and adult population. We have observed that some cases of pediatric Lyme arthritis may be confused with septic arthritis leading to unnecessary hospitalization and surgical drainage. We wondered how frequently this occurs in children and whether there are differences between the pediatric and adult population in the presentation and management of Lyme arthritis.

Methods: Charts of pediatric and adult patients evaluated for Lyme arthritis by rheumatologists and pediatric infectious disease specialists in Portland, ME between January 2002 and July 2008 were reviewed. Patients included for analysis had documented synovitis and positive Lyme serology. Data on clinical presentation, synovial fluid and peripheral blood results, treatment, and clinical course were extracted and subjected to statistical analysis.

Results: 29 adults and 50 children met inclusion criteria and were studied. Children were more likely than adults to present acutely ($p = 0.01$). They were less likely to be weight bearing ($p = 0.04$), had a higher mean synovial fluid WBC count ($p = 0.00004$), were more likely to be hospitalized ($p = 0.02$) and were more likely to have a suspected septic arthritis ($p = 0.02$), although there was no statistical difference between the two groups with respect to surgical intervention. In contrast, adults received more oral antibiotic courses ($p = 0.006$). They were less likely to have normal function within four weeks of initiating antibiotic treatment ($p = 0.0002$), were more likely to have intravenous antibiotics in subsequent treatment courses ($p = 0.01$), and were more likely to be diagnosed with a persistent arthritis ($p = 0.0007$).

Conclusions: The presentation of Lyme arthritis in children and adults in our study population differed in the acuity of presentation and subsequent management. Children were more frequently hospitalized for suspected septic arthritis whereas adults were more often managed in the outpatient setting. Yet children tended to have more prompt resolution of their synovitis and received less treatment overall. The clinical spectrum of Lyme arthritis is variable, ranging from chronic indolent synovitis to acute monoarticular arthritis mimicking septic arthritis. In the appropriate geographic and clinical setting, Lyme arthritis should be considered in children presenting with acute monoarticular arthritis. Considering the diagnosis early may prevent hospitalization and needless intervention including surgical drainage.

Autoantibodies to a Novel Cytoplasmic Rod/Ring Structure Target CTP/GTP Synthetic Pathway in HCV Infection after Interferon/ Ribavirin Therapy. Wendy C. Carcamo[2], Angela Ceribelli[3], Jason Y. F Chan[3], Westley H. Reeves[2], Giovanni Covini, Carlos A. Von Muhlen[1], Liu Chen[3], Minoru Satoh[2] and Edward K. L. Chan[2]. [1]Metanalysis, Porto Alegre, Brazil, [2]University of Florida, Gainesville, FL, [3]University of Florida

Purpose: Autoantibodies (aab) can be important disease markers and basic research tools in molecular and cell biology. Cytoplasmic antigenic structures identified by ANA screening consisting of rods and rings (RR) are novel subcellular structures. The current aim is to identify clinical occurrences associated with RR aab, elucidate the antigenic targets and their biologic function.

Methods: Sera collected from multiple clinical centers were analyzed by HEp-2 slides as well as other mammalian cell lines for the presence of anti-RR. Positive samples were then analyzed by immunoprecipitation of ^{35}S-labeled K562 cell extracts. Identity of candidate antigens associated with RR was validated by co-staining with established specific antibodies.

Results: Anti-RR recognized cytoplasmic rods of 3–10μm in length and rings with ~2–5μm in diameter in HEp-2 cells, distinct from all known aab reported to date. A total of 80 anti-RR samples were identified, clinically linked to Hepatitis C virus (HCV), mostly after interferon-alpha/ribavirin (IFN/R) therapy. Clinical data were available from 23 Italian anti-RR+ patients: 15 HCV+, 6 HCV-, and 2 unknown. Prevalence of anti-RR did not correlate with specific HCV genotypes: *Type 1* (6/15), *2a* (3/15), *3* (1/15), and *4* (1/15). 14/15 HCV+ were treated with IFN/R therapy, indicating a strong link of RR aab to this therapy. 75% (9/12) of HCV with anti-RR had no response to IFN/R therapy, suggesting anti-RR may be associated with poor response. The 6 HCV(−)RR+ patients had no common diagnosis. However, prevalence of anti-RR in general hepatic disease population was low (3.5%, ~35/1000), indicating that HCV infection alone seldom induces anti-RR aab. In an autoimmune disease center setting, prevalence of anti-RR was also very low: only 2 SLE patients were identified among >2,000 in database. Analysis of the 2 SLE patients over 3-yr span was available. Interestingly, patient #1 had HCV(*3a*) and anti-RR was detected within 4 mo after IFN/R treatment. This patient was unresponsive and treated again with IFN/R after 6 mo. Liver function then normalized and anti-RR disappeared. Patient #2 had anti-Sm/RNP, anti-phospholipid aab with lupus nephritis, but was apparently HCV- and had stable anti-RR for at least 2 yrs. About a third of anti-RR+ sera immunoprecipitated 55kDa doublets. Candidate 55kDa antigens cytosine triphosphate synthase (CTPS1) and inosine monophosphate dehydrogenase 2 (IMPDH2) were identified to be highly enriched in RR. Multiple inhibitors of these enzymes were shown to be sensitive inducers of RR formation in all mammalian cell types analyzed.

Conclusion: CTPS1 and IMPDH2 are key enzymes in CTP and GTP synthesis respectively, inhibitors to which were demonstrated to induce RR formation. Development of anti-RR is most common in HCV+ patients with IFN/R treatment, but anti-RR may be found in HCV- patients. Ribavirin is a sensitive inhibitor of IMPDH2 enzymatic activity, may thus lead to aberrant RR formation, and trigger aab production during HCV treatment. Anti-RR production in other systemic diseases remains unclear.

Chloroquine (CQN) Is Not Superior to Meloxicam (MCAM) in the Treatment of Early Persistent 'Musculoskeletal Pain and Polyarthralgias' (MSK-P) Following Chikungunya (CHIKV): A Non Commercial Investigator Initiated Community Based Controlled Drug Study. Arvind Chopra[2], Manjit Saluja[3] and Anuradha Venugopalan[1]. [1]Center for Rheumatic Diseases, [2]Center for Rheumatic Diseases, Pune, India, [3]Center for Rheumatic Diseases

CHIKV is predominantly a self limiting short duration febrile severe arthralgia illness.Though experimentally demonstrated (Sourisseau. PLoS Pathog 2007; 3(6):e89: 804), therapeutic role for CQN is flimsy. A CQN trial (CuraChik: NCT00391313) was abandoned. CQN was used rampantly in the recent India CHIKV epidemic(Chopra. Arthritis Rheum 2008; 58(9): 2921). We carried out an exploratory study during the epidemic.

Methods: 509 cases of CHIKV were identified in a survey of 1450 population in village Bavi (Sholapur, West India). Acute cases received symptomatic measures. 70 consenting patients (62 women, median age 50 years) with persistent MSK-P (minimal duration 4 weeks, active painVAS > 40 mm) and seropositive anti-CHIKV IgM/IgG antibody were enrolled into randomized, single blind (doctor) parallel efficacy two arm (CQN=38, MCAM=32) trial of 24 weeks duration; CQN phosphate (250 mg od) and meloxicam (MCAM, 7.5 mg od). Rescue analgesic(paracetamol) was monitored. MSK-P could not be further classified. 43 patients showed minimal few site synovitis/ tenosynovitis. We visited homes monthly, to complete trial procedures/assessments. Pain VAS (primary efficacy) and ACR efficacy measures (+ Indian version HAQ) were recorded. Besides routine laboratory investigations, selected cytokines [IL-6, γ-Interferon, TNF- α, CXCL-10/IP-10, and IL-13) were assayed and geometric mean (Fig 2) computed; pre-epidemic controls were used. XRays were not taken. An intention to treat analysis (last observation carried forward, ANOVA) was completed;significant $p < 0.05$ with CI (95% confidence interval). At baseline, the groups matched well.

Results: The mean change from baseline to completion for efficacy and cytokines did not differ significantly between the groups [Difference for pain VAS: CI −0.8, 1.3]. Paracetamol consumption was almost similar.

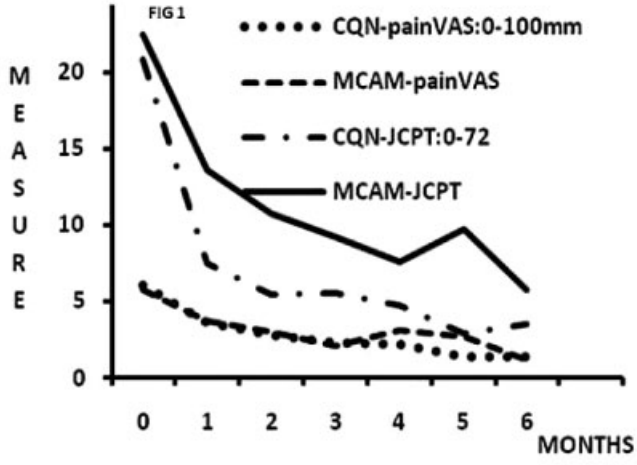

Figure 1.

Fig. 1 shows mean painVAS and pain/tender joint count. Amongst completers, beyond 3 months study, pain was aymptomatic, mild and moderately severe in 37%, 52% and 11% trial patients respectively; corresponding 42%, 42% & 15% for CQN. Seven patients withdrew but none due to AE. Five patients reported mild AE (usually dyspepsia; none skin/eye).

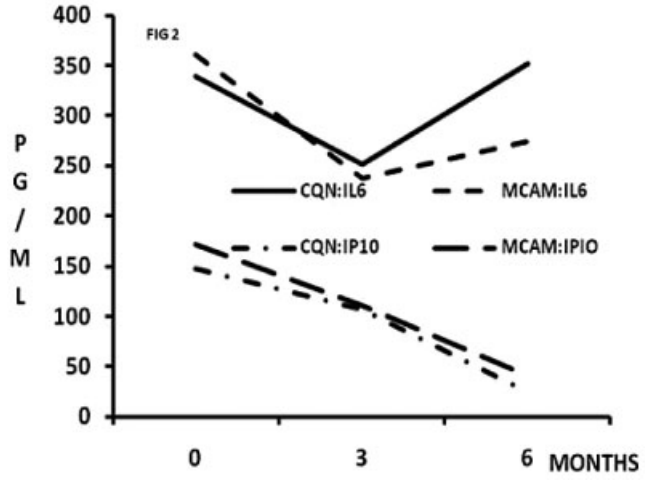

Figure 2.

Though decreased from baseline, cytokines remained elevated (above control) at 24 weeks endpoint.

Conclusion: In this first ever truly community based drug intervention trial, CQN did not offer any therapeutic advantage over symptomatic NSAID in the long term treatment of early persistent MSK-P following CHIKV. Despite clinical relief, cytokines (especially IL-6) remained elevated and this may implicate long term prognosis.

Disclosure: A. Chopra: None; **M. Saluja:** None; **A. Venugopalan:** None.

Clinical Features of Acute Human Parvovirus B19 in Adults: What We Could Learn from It? Hideto Oshikawa[1], Makiko Yamamoto[2], Akira Jibatake[2], Kiyoharu Muranaka[2], Kazuki Yoshida[2], Masako Utsunomiya[2], Tatsuo Kobayashi[2], Mitsumasa Kishimoto[3] and Kazuo Matsui[2]. [1]Department of Rheumatology, Kameda Medical Center, Kamogawa City, Chiba, Japan, [2]Department of Rheumatology, Kameda Medical Center, [3]St Luke's International Hospital, Japan

Background: Human parvovirus (HPV) B19 infection in adults often mimics rheumatic disease such as systemic lupus erythematosus (SLE) or rheumatoid arthritis (RA).

Purpose: To investigate the clinical features of acute HPV B19 infection in adults and examine the rate of patients who fulfill the classification criteria for SLE or RA.

Methods: Retrospective chart review of adult patients with newly-diagnosed acute HPV B19 infection from April 2006 to April 2010 was performed in a community-based hospital in Japan. The diagnosis was made with the positive serum anti-HPV B19 IgM antibody.

Results: Of the thirty-five patients diagnosed as acute HPV B19 infection, 24 patients (68.5%) were female and the mean age was 38.6 years. Nearly half of the patients (48.5%) had a history of recent sick contact with people who had a clinical manifestation of viral infection. The predominant signs and symptoms were: arthralgia/arthritis (85.7%), skin rash (60%), edema (54.2%), fever (51.4%), and lymphadenopathy (31.4%). Seventeen patients (48.5%) were diagnosed during the spring and 9 patients (25.7%) in the summer.

The involved joints were the hand (72.7%), followed by knee (63.6%), wrist (54.5%), elbow (54.5%), and ankle (45.4%). The most frequent type of arthritis was polyarthritis (81.8%), followed by oligoarthritis (18.2%). Monoarthritis was not seen in our study.

The following abnormal laboratory findings were observed: positive anti-nuclear antibody (ANA) (95.2%), lymphocytopenia (81.2%), elevated lactate dehydrogenase (68.7%), hypocomplementemia (50%), and anemia (21.2%). Rheumatoid factor and anti-CCP antibody were not detected in patients who were tested (22 and 10 patients).

Four patients (11.4%) fulfilled the 1997 revised ACR SLE Criteria and 9 patients (25.7%) fulfilled the preliminary 2010 SLICC/ACR SLE Criteria. Of 11 patients with physician identified arthritis, none fulfilled the 1987 ACR RA Criteria, and 4 patients (36.3%) fulfilled the 2010 ACR/EULAR RA Criteria. Three patients fulfilled the both new SLE and RA criteria.

During the mean follow-up of 5.6 weeks (range 0–42), the mean duration of arthritis was 22 days (range 11–36). As for treatment, NSAIDs were used in 11 patients (31.4%), and acetaminophen in 10 patients (28.5%).

Conclusion: HPV B19 infection in adults, often present with acute polyarthritis and skin rash accompanied with lymphocytopenia, hypocomplementemia, and positive ANA. About one-third of adult patients with acute HPV B19 infection fulfill the criteria for SLE or RA, or both. We should consider the possibility of HPV B19 infection in the differential diagnosis of SLE or early onset RA.

Cytokines in Chikungunya (CHIKV): Storm in a Teacup or Winds before the Storm. Arvind Chopra[2] and Anuradha Venugopalan[1]. [1]Center for Rheumatic Disease, Pune, India, [2]Center for Rheumatic Diseases, Pune, India

CHIKV is an acute severe (polyarthralgias) self limiting arboviral illness. 10% cases develop chronic RMSK. We witnessed a wide spectrum of inflammatory arthritis following CHIKV in our referral practise (Chopra. Arthritis Rheum 2008;58(9):2921). During the epidemic (2006), we completed a cross section house- house 1192 rural population (West India) survey in 10 weeks and identified 509 clinical cases (86% symptomatic);225 cases (81% symptomatic) consented blood investigations and are the basis of current report.

Methods: Clinical, diagnosis was substantiated by serology (49% IgM and 62% IgG CHIKV antibodies; immunochromatographic and IIF). Persistent RMSK cases followed upto 18–21 months. Lab investigations (inlcuding RF, CRP, ANA, CCP) repeated at predetermined timepoints: malaria and dengue excluded. None showed throbocytopenia. IL-6 (51.12 pg/ml), IL-13 (181.44 pg/ml), TNF-α (32.29 pg/ml), IFN-γ (3.12 pg/ml), and CXCL10/ IP-10 (3.16 pg/ml) assayed by standard ELISA; geometric means from healthy control (pre-epidemic) shown in parenthesis.

Observations: Post onset, 65% cases recovered within one month. None died. Rest suffered from predominantly (86%) persisted non-specific polyarthralgias (NSA). Overt synovitis/ tenosynovitis was mild and uncommon. 18% and 12% cases remained symptomatic at 6 and 12 months respectively. IgM response vanished by 6 months while IgG rising titer was demonstrated till study completion. Cytokine profile shown in the figures.

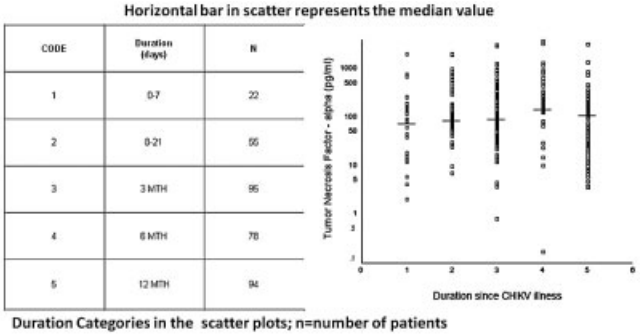

Figure 1.

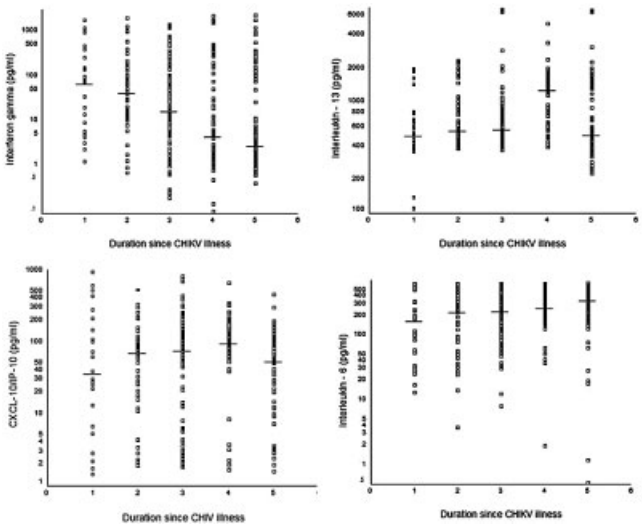

Figure 2.

The cytokine upsurge persisted irrespective of symptom resolution or the type of RMSK (NSA/OA/Inflammatory/soft tissue rheumatism). An early robust IFN -γ response was often associated with early resolution. High IL-13 was often evident in patients with chronic RMSK. Though conjointly elevated in early illness, a disconnect was observed between IL-6 (remained high) and C-Reactive Protein (low levels) during follow up. The overall seropositivity of autoantibodies was low (<5%).

Conclusions: This daunting community study of CHIKV epidemic demonstrates an intense proinflammatory cytokine milieu during early and persistent phase (RMSK) despite an overall benign clinical profile. It may be linked with persistence of RMSK. We continue to follow this story and hope to unravel the long term implication of this intriguing arbovirus.

Geographic Distribution of Endemic Fungal Infections among Older Americans. John W. Baddley[3], Kevin L. Winthrop[1], Nivedita M. Patkar[3], Elizabeth Delzell[4], Fenglong Xie[4], Lang Chen[4] and Jeffrey R. Curtis[2]. [1]Oregon Health Sciences University, [2]University of Alabama-Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham, AL, [4]University of Alabama at Birmingham, Birmingham, AL

Background: Histoplasmosis (histo), blastomycosis (blasto) and coccidioidomycosis (cocci) are major endemic fungal infections in the U.S. and have been associated with use of biologics for arthritis. Data regarding the epidemiology and geographic distribution of endemic fungal infections in older adults are limited. Identifying geographic areas with a relatively high incidence of endemic fungal infection may impact diagnostic or prevention measures in older adults receiving biologics.

Methods: We evaluated a 5% sample of national Medicare data for years 1999–2008. Fungal infections were identified by ICD-9 codes (histo, 115.x; blasto, 116.0; cocci, 114.x). A case required one inpatient claim or at least two outpatient claims at least 7 days apart but within 90 days. Co-morbidities were identified by ICD-9 codes and defined as one physician claim within 6-months prior to the index case date. We calculated national, regional and state-based incidence rates (per 100,000 person-years) and determined mortality 90-days post diagnosis date.

Results: Five-hundred fifteen cases (241 histo; 218 cocci; 56 blasto) were identified. Mean age was 77.7 years and 53.8% were male. Regional variation was evident (Figures 1, 2), with histo and blasto incidence higher in southern and midwestern states; and cocci incidence higher in the Southwest US. Of all histo cases, 3.8% had an underlying diagnosis of rheumatoid arthritis (RA); 5.2% of cocci cases had underlying RA. Ninety-day mortality was highest (12.5%) in histo patients.

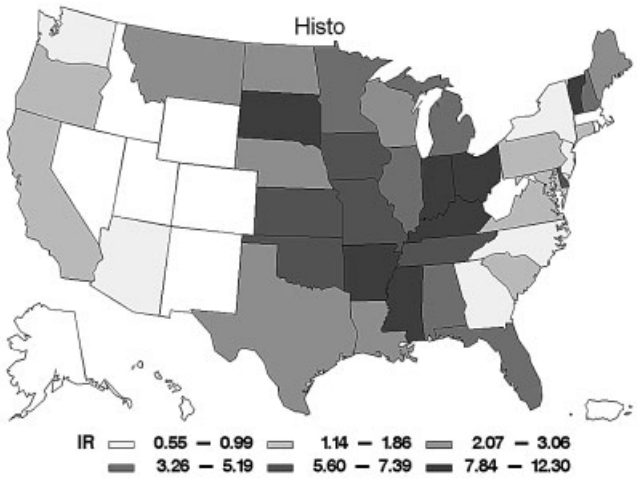

Figure 1. Geographic distribution of histo (rates per 100,000 person years).

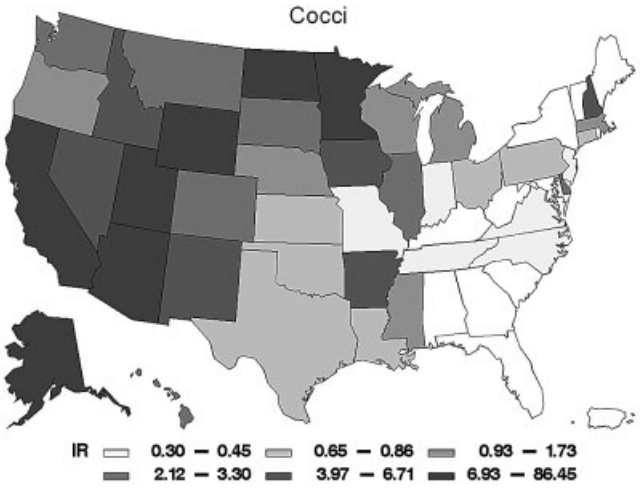

Figure 2. Geographic distribution of cocci (rates per 100,000 person years).

Conclusion: Histoplasmosis is the most common endemic fungal infection among older Americans. Geographic distribution for these mycoses is evident; however, it is important to note that cases occur outside of endemic areas. Histo and blasto incidence rates were higher in southern and midwestern states; and cocci incidence was higher in the Southwest US. Knowledge of areas of increased risk may impact diagnostic or prevention measures in older adults with inflammatory conditions and those receiving biologics.

Identification of *Borrelia Burgdorferi* in Brazil: The Etiologic Agent of Brazilian Lyme Disease-Like Syndrome (Baggio-Yoshinari Syndrome). Elenice Mantovani, Roberta G. Marangoni, Giancarla Gauditano, Virgínia L. N. Bonoldi and Natalino H. Yoshinari. Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo

Background: Baggio-Yoshinari Syndrome (BYS) is a new tick-borne infection, similar to Lyme Disease (LD) described in the northern hemisphere, except for essential differences in epidemiological, clinical and laboratory findings. The difficulty in identifying the BYS causative agent has delayed the dissemination of knowledge about this emerging zoonosis. The purpose of this study was identify the etiologic agent of BYS using a conserved gene that synthesizes the flagellar hook (flgE) of *Borrelia burgdorferi* sensu lato by molecular typing method based on Polymerase Chain Reaction (PCR).

Methods: Eight patients fulfilling the BYS diagnostic criteria were selected from November 2008 to October 2009. The patients had to present erythema migrans and positive epidemiologic history. Thirty healthy individuals, without history of tick bite or risk areas exposure, were included in the control group. The blood samples were collected and stored in −20°C. The DNA was extracted by commercial Kits. The PCR assay was performed targeting the gene flgE followed by sequence analysis.

Results: PCR targeting the gene flgE, which amplifies a fragment of ~470pb, showed positivity in 4 samples (50%). Sequences disclosed 99% of homology to *B. burgdorferi* flagellar hook protein (flgE) gene (L43849). All samples of the control group were negative for the primers used in this study. Partial sequences (flgE 470) of *Borrelia burgdorferi* flagellar hook protein generated in this study were deposited into GenBank and assigned nucleotide accession no. HM245929.

Conclusions: By the first time, we identified *B. burgdorferi* in South America and possibly in southern hemisphere. We also conclude that spirochete *B. burgdorferi* can cause two different clinical entities, Lyme disease in United States of America and Eurasia and Baggio-Yoshinari Syndrome in Brazil.

Prevalence, Impact and Risk Factors for Musculoskeletal Pain among HIV Infected Adults: An Epidemiologic Study. Karen Walker-Bone[1], Edwina Lawson[2], Duncan Churchill[2], Yvonne Gilleece[2], Martin Fisher[2] and Caroline Sabin[3]. [1]Brighton & Sussex Medical School, Brighton, United Kingdom, [2]Brighton & Sussex University Hospitals NHS Trust, [3]University College, London

Background: HIV is a global pandemic. Since the advent of antiretroviral therapies (HAART), mortality has been dramatically reduced in the western world but HIV-infected adults are living longer to acquire comorbidities. This cross-sectional epidemiologic study investigated the prevalence of musculoskeletal pain among a large cohort of HIV-infected adults.

Methods: Outpatient attendees at an HIV Unit in the UK were surveyed over a 6-month period. A questionnaire enquiring about demography, regional and widespread pain, symptoms of musculoskeletal disease (e.g. pain, swelling, rashes, sicca symptoms, fracture) was administered by trained nurses.

Results: In total 1050 HIV-infected adults were approached from whom 859 (82%) useable replies were received. 90% of the respondents were male, mean age 42 years, mean duration HIV infection 6 years. 76% were current users of HAART. In total, 539 (63%) reported pain lasting > 1 day in past month; 431 reported chronic musculoskeletal pain (> 3 months). The mean duration of chronic pain was 4.5 years. Pain was significantly increased in older age groups ($p=0.002$). Women reported pain more frequently than men throughout the age range, had higher mean pain scores ($p=0.022$) and were significantly more likely to take painkillers most days ($p<0.0001$). HIV patients with pain were significantly less likely to be working ($p=0.0001$). Back, shoulder and neck were the most common sites of regional pain. Current users of ARVs were significantly more likely to report pain in the past month, swollen joints and use of analgesics and were more disabled. Symptomatic HIV patients (stage 2 and 3) were significantly more likely to report pain and disability than asymptomatic (stage 1). In mutivariate analyses, significant predictors of pain were: age, duration of HIV infection and use of protease inhibitors.

Conclusions: Musculoskeletal pain is common amongst HIV-infected adults, particularly women. As in uninfected patients, psychosocial factors are importantly associated but so are HIV factors including duration of infection and exposure to Protease Inhibitors. Musculoskeletal pain impacts significantly in this population causing disability and sickness absence and reduced quality of life.

