two SNPs upstream of BLK (rs2736340, rs13277113) were significantly correlated with BLK transcript levels ($r=-0.21$, $p=0.0002$; ANOVA $p\leq0.001$). SNP rs266858 is in the kallikrein gene cluster on chromosome 19, near the SLE-associated KLK1 gene. This SNP was significantly correlated with KLK1 transcript levels ($r=0.16$, $p=0.006$; ANOVA $p=0.001$). A SNP within the gene that encodes the ubiquitin-conjugating enzyme UBE2L3 (rs5754217) was significantly correlated with UBE2L3 gene expression ($r=0.39$, $p<0.0001$; ANOVA $p<0.001$). We also identified significant correlations between the type I IFN gene score and SLE-associated SNPs in/near ATG5 ($p=0.0004$), COPS8 ($p=0.01$), PHRF1 ($p=0.01$), PRDM1 ($p=0.004$), PTPN22 ($p=0.04$), and STAT4 ($p=0.005$).

Conclusions: Our initial findings suggest that several cis interactions between SLE-associated alleles and transcript levels, and that SLE SNPs may influence the type I IFN signature. A complete validation analysis is required to identify the most promising genetic effects for further study.

Stratification of Rheumatoid Arthritis Patients into Disease Subtypes with Clinical Implications. Glynn Dennis, Cecile Holweg, Jason Hackney, Houston Glibert, Wei Yu Lin, Lauri Diehl, Judith Endres, David Fox, Mike Townsend and Flavius Martin. Genentech

Purpose: The study aimed to identify molecular subtypes of rheumatoid arthritis (RA) that differ in their biological composition and response to therapy.

Methods: Genome-wide transcriptional profiles for 81 synovial tissue samples obtained by surgery from 50 active RA patients fulfilling the 1987 ACR criteria were stratified by bootstrapped hierarchical clustering. Statistically supported sample subtypes were further characterized by significance analysis of microarrays and pathway analysis. Platform independent validation of subtypes was performed by immunohistochemistry, fluorescence-based cell sorting and semi-quantitative polymerase chain reaction. Subtype-intrinsic gene signatures were tested for their ability to classify external data using linear discriminant analysis. Protein biomarker assays measured the association between serum proteins and response to rituximab.

Results: Multi-scale bootstrapped hierarchical clustering of 81 samples inferred four molecular subtypes of RA. Each subtype represented a discrete transcriptional program that reflected differences in tissue cellularity and biological composition. Diffusely infiltrated tissues were assigned to one of two subtypes characterized by fibroblast-like transcriptional programs that differed slightly, but significantly, in their pathway composition. Tissues with substantial immune infiltration were assigned to one of two immunoregulatory subtypes distinguishable by either a potent B cell signature or a broad inflammatory signature reflecting various myeloid and T cell transcriptional programs. Predictive gene signatures for each subtype accurately classified institutionally independent microarray profiles of histologically similar samples. Protein-based assays of B cell signature genes in a large placebo-controlled study of rituximab in RA revealed a combinatorial relationship between low levels of certain B cell biomarkers in serum and a poor clinical response to B cell depleting therapy.

Conclusions: We reduced RA tissue heterogeneity down to 4 discrete molecular subtypes and provided subtype-intrinsic gene signatures that were able to accurately classify independently derived external data. The unique cellular and biological composition of each subtype suggests that molecular stratification of RA patients has the potential to improve clinical trial design and therapeutic intervention by identifying those patients that are most likely to benefit from a given therapy.

The Associations between RA Genetic Risk Alleles and Seropositive but Non-Erosive Rheumatoid Arthritis. Katherine P. Liao, Jing Cui, Michael E. Weinblatt, Christine Iannaccone, Nancy Shadick, Robert M. Plenge, Daniel H. Solomon and Elizabeth W. Karlson. Brigham and Women's Hospital, Boston, MA

Background: Presently, little is known about the subgroup of subjects with seropositive rheumatoid arthritis (RA) who never develop bone erosions in contrast to those with erosions that remain stable or progress despite treatment. Our objective was to determine whether specific RA genetic risk alleles were associated with remaining erosion-free in a longitudinal RA cohort.

Methods: Our study was conducted in a prospective observational cohort of >1100 RA patients recruited from the outpatient practice of an academic medical center. We included patients with bilateral hand radiographs obtained at baseline and at 2 yr follow-up with formally assessed Sharp scores. The primary outcome was erosion-free status at recruitment and at 2 yr follow-up. We genotyped 31 validated RA risk alleles in a seropositive (RF+ or anti-CCP+) subset of this cohort.

To assess whether individual risk alleles for seropositive RA were also associated with erosion-free status, we tested each polymorphism using a log additive model (0, 1, 2) in a logistic regression adjusted for significant clinical predictors of erosion-free status. The significant clinical predictors were determined in a previous study: younger age at RA onset, male gender, and shorter RA duration. We quantified the association between risk alleles and erosion-free status using odds ratios (OR), 95% confidence intervals (CI) and p-values from the logistic regression models.

Summary Three hundred-three RA subjects in the cohort had Sharp scores and genotype information; 18% were erosion-free at recruitment and 2 year follow-up: 75% female, mean age at RA onset of 44.3 yrs (SD 10.1) and mean RA duration of 8 yrs (SD 8); 94.6% were anti-CCP+, 83.6% were RF+, and 76.6% had ≥ 1 copy of the HLA-shared epitope (HLA-SE). In the erosive group, 84% were female, with mean age at RA onset of 41.8 yrs (SD 14) and mean RA duration of 18 yrs (SD 12.3). There was no significant difference between anti-CCP status, methotrexate and anti-TNF use at baseline between the erosion-free group and those with erosions.

Two alleles were independently associated with erosion-free status after adjusting for clinical factors (age at RA onset, gender, RA duration): *REL* (rs13031237, T allele) with erosion-free status and *KIF5A* (rs775322, T allele) with not remaining erosion-free (Table 1). Neither allele reached statistical significance after Bonferroni correction. The HLA-SE was not associated with erosion-free status in this seropositive cohort.

Table 1. Association between *REL* and *KIF5A* with erosion-free status in seropositive RA adjusted for clinical predictors of erosion-free status.

Variables	Clinical model* + *REL*			Clinical model* + *KIF5A*		
	OR	95% CI	p-value	OR	95% CI	p-value
Age at RA onset (every 5 yrs)	0.77	0.66, 0.90	0.0001	0.78	0.67, 0.91	0.0013
Male gender	2.87	1.25, 6.58	0.013	2.81	1.23, 6.42	0.015
RA duration (yrs)	0.86	0.82, 0.91	<0.0001	0.87	0.83, 0.91	<0.0001
Risk allele	1.95	1.19, 3.17	0.0076	0.54	0.33, 0.88	0.013

* Clinical model includes age at onset, gender, and RA duration.

Conclusion: *REL* which encodes a component of the osteoclastogenesis pathway may predict erosion-free status in seropositive RA beyond significant clinical predictors. *KIF5A*, whose role in RA is unclear, was associated with erosive disease in this small study. Larger studies in independent cohorts are needed to confirm these associations.

TNIP2 Is Associated with Joint Destruction in Patients with Rheumatoid Arthritis. Taku Suzuki[2], Katsunori Ikari[2], Koichiro Yano[2], Yoshiaki Toyama[1], Atsuo Taniguchi[2], Hisashi Yamanaka[2] and Shigeki Momohara[2]. [1]Department of Orthopaedic Surgery, Keio University, [2]Institute of Rheumatology, Tokyo Woman's Medical University, Japan

Background: Recently a large-scaled meta-analysis of genome-wide association studies (GWAS) and replication studies identified novel rheumatoid arthritis (RA) risk loci in European descent populations; CD2/CD58 (rs11586238), CD28 (rs1980422), PRDM1 (rs548234), TAGAP (rs394581), PTPRC (rs10919563), RAG1-TRAF6 (rs540386), PTPN2 (rs7234029), PLCL2 (rs4535211), CD247 (rs1773560), ICAM1-ICAM3 (rs892188), NHLH2 (rs4272626), TNIP2 (rs231707), REL (rs13017599), and BLK (rs13277113).

The aim of this study was to investigate the genetic association of these reported 14 genes and joint destruction in Japanese RA patients.

Materials and Methods: DNA samples of 1504 Japanese patients were collected from the IORRA (Institute of Rheumatology RA cohort) DNA collection (84% of the patients were female, 87% were anticyclic citrullinated peptides (ACPA) antibody positive, 88% were rheumatoid factor positive and the mean age of the patients was 59.3 years). Of the patients, Sharp/ van der Heijde score (SHS) of the hands at 5-year disease duration, which represents joint destruction, could be measured in 628 patients.

Tested SNPs on the genes were selected based on the published studies (1–3). Genotyping was performed using the TaqMan assay according to the manufacture's instructions (Applied Biosystems, Japan). Multiple regression analysis was performed with SHS (hands) as a dependent variable, and as independent variables, the number of HLA-DRB1 alleles encoding the shared epitope (SE), the number of the risk alleles of RA-susceptible genes, sex, ACPA, and age of onset. The analysis was performed using the R software package.

Results: Sex (female, $P = 1.3\times10^{-4}$), age of onset (younger, $P = 1.3\times10^{-4}$), the number of SE ($P = 0.034$), the risk allele of TNIP2 ($P = 0.0092$) had impact on radiographic joint damage in Japanese RA patients while the other RA-susceptible genes did not show any association with the joint destruction.

Conclusions: We identified TNIP2 as a genetic factor for the joint destruction in RA patients.

Trait-Stratified Genome-Wide Association Study Identifies Novel and Diverse Genetic Associations with Serologic and Cytokine Phenotypes in Systemic Lupus Erythematosus. Silvia N. Kariuki[4], Beverly S. Franek[4], Akaash A. Kumar[4], Jasmine Arrington[4], Racheal A. Mikolaitis[2], Tammy O. Utset[4], Meenakshi Jolly[2], Mary K. Crow[1], Andrew D. Skol[3] and Timothy B. Niewold[4]. [1]Hospital for Special Surgery, Mary Kirkland Center for Lupus Research, New York, NY, [2]Rush University, Section of Rheumatology, Chicago, IL, [3]University of Chicago Pritzker School of Medicine, Section of Genetic Medicine, Chicago, IL, [4]University of Chicago Pritzker School of Medicine, Section of Rheumatology and Gwen Knapp Center for Lupus and Immunology Research, Chicago, IL

Introduction: Systemic lupus erythematosus (SLE) is a highly heterogeneous disorder. SLE-associated autoantibodies and high serum interferon alpha (IFN-α) are important heritable phenotypes in SLE which are correlated with each other, and play a role in disease pathogenesis. We set out to detect genetic factors associated with autoantibody profiles and serum IFN-α in SLE.

Methods: SLE patients were stratified by extremes of phenotype in serology and serum IFN-α for a case-case genome-wide association study. Single nucleotide polymorphisms (SNPs) in seven loci were selected for follow up in a large independent cohort of 450 SLE patients and 522 controls using a multi-step screening approach based on novel metrics and expert database review. The seven loci were: LRRC20, PPM1H, LPAR1, ANKS1A, PTPRM, EFNA5, and VSIG2.

Results: SNPs in the LRRC20, PPM1H, LPAR1, ANKS1A, and VSIG2 loci each demonstrated strong association with a particular serologic profile (all OR>2.2 and $p<8\times10^{-4}$). Each of these serologic profiles was associated with increased serum IFN-α. SNPs in PTPRM and LRRC20 were associated with increased serum IFN-α independent of serologic profile ($p=3.2\times10^{-6}$ and $p=5.0\times10^{-3}$ respectively). None of the SNPs were strongly associated with SLE in case-control analysis, suggesting that the major impact of these variants will be upon subphenotypes in SLE.

Conclusions: This study demonstrates the power of using serologic and cytokine subphenotypes to elucidate genetic factors involved in complex autoimmune disease. The distinct associations observed emphasize the heterogeneity of molecular pathogenesis in SLE, and the need for stratification by subphenotypes in genetic studies.