1646

Surrogate Markers of B-Cell Non-Hodgkin Lymphoma in Patients with Hepatitis C Virus-Related Cryoglobulinemia Vasculitis. Guillaume Geri[2], Benjamin Terrier[2], Oren Semoun[1], David Saadoun[2], Damien Sène[2], Hélène Merle-Beral[2], Frédéric Charlotte[2], Lucile Musset[2], Mathieu Resche-Rigon[1] and Patrice Cacoub[2]. [1]INSERM URMS 717, Paris 7, Paris, France, [2]Pitié-Salpetrière Hospital, Paris, France

Background: Hepatitis C virus (HCV) is associated with mixed cryoglobulinemia (MC) vasculitis and B-cell non-Hodgkin lymphoma (B-NHL), with a risk for B-NHL 35-fold higher in HCV-MC patients than the general population. However, no surrogate markers associated with the presence of B-NHL are available in HCV-MC vasculitis patients in clinical daily practice.

Methods: 104 HCV-MC vasculitis patients (including 20 with B-NHL) were included. The main clinical and biological markers associated with the presence of B-NHL were evaluated.

Results: Main epidemiological and virologic features were similar between patients with and without B-NHL. Patients with B-NHL compared to those without showed higher rates of poor general status (40 vs 16.7%; $p=0.032$), purpura (90 vs 66.7%; $p=0.05$), renal involvement (50 vs 28.6%; $p=0.11$), and cardiac involvement (15 vs 0%; $p=0.0006$). Patients with B-NHL showed higher median cryoglobulin level (1.44 vs 0.67 g/L; $p=0.0004$), and lower median C4 (0.025 vs 0.06 g/L; $p=0.001$) and gammaglobulin levels (5.3 vs 13.3 g/L; $p<0.0001$) than patients without B-NHL. Free light chain kappa/lambda ratio was more frequently abnormal in patients with than those without B-NHL (64.3 vs 33.3%, $p=0.10$). In multivariate analysis, only gammaglobulin level was associated with the presence of B-NHL [OR 0.77 (95% CI −0.44; −0.13), $p=0.0006$]. Using receiving operating characteristics curves, the optimal cut-off value for gammaglobulin level was 9 g/L, with sensitivity, specificity, positive and negative predictive values for the presence of B-NHL of 75, 82, 50 and 93%, respectively.

Conclusion: In HCV-MC patients, low gammaglobulin level (< 9g/L) is strongly associated with the presence of B-NHL.

1647

The Diagnosis of Reactive Arthritis in the Real World and Factors That Might Contribute to Its Under/Misdiagnosis. Jenny Lin[2], Anjali G. Shetty[2] and John D. Carter[1]. [1]Univ of South Florida, Tampa, FL, [2]University of South Florida

Purpose: Epidemiological data indicate that reactive arthritis (ReA) is under/misdiagnosed. Most epidemiologic studies demonstrate that ReA is the second most prevalent type of spondyloarthritis (SpA) with one study suggesting it is the most common. Other data demonstrate that the incidence of ReA should rival that of rheumatoid arthritis. A breadth of clinical experience, however, suggests that rheumatoid arthritis (RA) and other types of SpA are diagnosed far more often than ReA. The purpose of this study was to see how often rheumatologists diagnose ReA and determine factors that might contribute to this under/misdiagnosis.

Methods: We designed an internet survey that was sent to rheumatologists worldwide. The aims of this 26 question internet survey were twofold: to determine how often practicing rheumatologists diagnose ReA compared to other types of SpA and RA, and to uncover factors that might lead to this under/misdiagnosis. The survey was sent out to random rheumatologists who are registered with the American College of Rheumatology.

Results: The survey was delivered to 3,200 rheumatologists and 377 replied (11.8% response rate). Of the rheumatologists who replied 257/377 (68.2%) were male, 289/377 (76.7%) spend at least half there time in clinical care, 271/377 (71.9%) see at least 100 patients per month, 300/377 (79.6%) have been in clinical practice longer than 5 years since completion of their fellowship, and 256/377 (67.9%) practice in the U.S. In adult patients with new-onset diagnoses (disease duration <6 months), RA was the most common diagnosis followed by psoriatic arthritis (PsA), ankylosing spondylitis (AS), undifferentiated spondyloarthritis (uSpA), ReA, and inflammatory bowel disease related SpA; in patients with a disease duration of > 6 months, the order in decreasing frequency was RA followed by PsA, AS, uSpA, IBD related SpA, and ReA. PsA sine psoriasis was diagnosed only slightly less often than ReA in patients with disease duration of <6 months and at a nearly identical rate to ReA in patients >6 months disease duration. RA patients are more likely to have a monoarthritis or oligoarthritis if they are seronegative. Patients with inflammatory arthritis are queried about the possibility of preceding sexually transmitted diseases and dysentery, but they are more likely to be asked about the latter. Keratoderma blennorrhagicum is rarely diagnosed with 283/377 (75.1%) of respondents stating that they diagnose this in 0–10% of ReA patients; yet palmoplantarpustular psoriasis with arthritis is diagnosed nearly as often as ReA with an average of 4.4 vs. 6.13 cases per year respectively. Radiographic and advanced imaging work-up performed for ReA is the same as other types of SpA. There does not appear to be an

overreliance on the HLA-B27 antigen or the complete triad of symptoms to make the diagnosis of ReA.

Conclusion: Rheumatologists diagnose RA far more often than any type of SpA. ReA, specifically, is the second least commonly diagnosed type of SpA in acute patients and the most infrequent diagnosis in those with chronic SpA. ReA patients could be misdiagnosed as seronegative RA, PsA sine psoriasis, or palmoplantarpustular psoriasis with arthritis.

1648

The Infectious Risk of the Lower Respiratory Tract Is Increased in Patients with Rheumatic Diseases Treated by Biologic DMARDs, in Particular in Case of Pre-Existing Colonisation. Guillaume Geri, Sabrina Dadoun, Simon Paternotte, Maxime Dougados and Laure Gossec. Cochin Hospital, Paris, France

Introduction: Bronchiectasis is frequently associated (up to 30%) with chronic inflammatory rheumatic diseases and leads to repeated infectious events of the lower respiratory tract. Objective: To evaluate the risk of infectious events lower respiratory tract in patients treated with biologic disease modifying anti-rheumatic drugs for chronic inflammatory rheumatic diseases.

Methods: Monocenter, retrospective systematic study of all patients with a chronic inflammatory rheumatic disease and with concomitant bronchiectasis, seen at least twice in the department between 2000 and July 2009. An episode of infection was defined as an infection necessitating prescription of antibiotics for pulmonary purposes. Pre-existing bacteriologic colonization of the lower respiratory tract was collected at each time point. Univariate and multivariate analyses were performed to pick up predictive factors of the number of infectious respiratory events.

Results: 47 patients were included (mean age 64.1±9.1 years, 33 (70.2%) women), with a mean follow-up per patient of 4.3±3.1 years, i.e., 194 patients-years of follow-up totalizing 98 treatment periods. Rheumatoid arthritis was the main rheumatic disease (90.1%). The mean number of infectious events was 0.7±1.0 event per patient-year. The factors predicting infections were the type of treatment (biologic vs synthetic disease-modifying treatments), with an odds ratio of 8.7 (95% confidence interval: 1.7–43.4) and bronchial colonization by any germ (odds ratio 7.4, 2.0–26.8). Five patients had previous colonization (by: Pseudomonas aeruginosa (60%), Staphylococcus aureus (20%) or Haemophilus influenza (20%)).

Conclusion: Infectious risk was much higher in patients treated with biologic DMARDs than in those with non-biologic DMARDs. Bronchial colonisation was an important and independent risk factor, including if the colonization was by usual germs. Physicians should regularly monitor for colonization during biologics treatment.

Usefulness of Procalcitonin Measurement in Differentiating between Activity of Systemic Autoimmune Disease and Bacterial Infection. Olga Sleglova[3], Helena Dejmkova[4], Jana Uhrova[2] and Jaromir Belacek[1]. [1]Department of Biostatistics, 1. Medical Faculty, Charles University, Prague, Czech Republic, [2]Institute of Clinical Biochemistry, Prague, Czech Republic, Czech Republic, [3]Institute of Rheumatology, Prague, Czech Republic, [4]Institute of Rheumatology, Prague, Czech Republic

Objective: To evaluate the usefulness of testing for serum procalcitonin (PCT) in the differential diagnosis of infectious complications and acute disease exacerbation in patients with systemic autoimmune diseases.

Methods: 125 patients with systemic autoimmune diseases who were admitted to the inpatient department for suspected acute infection or acute exacerbation of their disease were prospectively tested for PCT concentrations. Concurrently, the levels of C-reactive protein (CRP), white blood cell counts (WBC), C3 and C4 complement components were established. The group of patients with infection comprised of two subgroups: with systemic and localised infection. Control group included 87 ambulatory patients with autoimmune diseases without any signs of deterioration.

Results: The serum PCT levels were significantly higher in patients with infections than in patients with an active systemic disease (PCT mean ± SEM 4.560 ± 1,513 vs. 0,254 ± 0,029, p< 0,001). The levels of CRP and white blood cell counts were also higher in patients with infections; the differences between C3 and C4 complement component values were not statistically significant. PCT serum concentrations were not elevated in any of the patients included in control group, and they were not affected by the current corticosteroids or immunosuppressive treatment. The sensitivity of the PCT test for an infectious complication (cut-off value = 0.5ng/ml) was 52.4%, specificity 94.0% and diagnostic accuracy 80.2%. The area under ROC curve for PCT was 73.21%.

Conclusion: The increased serum PCT levels demonstrate good specificity for the evidence of infection in patients with systemic diseases. The sensitivity of PCT serum values is lower and it is therefore suitable to complement the assessment with another high-sensitivity indicator, such as CRP.

Adalimumab Therapy in 18 Patients with Severe Hidradenitis Suppurativa. Orlando Pompei Fernández[5], Ricardo Blanco Alonso[5], Ignacio Villa[4], Marcos Gonzalez López[2], Hector Fernández LLaca[1], M. Del Carmen González-Vela[3], Mario Agudo Bilbao[6], Cristina Martinez Dubois[6], Victor M. Martinez-Taboada[7], M. Enriqueta Peiro Callizo[5], Jose Luis Peña Salgredo[5], Alfonso Fernando Corrales Martinez[5] and Miguel Angel Gonzalez-Gay Mantecon[5]. [1]Department of Dermatology, Hospital Universitario Marqués de Valdecilla, Santander, Cantabria, [2]Department of Inmunology, Hospital de Liencres, Santander, Cantabria, [3]Department of Pathology, Hospital Universitario Marqués de Valdecilla, [4]Department of Rheumatology, Hospital Sierrallana, [5]Department of Rheumatology, Hospital Universitario Marqués de Valdecilla, Santander, Cantabria, Spain, [6]Department of Rheumatology, Hospital Universitario Marqués de Valdecilla, Santander, Cantabria, [7]Department of Rheumatology, Hospital Universitario Marqués de Valdecilla, Santander, Spain

Objective: Several case-reports describing successful response to TNF-α antagonists in patients with hidradenitis suppurativa (HS), especially with infliximab and etanercept, have been reported. However, most of them had a short follow-up, showed limited efficacy and/or unacceptable side effects. Our aim was to evaluate the efficacy and safety of adalimumab therapy in 18 patients with refractory HS.

Methods: All of them fulfilled the following criteria: (1) HS resistant to standard medical treatments; (2) lack of response to at least 1 systemic immunomodulating drug; (3) multifocal active HS. In all cases Adalimumab therapy (40 mg subcutaneously every-other-week) was started. If HS was not adequately controlled, adalimumab dosage was increased up to 40 mg/week. If persistent clinical remission was achieved adalimumab therapy was gradually decreased to a minimum dose of 40 mg every 3 weeks. Quality of life was assessed using the Dermatology Life Quality Index (DLQI).

Results: 18 patients (9W:9M) (mean age, 45.17±15.8 years) with severe HS (mean disease duration, 19.83 ± 17.3 years) were studied. In 6 patients HS was associated with other conditions; SLE (2 cases), rheumatoid arthritis (2 cases), idiopathic monoarthritis (1 case), and psoriasis (1 case). Five patients had initially been treated with infliximab and 1 with etanercept. All these 5 patients were switched to adalimumab due to inefficacy. At 1st month 13, 4 and 1 patient achieved high, moderate and none improvement in suppurative symptoms, respectively. The 6 patients with associated diseases also experienced improvement of these conditions. After a mean follow-up of 92 ± 88 weeks adalimumab efficacy was maintained. Adalimumab was well-tolerated. The most frequent side-effect was mild to moderate pain at injection site, and only 1 patient developed a severe facial skin reaction.

Conclusions: Adalimumab seems to be an effective and safe treatment in refractory HS. These promising results warrant the need of prospective controlled study.

1651

Association of Langerhans Cell Histiocytosis with Erdheim-Chester Disease: How Close Monocyte/Macrophage and Dendritic Cell Lineages Are? Baptiste Hervier, Frrederic Charlotte, Olivier Hermine, Antoine Neel, Nicole Brousse, Aude Rigolet, Christian De gennes, Eric Hachulla, Xavier Girerd, Antoine Dupuy, Zahir Amoura and Julien Haroche. CHU Pitié Salpetrière, APHP, Paris, France, French Reference Center for Lupus

Objectives: Histiocytoses are a heterogeneous group of diseases that can be classified into either Langerhans cell histiocytosis (LCH) or non-Langerhans cell histiocytosis. The latter includes Erdheim-Chester disease (ECD). This study investigated the clinical association between LCH and ECD.

Methods: This retrospective study included 16 patients (10 males, 6 females, median age 41 years) treated at twelve different university hospitals between 1970 and 2010. Inclusion criteria were biopsy-proven LCH in association with two or more diagnostic signs of ECD.

Results: LCH and ECD were diagnosed simultaneously in 4/16 cases, whereas LCH preceded ECD in 12/16 cases. The median time interval was 7.5 years (range 2–22) in these cases. Major organs involved in LCH were the bones (n=12), skin (n=8) and lungs (n=3). ECD mainly affected the large vessels (n=11), bones (n=11) and retroperitoneum (n=9). Non-biopsy proven central nervous system (n=6) and pituitary gland (n=6) involvement also occurred. No specific histologic features were identified in the 65 biopsies studied, including platelet-derived growth factor receptor β expression. Between one and four lines of treatment were required in nine patients diagnosed with LCH. Nine patients were treated with interferon α-2a after the diagnosis of ECD was made. A partial improvement occurred in all assessable patients concerning ECD (n=5) and/or LCH (n=2). These 16 patients were compared with a monocentric cohort of 48 ECD patients; the only difference between the groups was a lower frequency of bone involvement in ECD patients with concomitant LCH (9/13 vs 47/48, $p<0.003$).

Conclusions: This study suggests that a pathogenic link exists between LCH and ECD. Although the mechanisms responsible for both diseases remain unknown, the present association could argue for transitions between monocyte/macrophage and dendritic cell lineages.

The patient characteristics of LCH in association with ECD were similar to those in patients with LCH alone, whereas bone involvement may have been less common in ECD when it was in association with LCH. Clinicians should be aware of this association and should consider the possibility of ECD in patients with LCH, especially in the case of treatment resistance.

Objective: To assess multi-rater discrimination of polymyalgia rheumatica (PMR) from other conditions mimicking PMR.

Methods: A total of 23 investigators were asked to blindly rate 10 PMR cases and 20 controls derived from a large prospective study of candidate criteria for PMR. Investigators were asked to review the clinical features, examination findings (ie restricted shoulder/hip movement, synovitis), inflammatory markers (ESR/CRP), serology for RF and anti-CCP, the steroid response (categorized as rapid, complete, sustained). Each criteria was rated on a 5-point scale reflecting the degree of confidence of a PMR diagnosis (1=strongly influences diagnosis of PMR to 5=strongly influences the diagnosis was not PMR). After all criteria were rated, investigators were asked to provide a diagnosis of PMR or other condition and indicate whether they would enter such a subject in a clinical trial for PMR. To assess the diagnostic accuracy of each candidate criteria, the mean rating across all raters was taken. This composite score was then used to determine the areas under the ROC curve (AUC), denoted as the c-statistic. Patients were categorized into 3 groups based on raters' misclassification rates. Group 1: greater than 50% misclassified; Group 2: 20–50% misclassified, Group 3: less than 20% misclassified.

Results: Missclassification proportion was ≥20% in 10 patients. Factors that contributed to misclassification in Group 1 (n=3, 1 case, 2 controls) were normal ESR and/or CRP, poor or ill- sustained steroid response and RF positivity without peripheral synovitis. In Group 2 (n=7: 4 cases, 3 controls), misclassification was related to persistent synovitis, no complete/sustained steroid response, RF or CCP positivity and low baseline ESR and/or CRP. The AUC c-statistic suggested that gender, duration of symptoms, systemic symptoms such as weight loss, neck pain, limitation of movement and serum electrophoresis were unhelpful in discriminating cases from controls (c-statistic < 0.8 in all). Bilateral hip pain, morning stiffness, ESR and CRP levels (pre and especially post steroid), steroid response were good discriminators of cases from controls (c-statistic > 0.8 in all, table).

Candidate Criteria	PMR Cases M (SD)	Controls M (SD)	P value*	C-statistic	95% CI C-Statistic
Bilateral pelvic girdle aching	1.8 (1.1)	3.3 (1.1)	0.01	0.80	(0.54, 0.92)
Morning stiffness >45 min	1.7 (1.0)	3.0 (1.4)	<0.01	0.87	(0.63, 0.96)
Abnormal CRP at baseline	1.8 (0.9)	3.2 (1.4)	<0.01	0.81	(0.58, 0.92)
Abnormal ESR at 26 weeks	2.3 (1.0)	3.2 (0.8)	<0.01	0.89	(0.64, 0.97)
Abnormal CRP at 26 weeks	2.2 (0.9)	3.1 (1.1)	<0.01	0.85	(0.62, 0.94)
Rapid steroid response	2.6 (1.5)	4.6 (0.6)	<0.01	0.99	(0.90, 1.00)
Complete steroid response	2.2 (1.4)	4.5 (0.7)	<0.01	0.98	(0.84, 1.00)
Sustained steroid response	2.6 (1.4)	4.3 (0.7)	<0.01	0.99	(0.90, 1.00)

*P value from a Wilcoxon rank sum test for difference in rating scores between PMR cases and controls. Scores tested are mean score across the 23 raters, further averaged by case (n = 10) and control (n = 20).

Conclusions: The verification exercise showed the stepped diagnostic process and most candidate criteria items performed well in discriminating PMR cases from controls. However, a significant proportion of cases/controls were difficult to classify. Questions such as whether PMR may not always adequately respond to steroids and whether polymyalgic RF positive disease without peripheral synovitis can occur need further investigation.

Bone Events in Type 1 Gaucher Disease before and during Treatment. Jerome Stirnemann[2], Djazia Heraoui[1], Corine Vincent[3], Olivier Fain[2], Bruno Fantin[1], France Mentre[3] and Nadia Belmatoug[1]. [1]APHP-Referral Center of Lysosomal Diseases (RCLD), Clichy, France, [2]APHP-Referral Center of Lysosomal Diseases (RCLD), Bondy, France, [3]INSERM, Paris, France

Introduction: Gaucher disease (GD), a rare autosomal-recessive disorder, is due to a deficiency of a lysosomal enzyme (glucocerebrosidase) and is characterized by liver and spleen enlargement and severe bone complications. Enzyme replacement therapy (ERT), available since 1991 (alglucerase then imiglucerase), is the reference treatment. Bone complications generally decline after 2 years of ERT. However, no data are available on main bone events (BE) (avascular necrosis, bone infarcts, pathologic fractures) occurring during treatment. Several biomarkers (chitotriosidase, ferritin, angiotensin

converting enzyme and tartrate-resistant acid phosphatase) are elevated during GD evolution

The aim of this study was to retrospectively evaluate the frequency of bone events (BE) during 2 periods, diagnosis to first treatment and the latter to the closing date.

Methods: BE of 62 treated patients followed at Beaujon Hospital, Clichy, France, were described with Kaplan–Meier curves and linear-mixed models were used to evaluate their biomarker changes.

Results: BE occurred before treatment (54 events in 21 patients) but also during treatment (12 events in 10 patients), with respective frequencies (95% confidence interval) at 10 years of 22.4% (13.3–36.3) and 20.0% (10.2–36.9). Figure 1 represents the first BE in the 62 Gaucher-disease between diagnosis and first treatment during the first 30 years of follow-up; Figure 2 represents the first BE in these 62 patients receiving ERT between first treatment and closing date during 15 years of follow-up.

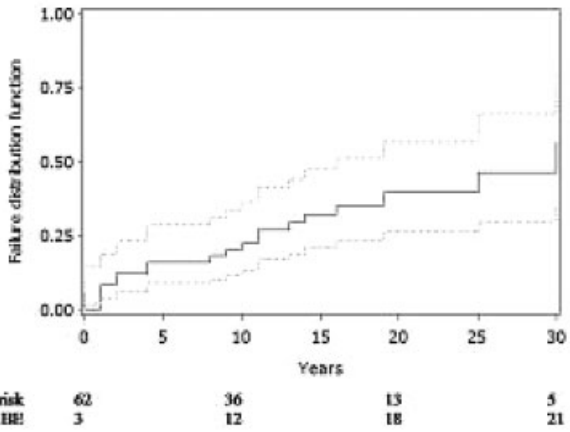

Figure 1. Bone events (BE) in the 62 Gaucher-disease patients between diagnosis and first treatment during the first 30 years of follow-up.

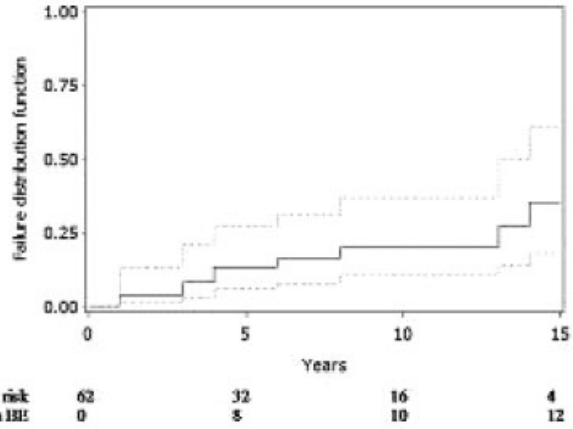

Figure 2. Bone events (BE) in the 62 Gaucher-disease patients between first treatment and closing date during 15 years of follow-up.

The 54 BE before treatment onset were [n (%)]: 28 (52%) avascular necroses, 7 (13%) bone infarcts, 12 (22%) pathologic fractures and 7 (13%) vertebral compression fractures. The 12 BE that occurred under treatment were [n (%)]: 3 (25%) avascular necroses, 4 (33%) bone infarcts with clinical bone crises and 5 (42%) pathologic fractures. The probability of suffering an BE by 10 years (95% CI) was 22.4% (13.3%-36.3%) before treatment and 20.0% (10.2%-36.9%) under ERT.

High ferritin levels and low platelet counts at treatment onset were significantly associated with BE during treatment (P=0.019 and P=0.039, respectively).

Conclusions: Bone complications could occur without but also under ERT (about 20% at 10 years). Platelet counts and ferritin levels at treatment onset at start of treatment seem to predict BE during treatment.

Objective: To develop ACR/EULAR classification criteria for PMR by assessing the performance of candidate criteria in a prospective longitudinal study of patients presenting with new onset bilateral shoulder pain.

Methods: Candidate inclusion/exclusion criteria for classification of PMR and assessment of steroid response were defined through a consensus conference and a wider Delphi survey. These criteria were then evaluated in a 6-month prospective study of patients ≥50 years of age including subjects with a diagnosis of new onset PMR and controls with newly diagnosed conditions mimicking PMR (i.e. new onset rheumatoid arthritis (RA), connective tissue diseases, shoulder conditions, fibromyalgia, osteoarthritis, etc.) presenting with recent onset of bilateral shoulder pain. All subjects were evaluated at baseline and week 26 resulting in reclassification of 9 PMR subjects and 4 controls. Data collection included clinical signs and symptoms, lab results, treatment details, ultrasound (US) evaluation, MHAQ, SF36, and pain rating. The c-statistic (i.e. area under receiver operating characteristic curve) was used to assess the ability of each criterion to discriminate controls from PMR subjects (based on diagnosis at week 26).

Results: Disease features present in >80% of the 92 PMR subjects were ≥2 weeks duration of symptoms, bilateral shoulder pain, morning stiffness >45 min duration and elevated c-reactive protein (CRP) or erythrocyte sedimentation rate (ESR). 73% of PMR subjects presented with all 3 features, while only 29% of the 131 controls had all 3. Features that best discriminated RA from PMR were peripheral synovitis, abnormal rheumatoid factor (RF) or anti-citrullinated protein antibody (ACPA) and hip pain/limited range of motion (c-statistic ≥ 0.7). Features best discriminating shoulder conditions from PMR were hip pain/limited range of motion, morning stiffness and elevated CRP/ESR (c-statistic ≥ 0.7). A scoring algorithm was developed and included morning stiffness >45 min (2 points), abnormal CRP/ESR (2 points), hip pain/limited range of motion (1 point),

abnormal RF or ACPA (-2 points), and other joint pain (-1 point). A score ≥ 3 had 76% sensitivity and 77% specificity for discriminating all controls from PMR. The specificity was higher (91%) for discriminating shoulder conditions from PMR and lower (71%) for discriminating RA from PMR. US findings were somewhat useful in discriminating PMR from shoulder conditions, but not from RA.

Conclusions: Patients ≥50 yrs old presenting with bilateral shoulder pain can be classified as having PMR in the presence of morning stiffness>45 min, elevated CRP/ESR and new hip pain in the absence of peripheral synovitis or positive RA serology.

Different Diagnostic Criteria in the Diagnosis of Polymyalgia Rheumatica. Samy Zakout and John R. Kirwan. University of Bristol, Bristol, United Kingdom

Background: Patients with polymyalgia rheumatica (PMR) are often treated in the community. General practitioners (GPs) may refer for rheumatological opinion in situations of diagnostic uncertainty or disease relapse, but PMR often presents a diagnostic dilemma as the differential diagnosis is wide. Published diagnostic criteria are primarily used for research or to distinguish between rheumatic diseases. Their sensitivity and specificity in a routine referral clinic are not known.

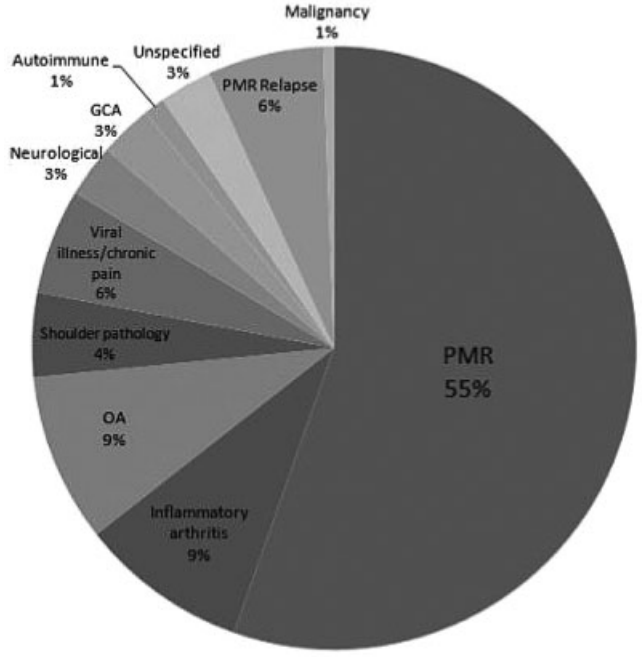
Objective: To explore how PMR diagnostic criteria perform when applied to patients with or without PMR, diagnosed on clinical grounds in a routine hospital outpatient department.

Methods: A hospital-based PMR rapid access clinic was established in our rheumatology department in July 2007. The aim of this clinic is to see new patients with suspected PMR within 2 weeks of referral. The diagnosis of PMR was made on clinical grounds. Published criteria were consulted at the time of this analysis.

Diagnostic criteria used are those of Bird[2], Hunder[2], Healey[3] and Hazleman[2].

Sensitivity and specificity of each of the diagnostic criteria were then calculated. The results of applying two criteria consecutively were also explored.

Results: 182 patients were referred over 28 months. 171 patients attended their hospital appointments. Patients with relapse were excluded from the analysis of the diagnostic criteria which were applied to 94 patients with a diagnosis of new PMR and 66 with an alternative diagnosis. Only half of the patients had new PMR (figure 1).



The ability of different criteria to identify PMR and non-PMR patients as well as sensitivity and specificity are shown in figure 2.

PMR Patients*

	All criteria	Bird, Hazleman & Healey	Bird & Hazleman	Bird & Hunder	Bird only	No criteria
No of pts	37	11	4	5	33	4
Percentage	39.3%	11.7%	4.3%	5.3%	35.1%	4.3%

Non-PMR Patients*

	All criteria	Bird & Hunder	Bird only	No criteria
No of pts	1	5	39	21
Percentage	1.5%	7.6%	59.1%	31.8%

*No patients met further combinations.

Sensitivity and Specificity

Criteria	Bird	Hunder	Healey	Hazleman
True positive	90	53	48	41
False positive	45	6	1	1
True negative	21	60	65	65
False negative	4	41	46	43
Sensitivity	95.7%	56.4%	51.1%	43.6%
Specificity	31.8%	90.9%	98.5%	98.5%

If patients are first classified as PMR using Bird criteria and are then rejected if they fail the Hazleman or Healey criteria, both high sensitivity (95.7%) and high specificity (98.5%) are achieved.

Conclusion: There is a clear potential for improving diagnostic accuracy using a rapid access PMR clinic where the diagnosis can be made or ruled out in most patients in one or two visits. No criteria have both high sensitivity and high specificity for identifying clinically diagnosed PMR in a routine referral clinic but a combination of criteria applied consecutively may offer an advantage.

Diseases Associated with Positive NOD2/CARD15 Gene Mutations: Blau's Syndrome Versus an Intermediate Subset of Blau's Syndrome and Crohn's Disease. Qingping Yao[4], Lan Zhou[3], Philip Cusumano[2] and Le-Chu Su[1]. [1]The Department of Gastroenterology, Cleveland Clinic, Cleveland, OH, [2]The Department of Internal Medicine, Cleveland Clinic, Cleveland, OH, [3]The Department of Neurology, Cleveland Clinic, Cleveland, OH, [4]The Department of Rheumatic and Immunologic Diseases, Cleveland Clinic, Cleveland, OH

Purpose: Blau's syndrome is an autosomal dominant autoinflammatory disease, characterized by dermatitis, arthritis, and uveitis. Since the report in 1985, the clinical features of the disease have chiefly derived from studies of the pediatric population. Fevers, eruptions, and internal organ involvement have been reported as well. However, sporadic adult onset Blau's syndrome has rarely been seen in the medical literature. NOD2/CARD15 gene mutations have been associated with both Crohn's disease and Blau's syndrome. It is hypothesized that an intermediate subset of Blau's syndrome and Crohn's disease could be present but no similar reports have appeared. A small case series are presented herein to expand the clinical spectrum of the diseases.

Method: Four adult patients were referred to the Department of Rheumatology at the Cleveland Clinic between January 2009 and April 2010 for unclear diagnoses. These patients were also seen by internists and consulted by other specialists. The medical records of the patients were reviewed and relevant clinical and laboratory data was excerpted and analyzed. The blood specimens of the patients were tested for NOD2/CARD15 gene mutations.

Results: We report 4 patients with clinical features of autoinflammatory diseases and positive NOD2/CARD15 gene mutations. The mean age was 45.5 (age 28 to 55), disease duration was 3.1 (0.5 to 7 yrs), with 3 female and 1 male, and 3 cases were Caucasian with 1 Jewish. Three of them presented with rash, 1 had subacute spongiotic dermatitis with superficial perivascular lymphoplasmacytic infiltrate, 1 had palisaded neutrophilic and granulomatous

dermatitis, and 1 had pigmented purpuric dermatitis and mesenteric granulomatous lymphadenitis. Three patients developed low to high grade fevers, 3 developed polyarthritis, with 1 patient with a history of bilateral total hip replacements, and 3 had ocular symptoms with a case of documented iritis. Of the 3 patients with abdominal pain and diarrhea, 2 carried the diagnosis of Crohn's disease with reports of colonoscopic evidence of cryptitis, and 1 had normal endoscopy. One case was found to have small fiber neuropathy. Therapeutically, 3 patients were treated with oral glucocorticoids, with response, 1 was treated with TNF blockers (infliximab and adalimumab) with some response, and 1 responded well to anakinra.

Conclusion: Adult onset patients with positive NOD2/CARD15 gene mutations may present with atypical clinical features of Blau's syndrome, and some features may be shared by Crohn's disease. Given the shared phenotype and genotype by Crohn's disease and Blau's syndrome, a subset of these two diseases, intermediate syndrome, may be entertained.

Efficacy and Safety of Thalidomide on Mucocutaneous Symptoms: A Systematic Review and Meta-Analysis. Juan A. Martinez Lopez[3], Estibaliz Loza[3], Jesús Maese[3], Maria Rosario Rodriguez Moreno[2], Maria Piedad Rosario Lozano[3] and Loreto Carmona[1]. [1]Fundación Española Reumatol, Madrid, Spain, [2]Hospital Virgen de las Nieves, Granada, Spain, [3]Sociedad Española de Reumatología, Madrid, Spain

Background: Adverse events lead to the suspension of thalidomide's commercial use in many states. However, it has immunomodulatory properties for which thalidomide is being used to treat oral and genital ulcers, and at present, it holds indication for multiple myeloma. Our objective was to analyze the efficacy and safety of thalidomide in mucocutaneous symptoms.

Methods: A systematic literature review on the efficacy and safety of thalidomide on mucocutaneous symptoms in patients with Behçet disease, Human Immunodeficiency Virus (HIV) infection, discoid chronic lupus erythematosus or angiodysplasia was performed. A broad search strategy was run at the following databases (inception to January 2010): Medline, Embase, Cochrane Library, IME, IBECS, Lilacs, Scielo, and The US National Institutes of Health Ongoing Trials Register databases. The abstracts of the ACR (2005–2009) and EULAR (2005–2009) annual scientific meetings were also searched. Additionally, we inquired manufactures of thalidomide about any published or unpublished trials, and we hand-searched the references of the included studies, and all the publications or other information provided by the manufactures. The selection criteria included: 1) randomized controlled trials (RCT), with a Jadad score ≥3, comparing thalidomide with placebo or with an active comparator—no dosage, route or frequency limits were applied; 2) patients had to be 18 or older, and present mucocutaneous symptoms and a diagnosis of: Behçet disease, discoid chronic lupus erythematosus, Human Immunodeficiency Virus (HIV) infection, prurigo or intestinal angiodysplasia; and 3) studies had to assess the efficacy of thalidomide—changes in the number, size and time needed for complete healing of lesions, and to register adverse events—teratogenicity, peripheral neuropathy, sedation, skin rashes, fatigue, constipation, neutropenia, headache, CD4+ and CD8+ lymphocytes counts, viral loads. Articles were restricted to English, Spanish, Portuguese, Italian or French. Two reviewers screened the titles and abstracts of the retrieved articles for selection criteria independently and collected the data by using ad hoc standard forms. For the grading of the quality we used Jadad score. A third researcher solved discrepancies.

Results: We screened 2,421 abstracts and evaluated 157 in detail, of which 6 RCT were included. Patients had mucocutaneous lesions; five studies reported patients with HIV and one reported patients with Behçet disease. Patients of the six included studies were mostly men, with mean age around 30 years. Thalidomide doses ranged from 100 mg/day to 300 mg/day. Meta-analysis was possible for the following outcomes and comparisons: 1) thalidomide versus placebo for the complete healing of ulcers (OR=12.1; CI 95% 4.49–32.7); 2) thalidomide versus placebo regarding adverse events: 2.a) polyneuropathy (OR=2.73; CI 95% 1.01–7.34); 2b) cutaneous rash (OR=16; CI 95% 4.75–53.9); 2.c) somnolence (OR=8.41; CI 95% 3.91–18.1).

Conclusions: Thalidomide is very effective in the treatment of mucocutaneous lesions in patients with HIV or Behçet disease, but it is likewise related to significant toxicity.

1658

Efficacy of High Doses of Interferon-a-2a (IFN]a) in Erdheim-Chester Disease. Baptiste Hervier, Laurent Arnaud, Bertrand Wechsler, Zahir Amoura and Julien Haroche. CHU Pitié-Salpétrière, APHP, Paris France, French Reference Center for Lupus & Autoimmune Diseases

Introduction: Erdheim-Chester disease (ECD) is a rare non-langerhans form of histiocytosis, characterized by a foamy histiocyte tissue infiltration. Treatments are not standardized. Efficacy of low doses of Interferon-a-2a (IFNα) have been suggested in small series but with variation depending of the organs involved. Indeed, central nervous system (CNS) and perivascular infiltration were reported to be resistant to low doses of IFNα.

Our aim is to report our single-center experience about the use of high doses of IFNα in ECD.

Methods: Twenty patients with biopsy-proven ECD have received high doses of IFNα (IFN$\alpha \geq$ 18 MUI/week or PEG-IFN$\alpha \geq$ 180 μg/week).

IFNα efficiency was systematically evaluated both clinically and morphologically (CT-scan or MRI for vessels & CNS, cardiac MRI, bone scintigraphy or MRI. ^{18F}FDG-PET)

Results: Sixteen men & four women were included (median age at diagnosis: 56 years (29–77). The median follow-up was 18 months (6–60). Treatments were IFNα 18 millions MUI/week (n=4), IFNα 27 MUI/week (n=8), PEG-IFNα 180 μg/week (n=8).

The treatment was started because of: CNS involvement (n=5), heart involvement (n=4), association of CNS & heart involvement (n=5), severe exophtalmos (n=1) and other (n=5). High doses of IFNα were started as first line treatment (n=12) or after a low dose course of IFNα (n=8), which was insufficient.

High doses of IFNα were efficient in 17 cases: incomplete remission (n=14, 70%) & stabilization (n=3, 15%). However, two patients did not respond to this treatment (10%) and another patient could not be evaluated (early treatment interruption). For these three patients the following treatments were inefficient (deaths, n=3).

Improvement concerned CNS (60%), lung (67%), bone (64%) and heart (56%). Median time before clinical improvement was 6 months (6–24). Nevertheless, improvement of sinusal involvement (33%), vascular involvement (20%), exophthalmos (33%) and retro-peritoneal fibrosis (20%) were rare.

High doses of IFNα were well-tolerated (n=14, 70%). However, six patients displayed side effects: severe asthenia (n=3), depression (n=2), eczema (n=1) requiring an interrupted treatment course (n=2) and an early definitive interruption (n=1). One responder patient died under IFNα after 24 months of follow-up.

Conclusion: High doses of IFNα may control severe ECD (85% of the cases) and are well tolerated (70%).

1659

Endothelial Anti-Inflammatory Effect of alpha2 Adrenergic Agonists. Ada Herrera[2], M. Jesús Domínguez[2], M. Teresa Arce[2], A. Diaz[2], Manuel Feria[1] and Federico Diaz[2]. [1]Medical School, Spain, [2]Rheumatology Service, Hospital Universitario de Canarias, Spain

Our group has observed that a2 adrenergic agonists are able to modulate the inflammatory response in animal models of inflammation. However, the mechanisms thought which a2 adrenergic receptors participate in the regulation of the inflammatory response have not been clarified.

Objectives: To study the mechanisms responsible for the antiinflammatory action of a2 agonists.

Methods: Surface expression of L-selectin, CD11b, ICAM-1 and VCAM-1 were assessed by flow cytometry. The a_2 agonists, xylazine and UK14304, and the a_2 antagonist, RX821002 were used in this work. The presence of the a_2 adrenergic receptor subunits: A, B and C were investigated by RT-PCT and Western blot. Neutrophil migration capability through activated endothelium was assessed in transwell assay (5μm). The dynamic interaction between neutrophils and activated endothelium was studied in a flow chamber. The endothelial intercellular junction was analyzed by the cell distribution of VE-Cadherin and CD31 by confocal microscopy. Wilcoxon signed-rank test ($p<0.05$) was used to evaluate the statistical significance.

Results: Both neutrophils and HUVEC expressed mRNA transcripts of the three subunits of a2 adrenergic receptor. However, only the presence of receptors a_2A, in PMN and a_2B, in HUVEC were detected by western blot.

Basal expression of L-selectin and CD11b, in neutrophils and VCAM-1, in HUVEC were not modified by the presence of a2 agonists. However, ICAM-1 basal expression in TNF-a-activated HUVEC showed a significative dose-dependent reduction in the presence of UK 14304. When HUVEC where activated in the presence of UK14304, the basal migration of human neutrophils through activated HUVEC in static conditions was decreased up to 40±8%. This effect was reverted by RX821002. When neutrophils were incubated with UK14304 no effect on cell migration was observed. The presence of the agonist a_2 UK 14,304 did not interfere with the ability of PMN rolling on activated vascular endothelium, but it reduced the transmigration ability of neutrophils by 60% under shear stress conditions. The endothelial intercellular surface positive for VE-Cadherin and CD31 staining was increased in a 50% by UK14.308 respect to the basal.

Conclusions: The a2 adrenergic agonists are able to modulate the inflammatory response at endothelium level. These compounds seem to increase the endothelial cell-cell interaction resulting in a reduction of the neutrophil movement across the endothelial barrier. This finding supports the endothelium as a therapeutic target for developing new anti-inflammatory agents potentially useful for inflammatory rheumatic diseases.

Erdheim-Chester Disease: Prospective Follow-Up of a Single-Center Cohort of 48 Patients Reveals Improved Survival in Patients Treated with Interferon-alpha. Laurent Arnaud, Julien Haroche, Baptiste Hervier, Bertrand Wechsler, Nathalie Costedoat-Chalumeau, Patrice Cacoub, David Saadoun and Zahir Amoura. Department of Internal Medicine, Groupe Hospitalier Pitié-Salpêtriere, UPMC Univ Paris 6, AP-HP, 47–83 bd de l'Hôpital, Paris, France

Background: Erdheim-Chester disease (ECD) is a rare form of non-Langerhans cell histiocytosis, with poor prognosis and non-codified therapeutic management. This study was undertaken to evaluate the impact of treatment with interferon alpha on survival in ECD patients.

Methods: Forty-eight patients (36 men and 12 women; median age: 59 years; median follow-up duration: 40.8 months) with biopsy-proven ECD were included in a single-center prospective cohort study, between Nov. 1981 and Jan. 2010. Five patients were excluded because of an overlap with another form of histiocytosis. Independent predictors of survival were identified using Cox proportional hazard model.

Results: Nine patients (18.8%) died after a median follow-up of 28.1 months (13.0–155.7 months). Univariate analysis revealed no difference in survival between gender (p=0.78), patients with and without biological inflammation (p=0.64), and treatment with or without corticosteroids (p=0.54). Comparison of patients treated with (n=40) and without (n=3) interferon-alpha and/or PEGylated interferon-alpha for at least 3 months (median duration of treatment: 23.4 months [3.2–148.2 months]) revealed an almost significant improvement (p=0.059) in patients treated with interferon (5 patients were excluded from this analysis because they received interferon for ≤ 3 months). Multivariate survival analysis using Cox proportional hazard model revealed that treatment with interferon alpha and/or PEGylated interferon-alpha for at least 3 months was the sole independent predictor of survival in our cohort (Hazard Ratio, HR: 0.10, IC95%: 0.01–0.82; p=0.03).

Conclusions: Although definitive confirmation would require a randomized controlled trial, our result strongly suggests that interferon-alpha improves survival in patients with ECD.

Expression of Type 1 Interferon Related Proteins and Plasmacytoid Dendritic Cells in the Lesional Skin of Morphea Patients. Mehran Ghoreishi[1], Cristián Vera Kellet[2] and Jan Peter Dutz[1]. [1]Department of Dermatology and Skin Science, University of British Columbia, Vancouver, BC, Canada, [2]Department of Dermatology, Pontificia Universidad Católica de Chile, Santiago, Vancouver, BC, Canada

Background: Morphea is a sclerosing condition limited to the skin and subcutaneous tissue. The co-existence of morphea with other autoimmune diseases, the elevated levels of rheumatoid factor and other auto-antibodies and the activated state of infiltrating inflammatory cells all suggest that morphea is an autoimmune disease. Type 1 interferons have been shown to promote autoimmune diseases involving the skin such as cutaneous lupus erythematosus, lichen planus and psoriasis. Type 1 interferons have recently been implicated in the pathogenesis of systemic sclerosis. The role of type 1 interferons in morphea is unknown. A type 1 interferon "signature" can be detected in tissues by the presence of interferon-α induced myxovirus A protein (MxA). Type 1 interferons are mainly produced by plasmacytoid dendritic cells (pDC), which normally do not home to the skin.

Purpose: To study the expression of type 1 interferon-induced MxA and the presence of pDCs in lesional and non-lesional skin of morphea patients.

Methods: Skin samples from 11 generalized morphea patients were collected. Paraffin embedded sections of lesional and non-lesional skin of morphea patients were stained with anti-human antibodies against MxA, CD123 and BDCA-2 and were compared with positive controls (lichen planus) and other sclerosing conditions (keloid).

Results: MxA expression was detected in keratinocytes, dermal vasculature and fibroblasts in the dermis and subcutis of morphea samples (10/11 samples). pDC can be identified by their expression of CD123 and BDCA-2. CD123 and BDCA-2 positive cells were abundant in lesions of morphea in superficial and deep dermis as well as in the subcutis (10/11). In contrast, non-lesional morphea samples (2/2) did not show detectable MxA and demonstrated few pDCs. Minimal expression of MxA was detectable in the vascular endothelium of keloid samples. There was no evidence of epidermal MxA expression in keloid.

Conclusions: To our knowledge this is the first study to show that type 1 interferons and pDCs are increased in skin lesions of morphea. This finding suggests that morphea shares the type 1 interferon dependent inflammatory pattern detected in lichenoid skin diseases such as cutaneous lupus erythematosus and lichen planus. This observation may explain the concurrence of other autoimmune diseases and the presence of auto-antibodies in morphea patients. Currently there is no useful tool to evaluate the disease activity in morphea. This study suggests that measurement of peripheral blood type 1 interferon signature, as in SLE, should be explored as a measurement of disease activity in morphea.

Idiopathic Retroperitoneal Fibrosis: Clinical Findings in 185 Patients. Tanaz A. Kermani[1], Cynthia S. Crowson[2] and Harvinder S. Luthra[1]. [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic

Purpose: To describe the clinical manifestations, laboratory, imaging findings and treatment of 185 patients with retroperitoneal fibrosis (RF) from a single tertiary-care center.

Methods: In this retrospective study all patients with newly diagnosed RF between 1/1/1996 and 12/31/2006 were included. Diagnosis was based on compatible imaging findings. RF associated with malignancy/radiation therapy and inflammatory abdominal aortic aneurysms were excluded. Medical records were reviewed and clinical information was abstracted using standardized case report forms. Descriptive statistics were used.

Results: We identified 185 patients; 113 (61%) men, 72 (39%) women with RF, mean age at diagnosis 57.6 (±11.81) years. Diagnosis was confirmed by biopsy in 140 cases (76%). The most common presenting symptoms were back pain (37.3%) and/or abdominal pain (36.8%). At diagnosis, 33 patients (17.8%) had exposure to a medication reported as associated with RF including beta-blockers (29 patients), methysergide (2 patients), ergotamine (1 patient), methyldopa (1 patient) and pergolide (1 patient). Five patients (3%) reported asbestos exposure, and 128 patients (69%) were ever-smokers. Preceding or subsequent autoimmune diseases were present in 26 patients (15%); inflammatory bowel disease was the most common (6 patients). Eleven patients (6%) had other fibrosing conditions including mediastinal fibrosis in 3 patients.

Mean hemoglobin at diagnosis was 12.6 (±1.74) g/dL. Baseline ESR and/or CRP was elevated in 62.3% (151 patients tested). Mean creatinine (Cr) at diagnosis was 2.43 (±2.78) mg/dL. New renal insufficiency was present in 74 patients (40%); median Cr 2.3 (range 1.2–13.0) mg/dL. ANA was positive in 6/118 (5%) patients tested while rheumatoid factor was positive in 8/89 (9%) subjects tested.

Baseline imaging studies in 182 patients showed a soft tissue mass which was periaortic in 115 cases (63%), periureteric in 10 patients (6%) and periaortic and periureteric in 39 patients (21%). Hydronephrosis and renal atrophy were present in 98 patients (53%) and 15 patients (8%) respectively.

Fifteen patients (8%) were treated with surgery alone, 57 patients (31%)

with medications alone and 106 patients (57%) received medical and surgical treatment. Corticosteroids were started in 116 patients. Tamoxifen was the most commonly used medication (120 patients) followed by methotrexate (51 patients).

Follow-up was available for 151 patients (82%), and 104 (69%) had normal Cr at last visit. There were 13 deaths. Nine patients developed cancer after RF diagnosis. Median duration from diagnosis of RF to cancer was 50 (range 4–112) months.

Conclusions: Idiopathic RF is a chronic inflammatory disorder of unknown etiology. This is the largest single-center study of RF with follow-up available in 82% cases. Additionally, 70% of patients were evaluated by one of us. In contrast to prior studies, we found only a slightly increased male predominance. Also, ANA was positive in only 5% patients tested. However, 15% patients had or developed autoimmune diseases. With close observation and appropriate management, outcomes such as worsening renal dysfunction or death due to renal failure were uncommon.

IL-1 Blockade for Schnitzler's Syndrome. Rona M. Smith[1], Helen J. Lachmann[2] and David R. W. Jayne[1]. [1]Addenbrooke's Hospital, Cambridge, United Kingdom, [2]UK National Amyloidosis Centre, London

Introduction: Urticarial vasculitis is a clinicopathological entity consisting of urticaria and a leucocytoclastic vasculitis on skin biopsy. It can be localised to the skin, or form part of a systemic condition, and tends to have a benign, self limiting prognosis. A few patients, however, pursue a refractory course. Schnitzler's Syndrome is a rare cause of refractory urticarial vasculitis, characterised by the presence of a monoclonal IgM component.

Methods: We have a cohort of six patients with Schnitzler's Syndrome. Detailed here are the complex courses of two patients (Patient A aged 60 and Patient B aged 35) who were diagnosed with the condition in 2009, selected to highlight the refractory nature of this condition, and the importance of making this rare diagnosis. They both presented with biopsy proven urticarial vasculitis to our clinic in 2005. Both had associated systemic symptoms, namely episodic fevers, sweats, arthralgias and significant weight loss in Patient A, and recurrent abdominal pain and distal limb parathesiae in Patient B.

Investigations: Both had marked elevations of ESR (>80mm/hr) and CRP; a persistent neutrophilia and an IgM paraprotein. Patient A had axillary and mesenteric lymphadenopathy on CT scan, but a lymph node biopsy revealed reactive cells only. Patient B had a bone marrow biopsy, which showed no evidence of lymphoproliferative disease. Both had normal PET scans, and angiograms which suggested the presence of renal and superior mesenteric artery aneurysms respectively.

Treatments: Both initially had good responses to high dose (>40mg/day) prednisolone, but relapsed on steroid taper. In light of the angiogram findings, both were treated as possible cases of polyarteritis nodosa with intravenous cyclophosphamide, but with only partial clinical effect. Multiple other immunosuppressive drugs including anti-TNF agents, calcineurin inhibitors, antimetabolites, rituximab, alemtuzumab and thalidomide were trialled over the years, but with minimal success.

Diagnosis: In view of the challenging nature of the cases, a second opinion was sought. A diagnosis of Schnitzler's syndrome was made, and therapy with anakinra (Kineret, Biovitrum AB) (an IL-1 receptor antagonist) was commenced. Both patients' clinical conditions dramatically improved within 48 hours of therapy, and their marked acute phase response completely subsided. Prednisolone doses are currently below 5mg/day—the lowest since presentation. After eight months therapy, both are tolerating anakinra well, and the transient neutropaenia that occurred in Patient B has resolved.

Conclusion: IL-1 blockade should be considered as a potential treatment for cases of refractory urticarial vasculitis, and has been shown to be particularly effective in Schnitzler's syndrome. Although extremely rare, with only about 100 reported cases in the literature, clinicians should be aware of the diagnosis of Schnitzler's Syndrome, as it responds exquisitely well to therapy, transforming patients' quality of life.

1664

IL-18 Binding Protein (IL-18BP) Dramatically Improves Liver Histological Lesions in an Animal Model of Macrophage Activation Syndrome (MAS). Laura Chiossone[3], Sandra Audonnet[3], Karin Mazodier[2], Marc Dalod[3], Catherine Farnarier[1], Daniela Novick[5], Charles A. Dinarello[4], Eric Vivier[3] and Gilles Kaplanski[2]. [1]Assiatnce Publique-Hôpitaux de Marseille, Marseille, France, [2]Assistance Publique-Hôpitaux de Marseille, Marseille, France, [3]CIML, Marseille, France, [4]University of Colorado Health Science, Denver, CO, [5]Weizmann Institute of Science, Rehovot, Israel

MAS is a severe complication of various infectious, inflammatory or neoplastic diseases. Severely impaired lymphocyte cytotoxicity and large excess of inflammatory cytokines, notably IFN-g, participate in its pathogenesis. In patients with MAS, concentrations of IL-18, a strong inducer of IFN-g, are largely increased, but not those of its natural inhibitor IL-18BP, favoring a severe IL-18/IL-18BP imbalance.

Aim: We asked whether IL-18BP may be an efficient treatment in an animal model of MAS consisting in perforin-KO mice infected with murine cytomegalovirus (MCMV), which has been previously reported to be IFN-g and TNF-a-dependent.

Results: 7–12 days after infection, 100% KO mice died whereas all wild type (WT) mice survived. Injection of 10 microgram/mice/day IL-18BP starting at day 0 or day 4 post-infection did not improve KO mice survival, nor did anti-TNF-a treatment.

Liver showed very severe histological lesions in MCVM-infected KO mice which was almost completely abrogated by IL-18 BP, in a comparable way to anti-TNF-a treatment. Combination of both did not further improve the lesions.