Imaging of Rheumatic Disease II: Ultrasound, PET, Capillary Microscopy and Molecular Imaging
Wednesday, November 10, 2010, 9:00 AM–6:00 PM

1613

[^{18}F]PEG-Folate: A New Potential Macrophage PET Tracer for Imaging of Arthritis. Conny J. van der Laken[3], Inge de Greeuw[2], Yoony Y. J. Gent[4], Karin Weijers[4], Alexandre E. Voskuyl[4], Gerrit Jansen[4], Ben A. C. Dijkmans[4], Adriaan A. Lammertsma[2], Phil S. Low[1], Sumith Kularatne[1], Albert D. Windhorst[2] and Carla F. M. Molthoff[2]. [1]Dept. of Chemistry, Purdue University, [2]Dept. of Nuclear Medicine & PET Research, VU Medical Center, Amsterdam, [3]Dept. of Rheumatology, VU Medical Center, Amsterdam, The Netherlands, [4]Dept. of Rheumatology, VU Medical Center

Background: Previous studies in rheumatoid arthritis (RA) patients have shown clear visualization of arthritis with Positron Emission Tomography (PET) and (18)F-fluorodeoxyglucose ([^{18}F] FDG). We found more specific imaging of arthritis with macrophage targeting, using the PET tracer, [^{11}C](*R*)PK11195[1]. Due to the relatively high level of non-specific binding of [^{11}C](*R*)PK11195 in surrounding tissues, we developed another macrophage PET tracer, [^{18}F]PEG-folate, with potential superior imaging characteristics. Our previous work has shown that the folate receptor (FR-β) on activated macrophages may be an attractive target for imaging of arthritis[2].

Objective: Pilot study to investigate the potential of [^{18}F]PEG-folate PET to image arthritis in a rat model.

Methods: FR binding affinity for F-PEG-folate relative to folic acid and the circulating plasma folate [6S]-5-methyltetrahydrofolate was assessed by FACS analysis and binding competition with Folate-FITC. Five Wistar rats were immunized with methylated bovine serum albumin (mBSA) and adjuvans. At day 21, arthritis was induced with an intra-articular injection (ia) of mBSA in the right knee. At day 30, 4 rats were injected with 20 MBq [^{18}F]PEG-folate and 1 rat with 10 MBq [^{18}F]FDG, followed by PET imaging during 2 hrs. Following imaging, rats were sacrificed to obtain ex vivo tissue biodistribution and (immuno)histopathological analysis.

Results: FR binding affinity for F-PEG folate was just 1.2-fold lower than for folic acid, but 5-fold higher than for [6S]-5-methyltetrahydrofolate. In all rats with induced arthritis, histopathology showed a macrophage-rich inflammation in the synovial tissue of the affected joint, resembling synovitis in RA patients. [^{18}F]PEG-folate cleared rapidly from the circulation, with levels decreasing from 2.1%ID/g at 1 min post-injection (p.i.) to 0.01 %ID/g at 1 hr p.i., 30 times lower than blood levels of [^{18}F]FDG at 1 hr p.i. On [^{18}F]PEG-folate PET images, the arthritic joints were clearly depicted. Inflamed-to-control knee ratios of [^{18}F]PEG-folate increased continuously up to 2.3 at 1 hr p.i and 2.6 at 2 hr p.i. In contrast, ratios of [^{18}F]FDG declined over time to 1.3 at 1 hr. Ex vivo tissue biodistribution data also revealed uptake of [^{18}F]PEG-folate in spleen, skin, fat and lymph nodes, suggesting binding to locally present (activated) macrophages in these tissues. This finding was confirmed by in vivo blockade of folate receptors by injection of i.v. glucosamine-folate prior to injection of [18FPEG-folate which significantly reduced uptake of [18F]PEG-folate in these tissues.

Conclusion: These first pilot data show that [^{18}F]PEG-folate may be a promising PET tracer for imaging arthritis by targeting of macrophages in synovial tissue. Further explorative rat studies, including comparison with [^{11}C](*R*)PK11195, are in progress and will be followed by investigation in humans.

1614

Asymptomatic Hyperuricemia: Ultrasonographic Findings. Carla Solano[3], Pedro José Rodríguez-Henríquez[4], Fritz Hofmann[4], Araceli Bernal[4], Norma Marín-Arriaga[4], Alberto Gabriel López-Reyes[4], Luis Guirado[1], Angelica Vargas-Guerrero[1], Luis Amezcua-Guerra[1], Marwin Gutierréz[5], Cristina Hernández-Díaz[4], Manuel Martínez-Lavín[1] and Carlos Pineda[2]. [1]Instituto Nacional de Cardiología, Mexico, [2]Instituto Nacional de Rehab, Mexico City, Mexico, [3]Instituto Nacional de Rehabilitación, El Salvador, [4]Instituto Nacional de Rehabilitación, Mexico, [5]Universitá Politecnicá delle Marche Ospedale "A Murri", Italy

Background: Musculoskeletal ultrasound (US) is a low-cost, widely accessible, non-invasive technique, which allows a multiplanar, real-time evaluation of joints without the use of ionizing radiation. Its use has recently been expanded to the evaluation of inflammatory arthritides, including gout. Ultrasonographic characteristics of gout are already well defined; however, the findings in asymptomatic patients have not been thoroughly described. US have shown to be superior in detecting changes in gouty arthritis than other imaging techniques.

Objective: To characterize the morphostructural abnormalities detected by US associated with the deposition of crystals in articular and extra-articular tissues of patients with asymptomatic hyperuricemia.

Methods: Men and women older than 18-years with asymptomatic hyperuricemia (serum uric acid ≥7.0 mg/dL and no joint complaints), without urate-lowering therapy; and normouricemic subjects without articular symptoms (control group) were recruited after informed consent was obtained. US scans of the femoral cartilage and tendons in the knee, tendons at the ankle, Achilles tendon and first metatarsophalangeal (1st MTP) joint were obtained. OMERACT definitions for US pathology were applied; tendinopathy: was defined as a loss of the fibrilar pattern, intratendinous tophi and/or calcifications.

Results: Demographics: 97 subjects were enrolled; 45 hyperuricemic and 52 normouricemic control subjects with a median age of 56 and 47.3 years. The average uric acid level in the hyperuricemic group was 8.17mg/dL (±0.95), see Table 1.

Table 1.

Variable	Hyperuricemia (n=45)	Normouricemia (n=52)	P
Age, years	56 ± 17.2	47.3 ± 10.9	0.003*
Male	30	35	0.9**
Uric Acid, mg/dL	8.17 ± 0.95	5.47 ± 0.90	<0.0001*

* Unpaired t test
** Chi-square test

In the hyperuricemic group tendinopathy was found in the posterior tibial tendon $p < 0.05$, as well as the presence of double contour sign in the 1st MTP joint $p < 0.0001$.

Table 2.

Variable	Hyperuricemia	Normouricemia	P
Osteophytes	12	8	Ns
Erosions	7	6	Ns
Power Doppler	0	0	Ns
Synovitis	32	25	Ns
Double contour sign	24	1	<0.0001

* All analyses were performed by chi-square tests.

Conclusion: Asymptomatic hyperuricemic patients show US morphostructural changes similar to those with established gout. Results confirm the notion that urate crystals are present in articular tissues before gout is clinically evident and may give further support for the use of urate-lowering therapy in asymptomatic hyperuricemic patients.

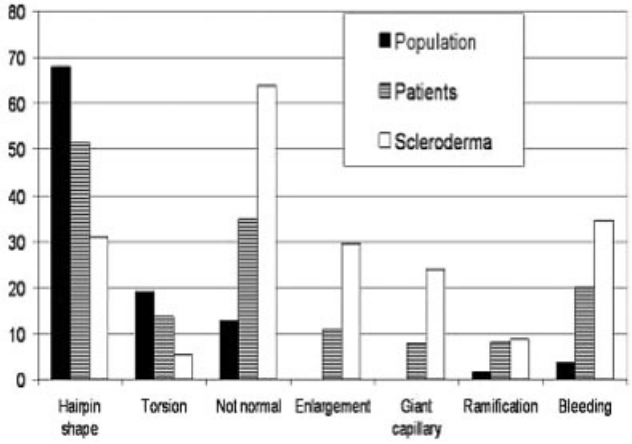
1615

Capillary Microscopy—A Cross-Sectional Study in the Population. Oliver Sander[1], Moritz Schroeder[3], Benedikt Ostendorf[1], Jutta Richter[1], Matthias Reppel[3], Hasan Acar[2], Martina Blumenroth[4] and Matthias K. Schneider[1]. [1]Dept. Rheumatology, Heinrich-Heine University, Duesseldorf, Germany, [2]Dept. Rheumatology, Heinrich-Heine University, [3]Heinrich-Heine University Duesseldorf, [4]Rheumazentrum Rhein-Ruhr

Objective: Application of capillary microscopy in the general population.

Method: Our mobile campaign for rheumatic diseases (RheumaTruck) visited 26 sites in the metropolitan region Rhine-Ruhr. The visitors could participate in different tests (including capillary microscopy of fingers III-V of both hands with standardized image documentation). Demographic data, self reported symptoms based on the connective tissue screening questionnaire (CSQ), and an ad hoc diagnosis by a rheumatologist were documented. 110 outpatient visitors of the rheumatologic department were documented the same way and served as controls. The capillary images were assessed by an experienced examiner semi quantitatively regarding density, edema, bleeding, hairpin shape, caliber equalization, enlargement, giant capillaries, ramification, bushy capillaries, elongation, torsion, flow properties and filling. The results were combined with the other collected data and analyzed statistically.

Results: 3196 visitors were counted. 754 visitors underwent capillary microscopy to availability of the device (mean age 54 years, 75% female, 10,000 images evaluable). Capillary microscopy and evaluation took 1 to 2 minutes each. The costs were restricted to the purchase of the device. 8% of the sample were not assessable. 68% of the capillaries showed the normal hairpin form, torsion (17%), ramification (3%), elongation (2%), enlargement (1%) was seen in the others. Hemorrhage was seen in 5% of subjects; 4 giant capillaries were detected. Hairpin shape was seen in only 52% of the rheumatologic outpatients and 31% of patients with known systemic sclerosis. Those had higher counts of divergences, esp. giant capillaries.



There are no gender differences in the capillary morphology. The number of normal capillaries decreases slightly with age (71% in the under-30s to 65% among 70–80 year olds). A previous described association of tortured capillaries and psoriasis (in the personal and family medical history) could not be confirmed. A new diagnosis of systemic sclerosis was not identified. In fibromyalgia, the rate of normal hairpin shape capillaries was with a rate of 79% significant higher than the average for the visitors. Raynaud's phenomenon was associated with altered blood flow and capillary filling, but no detectable differences in the morphology.

Conclusion: The expected high rate of inconspicuous findings in the visitors was confirmed, contrasting the observations in patients with rheumatic diseases. Raynaud's phenomenon was detectable by altered fillings and blood flow. The capillary microscopy is suitable for the application in larger populations.

Concordance between Ultrasound Readers Determining Presence of Monosodium Urate Crystal Deposition in Knee and Toe Joints. Rennie N. G. Howard[2], Michael H. Pillinger[2], Soterios Gyftopoulos[2], Ralf G. Thiele[4], Christopher Swearingen[3] and Jonathan Samuels[1]. [1]New York University Hospital for Joint Disease, New York, NY, [2]NYU Langone Medical Center, NYU Hospital for Joint Diseases, New York, NY, [3]University of Arkansas for Medical Sciences, Little Rock, AR, [4]University of Rochester, Rochester, NY

Background: Determination of monosodium urate (MSU) deposition in joints by musculoskeletal ultrasound (MSK-US) could have implications for uric acid (UA) management in patients with gout and possibly asymptomatic hyperuricemia (AH). Recently, criteria for sonographic diagnosis of MSU crystal deposition have been developed, but reproducibility of readings using these criteria has not been well established.

Methods: We consecutively recruited male patients ages 55–85 during primary care visits to an urban VA hospital. We assessed all patients for gout by ACR criteria, and obtained serum UA levels. Patients were divided into 3 groups: gout, AH (no gout, UA $\geq$ 6.9 mg/dL), and controls (no gout, UA $\leq$ 6.8 mg/dL). 50 patients (14 with gout, 17 with AH, and 19 controls) returned for subsequent evaluation which included MSK-US of knees and 1st metatarsalphalangeal (MTP) joints to evaluate for the double contour sign (knees) and tophi (MTPs). All images were read blindly by two observers trained in rheumatology and MSK-US. Kappa statistics were used to estimate the amount of agreement between ultrasound measures scored by the two raters. We also calculated the total percent of observations in agreement.

Results: Evidence of MSU crystal deposition was found in the same 10 patients by both observers (6 gout, 3 AH, 1 control), and in 3 additional patients by one of the observers (1 gout, 2 AH). These findings were further analyzed by site. MSU crystal deposition was identified in a total of 14 common joints by both observers, and in 4 additional joints by the first observer and 6 additional joints by the second observer. Percentage agreement and kappa statistics for our three primary ultrasound measures were as follows; total joints (n=200, 95% agreement, kappa 0.709), femoral articular cartilage (n=100, 95% agreement, kappa 0.679) and 1st MTPs (n=100, 95% agreement, kappa 0.734). Additional analyses by left and right side are shown in the table below. Ratings on only 10 out of 200 joints were in disagreement.