Serum cytokine concentrations at day 6 post-infection showed very high concentrations of IFN-g (38+/−5 vs 1+/−1 ng/ml in WT) and TNF-a (13.8 +/−2 vs 0.5 ng/ml in WT) in MCMV-infected KO mice, which were 50% reduced by IL-18BP treatment (20 +/−10 ng/ml for IFN-g and 7.5+/−2 ng/ml for TNF-a, respectively). Combination of IL-18BP and anti-TNF-a treatment 100% inhibited IFN-g levels.

Conclusions: In this model of MAS which has been shown to be entirely IFN-g and TNF-a-mediated, IL-18BP appears to be as efficient as anti-TNF-a treatment in preventing liver damage through inhibition of both IFN-g and TNF-a, confirming the role of IL-18 in the pathogenesis of this disease.

Is Pamidronate Useful as Very Effective Therapeutic Intervention in Midtarsal Arthropathy? Mani Nallasivan[2] and Tim Tait[1]. [1]Diana Princess of Wales Hospital Grimsby, Grimsby, Lincolnshire, United Kingdom, [2]Diana Princess of Wales Hospital, Grimsby, Northern Lincolnshire and Goole Hospital NHS Trust, Hull, Yorkshire, United Kingdom

Background: Midtarsal Arthropathy is a recognised cause of Foot pain. It usually presents as pain with or without swelling of the midfoot, extending from the ankle to the metatarso phalangeal joints. Parenteral pamidronate is used in the UK for the management of Paget's disease, tumour related hypercalcaemia, NSAID refractory AS, refractory SAPHO syndrome and in Charcot's arthropathy. Bisphosphonates are known to inhibit osteoclasts, improve bone density measurements and prevent fractures, suppress pro-inflammatory cytokines such as interleukin (IL-1), TNF-a and IL-6, and show anti-inflammatory properties in arthritis.

We have used Pamidronate for midtarsal arthropathy for the past five years and have previously reported our experience with six patients[1]. We hereby report our further experience in 20 patients, which demonstrates good clinical resolution.

Objectives: To assess the effectiveness of parenteral pamidronate in symptomatic control of midtarsal inflammatory arthropathy and also to assess improvement in imaging findings (MRI) in a few.

Methods: Retrospective case records of patients who had pamidronate infusion for midtarsal arthropathy were reviewed from 2005 until 2009. 20 patients had treatment of which 5 were male. Mean age was 64.6 years (37–79). All patients had pain in the midfoot and no history of trauma. Seven patients were having treatment for Rheumatoid arthritis but no active disease. Their Plain x-rays of the foot didn't show erosive arthropathy or fracture. These patients had isotope bone scan which showed increased uptake in the

midtarsal region. All had intravenous pamidronate infusion (60mgs) and some of them had 3–4 infusions over 2-year period.

Results: All patients reported significant improvement of pain after one infusion and became asymptomatic with five needing a second infusion. Median time interval before second infusion was 7 months. Follow up has been done for a maximum of three years.

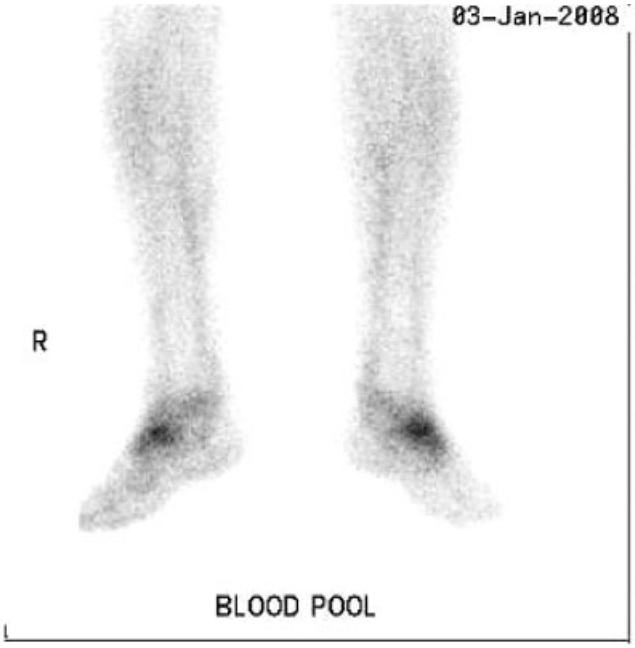

Image: Bone scan showing increased activity in midtarsal joint.

Conclusion: Pamidronate is very effective in treating midtarsal arthropathy. This warrants further study. Our five years experience further explores our understanding on the versatile benefits of this bisphosphonate.

Nonalcoholic Steatohepatitis as a Complication of Collagen Disease. Kae Takagi, Yasushi Kawaguchi, Yuko Ota, Akiko Tochimoto, Chikako Fukazawa, Takahisa Gono, Yasuhiro Katsumata, Masako Hara and Hisashi Yamanaka. Tokyo Women's Medical University, Tokyo, Japan

Background: Nonalcoholic fatty liver disease (NAFLD) is a silent disease, and is one of the most common causes of elevated liver enzymes. Nonalcoholic steatohepatitis (NASH) is distinguished from NAFLD by a liver biopsy revealing fatty change in the liver along with inflammation and damage. The development of NASH in collagen disease has been rarely reported. Our aims are to elucidate the frequency, clinical features, pathogenesis, and treatment of NASH associated with collagen disease.

Methods: A retrospective survey of collagen disease patients who were hospitalized and initially screened for NASH by identifying abnormalities in serum liver enzymes, and findings of severe fatty liver changes on abdominal computed tomography (CT) and ultrasound. NASH was confirmed by liver biopsy, and the clinical features of these patients before and after treatment were evaluated.

Results: Five patients were identified with NASH (3 patients with systemic lupus erythematosus and 2 patients with Weber-Christian disease). Mean age was 33.8 ± 15.6 years old. Three of five patients showed increased BMI and high HOMA-R. All patients showed the increase levels of serum aminotransferase (AST/ALT). Before diagnosis of NASH, 4 patients had been treated by small amount of corticosteroid against collagen diseases. Fatty change was revealed by CT and/or US in all patients. Three cases having ALT level higher than 150IU/l, showed more prominent fatty change in CT grading. The Liver/spleen (L/S) ratio measured by CT were observed around 0.8 higher than 0.4. Pathological examination using liver biopsy specimens showed NASH in all 5 patients. Based on Brunt's classification, pathological score of two patients were Grade 2 and Stage 2, whereas the score were 1 in other three patients.

Table 1. Clinical characteristic

	case 1	case 2	case 3	case 4	case 5
gender	F	M	F	F	F
age	29	36	21	19	62
BW	56	96	86	62	50

HL	(+)	(+)	(+)	(−)	(+)
AST (IU/l)	218	82	161	51	75
ALT (IU/l)	205	262	160	142	90
LDH (IU/l)	958	594	720	192	230
γGTP (IU/l)	344	167	100	32	157
ALP (IU/l)	308	234	159	146	332
Tchol (mg/dl)	223	256	172	175	121
HDL (mg/dl)	19	51	12	NE	37
LDL (mg/dl)	129	188	79	NE	147
TG (mg/dl)	393	104	405	220	262
Adiponectin (μg/ml)	9.17	29.4	6.5	5	11.8
Leptin (ng/dl)	11.1	20.8	24.4	14.7	19.3
Insulin (μU/ml)	1.9	72.5	175	85	14.6
BS (mg/dl)	62	181	108	120	118
HbA1C (%)	6	6.5	5.5	NE	NE
HOMA-R	0.29	29.3	46.6	25.2	4.8
TNFα (pg/ml)	37.4	1.5	4.3	3.2	5.6
CT grade	2	3	3	NE	1
CT L/S ratio	0.8	0.41	0.38	NE	
US (grade)	2	3	2	2	1
Pathology (grade)	2	1	1	1	2
(stage)	2	1	1	1	2

In order to suppress the collagen disease activity, all patients were treated by higher amount of corticosteroid (prednisolone 20–40 mg/day) with and without immunosuppressive drugs such as cyclophosphamide, ciclosporin or mizoribine. In all patients, serum AST/ALT levels were remarkably turned to be normal in parallel with improvement of collagen disease activity within six months (AST: 117.4 ± 31.2 vs.26.0 ± 3.7, $p < 0.05$; ALT: 171.8 ± 29.1 vs.48.4 ± 16.7, $p < 0.01$). Furthermore, fatty liver change determined by CT and US were diminished. The average of L/S ratio before and after treatment was changed from 0.49 ± 0.26 to 1.22 ± 0.17 with statistically significant difference ($p < 0.01$). Although HOMA-R was improved in three cases, there were no significant changes in other risk factors including body weight and BMI before and after treatment.

Conclusions: NASH is relatively rare in collagen disease patients. Corticosteroid treatment with or without immunosuppressant drugs was effective for collagen disease as well as for NASH, suggesting that autoimmune factors are involved in the development of NASH associated with collagen disease.

Prevalence of Atherosclerotic Risk Factors and the Metabolic Syndrome in Patients with Chronic Inflammatory Arthritis. Chi Chiu Mok[2], Tin Choi Ko[1], Ling Yin Ho[2], Ka Lung Yu[2], Pak To Chan[2] and Chi Hung To[2]. [1]Chinese University Hong Kong, [2]Tuen Mun Hospital

Objectives: To evaluate the prevalence of atherosclerotic risk factors and the metabolic syndrome (MetS) in patients with rheumatoid arthritis(RA), ankylosing spondylitis(AS) and psoriatic arthritis(PSA).

Patients and Methods: Consecutive patients with RA, AS or PSA who attended our out-patient arthritis clinics between July and November 2009 were recruited for a study of the prevalence of atherosclerotic risk factors and the MetS, defined according to the 2009 Joint Statements using the Asian criteria for central obesity. Participants were screened for the presence of vascular risk factors. Waist and hip circumferences, body weight, body height and blood pressure were measured; and fasting blood was taken for glucose

and lipid levels. Medications being received by patients were also reviewed. The MetS was present when ≥3 of the following components were present: (1) Increased waist circumference to ≥ 90cm in men or ≥ 80cm in women; (2) Elevated blood pressure to ≥130/85mmHg or requiring drug therapy; (3) Elevated serum triglyceride level to ≥1.7mmol/L; (4) Reduced serum high density lipoprotein (HDL)-cholesterol to ≤1.0mmol/L in men and ≤1.3mmol/L in women; and (5) Elevated fasting glucose level to ≥5.6mmol/L. The prevalence of vascular risk factors and MetS was compared among different inflammatory arthritis; and with age and gender-matched healthy controls in a 1:2 matching.

Results: 844 patients were studied (651 RA, 94 AS and 99 PSA; 72% women; age 51.7±12.6 years). The mean disease duration for patients with RA, AS and PSA was 5.1±5.4, 4.9±4.8, and 3.3±3.0 years, respectively. The prevalence of MetS was significantly higher in PSA (40%) than RA (20%) or AS (13%) ($p<0.001$). The odds ratios for the MetS compared to age and gender matched controls were 0.95 (0.75–1.19; $p=0.68$), 0.80 (0.39–1.65; $p=0.60$) and 3.27 (1.90–5.64; $p<0.001$), respectively, for RA, AS and PSA. Patients with PSA had significantly higher prevalence of impaired fasting glucose (33%; $p<0.001$), low HDL-cholesterol (34%; $p<0.001$), high triglyceride (22%; $p=0.01$) and central obesity (66%; $p=0.009$). In a logistic regression model, the odds ratio for the MetS in PSA was 2.64 (1.58–4.41) ($p<0.001$) compared to RA or AS. The adjusted odds ratios for central obesity, impaired fasting glucose, hypertriglyceridemia and low HDL-cholesterol were also significantly higher in patients with PSA. The prevalence of the MetS in all the three diseases studies was not significantly higher those patients with established (>2 years' duration) than early disease (<=2 years' duration).

Conclusions: Patients with PSA, but not RA or AS, have a significantly higher prevalence of the MetS syndrome compared to the general population. Among the three diseases studied, PSA has the highest prevalence of the MetS and is associated with highest cardiovascular risk.

Renal Dysfunction Is Associated with Increased Mortality in Adults with Macrophage Activation Syndrome. Bita Shakoory[3], W. Winn Chatham[3], Graciela S. Alarcon[1] and Randy Q. Cron[2]. [1]Oakland, CA, [2]Children's Hospital of Alabama, Birmingham, AL, [3]Univ of Alabama-Birmingham, Birmingham, AL

Background: Macrophage activation syndrome (MAS) remains a potentially fatal cause of multiorgan dysfunction (MOD) in adults, with an estimated mortality of 50%. This longitudinal study reports the short and long term outcomes in hospitalized adults with MAS due to various triggering factors from a single academic institution.

Methods: Patients diagnosed with MAS from April '08 to May '10 at a regional tertiary institution were identified from rheumatology consultation logs. The diagnosis was made in patients with MOD with at least one of the following: A. Tissue hemophagocytosis; B. Consensus of ≥2 physicians to treat; or C. Elevated ferritin >10,000 mg/L. Final decision for treatment was made independent of the study. The length of hospital stay (HS) and critical care (CC), the need for renal replacement therapy (RRT), vasopressor use (VP) and mechanical ventilation (MV), and death were recorded. Follow up data on survivors (chronic organ damage, readmission) were obtained from the time of discharge in 3–6 month intervals.

Results: Seventeen adults (age 17–74y), 59% non-whites (53% AA, 6% Asian), predominantly women (76%), were included. A definite predisposing disorder could not be identified in one patient. The following potential etiologies were suggested in the remaining.

Infectious: Ehrlichiosis in 3, CMV, HSV, EBV in 6.

SLE in 7, adult-onset Still disease, IgA nephropathy, Wegener disease in 3.

Hematological malignancies in 3.

Pregnancy in 2.

The average HS was 31 days (5–112d, median 28d), 76% of patients had a CC stay (mean 11.2d, median 11d). MV and VP and RRT required in 65% (n=11). Nine of the 17 patients did not survive the hospitalization (53% mortality). Follow up in survivors (Mean 13m, Median 12m, range 3–26m, last discharge March '10) showed 4 readmissions in 2 survivors (1 for delivery, 1 with 3 readmissions) with chronic organ damage in 4: stage II liver fibrosis per biopsy in 2, worsening of chronic kidney disease and RRT after discharge in 3 (<6 month in 1, permanent RRT in 2).

The need for CC, MV, or RRT occurred more frequently in those who died than in survivors. There were no differences in age, gender, ethnicity, the presence of two or more triggering factors, or the length of HS or CC stay between survivors and non-survivors (Table).

Conclusions: In adults, a diagnosis of MAS oftern results in prolonged and complicated hospital course with high mortality and should be investigated and treated in patients with early manifestations of MOD to prevent critical care interventions and associated morbidity and mortality.

The Outcomes Correlates of MAS

	Deceased (N = 9) Mean (SD)	Survived (N = 8) Student t Test	p Value	Total Mean (SD)
Age	54 (15)	38 (20)	0.3	46 (19)
LoHA	36 (31)	24 (13)	0.3	57 (24)
LoCC	11 (8)	6 (6)	0.2	8 (8)
	N (%)	N (%)	Fischer Exact Test	N (%)
Woman	7 (78)	6 (75)	1.0	13 (76)
Non-White	5 (55)	3 (38)	0.6	8 (47)
Two triggers	7 (78)	3 (38)	0.1	10 (59)
CC	9 (100)	4 (50)	<0.05	13 (76)
MV	8 (89)	3 (37)	<0.05	11 (65)
RRT	8 (89)	1 (13)	<0.005	9 (53)

MAS: macrophage activation syndrome, LoHS: length of hospital stay, LoCC: length of critical care admission, MV: mechanical ventilation, RRT: renal replacement therapy, CC: critical care

Retrospective Analysis of Relapsing Polychondritis in the US Department of Defense Population. Stephanie D. Mathew, Daniel F. Battafarano and Michael J. Morris. San Antonio Military Medical Consortium, Fort Sam Houston, TX

Purpose: Relapsing polychondritis (RPC) is a rare autoimmune disorder with an prevalence of 3.5 cases/million. RPC affects cartilaginous structures including the ear, nose, larynx, trachea, bronchi, joints, skin, heart valves and the aorta. Cardiopulmonary and vascular involvement can be life threatening. The objective of this study was to characterize the clinical features of RPC within our patient population and determine the utility of echocardiography, imaging studies and spirometry.

Methods: We performed a retrospective EMR chart review of all patients diagnosed with RPC within the Department of Defense between January 2004 and December 2009 from a beneficiary base of 9.5 million. Patients were included if they met McAdams diagnostic criteria for RPC or if they had recurrent chondritis with deformity plus vestibular dysfunction, ocular inflammation or inflammatory arthritis. Demographic information, along with disease duration, organ involvement, treatment history, imaging studies, echocardiography and pulmonary function tests (PFTs) were recorded.

Results: Thirty patients met McAdams diagnostic criteria and an additional 13 met our criteria as outlined above. Twenty-three of the patients (53%) were female; with a mean age of 51. The average age at diagnosis was 43 and disease duration of 7.1 years. Auricular chondritis was present in 38 (88%), inflammatory arthritis in 26 (60%), inflammatory eye disease in 23 (57%), pulmonary involvement in 16 (37%) sensorineural hearing loss in 16 (37%), nasal chondritis in 15 (35%) and keratoconjuntivitis in 7 (16%). Two patients had vasculitis and one presented with renal insufficiency and proteinuria. Twenty-one (49%) patients had concomitant connective tissue disease. Methotrexate was used in 18 (42%), corticosteroids in 13 (21%), NSAIDs in 10 (23%), other DMARDs in 8 (18%), biologics in 7 (16%), and dapsone in 4 (9%). Twenty (47%) required multiple medications. Thirty (70%) patients had PFTs, 18 with reviewable flow volume loops. Flow volume loop abnormalities were observed in 6 of 18 (33%); all had upper respiratory symptoms. Imaging with chest CT was performed in 27 (63%) and in 5 of 6 patients with flow volume loop abnormalities. Pulmonary CT abnormalities in 13 of the 27 patients (48%) revealed parenchymal lung disease (9), tracheal abnormalities (4) and enlargement of the great vessels (2). Echocardiography was abnormal in 12 of 25 (48%) with valvular (aortic and mitral) regurgitation or stenosis (8), aortic root dilatation (3), and pericarditis (1).

Conclusions: Our RPC patients were similar to previous studies in incidence, demographic data and organ involvement. The diagnosis of RPC was primarily based on physical examination and symptom driven diagnostic testing. There was no observable pattern for monitoring progression of

tracheobronchial tree and/or large vessel involvement. Abnormal flow volume loops are recommended with all PFTs in RPC patients to detect early laryngotracheal involvement. CT of the chest is warranted to monitor for progressive vascular and tracheobronchial tree abnormalities.

Retrospective Case Series of Single Center Experience of Methotrexate and Mycophenolate Mofetil Monotherapy for Patients with Non Infectious Posterior, Intermediate and Panuveitis. Mariam Khan[1], Careen Lowder[1] and Rula Hajj-Ali[2]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Clevelnad Clinic, Cleveland, OH

Background: Limited data is available in the literature regarding sustained clinical efficacy with the use of antimetabolites for treatment of uveitis. In addition most series have included patients with anterior inflammation which makes efficacy data appear more robust. The objective of this study was to report the sustained clinical efficacy in patients with non infectious posterior, intermediate and panuveitis.

Methods: 183 charts of patients followed in the Rheumatology and Ophthalmology Departments between 1997 and 2008 with the diagnosis of uveitis were screened. 36 patients fulfilled the inclusion criteria: a) diagnosis of non infectious posterior, intermediate or panuveitis, b) treatment with methotrexate (MTX) and/ or mycophenolate mofetil (MMF) monotherapy, c) at least six months of follow up after treatment initiation. Data extracted from the charts included demographics, detailed treatment course, disease associations and treatment response.

Initial clinical efficacy was defined as lack of inflammation at a prednisone dose of less than 10mg and without the use of antecedent (with in two months) intraocular steroid injection.

The primary outcome measure was sustained efficacy defined as lack of inflammation for at least six months following initial efficacy. Efficacy was not sustained if patients needed escalation in dose of immunosuppressive agents, intraocular steroid injections or course of oral steroids however those who were treated with brief course of topical steroids but not more than three times a year were included in this group.

Results: 30 patients received MTX, 11 received MMF (5 de novo and 5 after MTX failure). 53 % (n=19) had idiopathic disease, 17% (n=6) had ocular syndromes restricted to the eye and 30% (n=11) had systemic disease [64% (n=7) with sarcoidosis, 18 %(n=2) with multiple sclerosis, 9% (n=1) with behcet's and 9% (n=1) with crohn's disease]. 56% (n=20) had panuveitis, 42% (n=15) had posterior uveitis.One had intermediate uveitis. 5 patients treated with MMF de novo had ocular syndromes restricted to the eye, [80% (n=4) birdshot retinochoroidopathy]. Female to male ratio was 1.6:1. Mean disease duration was 7.7 years (1–20), mean age at diagnosis was 43.5 years (8–65). Average dose of MTX was 21 mg weekly (15–27.5) and of MMF was 2318 mg daily (1000–3000).

Initial and sustained clinical efficacy were higher in MMF compared to MTX (73% vs. 67 %, p =0.12) and (64 % vs. 47% p =0.16) respectively but this did not reach statistical significance. There was a trend towards significance with respect to steroid sparing effect (60% vs. 22%, p=0.069) and ability to taper antimetabolite (55% vs. 17%, p=0.06) in the MMF group compared to the MTX group respectively. Median duration of sustained clinical efficacy was significantly higher in the MMF compared to MTX group (48 vs. 20 months, p=0.002).

Conclusion: Sustained clinical efficacy in patients who received MTX was higher compared to the reported literature likely related the higher average dose of MTX used at our center. Median duration of sustained efficacy was significantly higher with MMF compared to MTX.

Disclosure: M. Khan: None; **C. Lowder:** None; **R. Hajj-Ali:** None.

1671

Rituximab Therapy Is an Effective Approach in Treatment of IgG4-Related Systemic Disease. Arezou Khosroshahi[3], Donald B. Bloch[2], Vikram Deshpande[4] and John H. Stone[1]. [1]Massachusetts General Hospital, Sudbury, MA, [2]Massachusetts General Hospital, Newton, MA, [3]Massachusetts General Hospital, Boston, MA, [4]Massachusetts General Hospital

Patients with IgG4-related systemic disease (IgG4-RSD) often have strikingly elevated serum concentrations of IgG4 and typically share certain histopathological features regardless of the affected organ(s). The histopathological features of IgG4-RSD include diffuse lymphoplasmacytic infiltration, extensive deposition of IgG4-positive plasma cells, obliterative phlebitis, and tissue fibrosis. Patients with IgG4-RSD frequently require prolonged treatment with glucocorticoids and are often unable to taper these medications. Traditional disease-modifying antirheumatic drugs (DMARDs) are generally ineffective.

Objective: We assessed the clinical and serologic responses of patients with steroid- and DMARD-refractory IgG4-RSD to B lymphocyte depletion therapy.

Methods: Eight patients with IgG4-RSD were treated with rituximab (1000 mg times two). Clinical improvement was assessed by monitoring patients' ability to taper/discontinue prednisone and DMARDs, and by measuring the serum concentrations of B lymphocytes, immunoglobulins, and IgG subclasses before and after rituximab therapy.

Results: The patients' organ involvement included the pancreas, biliary tree, aorta, salivary glands (submandibular and parotid), eyes, lacrimal glands, lymph nodes, and retroperitoneum. Five patients had elevated serum IgG4 levels at baseline, with a mean concentration of 1547 mg/dl (normal: 8–140 mg/dl). Among these patients, the serum IgG4 concentrations declined by a mean of 65% within 2 months of rituximab administration. The decline in serum IgG4 concentrations was substantially steeper than that of the autoantibody concentrations in immune-mediated conditions in which rituximab is known to be effective, such as in rheumatoid arthritis. In addition, the reduction in IgG-subclass levels was specific for IgG4.

All eight patients demonstrated striking clinical improvement within 1 month of the initiation of rituximab therapy. Tapering or discontinuation of both prednisone and DMARDs was achieved in all eight patients. Four patients had minor disease recurrences approximately six months after treatment, characterized by symptom recurrence or serum IgG4 elevations. These disease flares correlated with B cell return in the peripheral blood. All four disease flares responded to second courses of rituximab. All eight patients are now off glucocorticoids and DMARDs entirely.

Conclusion: Treatment with rituximab led to prompt clinical and serologic improvement in refractory IgG4-RSD. The swift improvement of IgG4-RSD suggests that rituximab achieves its effects in IgG4-RSD by depleting the pool of B lymphocytes that replenish short-lived IgG4-secreting plasma cells, offering insights into the mechanism of action of this treatment approach.

Anti-CADM-140/MDA5 Antibody Predicts Complication of Interstitial Lung Disease in Japanese Cases of Juvenile Dermatomyositis. Ichiro Kobayashi[1], Yuka Okura[1], Yasuhiro Yamazaki[1], Shunichiro Takezaki[1], Masafumi Yamada[1], Masataka Kuwana[2] and Tadashi Ariga[1]. [1]Department of Pediatrics, Hokkaido University Graduate School of Medicine, Sapporo, Japan, [2]Keio University School of Med, Tokyo, Japan

Background: Interstitial lung disease (ILD) is a life-threatening complication of both adult dermatomyositis (DM) and juvenile dermatomyositis (JDM). We have indicated that most of ILD develops at an early stage or at the time of relapse of JDM and is rapidly or moderately progressive (Kobayashi I, et al. Rheumatology 2003). Among ILD associated with DM, rapidly progressive interstitial pneumonia preferentially develops in clinically amyopathic DM (CADM) particularly in Asian races (Sontheimer RD. Arch Dermatol. 2010). Recently, anti-CADM-140/MDA5 antibody has been identified as a disease marker for ILD associated with adult CADM. In the present study, we examined the autoantibody in JDM complicated with or without ILD.

Materials and Methods: Thirteen cases of JDM including 6 cases with ILD were involved in this study. The diagnosis of JDM was made according to the diagnostic criteria by Bohan and Peters. Sera were obtained from the patients at the time of diagnosis of JDM and stored at −20°C until use. Anti-CADM-140/MDA5 antibody was measured by enzyme-linked immunosolbent assay using purified recombinant MDA-5 as an antigen as previously described (Sato S, et al., Arthritis Rheum 2009). The antibody units

were calculated from the optical density at 450 nm results (normal range: <8.0 U).

Results: Although case 1 died of respiratory failure, the other four previously reported cases showed recovery following the commencement of cyclosporine A in combination with methylprednisolone pulse therapy and oral high-dose prednisolone, and are drug-free for at least four years without relapse of either JDM or ILD. In an additional case, ILD developed approximately two months after the diagnosis of JDM which was associated with elevation of a serum KL-6 level (2,376 U/ml). This case is now successfully treated with cyclosporine A in combination with prednisolone following methylprednisolone pulse therapy. All the cases with ILD showed clinically apparent myositis associated with elevated levels of serum muscle derived enzymes during the course. Among the seven cases without ILD, two cases lacked both clinical myopathy and elevation of muscle-derived enzymes.

Five of the six cases with ILD were positive for the anti-CADM-140/MDA5 antibody (9.5–902.3 U). Three cases with rapidly progressive ILD showed extremely high levels of the antibody (357.6–902.3 U). In two cases in which ILD developed more than 1 month after the diagnosis of JDM, the antibody was detected before the development of ILD. All of the 7 cases without ILD were negative for the antibody (1.3–3.5 U).

Conclusion: Anti-CDMA140/MDA-5 autoantibody is not only a disease marker for ILD associated with JDM but also a predictive marker for the complication regardless of the muscle weakness. Our results suggest that common or similar mechanisms are involved in the development of ILD in both adult CADM and JDM.

Background: Descriptions of MPA are limited by the inability of definitions (e.g. Chapel Hill Consensus Conference) to uniquely define patients and exclude another related vasculitis. Classification algorithms have been used to distinguish patients with related vasculitides by applying in a hierarchical sequence, from the most specific to the least specific, diagnostic criteria for each patient in a population.

Aims: To describe interval to diagnosis, presenting features and initial treatment for children uniquely classified as having MPA in ARChiVe.

Methods: Time-of-diagnosis data on children with AAV diagnosed since 2004 by expert rheumatologists (MD-diagnosis) has been contributed to ARChiVe from 37 US/ Canadian sites. A pediatric modification of the European Medicines Agency (EMEA) for AAV and polyarteritis nodosa (PAN) classification algorithm was applied by computation to this cohort to uniquely classify patients with MPA. Descriptive data on these MPA patients were then extracted. Sensitivity and specificity of the algorithm classification of MPA were tested (MD-diagnosis reference standard). The recently validated EULAR/PRINTO/PRES pediatric Wegener's granulomatosis (WG) criteria were applied to children with MPA to determine if there was diagnostic overlap.

Results: Of the 155 patients, 18 (12%) had MPA, 113 WG, 2 Churg-Strauss syndrome, 1 PAN, and 21 were unclassifiable. For the 18 children with MPA (67% female, 56% Caucasian) the median age at diagnosis was 13 (range 3–16) y, and the median interval from disease onset to diagnosis was 23 (range 2–50) mo. Presenting features are shown in Table and included: renal 95%, constitutional 89%, pulmonary 28% and sinus-upper respiratory 17%. Anti-MPO and anti-PR3 were present in 61% and 28% of patients respectively. Necrotizing pauci-immune glomerulonephritis was reported in 20% of 15 kidney biopsies. In 14 (78%) patients corticosteroids (CS) and cyclophosphamide (6 PO, 7 IV, 1 PO+IV) were the initial treatment; plasmapheresis (n=3), rituximab (n=2), and methotrexate (n=1) were also used in these 14. The remainder (n=4) received CS alone. Sensitivity and specificity of the EMEA algorithm for MPA were 22% and 92%. No MPA patients were concurrently classified by EULAR/PRINTO/PRES as WG.

Table. Frequency of presenting clinical features in pediatric patients with microscopic polyangiitis in the ARChiVe cohort (n = 155)

Clinical feature	Affected patients, n (%)
CONSTITUTIONAL/GENERAL	58 (89)
Malaise, fatigue	14 (78)
Weight loss	9 (50)
Fever	7 (39)
RENAL	17 (95)
Elevated serum creatinine	13 (72)
Hematuria with proteinuria	11 (61)
Hematuria with red blood cell casts	6 (33)
PULMONARY	5 (28)
Shortness of breath	3 (17)
Chronic cough	3 (17)
Hemoptysis/alveolar hemorrhage	2 (11)
Respiratory failure requiring ventilation	1 (6)
EAR, NOSE, THROAT	3 (17)
Sore throat	2 (11)
Nasal stuffiness	1 (6)
ANCA SEROLOGY	
Immunofluorescence for cANCA/pANCA, positive	14 (78)
Anti-MPO positive ELISA	11 (61)
Anti-PR3 positive ELISA	5 (28)
Negative ELISA	1 (6)
ELISA not done/not available	1 (6)

Conclusion: Pediatric patients uniquely classified with MPA had predominantly renal and constitutional manifestations and a positive ANCA. A minority had upper or lower respiratory tract disease. Initial therapy varied considerably. The protracted interval from symptom onset to diagnosis suggests MPA is a poorly recognized entity in children.

Clinical and Serological Factors Associated with Lupus Serositis in Children: Results from the 1000 Canadian Faces Multiethnic Cohort. America G. Uribe[1], Jaime Guzman[1], Ross E. Petty[3], Lori B. Tucker[2], Laura Musyj[1], Earl D. Silverman[4], Gaelle Chedeville[7], Adam Huber[5], Suzanne E. Ramsey[6] and Christine A. Peschken[8]. [1]BC Children's Hospital, [2]BC Childrens Hospital, Vancouver, BC, Canada, [3]BCs Childrens Hosptial, Vancouver, BC, Canada, [4]Hosp for Sick Children, Toronto, ON, Canada, [5]IWK Health Centre, Halifax, NS, Canada, [6]IWK Health Ctr, Halifax, NS, Canada, [7]Montreal Children's Hospital, [8]Univ of Manitoba, Winnipeg, MB, Canada

Background: Studies in adult patients with systemic lupus erythematosus (SLE) report serositis prevalence of 30–60%, and more common in patients with younger age SLE onset. In childhood-onset SLE, serositis prevalence ranges from 5%-60%; positive anti-Ro,-La,-Sm and -Jo-1 antibodies are related factors. The association of ethnicity with serositis has not been explored in pediatric patients.

Aim: To determine the prevalence of serositis in a multiethnic Canadian cohort of children and adolescents with SLE, and sociodemographic, clinical and serological features associated with serositis.

Methods: Eligible patients in the 1000 Canadian Faces of Lupus cohort (a prospective multicentre observational study of incident and prevalent cases of adults and children with SLE), were those diagnosed with definite SLE at age ≤ 18 yrs (fulfilling >4 ACR criteria), regardless of disease duration. Selected baseline data included: socio-demographic information (age at diagnosis, ethnicity, gender); clinical characteristics [accrued SLE criteria, disease activity (SLEDAI, physician and patient global assessment on a 10-cm visual analogue scale) and damage (SLICC damage index)]; and serology results (ANA, anti-dsDNA, -Sm, -RNP, -La, -Ro, IgG and IgM anticardiolipin antibodies, lupus anticoagulant). Serositis was defined as the presence of pleuritis, pericarditis and/or peritonitis as per the ACR criteria or SLEDAI definitions. Factors related to serositis were examined using univariable descriptive statistics, followed by multivariable analyses.

Results: 193 children were studied (154 female). Mean (SD) age at diagnosis was 12.3 (3.3) yrs. Mean (SD) total disease duration at study entry was 2.5 (2.6) yrs. Serositis was present in 35 (18.1%) children; 18 patients had pleuritis only, 5 had pericarditis, and 12 had both. Serositis was present at diagnosis in 48.6%. Sociodemographic and clinical characteristics associated with serositis are presented in Table. In multivariable analyses, Aboriginal (OR=18.5, 95% CI 1.8–188.6) and African Canadian (OR=5.7, 95% CI 2.1–15.7) ethnicity and accrual of 5 or more ACR criteria at study recruitment (OR=12.7, 95% CI 4.0–40.9) were positively associated with serositis; conversely, mucocutaneous involvement (OR=0.1, 95% CI 0.1–0.5) and positive result for any anti-phospholipid antibody (OR=0.3, 95% CI 0.1–0.8) were negatively associated with serositis.

Variable	Serositis No (n = 158)	Serositis Yes (n = 35)	*p* value
Female, %	80.3	91.4	0.118
Age at diagnosis, years, mean (SD)	12.4	11.6	0.213
Ethnicity, %			0.002
Aboriginal	25.0	75.0	
African Canadian	52.7	47.3	
Asian	81.7	18.3	
Caucasian	87.0	13.0	
Hispanic	100.0	0.0	
Middle Eastern	75.0	25.0	
Mixed	83.3	16.7	
Mucocutaneous involvement, %	72.5	45.7	0.002
Arthritis, %	62.1	65.7	0.689
Neurologic involvement- T0, %	12.0	20.0	0.165
Renal involvement, %	38.6	40.0	0.875
Hematologic involvement, %	68.6	82.9	0.093
Fulfilled ≥ 5 ACR criteria, %	28.1	62.9	<0.001
SLEDAI score, mean (SD)	3.4 (4.4)	3.5 (3.8)	0.846
Physician global assessment, cm, mean (SD)	1.7	1.5	0.776
SLICC/ACR Damage Index, mean (SD)	0.3 (0.8)	0.4 (0.8)	0.660
Autoantibodies, positive, %			
Antinuclear	99.3	100.0	1.000
Anti-dsDNA	83.5	77.1	0.901
Anti-Sm	37.8	46.9	0.348
Any anti-phospholipid	60.0	40.6	0.080
Anti-RNP	38.1	36.1	0.853
Anti-La	16.0	30.6	0.057
Anti-Ro	33.7	41.7	0.443

Conclusion: We found a lower than expected prevalence of serositis in this multiethnic Canadian pediatric lupus cohort. Serositis was more prevalent among Aboriginal and African Canadian patients. Positive anti-phospholipid antibodies or mucocutaneous involvement were less frequent among patients with serositis.

Cogan Syndrome: A Rare but Severe Vasculitis in Pediatric Age. Ilaria Pagnini[3], Maria Elisabetta Zannin[4], Marianna Sari[2], Gabriele Simonini[1], Rolando Cimaz[6] and Francesco Zulian[5]. [1]Anna Meyer Children's Hospital, Florence, Italy, [2]Department of Medical and Surgical Specialties, Section of Otolaryngology, University of Padua, Italy, [3]Department of Pediatrics, University of Florence, Italy, [4]Department of Pediatrics, University of Padua, Italy, [5]Universita Di Padova, Padova, Italy, [6]University of Firenze, Firenze, Italy

Background: Cogan syndrome (CS) is a vasculitis characterized by systemic, ocular and vestibuloauditory symptoms. Only a few pediatric patients have been reported in literature so far and few information is available as far as disease course and outcome.

Methods and Materials: We describe three caucasian children (1M, 2F) with CS and compare them with the data of the literature. We reviewed the clinical records of patients with defined diagnosis of CS followed at two Pediatric Rheumatology Institutions and patients with pediatric-onset CS from a database search in Medline. Data collected included clinical features, ocular and ENT evaluations at onset and during the disease course, laboratory variables, treatment and outcome.

Summary of the Results: During the period 1990–2009, three patients with definite diagnosis of CS have been followed in our units and 20 more patients have been reported in 16 publications. In the whole cohort of 23 cases, the mean age at onset was 11.6 years (range 4–18) and the F:M ratio was 2:1. Half of the patients had systemic symptoms at onset such as fever (30%), or musculoskeletal pain (26%), 78% had ocular symptoms such as red eye, often with photophobia (57%), as presenting signs of interstitial keratitis (26%), episcleritis (9%) or uveitis (4%), conjunctivitis (17%), and visual loss (4%). Audiovestibular symptoms were present in 74% of the patients, most of them (65%) had sensory neural hearing loss (SNHL) and 35% vestibular dysfunction such as vertigo, vomiting or ataxia. Cardiac involvement, mainly aortic insufficiency, and skin rash were found in 22% and 13% of the patients, respectively. Treatment consisted in corticosteroids (83%), methotrexate (30%), cyclophosphamide or MMF (4%). After a mean 4 year follow-up, 35% of the patients were in complete remission with no organ damage, the remaining reported residual deafness or SNHL (35%), irreversible cardiac complications (13%), vestibular dysfunction (4%), ocular damage (4%), or chronic hepatitis (4%). Only one patient died one year after disease onset for subaracnoid hemorrhage.

Conclusions: Cogan syndrome is a rare, severe and, probably, under diagnosed vasculitis of the pediatric age. In older children with systemic symptoms, red eye, vertigo and/or hearing loss CS should be always considered in the differential diagnosis since a prompt treatment may prevent irreversible organ damage.

Decreased Vitamin D Levels in Children and Adolescents with Systemic Lupus Erythematosus. Octavio Augusto Bedin Peracchi[1], Regina Viviane Munekata[2], Maria Teresa Ramos Ascensão Terreri[2], Roseli Oselka Sacardo Sarni[2], Marise Lazaretti[2] and Maria Odete Esteves Hilario[2]. [1]Universidade Federal de São Paulo, São Paulo, Brazil, [2]Universidade Federal de São Paulo, Brazil

Background: The vitamin D deficiency has been related to the development of autoimmune diseases. There are only a few studies in the literature evaluating the nutritional status related to vitamin D in pediatric patients with rheumatic diseases.

Objectives: To evaluate the levels of 25(OH)D3 and to correlate them with disease activity, use of medications (chloroquine and glucocorticoids),

calcium and vitamin D intake, bone mineral density and parathormone (PTH) levels.

Methods: Determination of 25(OH)D3 and PTH was performed during the spring in 30 children and adolescents with Systemic Lupus Erythematosus according to the Hochberg classification criteria (1997). The patients with or without disease activity, with any clinical manifestation, in use of any medication, and with minimal disease follow-up of 6 months were compared to 30 healthy individuals age and gender matched. Controls (n= 30) were not on any medication and had no calcium metabolism impairment. Vitamin D normal levels were considered between 20–32 ng/mL. Bone mineral densitometry was also performed in the patients.

Results: We found significant different levels of 25(OH)D3 between patients and controls (mean 18.79 ng/mL and 27.18 ng/mL respectively—$p<0.001$). Fifteen (50%) patients and 6 (20%) controls had low levels of 25(OH)D3 (< 20 ng/mL). There was no association between PTH and vitamin D levels in patients and controls (mean of 35.86 pg/mL and 31.26 pg/mL respectively; $p=0.268$). Only one patient with low level of vitamin D presented with hyperparathyroidism. We found no association between disease activity when considered SLEDAI > 1 or SLEDAI > 4 and low levels of vitamin D. Eleven (37%) patients were taking vitamin D supplementation and 5 of them (17%) had low levels of vitamin D. Seven patients (23%) presented a bone mineral density under −2.0 SD and mean levels of 25(OH)D3 of 14.70 ng/mL (9.61–19.88) with no significant association between them ($p=0.456$).

Conclusion: Children and adolescents with lupus may present low serum levels of vitamin D, however with no association with disease activity, higher levels of PTH and bone mineral density alterations.

Does Atorvastatin Reduce Progression of Carotid Intimal Medial Thickening (CIMT) in Childhood SLE? Results from the Atherosclerosis Prevention in Pediatric Lupus (APPLE) Trial: A Multicenter, Randomized, Double-Blind Placebo-Controlled Study. Laura E. Schanberg[3], Christy I. Sandborg[4], Huiman X. Barnhart[3], Stacy P. Ardoin[2], Eric Yow[3], Gregory W. Evans[5], Kelly L. Mieszkalski[3], Normal T. Ilowite[2], Anne Eberhard[2], Lisa F. Imundo[1], Yukiko Kimura[2], Emily Von Scheven[2], Earl Silverman[2], Suzanne L. Bowyer[2], Lynn Punaro[2], Nora G. Singer[2], David D. Sherry[2], Deborah McCurdy[2], Marisa Klein-Gittelman[2], Carol A. Wallace[2], Richard Silver[2], Linda Wagner-Weiner[2], Gloria C. Higgins[2], Hermine I. Brunner[2], Lawrence Jung[2], Jennifer B. Soep[2], Ann Reed[2], Charles Tegler[6] and APPLE Investigators[2]. [1]Childhood Arthitis and Rheumatology Research Alliance, New York, NY, [2]Childhood Arthritis and Rheumatology Research Alliance, CARRA, [3]Duke Univ Medical Center, Durham, NC, [4]Stanford Medical Center, Stanford, CA, [5]Wake Forest Univ, [6]Wake Forest University

Background: SLE patients are at markedly elevated risk for premature cardiovascular events. Given lifelong exposure to increased atherogenic potential, children and adolescents with SLE are ideal targets for prevention. Statins reduce cardiovascular morbidity and mortality in the general population, but their efficacy in preventing atherosclerosis progression in pediatric SLE is unknown.

Methods: Children and adolescents with SLE, aged 10–21y, from 21 CARRA sites were randomized to receive atorvastatin (10–20 mg based on weight) or placebo and followed for 3 years. All subjects met 1997 ACR criteria for SLE. Exclusion criteria included nephrotic syndrome, cholesterol >350, creatinine >2.5, CPK >3X nl or liver functions >2X normal. Background therapy included hydroxychloroquine, aspirin, folate, risk factor counseling, the AHA Therapeutic Lifestyle Changes diet, and routine SLE management. The primary endpoint was rate of progression of mean common CIMT, a surrogate marker for atherosclerosis, using a standardized ultrasound protocol read by a central core. Secondary endpoints included progression of mean maximal CIMT and lipid levels. The total sample size of 220 provided 83–98% power to detect a 0.0045mm/y difference in mean-common CIMT progression rates between groups with an overall 0.05 type I error for several scenarios based on the estimated parameters for mean-mean common CIMT correlation of 0.6 between time points and SD (0.038–0.047mm), dropout (11.6–23.1%), and compliance rate (71–84%).

Results: A total of 221 subjects were randomized between 9/03–11/06 with 183 (83%) of them completing the trial. See table for baseline characteristics.

APPLE BASELINE CHARACTERISTICS (N=221)			
Age (SD)	15.7 (2.6)	CV RISK FACTORS	
% female	83%	CRP (SD)	3.6 mg/L (14)

SD – standard deviation, HX – history of
*Some subjects self reported more than one category

There were 138 SAEs with 7 considered related to study drug. Rhabdomyolysis was not reported. Database was locked on 6/21/10 and the final results of primary and secondary endpoints will be presented.

Conclusions: APPLE is an RCT designed to assess the safety and efficacy of atorvastatin in preventing progression of CIMT in pediatric SLE. APPLE represents the first RCT in pediatric SLE, the first CARRA clinical trial, and the longest study of statins in a pediatric cohort. Preliminary data demonstrate successful enrollment of the target population and completion of trial within study parameters. The data quality indicates that study results will determine whether use of statins in children and adolescents with SLE decreases CIMT progression and the risk of premature atherosclerosis.

Environmental Factors Preceding Illness Onset Differ in Phenotypes of the Juvenile Idiopathic Inflammatory Myopathies. Lisa G. Rider[11], Lan Wu[12], Gulnara Mamyrova[4], David D. Sherry[13], Maria D. Perez[9], Carol A. Wallace[14], Lisa F. Imundo[6], Catherine A. Bingham[3], Lawrence S. Zemel[1], Carol B. Lindsley[8], Rafael F. Rivas-Chacon[7], Patience H. White[11], Robert Rennebohm[12], Michael Henrickson[10], Ira N. Targoff[5], Frederick W. Miller[2] and Childhood Myositis Heterogeneity Study Group[12]. [1]Connecticut Childrens Med Ctr, Hartford, CT, [2]National Institute of Environmental Health Sciences, NIH, Kennsington, MD, [3]NIEHS, NIH, Zionsville, PA, [4]NIEHS, NIH, Washington, DC, [5]NIEHS, NIH, Oklahoma City, OK, [6]NIEHS, NIH, New York, NY, [7]NIEHS, NIH, Miami, FL, [8]NIEHS, NIH, Kansas City, KS, [9]NIEHS, NIH, Houston, TX, [10]NIEHS, NIH, Cincinnati, OH, [11]NIEHS, NIH, Bethesda, MD, [12]NIEHS, NIH, [13]The Children's Hospital of Philadelphia, Philadelphia, PA, [14]University of Washington and Seattle Childerns's Hospital, Seattle, WA

Purpose: We examined whether certain environmental factors are temporally associated with the onset of juvenile idiopathic inflammatory myopathies (JIIM) and differ among age, ethnic, disease course and autoantibody phenotypes.

Method: Physicians completed questionnaires regarding documented infections, medications, immunizations, and an open-ended question about other noted exposures within six months before illness onset for 285 patients with probable or definite JIIM. Medical records were available and reviewed

for 81% of cases to confirm the exposure. Myositis autoantibodies were identified by validated immunoprecipitation methods.

Results: Sixty percent of JIIM patients had a reported exposure within six months before illness onset. Most patients (62%) had one recorded exposure, 26% had two, and 12% had 3–5 exposures. Patients older than the median age at diagnosis, those with a longer delay to diagnosis and those with anti-signal recognition particle autoantibody had a higher frequency of documented exposures (OR 3.4–31). Infections were the most common exposure and represented 44% of the total number of reported exposures, with respiratory infections being the most common (66%). Pharyngitis was the most frequent specific infection (22%) and was more frequent in older patients (OR 2.7). Noninfectious exposures included medications (18%), immunizations (11%), stressful life events (11%), unusual sun exposure (7%), and others including, chemicals, animal contact, weight training, and dietary supplement use (<5% each). Exposures varied by age at diagnosis, delay to diagnosis, race, disease course, and the presence of certain myositis autoantibodies. Children younger than the median age at diagnosis, those with ≤4 months delay to diagnosis, or with a polycyclic illness course were more likely to have an infection within six months of diagnosis (OR 1.8–4.3), whereas older children had a higher frequency of stressful life events prior to illness onset (OR 3.5). Caucasian patients and those without a myositis autoantibody had a higher frequency of infections in the six months prior to illness onset (OR 2.7 – 3.9). Older children were more likely to have two drug exposures prior to illness onset (OR 18.9), and 36% of these were potentially myopathic or photosensitizing agents.

Conclusion: While infections were the most common exposure temporally associated with the onset of JIIM, supporting prior findings, many other exposures, including non-infectious agents, were also documented within six months before disease onset. The JIIM may be related to multiple exposures, and these exposures appear to vary among illness phenotypes. This exploratory study has identified a number of environmental exposures that are potential risk factors and suggests that controlled investigations of independent populations be performed to confirm and expand upon these findings.

High Prevalence of Inflammatory Myositis in Patients with Pediatric Systemic Lupus Erythematosus in a Southeastern US State. Jessica L. Record[3], Timothy Beukelman[2] and Randy Q. Cron[1]. [1]Children's Hospital of Alabama, Birmingham, AL, [2]University of Alabama-Birmingham, Birmingham, AL, [3]University of Alabama-Birmingham, Birmingham, AL

Background: Inflammatory myositis has traditionally been recognized as a feature in 5–11% of adult systemic lupus erythematosus (SLE) patients. The aims of this study were to determine the prevalence of myositis in a cohort of pediatric SLE patients from a single center in a southeastern US state, to compare this rate with the reported prevalence in the medical literature, and to evaluate clinical factors for possible association with myositis.

Methods: Records of 55 patients with the diagnosis of SLE who had been evaluated by the Division of Pediatric Rheumatology and satisfied at least 4 out of 11 ACR criteria for the classification of SLE were identified at an academic children's hospital in the southeastern US. Their electronic medical records were reviewed and information was collected regarding general demographics, complement levels, muscle enzymes, musculoskeletal exam, and clinical and serological manifestations. For the purpose of this study, patients were defined as having inflammatory myositis if they satisfied one of the following categories: 1) Proximal muscle weakness on physical exam with evidence of muscle edema on MRI (T2 or STIR image) of the lower extremity; 2) Proximal muscle weakness on physical exam with an elevation in one of the following muscle enzymes: CK, AST, aldolase, or LDH; or 3) Patient reported muscle weakness or muscle pain (without weakness noted on physical exam) and an elevated CK. The prevalence rate of myositis in our cohort was compared to previously reported rates using the chi-square test. Fisher's exact test and one-way ANOVA were used to determine possible associations between myositis and clinical and laboratory factors.

Results: The mean age of our cohort at the time of this study was 16.4 years. The mean age of onset of initial SLE symptoms was 13.2 years. 87.3% were female and 74.5% were African-American. Inflammatory myositis was present as a feature of SLE in 31% (n=17) with a 95% confidence interval of 19 to 45%, which is statistically different from the reported rates of 5–11% ($p<0.0001$). Myositis was shown to be positively associated with anti-ribonucleoprotein (RNP) antibodies ($p=0.009$) and anti-Smith (Sm) antibodies ($p=0.06$). Negative associations with myositis were the presence of anti-double stranded DNA antibodies ($p=0.02$) and hematological disorders ($p=0.02$).

Conclusions: In this southeastern US state, pediatric SLE myositis is present at a statistically higher rate than previously published values of adult SLE myositis. The association of myositis with anti-RNP antibodies is consistent with the medical literature. The presence of myositis can serve as a warning sign for a potential SLE flare and a marker of the effectiveness of a treatment regimen. The presence of both anti-RNP and anti-Sm antibodies further highlights the significant overlap SLE has with other autoimmune diseases such as mixed-connective tissue disease and the challenges that come with appropriately classifying and treating these overlap patients.

Infliximab for the Treatment of Intravenous Immunoglobulin Resistant Kawasaki Disease in Chinese Children. F. Q. Wu[1], X. M. Hu[2], Y. L. Zhang[2] and L. P. Yang[2]. [1]Capital Institute of Pediatrics, Beijing, China, [2]Capital Institute of Pediatrics

Objectives: Evaluate the efficacy and safety of Infliximab in patients with Kawasaki disease (KD) who were unresponsive to intravenous gamma globulin (IVIG) treatment.

Methods: The diagnosis of KD was made according to the diagnostic guidelines for Kawasaki disease (5th revised edition) of the Kawasaki Disease Committee in Japan and APP/AHA diagnostic guidelines for Kawasaki disease, published in 2004. Pediatric subjects diagnosed with KD with coronary artery lesions, and who failed treatment with IVIG, were enrolled in the study. Subjects were given a single infusion of Infliximab of 5–6mg/kg. The patients were followed up for 21 weeks. The persistence time of fever, CRP, ESR, ultrasonic cardiogram and infusion reaction were observed.

Results: A total of 12 subjects were enrolled in the study from May 2009 to Jan 2010 in Department of Rheumatology of Capital institute of Pediatrics, including seven boys and five girls. The mean age was 23.3 months and the mean duration of the symptoms was 6.6 days. Seven of the subjects were <1 year. All 12 subjects were treated with IVIG 2–3 times. Injectable dexamethasone was used in 4 subjects for fever. All subjects had taken aspirin (30mg/kg) orally before treatment with Infliximab. The Clinical and laboratory recovery times are listed in the table below. The subjects' temperature decreased within 12 hours after treatment with Infliximab. The CRP, ESR, blood cell counts and mild-to-moderate coronary artery lesions recovered within 8 weeks. No infusion reactions were observed.

Conclusion: Infliximab appears to have good efficacy and safety in the treatment of Kawasaki syndrome in patients who were unresponsive to treatment with IVIG.