Site	# of Joints Assessed	# of Joints Affected Rater 1	# of Joints Affected Rater 2	% Agreement	Kappa (95% CI)
Femoral Articular Cartilage	**100**	**8**	**9**	**95**	**0.679 (0.415, 0.943)**
-Right	50	6	6	96	0.832 (0.649, 1.000)
-Left	50	2	3	94	0.370 (−0.188, 0.928)
First MTP	**100**	**10**	**11**	**95**	**0.734 (0.512, 0.956)**
-Right	50	5	6	98	0.890 (0.701, 1.000)
-Left	50	5	5	92	0.556 (0.168, 0.944)
Total Joints	**200**	**18**	**20**	**95**	**0.709 (0.539, 0.880)**

Conclusions: Both percentage agreement and agreement beyond chance between the raters (as estimated by kappa statistics) were very high for the three ultrasound measures. These findings support the use of MSK-US as a reliable modality for detecting MSU deposition. Since MSU deposition is an indication for urate lowering, this type of imaging could be performed noninvasively at the bedside or in the clinic to help direct therapy in gout patients, with possible implications for treatment in AH patients as well should these findings be reproducible in larger cohorts.

Demonstrating Musculoskeletal Ultrasound Competency in a Valid and Reliable Way. Eugene Y. Kissin[4], Jingbo Niu[5], Ralf G. Thiele[11], Midori Jane Nishio[1], Jay B. Higgs[13], Janak R. Goyal[10], Daniel G. Malone[12], David A. Bong[2], Amy M. Evangelisto[3], Wolfgang A. Schmidt[7], Peter Balint[8], Carlos Pineda[6] and Gurjit S. Kaeley[9]. [1]Lafayette, CA, [2]Bruce, WI, [3]Arthritis Rheumatic & Back Disease Association, Philadelphia, PA, [4]Boston University, Boston, MA, [5]Boston University, Boston, MA, [6]Institutu Nacional de Rehab, Mexico City, Mexico, [7]Medical Center for Rheumatology Berlin-Buch, Berlin, Germany, [8]National Institute of Rheumatology and Physiotherapy, Budapest, Hungary, [9]University of Florida College of Medicine, Ponte Vedra Beach, FL, [10]University of Medicine and Dentistry of New Jersey, Robert Wood Johnson Medical School, Perth Amboy, NJ, [11]University of Rochester, Rochester, NY, [12]University of Wisconsin, Madison, WI, [13]Wilford Hall Medical Center/Brooke Army Medical Center, San Antonio, TX

Purpose: The amount of training needed to become competent in musculoskeletal ultrasound (MSUS) is debatable, and a valid exam to determine competency in MSUS is needed. While others have previously established training and testing procedures, no one has yet documented MSUS test reliability or validity. We aim to develop a reliable and valid MSUS test.

Methods: USA rheumatology fellows who had participated in an 8 month, standardized, MSUS curriculum completed an exam of MSUS consisting of multiple choice questions (MCQs), and practical scanning (PrE) of normal anatomy.

10 faculty members (> 4 years of practical and teaching experience in MSUS courses) individually submitted 250 MCQs covering 8 peripheral joint regions and typical rheumatic conditions. As a group, the faculty excluded 143 MCQs that were unclear or irrelevant to rheumatology. Remaining MCQs were tested in 2 groups: 3 rheumatologists without MSUS training, to exclude MCQs answered correctly by all 3, and 5 rheumatologists expert in MSUS to exclude MCQs answered incorrectly by 3 of 5, resulting in 76 MCQs on the exam.

To validate the MCQ exam, 3 additional groups completed it: rheumatologists who finished an intermediate course of training through the Mexican School of Musculoskeletal Ultrasound (Intermediate Group (IG), n=7), rheumatologists with > 2 years of experience in MSUS from both Mexico and the USA (Advanced Group (AG), n=7), and USA fellows (Fellow Group (FG), n=19).

All Fellows and 2 MSUS faculty members took an 8-station PrE for scanning technique in all 8 joint areas. Faculty graded images from the PrE, blinded to source, on a 5 point scale based on predefined quality measures.

Results: The MCQ exam was reliable (Cronbach's a= 0.76) and discriminated between IG and AG (median score 63% vs. 79%, p=0.003 Wilcoxon). The FG median MCQ test score exceeded that of the IG (72% vs. 63%, p=0.02 Wilcoxon), but had the greatest range - from worse than the IG to better than the AG (Figure 1). Fellows and faculty median PrE scores were

not significantly different (2.4 vs. 2.8, p=0.18), but 2 fellows scored significantly lower than the faculty members. PrE and MCQ results correlated well (Spearman r=0.63, p=0.004).

Conclusions: A written and practical exam proved moderately reliable and valid in a comparison of practitioners of varying levels of training. The correlation between results of the two exam parts adds further validity. Most fellows who completed an 8 month MSUS training program achieved similar essential MSUS knowledge to the advanced MSUS group (MCQ), and similar basic scanning technique to their mentors (PrE), thus demonstrating basic competence. However, fellow test results varied significantly despite completion of a standardized teaching program. Given the variability in achieving MSUS competency after uniform training, requisite MSUS experience should be based on outcome testing rather than a fixed time period of education.

1618

Effect of Musculoskeletal Ultrasound (MSKUS) Examination on Therapeutic Decision Making in Inflammatory Arthritis. Arnold Ceponis[2], John J. Cush[1] and Arthur Kavanaugh[3]. [1]Baylor Research Institute, Dallas, TX, [2]Division of Rheumatology, Allergy and Immunology, University of California San Diego, San Diego, CA, [3]University of California-San Diego, La Jolla, CA

Background: MSKUS is a sensitive and specific imaging modality with growing utilization in rheumatology. However, the impact that MSKUS examination may have on therapeutic decision making in the management of inflammatory arthritis is unknown.

Methods: Rheumatologists were presented with online survey including 4 standard clinical vignettes (3 RA and 1 PsA), and were asked to make management decisions before and after data from joint ultrasound was reported. Physician demographics, use and familiarity with MSKUS were also surveyed.

Results: Of the 332 respondents (mean age 53.7 yrs), who answered the survey, 30% reported performing MSKUS, 25% send patients to imaging centers, 34% reported being familiar, but not performing MSKUS themselves, and 29% were not familiar with /never using MSKUS. Confidence that MSKUS can detect active synovitis using power Doppler (PD) or visualization of synovial tissue/fluid was expressed by 59% and 78%, respectively, and for detection of enthesitis by 56% of respondents.

When presented with 4 clinical scenarios, the addition of typical data from MSKUS was shown to potentially have a very significant impact on rheumatologists' specific treatment plans ($p < 0.0001$). Case 1: for an obese RA patient on MTX 20 mg/wk with a high tender joint count, but equivocal clinical synovitis and lack of erosions on x-ray, a lack of synovial hypertrophy and hyperemia on MSKUS significantly decreased the number of respondents intending to add/increase prednisone (10% pre-MSKUS *vs* 3% post, $p < 0.00001$), DMARD (51% pre *vs* 27% post, $p < 0.0001$), or biologics (74% pre *vs* 35% post, $p < 0.0001$). Case 2: significantly more respondents chose to escalate treatment with prednisone (5% pre-MSKUS *vs* 10% post, $p < 0.001$), DMARD (36% pre *vs* 68% post, $p < 0.0001$) or biologics (9% pre *vs* 61% post, $p < 0.0001$) in a patient with early RA without x-ray erosions and low joint count after MSKUS showed erosions and more abundant synovitis on gray scale and PD. Case 3: in polyarticular PsA on MTX 15 mg/wk and a TNF-inhibitor without clinically active peripheral synovitis, but tender unilateral Achilles, a finding of bilateral Achilles paratenonitis and enthesitis by MSKUS prompted respondents to escalate prednisone (3% pre-MSKUS *vs* 11% post, $p < 0.0001$), DMARD (22% pre, *vs* 50% post, $p < 0.0001$) or escalate/change a biologic (8% pre *vs* 34% post, $p < 0.0001$). Case 4: no significant changes in therapy (prednisone, $p > 0.63$, DMARD, $p > 0.14$, or biologic, $p > 0.70$) occurred when MSKUS results were similar to those of clinical examination in severe active RA.

Lack of training, followed by reimbursement uncertainty and time concerns were reported as major barriers for MSKUS utilization among rheumatologists.

Conclusions: In specific clinical settings, typical results from MSKUS, can significantly impact therapeutic decision making. The most pronounced influence of the MSKUS examination was seen on the decisions to use biologic agents. This data is being validated in an ongoing clinical study using real time MSKUS on actual RA patients in a clinic setting.

Enthesopathy Detected by 18-Fluorodeoxyglucose Positron Emission Tomography in Patients with Polymyalgia Rheumatica. Hiroyuki Yamashita[2], Kazuo Kubota[1], Yuko Takahashi[3], Hiroshi Kaneko[3] and Akio Mimori[3]. [1]Department of Radiology, National Center for Global Health and Medicine, [2]Division of Rheumatic Diseases, National Center for Global Health and Medicine, Shinjuku-ku, Tokyo-to, Japan, [3]Division of Rheumatic Diseases, National Center for Global Health and Medicine

Background: Polymyalgia rheumatica (PMR) is characterised by acute-onset proximal muscle pain and stiffness in patients over 50 years of age, and is diagnosed by excluding other disorders that cause similar complaints. Although the exact pathology of PMR is unknown, synovitis and bursitis are also common in this disease. Magnetic resonance imaging (MRI) or ultrasonography frequently reveals inflammation of the tenosynovial sheaths on the patients' hands or feet. A study of PMR using 18-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) documented involvement of the spinous processes. Here, we present additional PET/CT findings in PMR.

Patients and Methods: Thirteen consecutive patients with PMR admitted to our institute between August 2007 and April 2010 were enrolled in the study. The number of the patients and the mean age ± SD was 13 and 76.2±6.5 years (range, 66–87), respectively.The diagnosis was based on the criteria of PMR of Chuang *et al.* and the exclusion of other inflammatory diseases. All 13 patients underwent FDG-PET/CT before starting steroid therapy. One patient also had clinical temporal arteritis.

Results and Discussion: FDG uptake was detected in the large joints and spinous processes in accordance with previous reports, and these sites were positive in 85% (11/13) and 54% (7/13) of the patients, respectively. In addition, muscle-tendon attachment sites in 69% (9/13) of the patients were FDG-positive, *i.e.*, a majority of our PMR patients had enthesopathy. Of the large joints, the shoulders (11/11), hips (11/11), and knees (7/11) were the main affected sites. The enthesopathy was predominantly detected in the ischial tuberosities (9/9) and greater trochanter of the femur (8/9). Some of the FDG-positive lesions were detected on MRI, and the ratio of positive results in patients examined was 4/4 in the large joints, 1/1 in enthesopathy, and 0/2 in the spinous processes. Large vessel involvement was detected in two patients as multiple FDG uptake lesions. Of these, one patient had clinical symptoms of temporal arteritis, while the other was completely asymptomatic for the vasculitis. Enthesopathy in the patients was difficult to detect on physical examination because of overlapping myalgias or arthralgias. PET/CT may be useful for evaluating organ involvement in PMR patients.

Conclusion: FDG-PET/CT shows that not only inflammation of the spinous processes and large joints but also enthesopathy may be common in polymyalgia rheumatica.

Erosive Osteoarthritis Is Not Associated with Invading Synovial Tissue: An Ultrasound Study. Ralf G. Thiele[1], Laura A. Paxton[3], Bethany A. Marston[2], Darren Tabechian[4] and Allen P. Anandarajah[1]. [1]University of Rochester, Rochester, NY, [2]University of Rochester, Rochester, NY, [3]University of Rochester, North Chili, NY, [4]University of Rochester School of Medicine, Rochester, NY

Background: In patients with osteoarthritis, bony defects in small joints of the hand can occasionally be seen with conventional radiography (CR). Such a condition may be called erosive osteoarthritis (EOA). Swelling may occur, and the term "inflammatory osteoarthritis" is occasionally used. The degree of actual synovial proliferation remains unclear. It also remains unclear if bony defects of EOA are associated with synovial proliferation, similar to rheumatoid arthritis (RA).

Objectives: To assess if synovial proliferation and synovial hyperemia can be detected sonographically in EOA.