Infliximab for the Treatment of Intravenous Immunoglobulin Resistant Kawasaki Disease in Chinese Children

	Patients (n)	Recover time
Clinical manifestation		
Fever	12	12–48 hours
Erythra	10	48 hours
Laboratory examination		
Increase of white cell count	12	7–10 days
Increase of platelet	12	3 months
Increase of CRP	12	7–10 days
Increase of ESR	12	7–10 days
Decrease of serum albumin	8	7 days
Increase of ALT	5	4–6 weeks
Increase of AST	5	4–6 weeks
Electrocardiogram		
T wave change	8	2 weeks
=* atrioventricular block	4	2 weeks
Echocardiography		
Left coronary artery distension	5	4–12 weeks
Left anterior descending distension	5	4–12 weeks
Circumflex coronary artery distension	2	4–12 weeks
Right coronary artery distension	1	4–12 weeks
Bilateral coronary artery distension	6	4–12 weeks
Mild coronary aneurysm	8	4–12 weeks

Recovery time of clinical manifestation and laboratory examination

Juvenile Fibromyalgia: Responsiveness of Tools, Greatest Areas of Impairment, and Impact of an Aerobic Exercise Program. Nadia J. C. Luca[2], Brian M. Feldman[3], Larisa Tshantshapanyan[4], Lusine Abrahamyan[4], Samantha Stephens[4], Nicolette Bradley[4], Jane Schneiderman[4], Virginia Wright[1] and Shirley M. L. Tse[3]. [1]Bloorview Kids Rehab, Bloorview Research Institute, [2]Hospital for Sick Children, Toronto, ON, Canada, [3]The Hospital for Sick Children, Toronto, ON, Canada, [4]The Hospital for Sick Children

Background: Patients with juvenile fibromyalgia (FM) have generalized MSK pain, fatigue, and poor sleep, as well as high rates of school absence and functional disability.

Objectives: This study determines which areas of functioning are most impaired in children with FM, as well as the effect of an aerobic exercise program on ability to do specific activities. Also, the responsiveness of various evaluation tools in juvenile FM was evaluated.

Methods: FM patients aged 8–18 were asked to complete the FM Impact Questionnaire and Functional Status and Symptom Questionnaire (FSSQ), as well as other questionnaires, while participating in a randomized, 12-week trial of either aerobic exercise or control (qigong). Data were collected before and after the intervention. A repeated measures analysis of variance was used to compare the rates of change in ability between the groups after the exercise intervention.

Results: Thirty patients participated in the study, and 24 patients completed the program (12 in aerobic and 12 in qigong group). At baseline, a minority of patients reported difficulties with daily function (homework 11%, chores 23%) and social function (31%); whereas, on average, 56% reported difficulty with physical function. Specific activities associated with great difficulty or inability included playing sports after school (43%), running long distances (35%), and participating in gym class (25%). The most prominent symptom during physical activities was pain. Subjects also reported difficulty with waking up for school and attending overnight camp (37% and 26% respectively), mostly due to fatigue and sleep difficulties.

After the exercise intervention, subjects in both groups showed improvement in function. However, when compared with subjects in the qigong group, those in the aerobic group demonstrated a significantly greater improvement in ability to run long distances ($P=0.023$), attend school every day ($P=0.036$), and complete homework ($P=0.003$).

Greatest responsiveness, as measured by effect size, was associated with PedsQLpain2, HR QOL, C-HAQ (total score), and the FSSQ questionnaires.

Conclusions: Juvenile FM causes significant difficulties in function, mostly seen in physical activities and activities affected by poor sleep. Daily and social activities tend to be relatively spared. The most prominent symptoms experienced are pain, fatigue and sleep difficulties. Aerobic exercise was found to have greatest impact in improving physical and daily functions but, in our sample, did not affect social function. The FSSQ, as well as other evaluation tools for juvenile FM, has a strong responsiveness.

Juvenile Localized Scleroderma of the Face: A Neuro-Cutaneous Disease? Francesco Zulian[2], Mattia Parolin[3], Fabio Vittadello[3], Milena Calderone[3], Giorgia Martini[3] and Susanne Ullman[1]. [1]Bispebjerg Hospital, Copenhagen, Denmark, [2]University of Padua, Padova, Italy, [3]University of Padua

Background: Neurological involvement has been reported in few case reports of patients with juvenile localized scleroderma of the face (JLS-F). Aim of the study was to systematically investigate frequency, clinical and radiological features of CNS involvement in JLS-F.

Methods: A cohort of consecutive patients with JLS-F (including *en coup de sabre* (ECDS) and Parry Romberg syndrome (PRS)) underwent a comprehensive clinical evaluation, EEG and brain MRI. All radiographic films were analyzed by 2 neuroradiologists who were blinded to the patients' identity and clinical records. Parenchymal lesions were assessed by a standardized protocol (1) and classified by number, laterality, gray or white matter involvement and concordance with the skin lesion.

Results: 34 patients with JLS-F entered the study, F:M ratio was 1.4:1, mean age at disease onset 8,6 years. Twenty nine patients (85.3%) had linear scleroderma of the face, 5 (14.7%) presented a mixed subtype, 23 patients (67.6%) had ECDS, 11 (32.4%) PRS. CNS involvement was found 21 (61.8%) patients, 11 (32,4%) had neurological symptoms such as chronic headache (5), seizures (3), hemiparesis (1), behavioural abnormalities (1) and cranial nerve palsy (1). Ten patients (29,4) presented MRI abnormalities without symptoms. EEG was abnormal in 5 patients (14,7%), all symptomatic and/or with MRI changes. Cerebral MRI resulted abnormal in 17/34 patients (50%). Twelve patients underwent more than one brain MRI which worsened in 5 patients (41,7%), unchanged in 5 (41,7%) and persisted normal in 2 (16.6%). Eight patients had a single brain lesion, 9 a multiple pattern. In 88,2% the site of skin and neurologic lesions were concordant. White matter involvement was present in 10/17 (58,8%), lesions extended to the grey matter in 7 (41,2%).

Four group of patients have been identified: group 1 patients with neurological symptoms and organic brain lesions (mainly multiple with white and grey matter involvement) concomitant or following the onset of the scleroderma skin lesion (no.7), group 2 (no.10) patients with just organic brain lesions following the skin lesions by 1–18 years, mainly single white matter lesions concordant with the site of skin lesion, group 3 (no. 4) patients with neurological symptoms but no organic brain lesions and group 4 (no.13) patients with no neurological involvement.

Conclusion: The high prevalence of neurological involvement in JLS-F reinforces the hypothesis of a possible pathogenetic link CNS-skin in localized scleroderma and confirms the need for a careful clinical and radiological monitoring of every patient since the disease onset.

Localized Scleroderma Therapy: When Would Be a Good Time To Stop? Thaschawee Arkachaisri[1] and Kathryn S. Torok[2]. [1]KK Women's and Children's Hosp, Singapore, Singapore, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA

Background: Localized Scleroderma (LS) is the most common form of juvenile scleroderma. Its long-term physical and psychological impact continues to cause significant disability. Different therapy options were reported with inconsistent results. Longterm followup (FU) data after the disease is under control is unknown. Combined high dose SC methotrexate and a weaning dose of oral corticosteroids have been shown to be effective in our pediatric LS cohort.

Purpose: We report a prospective data on the longterm outcome of a single center treatment protocol in a pediatric LS cohort and propose the duration of therapy for LS.

Methods: LS patients were recruited from the Scleroderma Clinic at the Children's Hospital of Pittsburgh. Patients with active disease, defined as those with erythematous lesions, and/or new lesions, or expansion of existing lesions; were started on oral prednisone 2 mg/kg/day (max 60mg/day) and SC methotrexate (MTX) at 1 mg/kg/week. Prednisone was weaned to reach 1 mg/kg/day by the end of 6–8 weeks, and then further weaned to 0.25 mg/kg/day to complete 12 months of steroid therapy. MTX was continued for a full 24 months of SC therapy with subsequent oral therapy for 12 more months. The disease outcome parameters used to assess effectiveness of therapy were the modified LS Skin Severity Index

(mLoSSI) and the physician global assessment of disease activity (PGA). All patients were followed every 4–8 weeks with appropriate therapy adverse reaction monitoring. Flare was defined by the reoccurrence of erythematous lesions, and/or new lesions, or expansion of existing lesions. Kaplan-Meier analysis was used to analyzed recurrence rate and survival-time data.

Results: Thirty-nine patients were included (70% female, 95% Caucasians). LS Subtypes are–4 plaque morphea, 14 linear scleroderma (Li), 6 *en coup de sabre*, 3 subcutaneous morphea (SqM), 5 generalized morphea and 7 mixed LS. Median age at onset was 7.9 years (IQR 4.5–11.6). Median duration of FU was 36.9 mo(range 8.7–105.8). Clinical improvement (mLoSSI and PGA) was demonstrated at the median of 1.1 mo (IQR 0.5–1.9). No patients developed flare during therapy. During FU period, 4 patients flared(3 Li and mixed LS and 1 SqM; 3 females) after discontinued therapy after completed 36 mo and in remission. Median duration to flare was 4.7 mo (range 0.99–10.1). This gives the flare incidence 0.0034 person-months. Cumulative probability risk of recurrence is estimated from our cohort that about 25% and 50% of flare within 46 and 54 mo, respectively. Over the study period(up to 78 mo), the probability of flare does not reach 75%. There was no major complication noted.

Conclusion: The uniform treatment protocol given to all LS patients who required systemic therapy in our center enables us to assess the longterm outcome of the regimen more accurately. The therapy is effective in controlling the disease, however, after discontinuing therapy, 10% flare within 6 months. We proposed to continue the therapy longer, at least 48–54 months in order to decrease the rate of flare.

Longitudinal Study on Growth Failure and Height Deflection in Juvenile Systemic Lupus Erythematosus (JSLE): The Result of a Prospective Multicentre PRINTO Study. Marite Rygg[3], Angela Pistorio[3], Angelo Ravelli[3], Mohamad Maghnie[3], Natascia Di Iorgi[3], Erkan Demirkaya[3], Srdjan Pasic[3], Huri Ozdogan[3], Brigitte Bader-Meunier[3], Carlos Henrique M. Da Silva[3], Liora Harel[3], Maria Rosa Roldan Molina[3], Helena Canhao[3], Johannes Roth[3], Carine Wouters[3], Judith Barash[3], Rym Hajri Ben Ammar[3], Christina Dracou[3], Sylvie Gandon-Laloum[3], Alberto Martini[2] and Nicolino Ruperto[1]. [1]IRCCS G. Gaslini/Università degli Studi di Genova, Genova, Italy, [2]IRCCS G. Gaslini/Università degli Studi di Genova, [3]PRINTO

Background: Growth failure is a unique feature of JSLE, caused by long-term disease activity, side effects of drugs, and/or co-morbid conditions.

Objective: The goal of the study was to obtain longitudinal data on growth in a large-scale, multi-national cohort of patients with JSLE followed for 26 months.

Materials and Methods: This prospective, multi-centric study on JSLE was carried out in 39 countries from Northern and Southern Europe, Latin America, US and Asia between 2001 and 2004. Patients seen at the participating centers with diagnosis of JSLE, at active phase, and age younger than 18 years at enrollment were included.

Results: Data was collected from 557 patients with JSLE. There was a significant reduction in parent-adjusted height z score with time in females and males ($p<0.0001$) with a significant gender difference ($p<0.0001$), male height being most affected. Median BMI z score peaked at 6 months and was still significantly above baseline after 26 months ($p<0.01$) with no gender difference. Standardized height reduction was inversely related to age at disease onset in females, especially pronounced at onset age <8 years. Females with onset age <12 years had a median parent-adjusted height z score of -0.87 with no catch-up growth. At the end of the study, growth failure was seen in 14.7% of the females and 24.5% of the males. Height deflection (less than-0.25/year) was found in 20.7% of the females and 45.5% of the males.

Conclusions: The longitudinal effect on height is modest in JSLE females with age at onset ≥ 12 years. In spite of all our knowledge and careful treatment, females <12 years at onset and males are still at risk of experiencing a considerable height loss during the course of the disease.

Long-Term Follow Up of Hyper IgD Syndrome: A National Multicentre Study. Silvia Federici[8], Alberto Tommasini[6], Antonella Meini[7], Giuseppina Calcagno[5], Francesco Zulian[2], Rita Consolini[3], Martina Finetti[8], Luciana Breda[1], Roberta Caorsi[8], Romina Gallizzi[5], Maria Alessio[4], Alberto Martini[8] and Marco Gattorno[8]. [1]Clinica Pediatrica, Divisione Reumatologia Pediatrica, Ospedale Policlinico di Chieti, [2]Dipartimento A.I. di Pediatria, Università di Padova, [3]Dipartimento di Medicina della Procreazione e dell'Eta' Evolutiva, Università di Pisa, Italy, [4]Dipartimento di Pediatria, Università Federico II, Napoli, Italy, [5]Dipartimento di Scienze Pediatriche, AOU "G. Martino", Messina, [6]IRCCS Burlo Garofolo, Trieste, [7]Unità di Immunologia e Reumatologia Pediatrica, Spedali Civili, Brescia, [8]UO Pediatria II Istituto G. Gaslini, Genova, Italy

Purpose: Hyper-IgD syndrome (HIDS) is an autosomal recessive disease caused by mutation in the MVK gene. Aim of the study was to analyze the long term follow-up of a group of children and young adults affected by HIDS.

Patients & Methods: The first 10 exons of MVK genes were analyzed in 720 consecutive patients with periodic fever by means of denaturing high-performance liquid chromatography (DHPLC) and DNA sequencing. 40 patients carried 2 mutations of the MVK gene. Detailed clinical information were collected at the time of molecular analysis and last follow-up through a standardized questionnaire. Spontaneous disease course was classified as follows: i) resolution (no episodes in the last 6 months), ii) improvement (reduction of more then 30% of fever episodes) iii) stationarity iv) worsening (increase frequency of fever episodes or appearance of new major clinical manifestation).The Child Health Questionnaire (CHQ-PF 50) was used to assess the health related quality of life

Results: the mean age of diseaseonset was 0.7 yrs (range1 months-3 yrs). At baseline, mean duration of fever episode was 4.7 days. The clinical features associated to fever episodes were abdominal pain (97.5%), cervical lymphadenopaty (97.5%) with pain (80%), diarrhea (77.5%), erythematous pharingitis (75%), vomiting (65%) and aphtous stomatitis (57.5%). So far, data on follow-up are available for 24 patients. The mean follow-up time was 13.8 yrs (range 2.3–38.2 yrs). Steroid on demand was effective in treating fever episodes. Ten patients showed a significant spontaneous reduction of the frequency of fever episodes. In the remaining 14 patients the frequency of fever episodes was stable (7 patients) or increased (7 patients). Complete resolution was achieved after introduction of Anakinra (2 patients) and tonsillectomy (1 patient). One patients improved after Anakinra, 2 after tonsillectomy. Two patient did not respond to Etanercept. Health–related quality of life at follow-up was generally affected when compared to a cohort of healthy age-matched individuals.

Conclusions: even if a relevant percentage of HIDS patient show a spontaneous amelioration of the disease, most of them display a tendency towards a persistence of fever episodes that affect their quality of life.

Measuring Changes in Calcifications in Juvenile Dermatomyositis (JDM) Using Single Slice Computerized Tomography (CT). Maria F. Ibarra[5], Cynthia Rigsby[3], Gabrielle Morgan[2], Deli Wang[1] and Lauren M. Pachman[4]. [1]Children's Memorial Research Center's Biostatistics Core, Chicago, IL, [2]Clinical Immunology, Children's Memorial Research Center (CMRC), Chicago, IL, [3]Division of Radiology, Children's Memorial Hospital (CMH), Feinberg School of Medicine, Northwestern University, Chicago, IL, [4]Division of Rheumatology and Clinical Immunology, Children's Memorial Research Center (CMRC), Feinberg School of Medicine, Northwestern University, Chicago, IL, [5]Division of Rheumatology, Children's Memorial Hospital (CMH), Feinberg School of Medicine, Northwestern University, Chicago, IL

Objective: To determine the utility of single slice CT to measure change in the volume of calcifications in patients with JDM over time.

Methods: Children with definite/possible JDM and severe calcifications had at least two CT scans over a 2 year period. Severe calcifications were defined as a deep sheet- like deposits within intramuscular fascia, and were identified by physical examination and/or previous x rays. The limited four slice CT study focused on the area of greatest calcium burden. The area enclosing the calcification was calculated from the CT images, using a CT post processing workstation. Demographic and baseline characteristics were summarized by descriptive statistics. Generalized linear models were applied to analyze changes in the volume of calcifications and their association between clinical variables including DAS (Disease activity score) skin, DAS muscle, and the number of nailfold ERL (end row capillary loops). Data analysis used SAS 9.2.

Results: 11 children with JDM and severe calcifications were recruited. 8 patients were female; 8 were Caucasian. The average age was 13.84 years (+/− 4.9 years). The average duration of untreated disease at JDM diagnosis was 7.57 (+/− 7.2) months, and they all had active disease for an average=100 months +/− 65. The volume of calcifications changed significantly over time ($p<0.0001$). Decrease in calcification volume was significantly associated with decrease in DAS skin ($p=0.0002$) and improvement in the number of nailfold ERL ($p=0.0025$) but not with change in DAS muscle.

Conclusion: This limited CT technique provides objective measurement of the volume of calcifications over time that may be helpful as a research tool to monitor progression and regression of dystrophic deposits in JDM and other rheumatic diseases.

Odontostomatologic Involvement in Juvenile Localized Scleroderma of the Face. Sabina Trainito[5], Troels Herlin[4], Thomas Klit Pedersen[3], Giorgia Martini, Chiara Scibetta[2], Giuseppe Fioretti, Vittorio Favero, Stefano Puggina[6], Lorenzo Favero and Francesco Zulian[1]. [1]Padova, Italy, [2]Department of Dentistry, Gnatology Unit, University of Padova, Italy, [3]Department of Orthodontics and Radiology, University of Aarhus, Denmark, [4]Department of Pediatrics, Rheumatology Unit, University of Aarhus, Denmark, [5]Department of Pediatrics, Rheumatology Unit, University of Padova, Padova, Italy, [6]Radiology Institute, University of Padova, Italy

Background: Juvenile Localized scleroderma (JLS) is the most frequent form of scleroderma in childhood. The linear facial subtype (known also as scleroderma en coup de sabre and Parry-Romberg syndrome) can lead to significant aesthetical and functional abnormalities. Despite their quite frequent clinical observation, the odontostomatologic complications are not thoroughly described in the literature and their management is challenging because of the lack of specific indicators of disease activity and progression. Aim of the study was to describe the clinical features and prevalence of the most frequent odontostomatologic abnormalities of JLS of the face and to propose clinical and radiologic criteria for the assessment and follow-up of these complications.

Methods: We performed a cross-sectional, multicenter study involving a multidisciplinary team formed by pediatric rheumatologists, orthodontists and radiologists. Selected patients with a diagnosis of JLS of the face underwent a comprehensive rheumatologic evaluation, dental examination (intraoral and gnatologic examination, orthodontic casts, photographs), conventional radiology (orthopantomography, frontal and lateral skull teleradiography) and Cone Beam Computed Tomography (CBCT). An Odonto-Maxillo-Facial score (OMF-score), based on four clinical-instrumental parameters, including facial anomalies (soft tissues and bone), dental abnormalities, asymmetry and malocclusion, was applied.

Results: 16 patients, 9 F, 7 M, aged 6.5–21.9 years, were investigated. The mean disease duration was 7.7 years (range 1.4–18.5), 62.5% had extracutaneous complications, 87.5% were in clinical remission. All patients reported at least one odontostomatologic complication. The main alterations were: overgrowth tendency of the lower third of the face (82%), malocclusion (75%), gnatologic alterations (67%), dental anomalies (63%), skeletal asymmetry (50%), bone involvement (50%), slight quantitative reduction of the soft tissues on the affected side (44%) and TMJ involvement (19%). According to the OMF-score, the odontostomatologic involvement was mild in 25% of the patients, moderate in 56% and severe in 19%. No correlation was found between degree of odontostomatologic involvement and disease duration.

Conclusions: A moderate-to-severe odontostomatologic involvement was found in the majority of the patients with JLS of the face. CBCT represents a new technique for a comprehensive assessment and monitoring of bone and soft tissues involvement. We propose a multistep clinical-radiological protocol to standardize the management of the odontostomatologic complications of JLS.

Preliminary Criteria for Global Disease Flares in Juvenile Systemic Lupus Erythematosus (jSLE). Rina Mina[8], Michael Beresford[12], B. Anne Eberhard[13], Edward H. Giannini[3], Deborah M. Levy[15], Clarissa Pilkington[10], Marilynn G. Punaro[14], Angelo Ravelli[11], Andreas O. Reiff[2], Claudia Saad-Magalhaes[16], Laura E. Schanberg[9], Lori B. Tucker[1], Marisa S. Klein-Gitelman[4], Shannen L. Nelson[6], Jamie Eaton[5], Jun Ying[17] and Hermine I. Brunner[7]. [1]BC Childrens Hospital, Vancouver, BC, Canada, [2]Childrens Hosp LA MS60, Los Angeles, CA, [3]Childrens Hosp Med Ctr, Cincinnati, OH, [4]Childrens Mem Hosp/NW Univ, Chicago, IL, [5]Cincinnati Children's Hospital, [6]Cincinnati Children's Hospital, Cincinnati, OH, [7]Cincinnati Children's Hospital Medical Ctr, Cincinnati, OH, [8]Cincinnati Children's Med Ctr, Cincinnati, OH, [9]Duke Univ Medical Center, Durham, NC, [10]Great Ormond Street and University College London Hospitals, [11]IRCCS G Gaslini, [12]Royal Liverpool Children's Hospital, [13]Schneider Children's Hospital, New Hyde Park, NY, [14]Texas Scottish Rite Hospital for Children, Dallas, TX, [15]The Hospital for Sick Children, Toronto, ON, Canada, [16]UNESP, [17]University of Cincinnati

Background: Widely accepted valid, reliable and feasible flare criteria to assess the effects of new medications and the benefits of current treatments in jSLE are lacking.

Objectives: Develop accurate flare criteria for jSLE by employing consensus formation methodology and statistical approaches.

Methods: As part of a consensus formation process, an international group of pediatric rheumatology experts (n=138) were randomized to rate a total of 400 different patient profiles that were abstracted from prospective jSLE cohorts. jSLE flare descriptors deemed important, as per previous Delphi surveys (patient global assessment, physician global assessment, disease activity score, health status, proteinuria, anti-dsDNA antibody titer, ESR, complement C3 and C4), were considered when generating candidate flare algorithms, using various percentage changes of the flare descriptors, examination of flare criteria used in adult SLE, multinomial logistic regression, and *Classification and Regression Tree (CART).* For each candidate flare algorithm overall accuracy, sensitivity and specificity was calculated, using the consensus of the profile raters (minor flare, moderate flare, major flare, no flare) as criterion standard. An international consensus conference was held to rank the generated candidate flare algorithms following the process previously suggested by the ACR Criteria Subcommittee (consensus level 75%).

Results: A total of 2,995 expert ratings were available for analysis (survey response rate 70%). Consensus was reached that jSLE flare criteria derived by multinomial logistic regression or CART analysis are most suitable to measure jSLE flares. The highest ranked such candidate flare criteria consider absolute changes in the score of a disease activity index (SLEDAI or BILAG), the physician global assessment (PGA), spot urine protein/creatinine (P/C) ratio, and ESR when calculating a jSLE flare score. This score is then used to determine the presence of a global flare and to discriminate among categories of flare severity (minor,

moderate and major). The highest ranked preliminary jSLE flare criteria have excellent to outstanding accuracy as measured by the area under the Receiver Operating Characteristic Curve (AUC) (see Table).

Preliminary Criteria for Global Flares (All algorithms use change in variables between follow up-baseline visit)	Accuracy (AUC) Minor Flare	Moderate Flare	Major Flare
A. 0.5 × SLEDAI + 0.45 × P/C ratio + 0.5 × PGA + 0.02 × ESR	0.90	0.92	1.00
B. 0.4 × BILAG + 0.65 × P/C ratio + 0.5 × PGA + 0.02 × ESR	0.89	0.92	0.96
C. 0.4 × SLEDAI + 0.33 × P/C ratio + 0.6 × PGA	0.87	0.92	1.00
D. 0.4 × BILAG + 0.55 × P/C ratio + 0.5 × PGA	0.88	0.92	0.95
E. CART analysis (patient is categorized by highest flare level)	0.89	0.94	0.99
Major Flare: SLEDAI ≥ 10 OR PGA ≥ 6			
Moderate Flare: 7 ≤ SLEDAI ≤ 9 OR P/C ratio ≥ 2.3 OR ESR ≥ 13			
Minor Flare: 3 ≤ SLEDAI ≤ 6 OR 2 ≤ PGA < 6 OR 0.7 < P/C ratio ≤ 2.2			

Conclusions: Consensus has been reached on the preliminary criteria for global flares in jSLE. Prospective validation of these criteria is needed to assess their usefulness as outcomes for clinical trials and other research settings.

Preliminary Findings of Functional Magnetic Resonance Imaging (fMRI) Assessments of Specific Cognitive Domains in Childhood-Onset Systemic Lupus Erythematosus (cSLE) Patients and Best-Friend Controls. Blair Dina[3], Aimee Baker[4], Anna Carmela Sagcal-Gironella[4], Marisa Klein-Gitelman[3], Frank Zelko[5], Dean Beebe[1], Darren Gitelman[6], Mark DiFrancesco[2] and Hermine Brunner[4]. [1]CCHMC Division of Behavioral Medicine and Child Psychology, [2]CCHMC Neuroimaging Research Consortium, [3]Children's Memorial Hospital (CMH) Division of Rheumatology, [4]Cincinnati Children's Hospital Medical Center (CCHMC), Division of Rheumatology, [5]CMH Division of Child and Adolescent Psychiatry, [6]Northwestern University, Feinberg School of Medicine

Purpose: 1) To use fMRI to identify brain regions and associated networks that support visuoconstructional ability (VCA), working memory and attention, which are cognitive domains often affected in cSLE. 2) To characterize both behavioral and neuro-functional differences in VCA, working memory, and attention in cSLE patients and matched best-friend controls using fMRI and formal neuropsychological (NP) testing.

Methods: 36 subjects (F:M=28:8; age 10–17 years; 50% African-American, 50% Caucasian; 11% Hispanic), 18 with cSLE and 18 controls matched for age, sex, and race, performed the square completion (SC), N-Back, and continuous performance (CPT) tasks to probe VCA, working memory, and attention, respectively during fMRI. Functional data, acquired at 3 Tesla, consisted of T2*-weighted echo-planar images with TR=3s, 64×64 matrix, 256 mm FOV, and 44 axial 3 mm slices. A high resolution T1-weighted anatomic reference image was acquired for each subject. Average responses were calculated ($p<0.001$ uncorrected) for both cSLE and control groups and analyzed per anatomic regions of interest (ROI). All subjects underwent formal NP testing, measuring the same domains probed by fMRI. Correlation between ROI activations and NP measures was calculated.

Results: Activation was observed in expected brain regions for each task *(Figure 1)*. Performance of the SC task activated both dorsal ("where") and ventral ("what") visual pathways, as expected for a task measuring VCA. The attention task, CPT, produced a similar pattern plus frontal and insular activations. The N-Back task, which probes working memory, activated the dorsolateral prefrontal, parietal, insular and anterior cingulate cortices (ACC). ROI analysis revealed differences between cSLE and control groups. Controls activated more strongly for SC in the insula, ACC and dorsal visual stream. CPT resulted in greater activation for controls in the insula as well as the ventral visual pathway. The ACC activated more in the controls than in the cSLE group for the N-Back task. Group analysis resulted in deactivation in some ROI. Particularly, the hippocampus deactivated more strongly for cSLE than it did for controls when doing the NBack task. Select Z-scores attained from formal NP testing were found to correlate with ROI activation by subject in the cSLE group. A positive correlation was found between the ventral stream ROI activation for the SC task and an NP test for VCA. Activation in the same ROI for the CPT task correlated negatively with an NP test for attention.

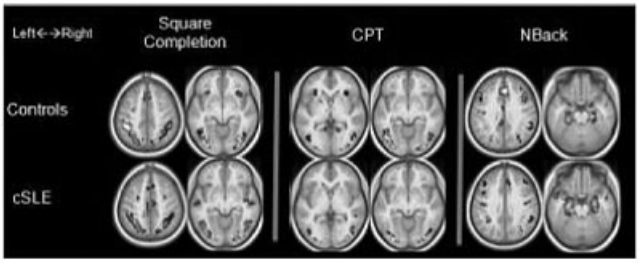

Figure 1. Group activation shown in select slices for each fMRI task. Controls are on top with corresponding cSLE patients below. Activations are in hot colors, deactivations in cool colors. For each, $p<0.0001$ uncorrected. Orientation is as indicated.

Conclusions: In this ongoing study, cSLE patients and their best-friend controls differed regarding the extent of fMRI activation in anatomic regions of interest (ROI) relevant to specific cognitive domains. Some ROIs activated per subject with correlation to performance in corresponding formal NP testing. The observed trends await confirmation as the sample size is augmented.

Pre-Pubertal Onset Systemic Lupus Erythematosus in Girls: Clinical and Serologic Manifestations Differ from Post-Pubertal Onset SLE. Kathleen M. O'Neil[4], Lauren M. Kickingbird[7], Andrew S. Zeft[8], Hermine Brunner[2], Marilynn G. Punaro[5], Barry L. Myones[1], Suzanne C. Li[3] and Tracey Wright[6]. [1]Baylor College of Medicine, Houston, TX, [2]Cincinnati Child Hosp Med Ctr, Cincinnati, OH, [3]Hackensack University Medical Center, Short Hills, NJ, [4]OU Health Science Center, Oklahoma City, OK, [5]Texas Scottish Rite Hospital, Dallas, TX, [6]Univ of TX Southwestern, Dallas, TX, [7]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [8]University of Utah, Salt Lake City, UT

Objective: Children with pre-pubertal onset systemic lupus erythematosus (SLE) represent a small minority of children with the disease. To better understand this subset of children with lupus, and to define the role of specific hormones in SLE expression, we enrolled a cohort of girls with early onset disease in a longitudinal prospective observational study spanning the period of physiologic puberty.

Methods: The study was approved by CARRA and the institutional review boards of each participating CARRA site. Girls with 4 or more ACR diagnostic criteria of SLE between the ages of 8 and 13 years who had achieved only Tanner I or II stage of sexual development were evaluated with medical history, review of systems, physical examinations and laboratory studies every 3 months until 2 years after menarche. Clinical and laboratory manifestations of the first 28 girls enrolled were compared to 23 girls with disease onset after menarche. Abnormalities present or absent were compared as categorical variables using the chi square statistic.

Results: The two groups differed ($p<0.05$) in several clinical characteristics. The girls with pre-pubertal onset SLE had more frequent thrombocytopenia (32% vs 4%, p=0.013), anemia (57% vs 30%, p=0.05), GI complaints (46% vs 4%, p=0.0008) and depression (43% vs 4%, p=0.0017) than the girls with older onset disease. The older girls, in contrast, had more frequent morning stiffness (78% vs 43%, p=0.011), pleuritis (65% vs 18%, p=0.0006), pericarditis (39% vs 7%, p=0.006), fatigue (96% vs 39%, p=0.0003), and weight loss (39% vs 18%, p=0.01) than the girls with prepubertal SLE. In contrast, the pre-pubertal cohort had more frequent autoantibodies: anti-cardiolipin (50% vs 22%, p=0.038), dsDNA (100% vs 57%, p=0.0001), SS-A (39% vs 13%, p=0.037) and SS-B (39% vs 8%, p=0.013) compared to the teens. The occurrence of malar or discoid rash, arthritis, myositis, hematuria, fever, Raynaud phenomenon, oral/nasal ulcers, alopecia, hypertension, headache, and peripheral vasculitis did not differ between the two groups. The presence of Sm and RNP antibodies, likewise, was similar in both groups.

Conclusions: Girls with pre-pubertal onset SLE have different clinical manifestations and autoantibody profiles than girls with teen-onset SLE. In particular, the younger girls have more autoantibodies, more hematologic abnormalities, and more GI complaints; the older girls have more serositis, fatigue and morning stiffness. Further study of this large prospective cohort of children with prepubertal SLE is important to understanding the role sexual maturity and hormone changes of puberty play in SLE.

Background: The European League Against Rheumatism/Paediatric Rheumatology International Trials Organisation/Paediatric Rheumatology European Society (EULAR/PRINTO/PRES) classification criteria for Wegener's Granulomatosis (WG), proposed to be more applicable to children than American College of Rheumatology (ACR) criteria, were recently validated in Ankara. The European Medicines Agency (EMEA) classification algorithm aimed to more uniquely classify related small to medium size vessel vasculitides was also recently validated in adults.

Purpose: To test the relative performance of the EULAR/PRINTO/PRES classification criteria for WG versus the ACR, applied in a cohort of children with AAV, and concurrently test the EMEA algorithm.

Methods: Data from time of diagnosis on children with diagnosed AAV by pediatric rheumatologists (MD-diagnosis) have been contributed to ARChiVe from 37 US/Canadian centers since 2004. EULAR/PRINTO/PRES and ACR criteria for WG and the EMEA algorithm were applied to all patients. Sensitivity and specificity for the EULAR/PRINTO/PRES and ACR classification criteria, and the EMEA algorithm were calculated (MD-diagnosis as reference standard). Cases where classification of a patient by EULAR/PRINTO/PRES versus ACR differed were described.

Results: MD-diagnoses for 155 patients (105 female) were: 100 WG, 25 Microscopic polyangiitis, 6 ANCA-positive pauci-immune glomerulonephritis, 3 Churg-Strauss syndrome, and 21 unclassified vasculitis. Among these patients, 87 had WG as defined by ACR, 98 by EULAR/PRINTO/PRES, and 113 by the EMEA algorithm. Respectively, the sensitivity of the ACR and EULAR/PRINTO/PRES criteria, and the EMEA algorithm for classifying WG patients in the spectrum of patients in an AAV cohort was 69%, 77%, and 90%; and specificity 67%, 62% and 60%. There were 17 patients in whom WG classification by EULAR/PRINTO/PRES versus ACR criteria differed. 14 were identified as WG by EULAR/PRINTO/PRES but not by ACR criteria: features that enabled classification were sinus involvement, ANCA positivity, subglottic-tracheal-endobronchial stenosis, or significant proteinuria. Conversely, 3 cases with WG were classified by ACR but not by EULAR/PRINTO/PRES: 2 patients had nasal-sinus involvement and granulomatous vasculitis on biopsy, and 1 patient had lung and renal involvement; all three had negative ANCA serology. Using the EMEA algorithm, 134 children could be classified as a named AAV category; 21 (14%) patients could not be classified.

Conclusion: The EULAR/PRINTO/PRES criteria are more sensitive than the ACR criteria in classifying pediatric WG. Performance of both criteria were limited when applied to a cohort that includes patients with MPA for which neither classification systems have established criteria, unlike the most sensitive EMEA classification algorithm which specifically aims to uniquely classify all patients. However, even when using the EMEA algorithm many children diagnosed with AAV remained unclassified.

Resistance to Annexin A5 Anticoagulant Activity in Children with Rheumatic Disease Correlates with Persistent Antiphospholipid Antibodies and Thrombosis. Dawn M. Wahezi[4], Jacob H. Rand[2], Swapnil Rajpathak[3] and Norman T. Ilowite[1]. [1]Children's Hospital Montefiore, Bronx, NY, [2]Department of Pathology, Hematology Laboratories, Montefiore Medical Center, Bronx, NY, [3]Departments of Medicine, Epidemiology and Population Health, Albert Einstein College of Medicine, [4]Division of Pediatric Rheumatology, Children's Hospital at Montefiore, Bronx, NY

Background: Antiphospholipid antibody syndrome (APLS) is the most common acquired autoimmune thrombotic state in children. The underlying mechanism(s) by which aPL antibodies result in thrombosis remains poorly understood. Annexin A5, a potent anti-coagulant protein, shields anionic phospholipids on vascular endothelial cells from availability for coagulation reactions. There is a significant body of evidence to support the hypothesis that disruption of this shield by aPL antibodies plays a role in the pathogenesis of APLS in adults. In this study, we investigated the association between aPL antibodies and annexin A5 resistance in children with rheumatic diseases.

Methods: Clinical and laboratory data were collected from children with rheumatic diseases (n=90), including systemic lupus erythematosus (SLE) (n=49), juvenile idiopathic arthritis (JIA) (n=21), juvenile dermatomyositis (JDM) (n=8), primary APLS (n=6), Sjogren's syndrome (SS) (n=3), mixed connective tissue disease (MCTD) (n=1), systemic sclerosis (n=1) and systemic vasculitis (n=1). Assays for lupus anticoagulant (LA), anti-cardiolipin (aCL), anti-β2 glycoprotein I (anti-β2GPI) and anti-phosphatidyl serine (APS) antibodies were performed on all patients. Positive values were repeated 12 weeks later to confirm antibody persistence. A novel assay, the annexin A5 resistance assay (A5R), was performed measuring coagulation times in the presence and absence of annexin A5. Resistance to the anticoagulant effects of annexin A5 is expressed as a reduction in this value.

Results: Patients with persistently positive aPL antibodies had significantly lower A5R levels as compared to patients without evidence of persistent positivity (see table). Patients with an underlying diagnosis of primary APLS, SLE, SS or MCTD had significantly higher prevalence of persistently positive aPL antibodies, thrombotic events, aPL associated manifestations and low annexin as compared to the remainder of the cohort. The prevalence of reduced A5R in these patients was 49% versus 26% in the remainder of the cohort (p=0.032) with a mean A5R level of 227 vs. 246 respectively (p=0.030).

	Low A5R (%)	p value	Mean A5R	p value
Lupus Anticoagulant				
Persistent (n = 13)	69	*0.026*	191	*<0.001*
Transient (n = 8)	75	*0.041*	229	0.754
Anti-β2GPI antibodies				
Persistent (n = 10)	80	*0.008*	183	*<0.001*
Transient (n = 6)	50	0.647	226	0.679
Anti-cardiolipin antibodies				
Persistent (n = 14)	64	0.055	198	*0.001*
Transient (n = 19)	47	0.533	224	0.289
Any positive aPL				
Persistent (n = 19)	63	*0.028*	202	*<0.001*
Transient (n = 21)	48	0.489	231	0.743
Number of persistently positive aPL				
Zero (n = 71)	35	—	242	—
One (n = 7)	43	0.687	230	0.470
Two (n = 6)	67	0.127	204	*0.038*
Three (n = 6)	83	*0.020*	168	*<0.001*
Clinical correlation				
Thrombosis (n = 10)	70	*0.049*	207	*0.048*
Recurrent thrombosis (n = 3)	67	0.360	199	0.176

Conclusions: The A5R assay is the first mechanistic assay targeted at the underlying pathogenesis of APLS. This is the first report demonstrating significantly lower mean A5R levels in children with rheumatic diseases and persistent aPL antibodies. Furthermore, patients with prior history of thrombosis were shown to have reduced A5R levels as compared to patients with no history of thrombosis. We plan to expand these findings into a larger, multi-center cohort of children with SLE to determine if A5R is highly associated with thrombosis or other aPL related manifestations.

Safety and Efficiency of Rituximab in Juvenile Dermatomyositis: A Series of Eight Cases from the French AIR Registry. Brigitte Bader-Meunier[3], Helene Decaluwe[5], Pierre Quartier[3], Albert Faye[4], Vincent Guigonis[1], Anne Pagnier[2], Christine Barnerias[3], Jacques E. Gottenberg[6] and Christine Bodemer[3]. [1]Dupuytren Hospital, [2]Grenoble Hospital, [3]Necker Hospital, [4]Robert Debre Hospital, [5]Sainte Justine Hospital, [6]Strasbourg Hospitals, Strasbourg, France

Background: Juvenile dermatomyositis (JDM) is a rare vasculopathic condition of presumably autoimmune etiology. No data are available regarding the safety and efficacy of anti-CD20 treatment in patients with JDM refractory to conventional treatments except for six case reports with conflicting results.

Aim: To describe the efficacy and safety of rituximab (RTX) in JDM patients.

Methods: French multicenter retrospective study of patients with JDM diagnosed according to the criteria of Bohan and Peter treated with RTX and included in the French Autoimmunity and Rituximab (AIR) registry. Complete remission was defined by the normalization of manual muscle testing (MMT) and child myositis assessment scale (CMAS) for muscular involvement and by the disappearance of active skin lesions and abdominal pain for cutaneous and abdominal involvement.

Results: Eight patients (7 girls and 1 boy) were included. Age at diagnosis of JDM ranged from 2,5 to 10 years, and JDM duration at onset of rituximab therapy from 0,15 to 11 years. All the patients had been previously treated with immunosuppressive agents, and received rituximab because of the lack of efficiency of these treatments. The main indication for rituximab treatment was refractory muscle, skin and/or gastrointestinal involvement (6 patients) (group 1) and chronic complications consisting of severe calcinosis and severe abdominal pain associated with abdominal lipomatosis (2 patients) (group 2). The number of rituximab infusions (375–500 mg/m^2/infusion) ranged from 2 to 5. RTX was associated with corticosteroids and with immunosuppressive drugs in 8/8 and 4/8 patients respectively. The first RTX infusion had to be stopped in 1 patient (group 1) because of an infusion-related event. Clinical muscular, cutaneous and abdominal remission was achieved in 3/5 evaluable patients in group 1, including one patient with severe JDM who received plasmapheresis before and during the RTX course; MMT and CMAS returned to normal values within 3 to 12 months; normal values of serum CPK level were observed before and after RTX. In these responders steroid therapy was stopped in 1 patient 1,5 years after the first infusion of RTX, and was tapered at 10 and 15% of the baseline dosage respectively in the two others; the mean follow-up was 1,5 to 4 years, and complete remission lasted in 2 patients, while 1 patient has a relapse occurring 16 months after the start of the first course, successfully retreated with a second course of rituximab. RTX was ineffective in four patients (2 patients in each group). Calcinosis did not improve in two responders as well as in one non responder. Two patients presented localized bacterial infection of the calcinosis sites 2 and 11 months after RTX, and 1 patient died from non-related DM cause. Effective depletion of peripheral blood B cells was observed in all the patients and lasted more than 7 months in all patients except in one non responder.

Conclusion: This small series suggests that rituximab may be an effective and safe co-therapy for treating muscular and skin involvement in a subset of children with refractory JDM, but had no effect on calcinosis.

1694

Safety and Immunogenicity of Influenza Vaccine (FluVac) in Patients with Juvenile Systemic Lupus Erythematosus (JSLE). Luciana M. de Carvalho[2], Rodrigo V. D. Silvestre[1], Wyller A. Mello[1] and Virginia P. L. Ferriani[2]. [1]Evandro Chagas Institute (WHO National Influenza Center), Ananindeua, Brazil, [2]School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil

Background: The FluVac is highly effective in general population. However there have been concerns about safety and immunogenicity of this vaccine in patients with SLE.

Objective: To evaluate safety and immunogenicity of FluVac in JSLE.

Patients and Methods: Twenty-six JSLE patients (10–18 years; mean SLEDAI score of 5.8), were immunized with trivalent split FluVac (A/Solomon Islands/3/2006, A/Brisbane/10/2007, B/Florida/2006), licensed for the 2008 Winter season in the South Hemisphere (Sanofi Pasteur SA/Butantan Institute Brazil). All but one patient were receiving prednisone (mean dose 12.2mg/day), and 17 were also receiving other drugs (methotrexate/leflunomide:4; azathioprine:12; mycophenolate mofetil:3). Influenza antibodies were measured before and 4–6 weeks after vaccination using hemagglutination inhibition (HAI) test according to standard World Health Organization procedure. Immune response (seroconversion) was defined as a 4-fold or greater rise in HAI antibodies and seroprotection rate was considered when HAI titers were at least 1:40. Local symptoms at the injection site and systemic symptoms were assessed by diary. The SLEDAI score, erythrocyte sedimentation rate (ESR), anti-dsDNA and anti-cardiolipin antibodies where evaluated before and 4–6 weeks after vaccination.

Results: All patients responded to at least 2 FluVac strains. Seroprotection rates after vaccination were 92% to A/H1N1, 73% to A/H3N2 and 100% to B-strain. Seroconversion rates were 91% to A/H1N1, 60% to A/H3N2 and 45% to B-strain. Use of medications did not interfere in seroprotection or seroconversion rates. No significant differences were found in SLEDAI score, ESR, or antibody titers against dsDNA and cardiolipin 4–6 weeks after vaccination. Local symptoms at the injection site (tenderness and/or redness) were described in 5/26 patients; 1 patient had a quickly reversible lipothymia five minutes after receiving the vaccine and 2 patients developed cough and rinorrhea without fever, one and nine days after receiving the vaccine.

Conclusion: Trivalent split influenza vaccine seems to be safe and immunogenic in patients with JSLE.

Serum Tumor Necrosis Factor alfa (TNFα) Is Associated with Disease Activity in Juvenil Systemic Lupus Erythematosus (jSLE). Mariana Postal, Karina Pereira, Karina Peliçari, Barbara Longhi, Roberto Marini, Lilian T. L. Costallat and Simone Appenzeller. State University of Campinas

Objective: To compare serum TNFα concentrations in jSLE patients, first-degree relatives and healthy volunteers. To determine clinical, laboratory and treatment features associated with TNFα in jSLE.

Methods: We included consecutive SLE patients with disease onset before the age of 16 (jSLE), first-degree relatives and age and healthy age and

sex matched controls. SLE patients were assessed for the number of non-renal and renal American College of Rheumatology (ACR) criteria ever present, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current drug exposures. Mood disorders were determined through Becks Depression and Becks Anxiety Inventory (BDI and BAI). TNFα levels were measured by enzyme-linked immunosorbent assay using commercial kits from R&D Systems (London, UK). Analysis of variance was used to compare TNFα concentrations between groups. We assessed the effects of various demographic and clinical factors and TNFα concentrations in jSLE using univariate analyses. Multivariate analysis was performed including sex, age, SLE duration, disease activity, damage, number of non-renal and renal ACR criteria ever present, and current drug exposures.

Results: We included 50 jSLE (mean age 17.8±3.9), 45 first-degree relatives (mean age 40.2±6.3) and 49 controls (mean age 20.8±4.6). The mean level of serum TNFα was 4.6±9.6 pg/ml in jSLE, compared to 2.52 ± 2.7 pg/ml (p=0.15) in first-degree relatives and 1.8±1.9pg/ml in healthy controls (p=0.04). No difference between first-degree relatives and healthy controls was observed (p=0.13). TNFα concentrations correlated directly with SLEDAI scores (r=0.41; p=0.003), renal ACR criteria (r=0.3; p=0.05), and anxiety (r=0.34; p=0.03). No association between TNFα and SDI scores, depression, current use and dose of corticosteroids, hydroxychloroquine and immunosuppressants was observed. In adjusted analysis, TNFα levels was independently associated with SLEDAI scores (OR=3.1; 95%CI=1.6–6.5). When analyzing individual SLEDAI items, TNFα was associated with the presence of vasculitis (OR=3.9; 95%CI=1.3–4.9).

Conclusion: TNFα was significantly higher in jSLE patients when compared to healthy controls and was associated independently with disease activity in adjusted analysis. TNFα may be a useful marker for disease activity in jSLE, however longitudinal studies are necessary to determine if TNFα may predict flares in jSLE. The heterogeneity of clinical manifestations observed in SLE may be explained by different cytokine profile. Since TNFα was associated with the presence of vasculitis, anti-TNF treatment may be a treatment option for this manifestation.

Study of the Growth and Body Mass Index (BMI) of 86 Children with Familial Mediterranean Fever (FMF): Results of the French Referral Centre for Auto-Inflammatory Diseases (CeReMAI). Aurelie Klein[1], Alexia Letierce[1], Anuela Kondi[1], Veronique Hentgen[2], Isabelle Kone-Paut[1] and Severine Guillaume-Czitrom[1]. [1]Bicetre University Hospital, Le Kremlin Bicetre, France, [2]Versailles Hospital, Versailles, France

Background: Little is known on growth and BMI in FMF children.

Objective: To study the growth and BMI of FMF children, and evaluate the impact of disease severity and mutation load.

Methods: FMF children from the CeReMAI with available measures of height and weight were included. These measures were recorded at disease onset, genetic diagnosis, Colchicine start, and last visit, and Z-scores of growth and BMI matched for age and gender, calculated; Z-scores of heights were compared with the paired Wilcoxon test to Z-scores of target heights. Likewise, the BMI Z-scores were compared to the general population. Differences were analysed according to the severity of FMF evaluated with the modified Pras score and to the mutation load.

Results: 86 children were included, 49 girls and 37 boys, of whom 77 were under Colchicine therapy (90%). The median age at onset was 2.5 yrs, 4.5 yrs at genetic diagnosis and at Colchicine start, and 9.1 yrs at the last visit. Compared to the general population, target heights of FMF children were significantly lower (mean of Z=-0.24, p=0.003). Z-scores of heights at disease onset and at genetic testing were not different from the target heights. However, the Z-scores of heights at the last visit were significantly low (Z=−0.62; p<0.0001), and also lower than the Z-scores of target heights (Z=−0.62 versus Z=-0.24 p=0.014), despite Colchicine. The Z-scores of BMI were not different from those of the general population, whatever the time of evaluation. We found a significant difference between the Z-scores at the last visit and the Z-scores of target heights in children harbouring 2 mutations in the MEFV gene (n=52; p=0.002) compared to children with one mutated allele (n=34; p=0.65) and this difference was not dependent on FMF severity.

Conclusion: this series shows that height, but not BMI, is reduced in FMF after 6 yrs of evolution, despite Colchicine therapy. Our study indicates that FMF severity determined by the Pras modified score does not influence growth in FMF children. It rather suggests that FMF mutations would play a significant role in growth impairment.

The Disease Presentation and Outcome in Juvenile Behcet's Syndrome. Emire Seyahi[3], Huri Ozdogan[3], Yilmaz Ozyazgan[2], Serdal Ugurlu[3], Yesim Ozguler[1], Gulen Hatemi[3], Hasan Yazici[3] and Sebahattin Yurdakul[3]. [1]Cerrahpasa Medical Faculty, Internal Medicine Department, [2]Cerrahpasa Medical Faculty, Ophtalmology Department, [3]Cerrahpasa Medical Faculty, Rheumatology Department

Objectives: To assess clinical characteristics and outcome among patients with juvenile onset Behcet's syndrome (BS) all attending a single dedicated center.

Methods: We reviewed the charts of around 7000 patients registered between July 1977 and December 2009 at our multidisciplinary BS outpatient clinic. We surveyed patients who fulfilled the International Study Group (ISG) criteria for BS and who were 16 or younger at their initial visit. All these patients were called back within a survey period of 3 months. Demographic and clinical characteristics at initial and final visit were determined.

Results: There were 166 patients (86 boys, 80 girls). The mean age at first visit was 14.2 ± 1.9 years, the mean age at appearance of first symptom 10.9 ± 3.1 years, and the mean age at ISG fulfillment 13.1 ± 2.6 years. At the time of first visit, patients had oral ulcers (100%; 166/166), genital ulcers (68%; 113/166), pathergy positivity (63%; 104/166), papulopustular lesions (57%; 94/166), erythema nodosum (42%; 69/166), arthritis (20%; 33/166), eye disease (48%; 80/166), vascular disease (13%; 22/166) and neurological disease (8%; 13/166). The clinical manifestations at first visit such as genital ulcer, papulopustular lesions, erythema nodosum and arthritis were less frequent compared to the adult population (1). The dural sinus thrombi type of neurological involvement was the most common type of involvement (85%; 11/13). Familial history of BS was present in 41 (25%) patients. Information on the onset of puberty was available only in 94 patients. The onset was prepubertal in 39 and postpubertal in the remaining 55. While erythema nodosum was more common among those with prepubertal onset (24/39 vs 16/55), genital ulcer was more common among those with postpubertal onset (18/39 vs 44/55). A total of 13 (8%) were lost to follow-up after a single visit. Six (4%) (all males) had died. The median follow-up time in the remaining was median 10 years [4–17]. Causes of death in 6 males were pulmonary artery aneurysms (n=2), hepatic failure due to Budd-Chiari syndrome (n=1), suicide (n=2) and pneumonia (n=1). At the end of follow-up 18 patients (22.5%) had lost useful vision (bilateral: 8, unilateral: 10). The visual acuity in either eye was between 0.6–1.0 in 44 (56%) and between 0.5–0.1 in the remaining 18 (22.5%). Two patients (all males) with neurological involvement had severe neurological deficit (hemiplegia and optic atrophy. As seen adults, skin-mucosa lesions and joint involvement stopped occurring during the follow-up. Among 77 patients (50 M/27 F) in whom a final evaluation was available after a median of 9 [4–18] years, we observed that oral ulcer (90%) and papulopustular lesions (55%) were more frequent compared to genital ulcers (18%), erythema nodosum (29%) and arthritis (14%).

Conclusions: Pediatric cases made up around 0.2% of all Behçet patients. As in the adult, BS runs a severe course among the boys considering overall mortality in addition to the vascular and neurological involvement.

1698

The Role of Montelukast in the Management of Hyperimmunoglobulinemia D with Periodic Fever Syndrome (HIDS). Donald P. Goldsmith[2], Karyl S. Barron[1], Anne Jones[1], Dawn Chapelle[1], Beverly Barham[1], Robert Lembo[1], Eric Hanson[1], Amanda Ombrello[1], Deborah Stone[1] and Daniel L. Kastner[3]. [1]National Institutes of Health, Bethesda, MD, [2]National Institutes of Health, Drexel University College of Medicine, Philadelphia, PA, [3]NIAMS, NIH, Bethesda, MD

Introduction: In 2001 Frenkel et al reported elevated urinary levels of leukotriene E_4 in 7 patients with HIDS and suggested that cysteinyl leuko-

trienes might play a role in its pathogenesis (Arch Dis Child 85:158). There is anecdotal evidence of benefits from treatment with the leukotriene receptor antagonist, montelukast.

Aim: To assess the therapeutic response of a pediatric HIDS cohort to montelukast.

Methods: This study is a retrospective chart review of 21 children with HIDS followed at the NIH Periodic Fever Program. Seventeen of 21 patients, ages 2–16 (mean 7.2y) were treated with montelukast. All were started on once daily standard doses of montelukast based on age (2–5y 4mg; 6–14y 5mg; >15y 10mg). Daily dosage was increased up to 8–12mg in 3 children; 6 patients were also treated with one additional similar dose on the first day of each febrile episode. Clinical response was assessed at each outpatient visit by the same attending physician by interview, clinical examination, and patient score cards.

Results: In 7 children there was no clinical response. In 2 the frequency of febrile episodes decreased slightly but each episode was more severe (not considered to be clinically beneficial). In 3 children, febrile episodes were judged to be less frequent and of reduced severity but montelukast was stopped because of behavioral side effects (one of these being parental fear [but not actual] of suicidal ideation). Similar improvement was noted in 4 additional children, but in all of these patients, benefit was judged to have dissipated after 6–8 months and montelukast was then stopped. Only 1 child still remains on montelukast. One child was lost to follow-up after starting montelukast.