Methods: 1091 US studies obtained over 16 months were reviewed. All US studies were performed by a rheumatologist certified in musculoskeletal US, with >15 years of US experience. Studies were performed using a Toshiba Xario US machine with an 18 MHz linear transducer with differential tissue harmonic imaging and high-sensitivity Doppler capability, and a SonoSite M-Turbo machine.

Patients with a CR diagnosis of EOA were identified. For the diagnosis of EOA, the radiologist's final assessment was counted.

US studies of joints in which EOA had been described by CR were assessed for the following:

1. Effusion, defined as a distension of the hyperechoic, fibrous joint capsule by anechoic synovial fluid; 2. Synovial proliferation, defined as hypo- to hyperechoic tissue within the joint cavity and emanating from the hyperechoic, fibrous capsule; 3. Synovial hyperemia, defined as a pulsatile Doppler signal within the joint capsule, associated with synovial tissue. Doppler signals were graded as follows: 0 = no signal; 1 = single vessel dots; 2 = confluent Doppler signals occupying less than half of the identified synovial tissue; 3 = confluent Doppler signals occupying more than half of the identified synovial tissue.

US studies of 13 RA patients were randomly selected and scored as a comparison group.

Results: Results were available for 13 EOA patients and 21 joints: DIP, n = 15; PIP, n = 6 (13 RA patients: MCP, n = 104; PIP, n = 104).

Effusions were seen in 4/21 (19%) joints in EOA and 67/208 (32%) joints in RA. When effusions in EOA patients were seen, they were seen over the volar aspects of DIP and PIP joints, or immediately adjacent to bone spurs, where the spurs mechanically distended the joint capsule. Synovial proliferation was seen in 2/21 (9.5%) joints in EOA and 120/208 (58%) in RA. The degree was minimal in all cases of EOA. Only a concentric proliferation of the synovial lining was seen, but no invading pannus tissue was appreciated in EOA. Doppler scoring was 0 in 19/21 (90.5%) or 1 in 2/21 (9.5%) in EOA and 3 in 28/208 (13.5%), 2 in 52/208 (25%), 1 in 30/208 (14%) and 0 in 98/208 (47%) in RA.

Conclusion: In this US study, synovial changes were found to be fundamentally different in EOA and RA. Increases in synovial fluid around bone spurs in EOA did not have an inflammatory character. Synovial proliferation in EOA was, in stark contrast to RA, minimal. Similarly, synovial hyperemia was rarely seen in EOA, while this is common feature of RA. Invading synovial tissue was not seen adjacent to bony defects in EOA. Using sensitive US technology, synovial proliferation and hyperemia were not characteristic of EOA.

Evaluation of the 7-Joint Ultrasound Score (US7) by Detailed Joint Region-Analysis of an Arthritis Patient Cohort over One Year. Sarah Ohrndorf[3], Beatrice Halbauer[3], Lydia Naumann[3], Ekkehart Dietz[2], Gerd R. Burmester[1] and Marina Backhaus[4]. [1]Charite-University Medicine, Berlin, Germany, [2]Department of Medical Statistics Charité, Berlin, Germany, [3]Department of Rheumatology and Clinical Immunology, University Hospital Charité, Berlin, Germany, [4]University Medicine Berlin: Campus Charité Mitte, Berlin, Germany

Purpose: To evaluate the 7-joint ultrasound score (US7) by joint region-analysis of a cohort of arthritis patients over one year.

Methods: US7 examines the clinically dominant wrist, MCP and PIP II and III, MTP II, and V joints for synovitis, tenosynovitis/paratenonitis and erosions. Synovial inflammation is scored semi-quantitatively (grade 0–3) by grey scale (GS) and vascularity by power Doppler (PD) ultrasound (US), respectively. Tenosynovitis/paratenonitis and erosions are scored qualitatively (grade 0–1) by GS US.

Forty-five patients with RA (84.4%), PsA (13.3%) and AS with peripheral joint involvement (2.2%) with a mean disease duration of 9.0 years (SD 7.9, range 7.5 mths-47.6 years) were included and examined before (baseline) and after 3, 6 and 12 months (t3, t6 and t12) starting or changing therapy (DMARD±TNFinh.).

A detailed US7 analysis was performed for the baseline examination, referring to each examined joint region.

Results: N=45 patients with longstanding arthritis were recruited from the rheumatology Outpatient Clinic of the Charité-University Hospital Berlin, Germany.

The *initial* joint region-analysis resulted in 95.6% involved wrists from dorsal, of which grade 2 was most often detected (48.9%). Furthermore, erosions in this joint region were detected in 68.9% of patients, respectively. Wrist joints from palmar also showed synovitis in 88.9% with nearly the same number each for grade 1 (40%) and grade 2 (37.8%). Here, erosions were deteced in 57.8%. Tenosynovitis of the extensor carpi ulnaris tendon being considered as an early finding in RA, was just found in 40% with a PD activity in 6.6%.

GS synovitis was evaluated in 95.6% both in MCP joint II and III from palmar. Most erosions in the MCP joint II were detected from radial (68.9%) in comparison to palmar (44.4%) and dorsal (48.9%). In the MTP joint V 75.6% erosions were seen from lateral.

With regards to paratenonitis, MCP joint II showed changes in 4.4% of patients, and MCP joints II only in 2.2%.

Conclusion: Synovitis in GS US was more often detected in the wrist from dorsal than from palmar. Tenosynovitis of the extensor carpi ulnaris tendon is often involved in RA and could be presented by GS US in 40%, respectively. Most erosions were found in the lateral scan of the MTP joint V and the radial scan of the MCP joint II. The detailed joint region-analysis showed that paratenonitis was a rare finding with the consequence that paratenonitis might not be a necessary component in the US7.

1622

Fluorescence Imaging of Articular Proteinase Activities and Osteoblast Activity Showed Treatment Response to Anti-Interleukin-1 Antibodies in a Mouse Model of Collagen-Induced Arthritis. Fons A. J. van de Loo, Eline Vermeij, Onno J. Arntz, Marije Koenders and Wim B. van den Berg. Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands

Objective: To monitor the response of anti-IL-1$\alpha\beta$ antibody treatment on collagen-induced arthritis (CIA) using cathepsin- and matrix metalloproteinase (MMP) cleavable near-infrared probes, and a probe of osteoblast activation.

Methods: CIA was induced in male DBA1/J mice by immunization with bovine collagen-type II. Mice received either anti-IL-1$\alpha\beta$ sera (200 μl i.v.) or normal rabbit serum as a control at day 21. Ten days later, probes were injected i.v. and 6 hours later mice were imaged using the IVIS Lumina (Caliper Life Sciences). Thereafter, ankle and knee joints were dissected and processed for RNA, histology or X-ray. The ProSense 680 probe (VisEn Medical Inc, Bedford, USA) becomes activated upon enzymatic cleavage by cathepsins (B, K, L, S, D), collagen degrading lysosomal cysteine proteinases. The MMPSense 680, can be activated by different MMPs (2,3,9,13), known to degrade collagen and proteoglycans during arthritis. OsteoSense 680 is a fluorescent biphosphonate that binds to hydroxyapetite, a biomarker for osteoblast activation. Gene expression profiling was done of synovial biopsies from (non)-inflamed knees of untreated mice (MOE430_2 oligonucleotide array, Affymetrix, CA). Ankle joints were X-ray photographed and analyzed using a stereo microscope and scored on a scale ranging from no damage (0) to complete bone destruction (5).

Results: Inflamed synovia of CIA showed enhanced expression of the extracellular matrix degrading enzymes cathepsin-K (13-fold, osteoclasts specific gene), cathepsin-S (9-fold, specific for monocytes), MMP-13 (50-fold), MMP-3 (22-fold), MMP-14 (9-fold), MMP9 and MMP-2 (4-fold). Genes related to bone destruction as cathepsin K (13-fold), TGFβ1 (5-fold), TRAP5 (9-fold) and RANKL (10-fold) were upregulated as were also the

osteoblast specific enzymes osteocalcin (10-fold) and periostin (7-fold). The signal of ProSense and MMPSense in both knees and paws correlated with joint inflammation and cartilage destruction, but only the MMPSense and not the ProSense correlated with chondrocyte death, a marker of irreversible cartilage destruction. Anti-IL-1$\alpha\beta$ antibody treatment alleviated CIA and markedly diminished the ProSense and MMPSense imaging signal. OsteoSense signal was increased during inflammation and was higher in mice showing mild bone loss as measured by X-ray and was significantly lower in the anti-IL-1 treated mice.

Conclusion: The correlation of both ProSense and MMPSense to inflammation and destruction is in line with the upregulation of Cathepsins and MMP's during CIA, and the connective tissue destructive properties of these enzymes. Interestingly, only the MMPSense signal correlated with chondrocyte death and we speculate that MMPs are directly involved as both MMP9 and 13 have galectin-3 as a substrate, an anti-apoptotic protein in chondrocytes. The OsteoSense signal in CIA showed that new bone formation by osteoblasts occurred under mild bone loss conditions. Imaging of these three probes is a sensitive method to measure joint inflammation, connective tissue destruction and repair, and overall is fluorescence imaging a valuable tool to monitor a treatment response.

High Reliability of Nailfold Videocapillaroscopy—An Outcome Measure for Systemic Sclerosis-Related Microvsacular Disease? Herman Hofstee[4], Erik Serné[4], Chris Roberts[2], Roger Hesselstrand[1], Agneta Scheja[1], Tonia Moore[3], Marie Wildt[1], Joanne Manning[2], Anton Vonk Noordegraaf[4], Alexandre Voskuyl[4] and Ariane Herrick[2]. [1]Lund University, Sweden, [2]The University of Manchester, United Kingdom, [3]The University of Manchester, United Kingdom [4]VU University Medical Center, Amsterdam, The Netherlands

Background: Systemic sclerosis (SSc)-related structural microvascular abnormalities can be directly visualised using the non-invasive technique of nailfold capillaroscopy. Computerised techniques combined with high magnification videocapillaroscopy bring the potential of capillaroscopy being not only a diagnostic tool but also an outcome measure in longitudinal studies of SSc-related microvascular disease, including studies of treatment response. Good reliability is a necessary prerequisite for a test to be a valid clinical or research tool. The aim of our study was to investigate the inter- and intra-observer reliability of both qualitative and quantitative nailfold capillaroscopic parameters.

Methods: Mosaic nailfold images were acquired from the non-dominant ring finger of 10 healthy controls, 10 patients with primary Raynaud's phenomenon, and 30 with SSc using a computerised videocapillaroscopy system (magnification 300x). Each image was assessed 'blindly' by 6 observers (2 from each of 3 centres from 3 different countries). Images were graded for both qualitative (including capillary architecture, avascularity, haemorrhages, and tortuous, ramified, bushy and bizarre loops) and quantitative parameters (including number of mega- and giant capillaries, capillary density, and capillary dimensions). Inter-and intra-rater reproducibility were assessed for (a) ordered categorical scores (qualitative and quantitative) using a weighted kappa co-efficient with quadratic weights and (b) quantitative measurements using intra-class correlations.

Results: These are summarised in the table.

	Inter-observer reliability	Intra-observer reliability
Weighted Kappa of ordered categories (95% CI)		
Architecture	0.72 (0.55, 0.82)	0.75 (0.64, 0.83)
Avascularity	0.61 (0.37, 0.75)	0.74 (0.62, 0.82)
Haemorrhage	0.56 (0.16, 0.79)	0.73 (0.57, 0.86)
Tortuous	0.39 (0.25, 0.50)	0.68 (0.60, 0.76)
Ramified	0.58 (0.30, 0.73)	0.73 (0.59, 0.84)
Bushy	0.73 (−0.02, 0.90)	0.80 (0.58, 0.94)
Bizarre	0.21 (0.00, 0.32)	0.76 (0.55, 0.92)
Mega capillary	0.76 (0.64, 0.84)	0.87 (0.82, 0.91)
Giant capillary	0.84 (0.71, 0.92)	0.92 (0.87, 0.96)
Intra-class correlation coefficient of quantative measurements (95% CI)		
Density	0.87 (0.88, 0.92)	0.92 (0.91, 0.97)
Apex	0.94 (0.93, 0.97)	0.97 (0.96, 0.99)
Arterial	0.88 (0.87, 0.93)	0.96 (0.95, 0.99)
Venous	0.91 (0.90, 0.96)	0.96 (0.95, 0.99)
Total width	0.94 (0.93, 0.97)	0.98 (0.98, 0.99)

Inter- and intra-observer reliability of quantitative parameters showed substantial to almost perfect agreement. Certain qualitative parameters (architecture, avascularity, haemorrhage, ramified, and bushy capillaries) showed moderate to substantial inter-observer agreement and substantial intra-observer agreement, whereas other parameters including tortuous and bizarre capillaries showed moderate to poor inter-observer agreement.

Conclusions:

1) All quantitative and some qualitative parameters are highly reliable in terms of inter- and intra-observer agreement.

2) Other qualitative parameters, including tortuosity, are less reliable.

3) Capillaroscopy is likely to be a useful diagnostic tool and an outcome measure in studies of SS-related microvascular disease, provided that parameters selected are those with high reliability.

1624

Hypodermal Compressibility as a Diagnostic Test for Eosinophilic Fasciitis. Eugene Y. Kissin[1], Michael R. York[2] and Robert W. Simms[3]. [1]Boston University, Boston, MA, [2]Boston University Medical Ctr, Boston, MA, [3]Boston University School of Medicine, Boston, MA

Purpose: Eosinophilic fasciitis (EF) is an autoimmune, fibrotic disorder that presents with painful swollen extremities. Though there are clinical characteristics that may distinguish it from diffuse systemic sclerosis (dSSc), frequently a deep wedge biopsy of the skin and fascia is felt to be necessary to confirm the diagnosis. We sought to determine whether high resolution B-mode ultrasound could distinguish forearm involvement by EF from similar fibrotic diseases such as systemic sclerosis, and diabetic cheiroarthropathy (DMc), and from controls with normal skin and fascia.

Methods: Consecutive patients with clinically diagnosed EF, DMc, dSSc, and fibromyalgia (FM) (FM with normal skin and subcutaneous tissue) were recruited from a rheumatology clinic over a period of 2 years to undergo ultrasound evaluation of the forearm. A GE LOGIQ e ultrasound unit with an L12 probe was used to evaluate the more clinically affected mid-dorsal forearm. The hypodermal tissues between the deep dermal interface and the muscle edge at the groove formed between the extensor digitorum and extensor carpi radialis was evaluated in short axis for the following variables: tissue depth with no transducer pressure (gel layer used to "float" the transducer to avoid any pressure), tissue depth with maximal tissue compression by transducer, and tissue echogenicity measured by densitometry (NIH Image). Dermal thickness was also measured. Tissue compressibility was calculated as (non-compressed tissue depth–compressed tissue depth)/non-compressed tissue depth. Statistical analysis was by T-test.

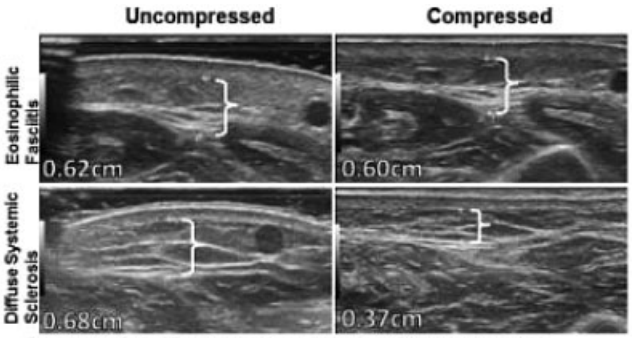
Results: The following numbers of patients were studied in each group: EF–8, dSSc–23, DMc–8, FM–8. Hypodermal percent compressibility was significantly less in EF compared with the other groups (means ± SD): EF–9 ± 7, dSSc–30 ± 13 ($p<0.004$ vs. EF), DMc–29 ± 20 ($p<0.02$ vs. EF), and FM–29 ± 14 ($p<0.003$ vs. EF) (figure). Hypodermal atrophy, measuring less than 4mm in thickness, was apparent in patients with EF–3/8 (38%), dSSc–7/23 (30%), and DMc–4/8 (50%), but not FM–0/8 (0%). DMc or dSSc patients only had < 20% hypodermal compressibility if they also had hypodermal atrophy, while all but one EF patient had compressibility of less than 20% regardless of hypodermal atrophy. Hypodermal tissue average echogenicity did not differ between the 4 groups (EF=155 ± 21 densitometry units (du), dSSc=145 ± 16 du, DMc=157 ± 12 du, FM=149 ± 17 du, p=NS). Dermal thickness also did not vary significantly between the 4 groups (EF=1.3mm ± 0.2, dSSc=1.4mm ±0.3, DMc=14mm ±0.3, FM 13mm ±0.3, p=NS).

Hypodermis Compression Test for Eosinophilic Fasciitis

Patient group	Hypodermal % compression	Hypodermis <4mm thick (% of patients)	Hypodermis echogenicity
Eosinophilic Fasciitis (n=8)	9 ± 7	38	155 ±21
Diffuse systemic sclerosis (n=23)	30 ± 13 p<0.004*	30	145 ±16
Diabetic (n=8) cheiroarthropathy	29 ± 20 p<0.02*	50	157 ±12
Fibromyalgia (control) (n=8)	29 ± 14 p<0.003*	0	149 ±17

A. comparison of hypodermis in patient groups. * P for comparison with eosinophilic fasciitis. Echogenicity measured in densitometry units.

Figure 1.



B. representative B-mode ultrasound images from a patient with eosinophilic fasciitis and with diffuse systemic sclerosis.

Figure 2.

Conclusions: Ultrasound can easily measure hypodermal compressibility. Our data suggest that reduction in hypodermal compressibility to less than 20% in non-atrophied hypodermis can be used to distinguish EF from dSSc and DMc, potentially obviating the need for wedge biopsy.

Novel PET/MR Fusion Imaging and Quantification of Knee Synovitis in Rheumatoid Arthritis. John T. Ryan[4], C. T. Ng[1], Aisling Kennedy[2], Robert G. Gibney[1], Oliver Fitzgerald[1], Patrick C. Brennan[5], Eric Heffernan[1], Jonathan McNulty[3], Louise Rainford[3], Ursula Fearon[1] and Douglas Veale[1]. [1]Dublin Academic Medical Centre, Dublin, Ireland, [2]Dublin Academic Medical Centre, [3]University College Dublin, [4]University of Sydney, Lidcombe, NSW, Australia, [5]University of Sydney

We recently identified hypoxia and altered blood vessel stability in the rheumatoid arthritis (RA) joint suggesting the vessels are dysfunctional, as they do not match metabolic demand. PET/CT imaging is recognized as an important advance in health care and research. In this study we aim to develop an innovative imaging approach to visualize and quantify synovial tissue (ST) blood flow and metabolic activity in inflamed joints of RA patients.

RA patients with an active knee joint synovitis were recruited and underwent clinical assessment prior to contiguous imaging initially with MR, then PET/CT followed by a needle videoarthroscopy, ST biopsy and pO2 measurement (novel LICOX probe). The PET radiotracer - Fluorodeoxyglucose (18F) was used and image-data intensity resolution was optimised for ST. These images exhibit the qualities of MRI with higher intensity regions in the areas of ST inflammation with extra heat-map information from the PET imaging. Semi-quantitative scoring of the MRI datasets was performed using the RAMRIS score. ST biopsies were stained for CD3+ (T cells), CD68+ (macrophages), and Factor VIII/ SMA (Blood vessel maturity) and NCAM expression.

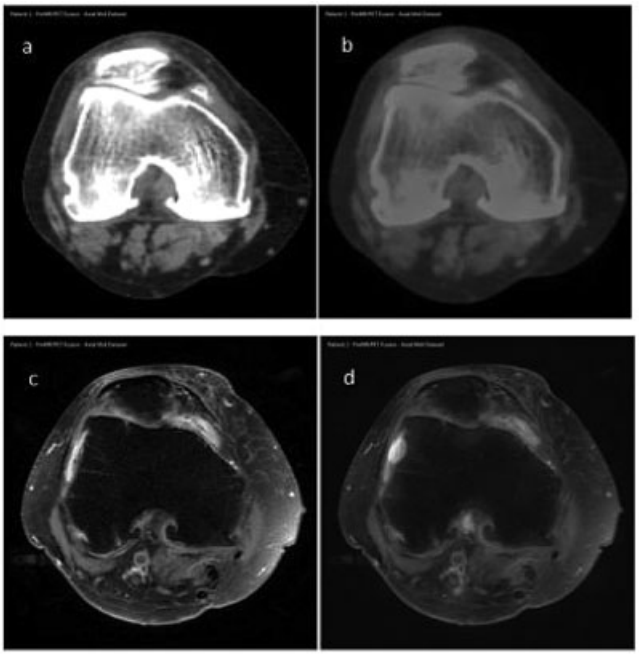

Figure 1. (a) Axial CT slice, (b) Axial PET/CT, (c) Axial contrast-enhanced MRI, (d) PET/MR fusion image.

RA patients (n=9) have completed combined scanning/arthroscopy protocols. Proof-of-concept images and quantitative assessments have been developed (Fig. 1, 2). Fig. 1a and b show the CT and PET/CT scans, 1c shows MR and the PET/MR fusion image is shown in Fig 1d. Evaluation of disease activity, blood flow or metabolic activity is not possible in Fig 1a or 1c, while Fig. 1b only provides information of metabolic activity. Fig. 1c does illustrate areas of high signal representing inflammation. Fig. 2 shows the contrast of PET imaging of an inflamed knee compared to the uninflamed contralateral knee and good PET/MRI structural agreement. A region of interest (ROI) was evaluated (n=3) of the target and the opposite knee to calculate a ratio of affected:unaffected. A significant correlation was found between PET activity with MRI score ($r = 0.9986$, $p < 0.0001$), with low tpO2 in vivo levels (xyz), while an inverse relationship was found with blood vessel maturity and stability, reflected by factor VIII/ SMA and NCAM expression on ST immunohistology of the blood vessels ($r = -0.99$, $p < 0.0001$).

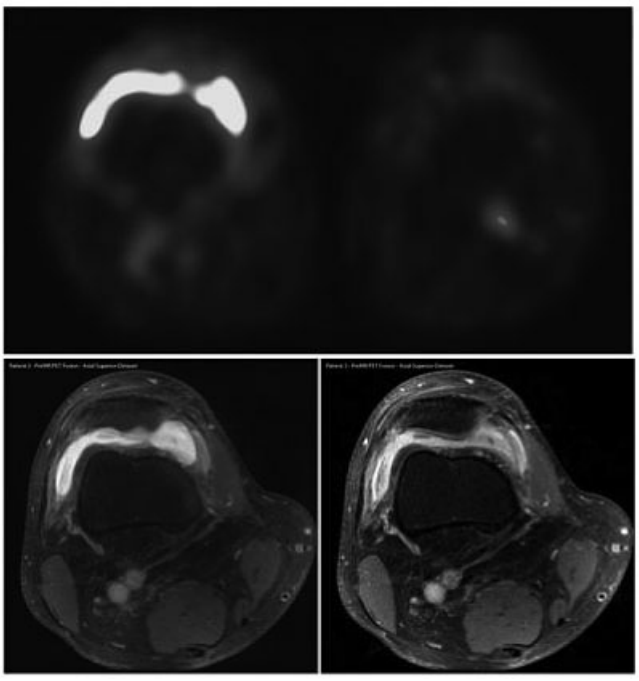

Figure 2. PET image of affected side versus unaffected contralateral side (top). Structural agreement of PET with MRI (bottom).

This is the first description of hybrid PET/MRI fusion imaging of inflamed joint in RA. The preliminary data suggest a close correlation between measures of inflammation, blood flow and metabolic activity. The potential correlation with cellular and molecular biomarkers suggests this novel imaging protocol may be extremely powerful in assessing response to therapies in vivo.

Outcomes and Cost-Effectiveness of Carpal Tunnel Injections Using Sonographic Needle Guidance. Natalia R. Chavez-Chiang[2], Suzanne Delea[1], Wilmer L. Sibbitt[3], Arthur D. Bankhurst[4] and Hillary Norton[2]. [1]University of New Mexico, Albuquerque, NM, [2]University of New Mexico, [3]University of New Mexico HSC, Albuquerque, NM, [4]University of NM Med Ctr, Albuquerque, NM

Objective: This randomized controlled study addressed whether sonographic needle guidance affected the outcomes of corticosteroid injection for carpal tunnel syndrome.

Methods: 76 symptomatic carpal tunnels were randomized to injection by conventional palpation-guided or sonographic image-guided injection enhanced with a one-handed RPD (the reciprocating procedure device) syringe. A one needle, two-syringe technique was used where sonographic-guided hydrodissection with 1% lidocaine with a first syringe was performed followed by injection with 80 mg of triamcinolone acetonide.

Baseline pain, procedural pain, pain at outcome (2 weeks and 6 months), responders, therapeutic duration, reinjection rates, total cost, and cost per responder were determined.

Results: There were no complications in either treatment group. Relative to conventional palpation-guided methods, sonographic guidance for injection of the carpal tunnel resulted in 77.1% reduction in procedural pain ($p<0.001$), a 63.3% reduction in pain scores at outcome ($p<0.002$), 84.6% increase in the responder rate ($p<0.001$), 51.6% reduction in the non-responder rate ($p<0.001$), a 71.0% increase in therapeutic duration ($p < 0.001$), a 59.3% ($150) reduction in cost/responder/year for a hospital outpatient ($p<0.001$) and a 20.8% reduction in cost/patient/year for a hospital outpatient ($p<0.001$).

Figure 1.

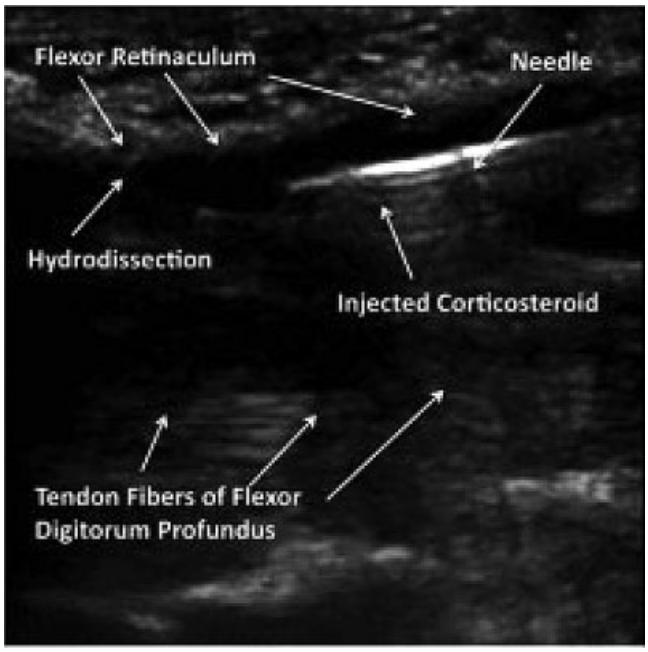

Figure 2.

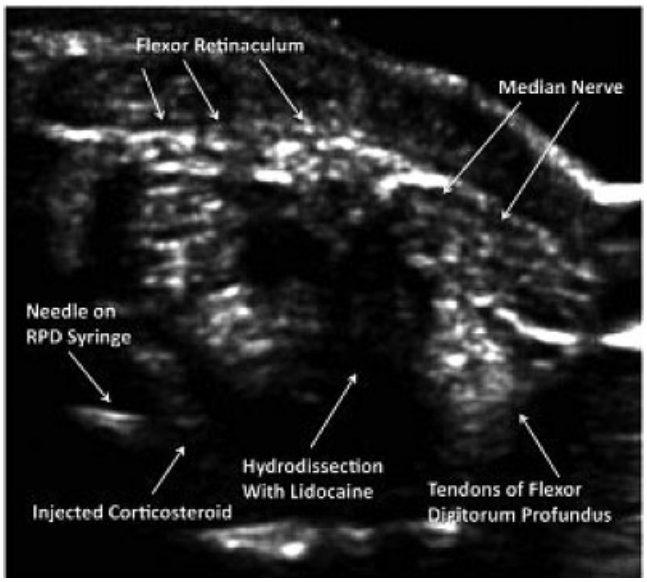

Figure 3.

Conclusion: Sonographic needle guidance improves the performance, clinical outcomes, and cost-effectiveness of injection of the carpal tunnel.

Potential Use of Matrix Metalloproteinase-13 Fluorogenic Probe for Imaging Osteoarthritis Development *In Vivo*. Sung Jae Choi[2], Young Ho Lee[2], Jong Dae Ji[2] and Gwan Gyu Song[1]. [1]Korea Univ College of Med, Seoul, Korea, Republic of, [2]Korea Univ College of Medicine, Korea, Republic of

Objective: the early detection of osteoarthritis (OA) is currently a key challenge in the field of rheumatology. Biochemical studies of OA have indicated that matrix metalloproteinase-13 (MMP-13) plays a central role in cartilage degradation. In this study, we describe the potential use of a dark-quenched fluorogenic MMP-13 probe to image MMP-13 in both *in Vitro* and rat models *in Vivo*.

Method: the imaging technique involved using a MMP-13 peptide substrate, near-infrared (NIR) dye, and a NIR dark quencher. This compound is composed of (i) Cy5.5, which was used as the near-infrared (NIR) dye (ex/em; 675/695), (ii) a short peptide sequence, G*PLGMRG*LGK, which was used as the MMP-13 cleavable substrate, and (iii) black hole quencher-3 (BHQ-3), which was used as the NIR dark-quencher specific for Cy5.5 (abs. 650 nm). The quenching properties of the probe were analyzed and visualized using a spectrofluorometer with a fixed excitation wavelength of 675 nm and a Kodak Image Station 4000MM equipped with filter for Cy5.5.

Results: OA-induced cartilage produced strong NIR fluorescence signals that were clearly visualized in the fluorescent images (1.30.2, 3.3 0.7, and 7.4 1.4-fold vs normal side for 0, 6, and 8 weeks, respectively; $n = 3$). NIR fluorescence signals in the eight-week OA rat had a 2.2-fold increase relative to the six week OA rat. Furthermore, the histological section of the normal cartilage showed a smooth articular surface with clear demarcation between the cartilage and subchondral bone the results from this study demonstrate that the use of a dark-quenched fluorogenic probe allows for the visual detection of MMP-13 *in* V*itro* and in OA-induced rat models. In particular, by targeting this OA biomarker, the symptoms of the early and late stages of OA can be readily monitored, imaged, and analyzed in a rapid and efficient fashion.

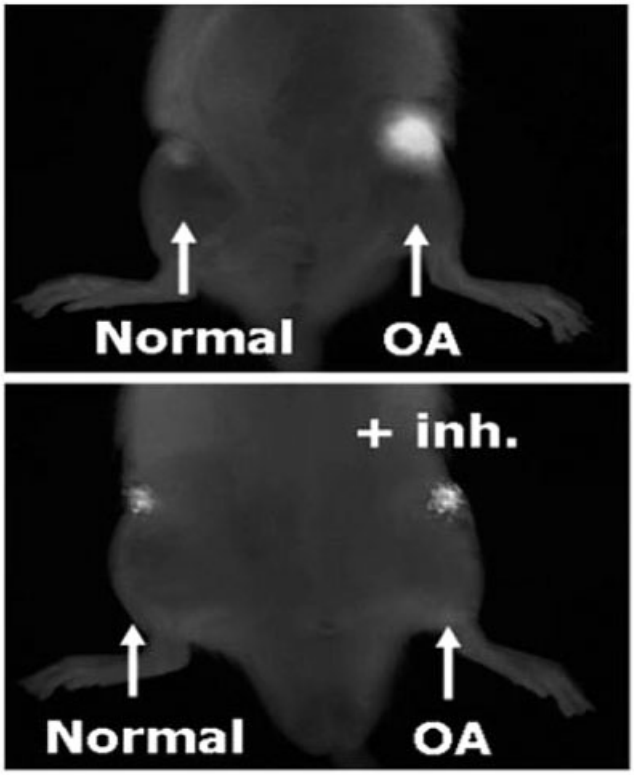

Figure 1. In Vivo imaging of upregulated MMP-13 in OA-induced cartilages 1 hour after intracartilage-injection of probe 1.

Conclusion: we anticipate that this simple and highly efficient fluorogenic probe will assist in the clinical management of patients with OA, not only for early diagnosis but also to assess individual patient responses to new drug treatments.

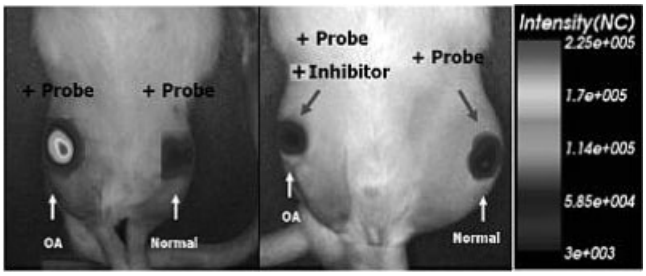

Figure 2. In ViVo NIR fluorescence tomographic images of normal and OA cartilage after local injection of probe 1 with or without the addition of the MMP-13 inhibitor in eight week OA-induced rat model.

Psychometric Properties of Synovitis Assessed in Rheumatoid Arthritis: Improved Intraobserver Reliability of Ultrasound vs. Clinical Evaluation in an Ancillary Study of the "Etanercept Versus DMARDs" Randomized, Prospective, Multicentre Study. Peter Mandl[5], Peter V. Balint[5], Yves Brault[4], Marina Backhaus[9], Maria Antonietta D'Agostino[7], Walter Grassi[1], Desiree M. Van Der Heijde[3], Eugenio De Miguel[8], Richard J. Wakefield[6], Isabelle Logeart[4] and Maxime Dougados[2]. [1]Clinica Reumatologica, Università Politecnica delle Marche, Jesi, Ancona, Italy, [2]Hospital Cochin, Paris, France, [3]Leiden University Medical Center, Meerssen, The Netherlands, [4]Pfizer, La Défense, Paris, France, [5]Rheumatology Department III, National Institute of Rheumatology and Physiotherapy, Budapest, Pest, Hungary, [6]Rheumatology Department, University of Leeds, Chapel Allerton Hospital, Leeds, United Kingdom, [7]Rheumatology Department, Versailles-Saint Quentin en Yvelines University; APHP, Ambroise-Paré Hospital, Boulogne-Billancourt, France, [8]Rheumatology Unit, La Paz University Hospital, Madrid, Spain, Spain, [9]University Medicine Berlin: Campus Charité Mitte, Berlin, Germany

Objectives: To propose different global ultrasound (US) and Power Doppler ultrasound (PD) scoring systems for measuring synovitis in rheumatoid arthritis (RA), with regard to the optimal number of joints to be evaluated. To evaluate for each proposed scoring system intra-observer reliability, face validity and discriminant capacity of US and PD synovitis versus clinical synovitis.

Methods: This 52-week, prospective, open-label, randomized, parallel-group, multicenter, outpatient study was conducted in RA subjects with moderate disease receiving etanercept combined with methotrexate (ETN+MTX) or various DMARDs. Due to early termination of the study, analyses were restricted to data collected from screening to the week-12 visit period. To study selected global scoring systems for clinical, US and PDUS techniques, 42 joints were evaluated: 28 joints (DAS28 joints), bilateral metatarsophalangeal, ankle and talonavicular joints using either a binary count (yes/no) or a 0–3 semiquantitative score. A total of 66 different scoring systems were evaluated consisting of 11 different joint combinations, clinical, US and PDUS derived data, including both counts and scores. Intra-observer reliability was calculated at several timepoints by intraclass correlation coefficient (ICC) and standard error of measurement. Face validity was evaluated as the degree of association between CRP or ESR and each scoring system; correlation was assessed at screening (Pearson's). To calculate discriminant capacity of scoring systems, the ETN+MTX and the conventional DMARD groups were evaluated separately and the difference in SRM was calculated.

Results: 66 patients were randomized in the study; 62 patients (mean age 53.8 years, 80.6% female, mean disease duration: 8.8 years) were included in the modified intention to treat population with 30 patients receiving various DMARDS, and 32 receiving ETN+MTX. Reliability was better for US and PD than for clinical evaluation of synovitis in stable subjects between baseline and screening visit ranging from 0.6–0.95 and 0.56–0.93 vs. 0.33–0.75 (respective ICC values of US, PD, clinical indices). Face validity was similar between the techniques. Difference in discriminant capacity (difference of difference in SRM between treatment groups) of US and PD vs. clinical synovitis, was −0.25 (−0.96/0.64) and 0.08 (−0.37/0.59) (median, range) respectively in the baseline to 12 weeks period. No relevant differences in psychometric properties were observed regarding the number and specific localizations of the evaluated joints between the different scoring systems but with a trend in favor of better performance while referring to PD indices.

Conclusion: This study suggests that US and PD have not only similar but better reliability than generally used clinical indices for evaluating synovitis in RA. PD was also found to have better discriminant capacity than clinical synovitis for distinguishing between treatment arms. Such findings were observed for the different tested scoring systems suggesting that a simplified scoring system referring to the PD findings might be sufficient; these findings require further evaluation in larger study populations.

Sensitivity and Specificity of the Physical Examination Compared to Ultrasound in Identifying Knee and Ankle Arthritis in JIA.

Ginger L. Janow[3], Vikash Panghaal[2], Terry L. Levin[2] and Norman T. Ilowite[1]. [1]Children's Hospital Montefiore, Bronx, NY, [2]Department of Radiology, Montefiore Medical Center, [3]Division of Pediatric Rheumatology, Children's Hospital Montefiore, New York, NY

Background: JIA can be an extremely debilitating disease of childhood with significant physical, psychological and financial costs to affected children. Early identification of active arthritis and treatment are crucial to the prevention of long term joint damage and disability. There is significant inter-user variability in the physical examination diagnosis of active arthritis, even among experienced pediatric rheumatologists. Ultrasound (US) with power Doppler has been shown to be a helpful tool in assessing joint involvement and has the capability to identify sub-clinical disease. Use of US in all children with JIA may not be justifiable because of the cost.

Objective: (1) To determine the sensitivity and specificity of physical examination for identifying synovitis in knee and ankle joints of children with juvenile idiopathic arthritis. (2) To identify patients who would benefit most from additional screening via ultrasound.

Methods: A total of 22 patients with JIA were referred for ultrasound. Bilateral knees and ankles were examined using US with and without power Doppler in a blinded manner. Active arthritis on physical examination was defined as non bony swelling (criteria 1) or limitation of motion with either pain on motion or tenderness (criteria 2). Active arthritis on ultrasound was defined as synovial hyperplasia, effusion or increased vascularity on power Doppler. Eighty-eight joint assessments were completed by both a pediatric rheumatologist and a radiologist. Rheumatologist assessments were collected via chart review.

Results: Physical exam had a sensitivity of 61%, a specificity of 75%, positive predictive value of 71% and negative predictive value of 66% as compared to US. When the definition of clinical synovitis was restricted to include only joints that met both of the clinical criteria (1 and 2), the specificity improved to 90%, with a decrease in sensitivity to 50 %. Overall, the physical exam was more specific for identifying synovitis in the ankle than knees (specificity of 81% and 58% respectively).

Discussion: These data support the use of US to assess joints that do not meet both of the clinical criteria. Addtionally, the physical exam is less sensitive for identifying knee arthritis which could support further US screening of these joints. Prudent use of ultra-sound in situations where the physical exam is less reliable could help identify sub-clinical disease and improve long-term outcomes.

The Comparison of Ultrasound & Physical Findings (CUSP) Remission Study—Ultrasound Remission Is Attained in Only 20% of Patients on Anti-TNF Therapy.

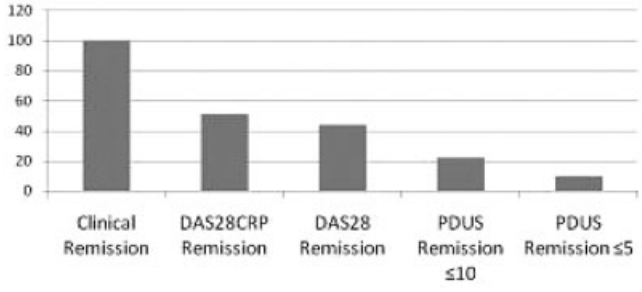
Joanne M. Kitchen[1], Bernadette M. Lynch[3], Oliver M. FitzGerald[2], Douglas J. Veale[3] and David Kane[1]. [1]Adelaide and Meath Hospital, Dublin, Ireland, [2]St Vincents Univ Hospital, Ranelagh Dublin, Ireland, [3]St Vincents Univ Hospital, Dublin, Ireland

Background: Studies show persistent inflammation on imaging in a proportion of patients in clinical remission on traditional DMARDs. This study aimed to evaluate clinical remission in patients on anti-tumour necrosis factor alpha (anti-TNF) drugs using objective measurement with DAS scores & ultrasound scoring using gray scale (GS) & power Doppler (PD) imaging.

Methods: Patients with Rheumatoid (n=29) and Psoriatic arthritis (n=12) on anti-TNF therapy & deemed by their supervising clinician to be in remission were assessed. Patient joint counts were performed. C-reactive protein (CRP) was measured and DAS28CRP was calculated. Visual analogue scales (VAS) (pain, general wellbeing) & Health Assessment Questionnaires (HAQ) were completed. Ultrasound examination of the DAS28 joint set and of the ankles and metatarsophalangeal joints was performed (GE Logiq 9) with a high frequency (15MHz) linear array transducer. GS and PD synovitis were graded using an established semi-quantitative scale (0–3).

Results: The mean disease duration was 9.9 years (range 2–30) & mean patient age was 56 years (range 33–75). Average duration of biologic therapy was 31.5 months (4–67) and 95% were on their first biologic. Mean DAS28CRP was 2.57 (1.35–4.85) while mean DAS28 was 2.74 (0.91–4.9). 21/41(51%) of patients were in DAS28CRP remission, 14 had low disease activity (DAS28CRP >2.6, <3.2) while 5 patients had active disease. Mean HAQ score was 0.58 (0–1.63). 34/41 (83%) had GS synovitis of at least Grade 2 in one joint, while the remainder (7/41, 17%) had Grade 3 synovitis in at least one joint. All patients had positive PD signal in at least one joint. Mean total score of PD was 19 (range 2–64). 22/41 (54%) patients had Grade 2 PD and 4/41 (10%) had grade 3 PD. If PD remission was defined as PD total score of 10 or less, 9/41 pts (22%, mean 6.4, range 2–10) fulfilled criteria. If PD remission was defined as PD total score of 5 or less, 4/41 pts (10%, mean 3.75, range 2–5) fulfilled criteria. GS and PD synovitis scores were significantly positively correlated with DAS28CRP (r=0.575 and r= 0.793 respectively, p<0.01 for both).

Percentage of patients in Remission



Conclusion: Ninety percent (37/41) of patients in clinical remission & 81% (17/21) of patients in DAS remission on anti-TNF show persistent inflammation on GS & PD imaging. Standard clinical assessment alone is

insufficient to determine remission in patients on anti-TNF therapy. Formal DAS28 scores should be performed routinely to ensure therapeutic response is adequate. Ultrasound assessment of remission reveals ongoing inflammation in patients in clinical remission.

1632

The Power Doppler Ultrasonography Score from 24 Synovial Sites or 6 Simplified Synovial Sites, Including the Metacarpophalangeal (MCP) Joints, Reflects Well the Clinical Disease Activity and Serum Biomarkers in Patients with Rheumatoid Arthritis. Atsushi Kawakami[1], Shin-ya Kawashiri[1], Naoki Iwamoto[1], Mami Tamai[1], Hideki Nakamura[1], Junko Kita[1], Akitomo Okada[1], Tomohiro Koga[1], Satoshi Yamasaki[1], Tomoki Origuchi[1] and Katsumi Eguchi[2]. [1]Nagasaki University, Nagasaki, Japan, [2]Sasebo City General Hospital, Sasebo, Nagasaki, Japan

Purpose of Study: We evaluated the significance of the power Doppler ultrasonography (PDUS) score by comparing it with serum biomarkers and clinical disease activity.

Methods: We measured the PDUS scores of 24 synovial sites in 12 joints in 22 RA patients. For convenience, the PDUS scores of 6 synovial sites in 6 joints were also examined. Both PDUS scores included the metacarpophalangeal (MCP) joints. Each joint was scored for a power Doppler (PD) signal on a scale from 0 to 3. The PDUS scores are the sums of the PD signal scores for the 24 synovial sites or the 6 synovial sites. On the same day, serum variables as well as clinical disease activity were evaluated. Serum variables included vascular endothelial growth factor (VEGF), matrix metalloproteinase-3 (MMP-3), MMP-9 and tissue inhibitor of metallo-proteinases-1 (TIMP-1). The clinical disease activity included the disease activity score of 28 joints (DAS28), the simplified disease activity score (SDAI) and the clinical disease activity score (CDAI).

Results: The PDUS scores from the 24 joint sites were significantly positively correlated with tender joints counts, swollen joint counts, DAS28, SDAI, CDAI and serum biomarkers including MMP-3, VEGF and TIMP-1, whereas it did not correlate with MMP-9. Accordingly, the PDUS scores from the 6 synovial sites greatly correlated with those from the 24 joint sites. Clinical disease activities as well as serum variables were also clearly correlated with the PDUS scores from the 6 synovial sites.

Conclusions: The standard as well as the simplified PDUS scores well reflected clinical disease activity and serum variables, including angiogenic factors. Our data reaffirm the utility of ultrasonography for monitoring disease activity in patients with RA.

The Role of Ultrasound in B Mode and Power Doppler Sonography in the Diagnosis of Enthesitis in Children. Dana Toib[1], Anthony R. French[1], Nirvikar Dahiya[2], William D. Middleton[2], Richard Brasington[1] and Andrew J. White[1]. [1]Washington Univ Schl of Med, St Louis, MO, [2]Washington Univ Schl of Med

Purpose: Enthesitis is a distinctive feature of Juvenile SpA (JSpA). Recently, ultrasound in B mode and power Doppler sonography has been suggested to be a valuable tool in the assessment of enthesitis. The aim of this study was to compare the physical exam (PE) with ultrasonography (US) in the assessment of enthesitis in children.

Methods: 20 JSpA patients, 19 polyarticular/pauciarticular JIA patients, 8 adolescent patients with idiopathic arthralgias and 9 healthy pediatric controls underwent US exam of 16 peripheral entheses using Terason t3000 equipment with 12-MHz linear array transducer. The US images were interpreted independently by two radiologists and abnormalities were quantified using a modification of the Madrid sonographic enthesitis index (MASEI). Entheseal PE was completed independently by two pediatric rheumatologists. Current treatment, inflammatory markers and CHAQ scores were recorded on all patients.

Results: Sonographic evidence of enthesitis was most common in the JSpA group (53% of patients; 6.9% of examined entheses), but was also found in all other study groups, including pauciarticular/polyarticular JIA (37% of patients; 5.0% of entheses), idiopathic arthralgias (38% of patients; 2.7% of entheses) and healthy controls (28% of patients; 2.1% of entheses).

PE evidence of enthesitis was most common in the idiopathic arthralgias group (56% of patients; 18.4% of entheses), followed by the JSpA group (43% of patients; 7.8% of entheses) and the polyarticular/pauciarticular JIA group (26% of patients; 3.0% of entheses). None of the healthy controls had PE evidence of enthesitis.

Sonographic severity of enthesitis was highest in the JSpA group with an enthesitis score of 4.7, followed by 1.6 in the polyarticular/pauciarticular JIA group, 1.1 in the idiopathic arthralgias group and 0.8 in healthy controls.

Follow-up PE and US were performed on two of the JSpA patients who had the highest US enthesitis scores and were the only patients who at the initial study visit time were untreated or treated only with NSAIDs. Repeat US revealed resolution of entheseal vascularization and development of calcifications consistent with post-inflammatory changes corresponding with clinical improvement. The PE did not correlate with these changes.

Agreement on presence of enthesitis between two examiners in PE and US were 26% and 41% respectively. Agreement on presence of enthesitis between PE and US was only 3%.

Neither the PE nor the US enthesitis scores correlated with other measures of disease activity including white blood cell count, hemoglobin, platelet count, ESR, CRP or CHAQ score.

Conclusions: US detected the highest frequency of enthesitis among the JSpA group whereas PE detected the highest frequency of enthesitis among the idiopathic arthralgias group. Agreement on presence of enthesitis between PE and US was poor. US interobserver agreement was limited, but superior to that of the PE. Sonographic findings consistent with mild enthesitis were found in healthy controls. These findings suggest that although US might have a role in the diagnosis of enthesitis in children, it should be used cautiously due to a limited inter observer reliability and specificity.

Ultrasound Bone Erosions—Their Morphological Basis Obtained by High-Resolution Micro-Computed Tomography Imaging. Stephanie Finzel[2], Sarah Ohrndorf[1], Matthias Englbrecht[2], Christian M. Stach[2], Janin Messerschmidt[1], Georg Schett[3] and Marina Backhaus[4]. [1]Charite University Hospital, Berlin, Germany, [2]Department of Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany, [3]Friedrich Alexander Univ, Erlangen, Germany, [4]University Medicine Berlin: Campus Charité Mitte, Berlin, Germany

Objectives: To validate, whether bony lesions appearing in high-resolution ultrasound (HRUS) are true bone erosions.

Methods: In total, 26 individuals (14 with rheumatoid and 6 with psoriatic arthritis as well as 6 healthy controls) were assessed for bone erosions at the radial, palmar and dorsal side of the MCP2 and the palmar and dorsal sides of the MCP3 and MCP4 joint. All patients received a HRUS and for validation of results a micro-computed tomography scan (μCT). The prevalence (0/1) and severity of bone erosions obtained in HR US and μCT were recorded and compared.

Results: Overall there was a good correlation between the severity of US erosions and μCT erosions ($r = 0.463$, $p < 0.0001$).

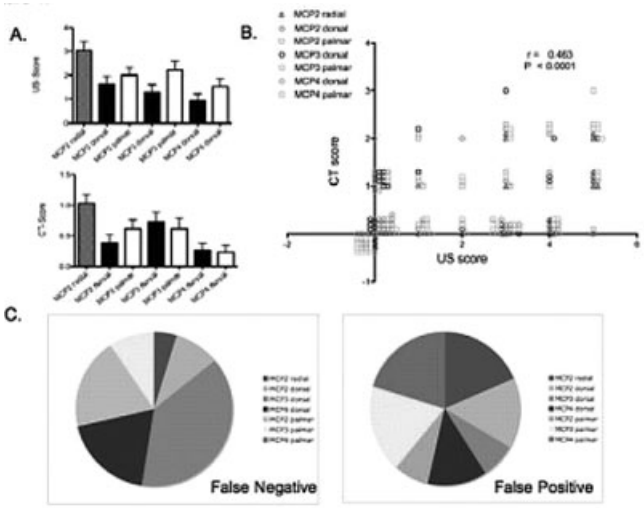

Figure 1.

False-negative (US 1/ μCT 0) results were obtained in only 10% of the joint regions and were mostly due to small erosive lesions at the dorsal sides of the MCP joints. False-positive results were more frequent (28%) and primarily based on vascular bone channels at the palmar sides of the MCP joints as well pseudo-erosions created by osteophytes.

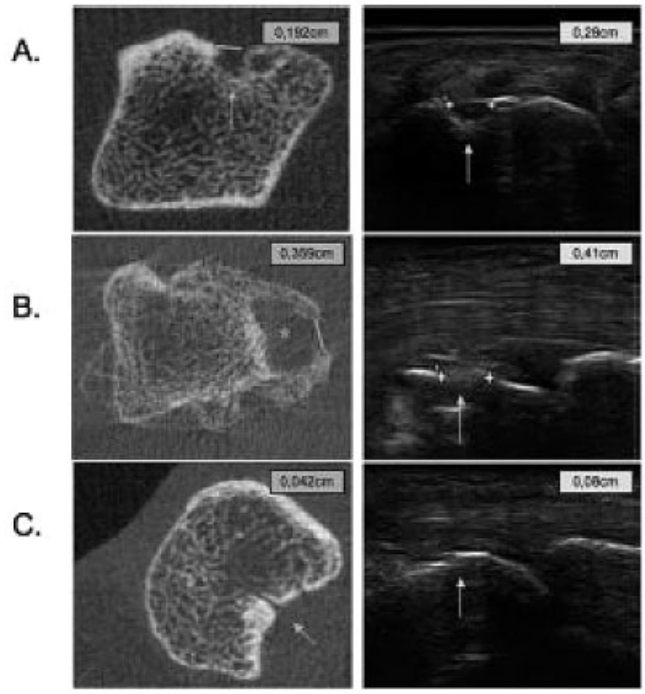

Figure 2.

Conclusions: These data show that the majority of erosion in the US was indeed based on true bone erosions with a cortical break. The sensitivity of US for detecting bone erosions was high and there was a good correlation between the severity of bone erosions in the US and the μCT imaging. Specificity of US for bone erosions was substantially lower, suggesting that smaller US lesions do not always refer to true breaks in the cortical bone surface.

Ultrasound Lung Comets. Validity, Reproducibility and Feasibility of a Simplified Assessment of Pulmonary Interstitial Fibrosis in Connective Tissue Disorders. Marwin Gutierrez[1], Fausto Salaffi[1], Marina Carotti[3], Marika Tardella[1], Chiara Bertolazzi[1], Elisabetta Bichisecchi[3], Mara Giorgi[3], Alarico Ariani[1], Carlos Pineda[2], Emilio Filippucci[1] and Walter Grassi[1]. [1]Clinica Reumatologica, Università Politecnica delle Marche, Jesi, Ancona, Italy, [2]Instituto Nacional de Rehabilitacion, Mexico City, Mexico, [3]S.O.D Radiologia Clinica, Dipartimento di Scienze Radiologiche, Ospedale Riuniti, Ancona.

Objective: To investigate the validity, reproducibility and feasibility of a simplified ultrasound lung comets (ULC) assessment compared with a comprehensive assessment of pulmonary interstitial fibrosis in patients with connective tissue disorders (CTD).

Methods: A total of 36 consecutive patients (32 female, 4 male, mean of age: 58.5 years, mean of disease duration: 60 months) with diagnosis of CTD (28 with systemic sclerosis, 2 with Sjögren's syndrome, 1 with undifferentiated CTD, 2 with anti-synthetase syndrome, 2 with dermatomyositis and 1 with mixed CTD) of Rheumatology Department of Università Politecnica delle Marche were enrolled in this study. The inclusion criteria were: previous diagnosis of CTD according to international criteria and a high resolution computed tomography (HRCT) performed no longer than 10 days prior to the beginning of the study. Each patient underwent a chest ultrasound exam by a rheumatologist experienced in ultrasound blinded to the HRCT findings, using a MyLab 70 XVG (Esaote Spa, Genoa-Italy) equipped with a 2–7 MHz multifrequency convex transducer. Both comprehensive, as previously proposed (1, 2) and simplified ULC assessments were scanned. The simplified ULC assessment included 14 sites bilaterally: third para-sternal, fifth mid-clavicular, anterior axillary, medial axillary and posterior axillary, and eighth sub-scapular and para-vertebral intercostal spaces. These sites were chosen on the basis of both the width of the acoustic window and the prevalence of ULC. The number of ULC was summed for each intercostal space and the total was scored using the following semiquantitative scoring (0= < 5; 1= 5–15; 2= 16–30; 3= >30 ULC) (3). For criterion validity, HRCT was considered the gold standard and an experienced radiologist interpreted it, adopting the topographic semiquantitative score proposed by Warrick et al. Inter and intra-observer reliability, with an other rheumatologist sonographer with less experience in the field of ultrasound, was also investigated.

Results: A total of 1440 sites were evaluated by ultrasound. A highly significant agreement between the comprehensive and simplified ULC assessment was found (chi-square, p=0.0001). A significant positive correlation was also found between the simplified ULC assessment and Warrick scores (Spearman rank test, rho= 0.656, p< 0.0001). The concordance correlation coefficient values for the inter and intra-observer were in a range from 0.832 to 0.956 and 0.786 to 0.943 (p < 0.0001), respectively. Finally, there was a relevant difference in time spent on comprehensive (mean 20.6 minutes) with respect to the simplified (mean 7.4 minutes) ULC assessment.

Conclusion: Our results provide evidence in favour of the validity, reproducibility and feasibility of a simplified 14 sites ULC assessment as an adjunct method to assess pulmonary interstitial fibrosis in patients with CTD.

Use of Musculoskeletal Ultrasound in Diagnosis of Early Inflammatory Arthritis: Are Limited Joint Surveys Adequate? Paramvir Sidhu, Jeffrey Lisse, Rafael Grau, Eric P. Gall and Mihra Taljanovic. University of Arizona, Tucson, AZ

Objectives:

1. To study the impact of using musculoskeletal ultrasound in diagnosis of early inflammatory arthritis.

2. To examine feasibility of using limited form of musculoskeletal ultrasonography for diagnosis of early inflammatory arthritis without significantly compromising diagnostic accuracy.

Subjects: Patients with clinical suspicion of inflammatory arthritis but non-diagnostic work up including RF, CCP antibodies, ESR, CRP and plain radiographs.

Methods: 80 patients underwent comprehensive musculoskeletal ultrasound of 22 joints of hands & wrists (bilateral PIP, MCP & wrist joints) from year 2003 to 2010. Parameters analyzed at imaged joints included synovial thickening,

increased vascularity and erosions. Retrospective review of this imaging data as well as clinical data including age, sex, serological status (RF & CCP antibody positivity), inflammatory markers (ESR & CRP) and final diagnosis was performed.

Results:

Total Patients	80
Clinical Data Available	53
Female	65
Male	15
Age	19 to 82 yrs (Median Age = 52)
RF positive	6
CCP antibody positive	4
Elevated ESR	10
Elevated CRP	9

	Synovial Thickening		Increased Vascularity		Erosions	
Joints	Right	Left	Right	Left	Right	Left
2nd MCP	40	43	35	33	25	25
3rd MCP	32	31	28	22	21	17
5th MCP	22	26	15	12	9	11
Wrist	28	29	26	30	4	1

There were 48 patients with synovial thickening and increased vascularity and 35 patients with erosions at one or more joints. Changes suggestive of inflammatory arthritis were most commonly seen at 2nd & 3rd MCP and wrist joints. Thirty patients were found to have synovial thickening, 25 increased vascularity and 13 erosions at one or more joints despite having negative RF & CCP antibodies and normal inflammatory markers (ESR & CRP). Fourteen patients were given final diagnosis of inflammatory arthritis primarily based on musculoskeletal ultrasound results and all 14 had synovial thickening and increased vascularity at one or more of 2nd & 3rd MCP and wrist joints.

Conclusions: 1. Musculoskeletal ultrasound is a very useful tool in diagnosis of early inflammatory arthritis in clinical practice.

2. Brief musculoskeletal ultrasound, restricted to just 6 joints (bilateral 2nd & 3rd MCP and wrist joints) instead of 22 joints, can be used to make the diagnosis of early inflammatory arthritis without significantly compromising diagnostic accuracy and thus reducing time required to perform the exam.

Objective: To evaluate the performance of musculoskeletal ultrasound (US) in the initial assessment and follow up of patients over the age of 50 years presenting with recent onset bilateral shoulder pain.

Methods: US of shoulder and hips was performed in 89 patients with an initial diagnosis of new onset PMR, 117 control subjects with newly diagnosed conditions mimicking PMR presenting with recent onset of bilateral shoulder pain (includes 37 subjects with new onset rheumatoid arthritis (RA), 30 subjects with other shoulder conditions) and 21 controls without shoulder conditions. All subjects were ≥50 years of age. US evaluations were performed using a standardized protocol developed as part of a 6-month prospective study and included assessment of subdeltoid bursitis, biceps tenosynovitis, glenohumeral or hip synovitis and trochanteric bursitis. A preceding training and standardization exercise of US operators at different sites in the study demonstrated very good intercenter comparability of results.

Results: Patients with PMR were more likely to have abnormal US findings in the shoulder (particularly subdeltoid bursitis and biceps tenosynovitis), and somewhat more likely to have abnormal findings in the hips than control subjects as a group. PMR could not be distinguished from RA on the basis of US, but could be distinguished from non-RA shoulder conditions and subjects without shoulder conditions.

Ultrasound Findings	PMR (N = 89)	Controls with shoulder conditions (N = 117)	RA with shoulder involvement (N = 37)	Non-RA Shoulder Condition (N = 30)	Controls without shoulder conditions (N = 21)
at least ONE shoulder with subdeltoid bursitis, biceps teno-synovitis or glenohumeral synovitis	85%	72%*	84%	63%**	19%**
BOTH shoulders with subdeltoid bursitis, biceps teno-synovitis or glenohumeral synovitis	62%	49%	73%	27%**	0%**
at least ONE shoulder with subdeltoid bursitis or biceps tenosynovitis	84%	67%**	76%	57%**	19%**
BOTH shoulders with subdeltoid bursitis or biceps tenosynovitis	60%	43%*	60%	23%**	0%**
at least ONE hip with synovitis or trochanteric bursitis	35%	20%*	23%	9%*	0%**
BOTH hips with synovitis or trochanteric bursitis	17%	9%	5%	3%	0%*
at least ONE shoulder and ONE hip with findings as above	33%	15%**	19%	7%**	0%**
BOTH shoulder and BOTH hips with findings as above	10%	8%	5%	3%	0%

*$p < 0.05$; **$p < 0.01$ compared to PMR

Conclusions: In this largest and first multicenter study of US in PMR, most subjects with PMR have abnormal findings on shoulder US. US had limited value in distinguishing PMR from RA, but had value in discriminating PMR from other conditions associated with shoulder pain. US of the shoulders and hips may have added value for diagnosis of PMR.