Conclusions: Therapeutic benefit from montelukast is seen only in 7 (41%) of children and is not enduring. Significant side effects are not uncommon. In our experience montelukast is not likely to favorably alter the long term clinical course of pediatric HIDS. It seems improbable that leukotriene activation is primarily involved in the pathogenesis of HIDS but is more likely a secondary phenomenon associated with generalized immune stimulation.

The Use of Lenalidomide for Cutaneous Manifestations of SLE. Eveline Wu, Laura E. Schanberg, Heather VanMater and Egla C. Rabinovich. Duke University Medical Center, Durham, NC

Purpose: Cutaneous manifestations are common in pediatric SLE and cause significant morbidity. In the past, thalidomide has proved effective in the treatment of cutaneous disease. Its use, however, is limited by its teratogenecity and the potential for peripheral neuropathy. Lenalidomide, a thalidomide analogue, has shown promise with a more favorable side effect profile. Though their mechanism of action is not completely understood, both appear to have anti-inflammatory and immunomodulatory properties. Our objective was to evaluate the efficacy and safety of lenalidomide in the treatment of cutaneous SLE.

Methods: We performed a retrospective chart review of 5 children who received lenalidomide for treatment of cutaneous aspects of SLE. Lenalidomide dosing was 5–15 mg daily. One subject was initially taking thalidomide 100 mg daily. Patients were evaluated at drug initiation and at 6 month follow up using a standardized case report form. Statistical analysis was performed using the paired t-test. If a significant value was obtained ($P<0.05$), further statistical analysis was performed using Wilcoxon's signed rank test.

Results: All of our subjects were female and 80% were African-American. Average age at diagnosis was 12.4 years (SD +/− 3.5). Average age at time of lenalidomide or thalidomide initiation was 16.4 years (SD +/− 4.7). Subjects started the medications for treatment of skin disease, including alopecia, nasal and oral ulcers, extensive malar rash, diffuse maculo-papular eruption, discoid lesions, bullous lesions, panniculitis, and severe Raynaud's phenomenon with digital ulcerations. One patient initially received thalidomide before switching to lenalidomide 28 months later due to complaints of numbness over her anterior shin with a normal EMG. Within the first 6 months, all 5 subjects demonstrated excellent response with resolution of skin lesions. Lenalidomide maintained the remission in skin disease achieved by thalidomide in the one patient. No subject relapsed on continued therapy. Prednisone dose was decreased in all patients, from a mean of 23 mg (SD +/− 10.9) to a mean of 11 mg (SD +/− 7.4) at 6 months ($P=0.005$). ESR also decreased from a mean of 26.2 mm/hr (SD +/− 8.9) to a mean of 19.2 mm/hr (+/− 7.5) at 6 months ($P=0.015$). The results remained statistically significant with analysis using Wilcoxon's signed rank test. One patient with nephritis started IVIG during the follow up period. Others did not start a new DMARD, further supporting the positive effect of lenalidomide on prednisone dose and ESR. Both medications exhibited a favorable side effect profile. All patients had lymphopenia, but this was not statistically significant during the 6 month evaluation. One patient developed pyelonephrits.

Conclusions: Skin disease is highly prevalent among children with SLE and can be quite disfiguring. Lenalidomide is both effective and safe for the treatment of a spectrum of dermatologic conditions in pediatric SLE. Its use may allow for a reduction in prednisone dose. Prospective study of lenalidomide is needed to clarify its role in the treatment of cutaneous manifestations of SLE.

Therapeutic Approaches for the Treatment of Active Juvenile Dermatomyositis: An International Multicenter Study. Rachana Hasija[3], Angela Pistorio[3], Angelo Ravelli[3], Erkan Demirkaya[3], Raju Khubchandani[3], Dinara Guseinova[3], Clara Malattia[3], Carmen De Cunto[3], Tomas Brent Graham[3], Kathleen Haines[3], Christian Huemer[3], Yukiko Kimura[3], Harald Mangge[3], Silvana Martino[3], Carlo Minetti[3], Ellen Berit Nordal[3], Pierre Philippet[3], Manuel Salgado[3], Alberto Martini[2] and Nicolino Ruperto[1]. [1]IRCCS G. Gaslini/Università degli Studi di Genova, Genova, Italy, [2]IRCCS G. Gaslini/Università degli Studi di Genova, [3]PRINTO

Background: Recently published articles have documented a marked improvement in long-term outcome and survival of juvenile dermatomyositis (JDM) patients but little information is available on standardized evaluations of response to therapy based on current treatment options.

Objective: Our aim was to evaluate in large prospective cohort of JDM patients the response to therapy over a 24 months period, according to the PRINTO JDM response criteria.

Patients & Methods: Clinical, laboratory and therapeutic modalities were collected prospectively between 2001 and 2004 in JDM patients by PRINTO/PRCSG members from 36 countries. Patients with probable or definite JDM, age < 18 years, in an active phase of their disease, at 4 time points (baseline, 6, 12 and 24 months), were included. The validated core set variables were the global assessment by the physician and parent, muscle strength, functional ability, quality of life and disease activity tool. Patients were defined as improved if able to demonstrate at least 20% (50, 70, or 90) improvement from baseline in 3 of any 6 core set variables with no more than 1 of the remaining worsening by more than 30%, which cannot be muscle strength. Remission was defined as patients with normal muscle strength (CMAS ≥48; nv 0–52) and physician global assessment of disease activity ≤ 0.5 cm (nv 0–10) and normal CPK (≤150 U/L)

Results: The analysis data set included 275/294 (94%) patients. Patients median ages at onset and disease duration visit were 7.2 and 6 months respectively with 168 (61%) being female. The greatest improvement in clinical and laboratory measures was observed in the first 6 months of therapy and maintained thereafter. At baseline treatment options included steroids in 269 (97.8%), metotrexate (MTX) in 134 (48.7%) with 91 newly started, cyclosporine A in 44 (16%), hydroxychloroquine in 37 (13.5%), and IVIG in 38 (13.8%). Oral steroids dose at baseline and 6 months were 1 and 0.3 mg/kg/day respectively, at 24 months 91 patients (52.3%) were still on steroids at 0.21 mg/kg/day; steroids pulses were used in 100 (36.4%) at baseline. Figure reports the 20, 50, 70, 90 response and remission over time.

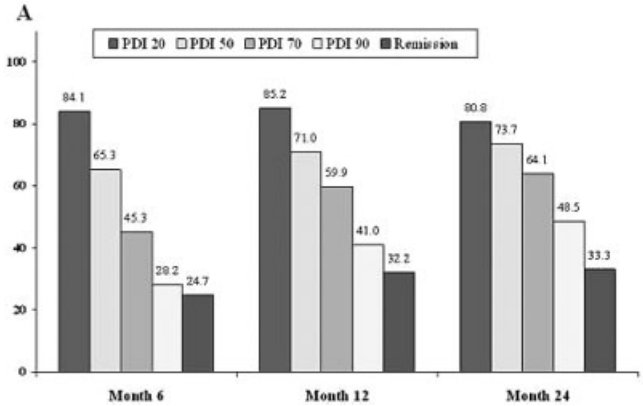

Figure 1. PRINTO JDM PDI 20, 50, 70, 90 and remission rate in 275 patients at 6, 12 and 24 months.

A substantial improvement was observed in the initial 6 months (PRINTO 20 criteria 84%) and maintained thereafter.

Conclusions: Six months of therapy lead to a significant improvement in JDM core set measures and response criteria, that was maintained up to 2 years follow-ups. These data provided standardized response to therapy data in patients with JDM treated according to the current available options.

Towards Defining Clinical Remission in Juvenile Systemic Lupus Erythematosus (jSLE). Rina Mina[5], Laura E. Schanberg[6], B. Anne Eberhard[14], Marisa S. Klein-Gitelman[3], Gloria C. Higgins[12], Karen Onel[17], Nora G. Singer[11], Kathleen M. O'Neil[13], Lori B. Tucker[1], Lisa F. Imundo[2], Emily Von Scheven[16], Shannen L. Nelson[4], Frank Dressler[10], Ruben Cuttica[7], Claudia Saad Magalhães[15], Angelo Ravelli[9], Alberto Martini[8] and Hermine I. Brunner[5]. [1]BC Childrens Hospital, Vancouver, BC, Canada, [2]Childrens Hospital of NY, New York, NY, [3]Childrens Mem Hosp/NW Univ, Chicago, IL, [4]Cincinnati Children's Hospital, Cincinnati, OH, [5]Cincinnati Children's Med Ctr, Cincinnati, OH, [6]Duke Univ Medical Center, Durham, NC, [7]Hospital General de Ninos Pedro de Elizalde, Buenos Aires, Argentina, [8]IRCCS G Gaslini, Genova, Italy, [9]IRCCS G Gaslini, [10]Medizinische Hochschule, Hannover, Germany, [11]MetroHealth Medical Center, Cleveland, OH, [12]Nationwide Childrens Hosp, Columbus, OH, [13]OU Health Science Center, Oklahoma City, OK, [14]Schneider Children's Hospital, New Hyde Park, NY, [15]UNESP, [16]Univ of Calif San Francisco, San Francisco, CA, [17]Univ of Chicago, Chicago, IL

Background: There is no established definition for global clinical remission in jSLE.

Objectives: To develop a definition of global clinical remission in jSLE and to identify candidate criteria for measuring jSLE clinical remission.

Methods: Pediatric rheumatologists from all over the world (n=137) were surveyed about issues pertaining to defining and measuring clinical remission in jSLE. Consensus for the Delphi survey was set at 70%. Survey-responses were compared to prospective clinical data from a cohort of jSLE (n=33) considered to be in clinical remission by their treating physician.

Results: Survey response rate was 65%. There was consensus that 'clinical remission' is different from 'minimal disease activity' in jSLE. There was consensus that a jSLE patient in clinical remission (a) may have some subjective symptoms (i.e. fatigue, joint pains, headaches) but should not have any objective physical signs of disease activity; (b) may have a persistently positive ANA but should not have abnormal ESR, C3 level, complete blood count and urine sediment; and thus (c) may have disease activity scores > 0. No consensus was reached as to whether remission constitutes a time point or a time period and whether medication use is important in its definition. Clinical data of jSLE patients considered to be in remission supported the survey responses (see Table).

Clinical Data from jSLE patients in Clinical Remission (n = 33)

Outcome measure	Median ± IQR	Range
SLEDAI	2 ± 3	0–6
ECLAM	1 ± 0	0–3
SLAM	2 ± 3	0–5
BILAG	1 ± 2	0–10
Physician Global Assessment	0 ± 0	0–1
Patient well being	8 ± 1	6–9
Peds QoL	90.22 ± 20.11	56.52–100
Rheum QoL	92.05 ± 10.23	59.09–100
CHQ PhS	42.76 ± 4.52	35.43–48.89
CHQ PsS	40.31 ± 5.44	31.65–48.20
SLICC-ACR DI	0 ± 0	0–3

Conclusions: Consensus has been reached on preliminary variables useful to define and measure clinical remission in jSLE. Further studies are in progress.

Towards the Development of Standardized Treatment Protocols for Proliferative Nephritis in Juvenile Systemic Lupus Erythematosus (jSLE). Rina Mina[6], Hermine Brunner[5], B. Anne Eberhard[12], Marilynn G. Punaro[14], Stacy P. Ardoin[10], Marisa S. Klein-Gitelman[4], Joyce J. Hsu[13], Lakshmi N. Moorthy[11], Linda Wagner-Weiner[8], Eyal Muscal[1], Suhas M. Radhakrishna[2], Jenny Palter[9], Laura Schanberg[7], Carol A. Wallace[16], Norman T. Ilowite[3], Emily Von Scheven[15] and for the CARRA Lupus Disease-Specific Group. [1]Baylor College of Medicine, Houston, TX, [2]Children's Hospital Los Angeles, Los Angeles, CA, [3]Children's Hospital Montefiore, Bronx, NY, [4]Childrens Mem Hosp/NW Univ, Chicago, IL, [5]Cincinnati Child Hosp Med Ctr, Cincinnati, OH, [6]Cincinnati Children's Med Ctr, Cincinnati, OH, [7]Duke Medical Center, Durham, NC, [8]La Rabida Children's Hospital, Chicago, IL, [9]Lupus Foundation, [10]Ohio State University, Columbus, OH, [11]Robert W Johnson University, Metuchen, NJ, [12]Schneider Children's Hospital, New Hyde Park, NY, [13]Stanford University, Stanford, CA, [14]Texas Scottish Rite Hospital for Children, Dallas, TX, [15]Univ of Calif San Francisco, San Francisco, CA, [16]University of Washington and Seattle Childerns's Hospital, Seattle, WA

Background: There is a paucity of clinical trials (RCTs) to help guide treatment of proliferative lupus nephritis (LN) in jSLE. Comparison of outcomes resulting from standardized treatment protocols may offer an alternative to expensive RCTs for elucidating the best therapy in this population.

Objectives: Describe current clinical practice patterns and patient-specific features that influence the management of proliferative LN in jSLE as a first step towards the development of standardized treatment protocols for LN in children.

Methods: Based on literature review, a Delphi survey pertaining to issues in LN induction and maintenance therapy was sent to 103 members of the SLE Subcommittee of the Childhood Arthritis and Rheumatology Research Alliance. Consensus was set at 80%.

Results: Survey response rate was 80%; most of the respondents had at least 6 years of clinical experience. The majority (79%) use cyclophosphamide according to the NIH protocol as induction therapy for Class IV LN. Mycophenolate mofetil (MMF) is less commonly used (17%) and rituximab and azathioprine were rarely prescribed for induction. The choice for induction agent is influenced by co-existent cerebritis and risk for non-adherence but not patient age, race or gender. MMF is the medication of choice for maintenance therapy. Although corticosteroids are almost universally utilized for LN therapy, there is a striking variability in the regimen (dose, route, and duration) employed. There was consensus that definitions of flare and response based on ACR/EULAR renal outcomes criteria are useful to guide treatment decisions. No consensus was reached about duration of induction or maintenance therapy; treatment adjustment for LN relapse; treatment-effects of nephrosis or persistent proteinuria, and strategies for prevention of medication side-effects. LN is typically monitored with C3/C4 levels, spot urine protein to creatinine ratio, anti-dsDNA antibody titers, GFR, and urine sediment while repeat kidney biopsy is not routine.

Conclusions: While there is a marked variation in practice patterns among pediatric rheumatologists in the treatment of Class IV LN in jSLE, cyclophosphamide is often the preferred induction medication, and MMF is the maintenance therapy of choice. These survey responses will help guide the development of standardized treatment protocols. Based on the experience from other chronic diseases, this will allow for comparative effectiveness studies to determine the optimal therapy for LN in children, thereby leading to improved outcomes.

Trends in Incidence and Drug Therapy of Complex Regional Pain Syndrome in Children's Hospitals across the U.S. Cara M. Hoffart[1], Pamela F. Weiss[2], Andrew J. Klink[2], D. D. Sherry[2] and Chris Feudtner[2]. [1]The Children's Hospital of Philadelphia, Philadelphia, PA, [2]The Children's Hospital of Philadelphia

Background: The incidence of complex regional pain syndrome (CRPS) in hospitalized pediatric patients has been incompletely characterized and optimal treatment is debated.

Methods: We conducted a retrospective observational study using Pediatric Health Information Systems (PHIS), an administrative database from 40 freestanding US children's hospitals. We determined admission temporal trends, patient characteristics, and drug therapy of children with a discharge diagnosis of CRPS between 1 January 2004 and 31 December 2009.

Results: During this 6-year study, there were 848 hospitalizations for CRPS, of which 644 were an initial admission. The median age was 14 (IQR: 11, 16 years), and three-quarters of the patients were females. Seventy-five percent were white, 9% black, 2% Asian, 5% other, 9% unknown. Over time, there was a significant increase in cases of CRPS (from 18.6 cases per 100,000 admissions in 2004 to 49.2 cases per 100,000 admission in 2009; P = 0.03, by test for trend). The median length of stay for all 848 admissions was 5 days (IQR: 3, 9 days). Pharmacologic drug therapy during the initial admission included narcotics (490 patients, 78.4%), non-narcotic analgesics (410 patients, 65.6%), non-steroidal anti-inflammatory drugs (382 patients, 61.1%), psychotherapeutics (363 patients, 58.1%), sedative hypnotics (149 patients, 23.8%), and anesthetics such as ketamine (178 patients, 28.5%).

Conclusions: The number of hospitalized children with CRPS has increased significantly over the last 6 years, due to either increasing incidence of this chronic pain syndrome, improved recognition and diagnosis, a shift in diagnostic coding, or some combination of these mechanisms. Regardless, the treatments received by these patients are diverse and warrant study regarding short and long term effectiveness.

Figure: Annual hospital admissions for children with CRPS.

Update on the Juvenile Systemic Sclerosis Inception Cohort. www.juvenilescleroderma.com. Ivan Foeldvari[2], Angela Wierk[1], Claudie Len[8], Maria Martha Katsicas[4], Avcin Tadey[6], Till Kallinich[7], Isabelll Kone-Paut[9], Kirsten Minden[7], Luc Mouthon[10], Juergen Brunner[5] and Yuoef Uziel[3]. [1]Hamburger Zentrum Für Kinder- und Jugenrheumatologie, Hamburg, Germany, [2]Hamburger Zentrum Fuer Kinder- und Jugendrheumatologie, Hamburg, Germany, [3]Universitiy Childrens Hospital, Israel, [4]Universitiy Childrens Hosptial, Brazil, [5]Universitiy Childrens Hosptial, Austria, [6]University Childrens Hospital, Slovenia, [7]University Childrens Hospital, Germany, [8]University Childrens Hospital, Brazil, [9]University Childrens Hosptial, France, [10]University Hospital, France

Background: Juvenile systemic sclerosis (jSSc) is a rare autoimmune disease. Currently just retrospective data exist without a standardized assessment of the organ involvement. Our project is the first projects, where prospectively and with a standardized assessment data of early jSSc patients are collected.

Objectives: to learn about the evolvement of juvenile systemic sclerosis

Methods: Using the proposed standardized patient assessment protocol patients with early jSSc, entry into the cohort within the first 24 months of disease, are prospectively assessed. All participating centres approved the protocol over the own IRB.

Results: 42 centers from 20 countries applied to participate on the project. The assent and consent forms were translated into the local native languages. Up till now 16 patients were enrolled, the mean follow up of the patients in the cohort are 1.6 years. Thirteen of the 16 patients were female. The mean age at the onset of the non-Raynaud symptomatic were 12.4 years. Nine of the 16 have diffuse subtype, 5 of them have an overlap symptomatic. At the time of the inclusion the mean modified Rodnan Skin Score was 16.5 (range, 2 to 51). 14 were ANA positive, and 5 of them were anti-Scl 70 positive. None of them was anticentromere positive. Fourteen of the 16 have Raynaud′s, 12 of them have capillary changes and 4 of them already ulcerations. 7 of them have cardiopulmonary involvement, 4 of them have interstitial lung disease. Two of them have renal involvement. Eight of them have gastrointestinal involvement, and 5 of them oesophageal involvement. Fourteen of them have musculoskeletal involvement.

Conclusion: We present the data on the first 16 prospectively assessed patients with jSSc. The current recruitment data confirms that pediatric patients are different from the adult patients. We are only at the first phase of this project and hope to recruit up to 50 patients and follow them prospectively over the next 2 to 4 years at least.

Validation of Birmingham Vasculitis Activity Score in Childhood Vasculitis. Erkan Demirkaya[1], Seza Ozen[3], Angela Pistorio[3], Angelo Ravelli[3], Rachana Hasija[3], Raju Khubchandani[3], Salvatore Scarpato[3], Michel Fischbach[3], Nicolae Iagaru[3], Srdjan Pasic[3], Esra Baskin[3], Frank Dressler[3], Marion A. J. van Rossum[3], Julia García-Consuegra[3], Maria Teresa Apaz[3], Maka Ioseliani[3], Henryka Mazur-Zielinska[3], Alberto Martini[2], Roberta Galasso[3], Nicolino Ruperto[2] and Pavla Dolezalova[3]. [1]IRCCS G. Gaslini, Genova, Italy, [2]IRCCS G. Gaslini/Università degli Studi di Genova, [3]PRINTO

Background: Unlike for adults patients with systemic vasculitis, there are no validated tools to measure disease activity status in childhood (c-) systemic vasculitis.

Objectives: Our aim was to validate the last version of Birmingham Vasculitis Activity Score (BVAS v.3) and the Disease Extend Index (DEI) for comprehensive assessment of paediatric primary c-systemic vasculitis.

Methods: We extracted from the PRINTO database all patients who fulfilled the Henoch-Schoenlein (HSP), childhood (c) polyarteritis nodosa (c-PAN), c-Wegener (c-WG) and c-Takayasu (c-TA) EULAR/PRINTO/PRES c-vasculitis classification criteria and whose disease duration at the time of diagnosis was ≤ 3 months. Data were also available for follow-up evaluation ≥ 3 months after diagnosis. The validation of the BVAS and DEI were examined by assessing discriminant ability among the 4 vasculitis, convergent validity by Spearman correlation coefficient with physician's global assessment of disease activity (MD global), indexes of inflammation (ESR/CRP), responsiveness to change over time through the standardizes response mean (SRM); A SRM value <0.5 is considered small, ≥0.5 and <0–8 moderate, and values ≥ 0.8 represent large effect.

Results: The analysis data set included 796/1124 (71%) patients (M:F 0.96:1): there were 669 HSP, 80 c-PAN, 25 c-WG and 22 c-TA. The median age of the diagnosis was 6.99-year (6.6–11.96) and median delay for the diagnosis from the onset of signs or symptoms was 0.01 (0.003–0.027) years. In the table 1 are reported the 9 subscore of the BVAS, the total BVAS score, the DEI, the MD global and indexes of inflammation.

The BVAS was able to discriminate between the 4 c-vasculitides with total BVAS scores equal to 9 (6.0–14.0), 17.5 (11.5–24.5), 23 (19–29), 15 (11–20) in HSP, c-PAN, c-WEG and c-TA respectively.

Table 1. Discriminant ability of the BVAS total scores and the other tools:data are medians (1*-3* quartiles)

	All patients n = 796	HSP n = 669 (%)	c-PAN n = 80 (%)	c-WG n = 25 (%)	c-TA n = 22 (%)	P values*
BVAS	10 (8.0–16.0)	9 (6.0–14.0)	17.5 (11.5–24.5)	23 (19–29)	15 (11–20)	<0.001
DEI	5 (4.0–6.0)	5 (4.0–6.0)	5 (3.0–7.0)	7 (6–9)	3 (2–5)	<0.001
MD global	5 (3–7)	4 (2.5–6)	7 (7–8)	8.5 (8–9)	8 (7–8.5)	<0.001
CRP	1.38 (0.5–4.33)	1.01 (0.45–2.21)	8.14 (4.45–16.4)	9.8 (5.36–16.38)	4.63 (2.23–8.49)	<0.001
ESR	29 (14.0–51.5)	22 (12.0–36.5)	86 (53.0–115.0)	76.5 (58–107.5)	48 (40–72)	<0.001

*P values refers to ANOVA with Dunn test as a posthoc.

The cutaneous and cardiovascular sub-score are able to distinguish TA patients from the others; the ENT sub-score shows a significant ability to discriminate the c-WG patients from the others.

A strong correlation was found between the BVAS and DEI (r_s=0.80) while correlation with MD global were moderate (r_s=0.49) and poor with CRP and ESR (r_s=0.34, r_s=0.31). Responsiveness was large for BVAS total score (SRM=1.38), DEI (SRM=1.9), MD global (SRM=1.3) and ESR (SRM=0.85).

Conclusion: BVAS and DEI showed adequate discriminant ability and sensitivity to change but, poor to moderate convergent validity. Further work is needed in order to improve activity measurement in c-vasculitides.

Validation of the Newly Developed Pediatric Criteria for the Diagnosis of Familiar Mediterranean Fever in a Large Pediatric Cohort of Western European Children with Periodic Fever. Silvia Federici[7], Giuseppina Calcagno[5], Martina Finetti[7], Antonella Meini[6], Agata Vitale[5], Marco Cattalini[6], Roberta Caorsi[7], Francesco Zulian[1], Alberto Tommasini[3], Maurizia Baldi[2], Joost Frenkel[8], Isabella Ceccherini[4], Alberto Martini[7] and Marco Gattorno[7]. [1]Dipartimento A.I. di Pediatria, University of Padua, [2]Dipartmento di Genetica Umana, Ospedale Galliera, Genoa, [3]IRCCS Burlo Garofolo, Trieste, [4]Lab Genetica Molecolare Istituto G. Gaslini, Genoa, Italy, [5]Sezione di Reumatologia Pediatrica, Dipartimento di Scienze Pediatriche, AOU "G. Martino", Messina, [6]Unità di Immunologia e Reumatologia Pediatrica, Spedali Civili, Brescia, [7]UO Pediatria II Istituto G. Gaslini, Genoa, Italy, [8]Wilhelmina Children's Hospital, Utrecht, The Netherlands

Purpose: FMF belong to the group of the periodic fever and is caused by mutations in the MEFV gene. Despite the possibility of a molecular characterization the diagnosis of the disease is mainly based on clinical criteria. Several diagnostic criteria have been developed, but none of them are specific for the pediatric age. A new set of criteria for the diagnosis of FMF in children were recently proposed (Yalçinkaya et al., Rheumatology 2009; 48(4):395). Aim of the study was to verify in a pediatric cohort of Caucasian patients with periodic fever the sensitivity and specificity of the new pediatric criteria in comparison to classical adult criteria (Livneh et al A&R 1997; 40(10):1879).

Patients & Methods: Detailed clinical information on 389 pediatric patients (mean age 8,5 yrs; SD± 8,3) with periodic fever were collected. All patients were screened for mutations of *MVK*, *TNFRSF1A* and *MEFV* genes. For each patient adult FMF criteria and new pediatric FMF criteria were applied.

Results: 106 children carried mutations of MEFV gene (40 were homozygous or compound heterozygous, 66 with a single mutation), 38 patients displayed two mutations of MVK gene. Structural mutations of *TNFRSF1A* gene were found in 12 patients, whereas 18 patients displayed low-penetrance (R92Q or P46L) TNFRSF1A mutations. 215 patients were negative to all three genes. All patients (100%) carrying two mutations of MEFV gene and 49 heterozygous individuals (74%) were positive for adult FMF criteria. The same criteria were also positive in 135 (63%) of genetically negative and 71 % of individuals affected by other monogenic periodic fevers, with an overall specificity of 33.2%. Conversely, the new pediatric criteria were positive in 33/40 (82,5%) patients carrying two MEFV mutations and in 27/66 (41%) heterozygous patients, whereas its overall specificity was 76 %.Six out of the 7 patients carrying two MEVF mutations that did not satisfied the new pediatric criteria carried low penetrance mutations and generally displayed a mild phenotype.

Conclusions: Pediatric FMF criteria show an higher specificity when compared to classical adult FMF criteria.

(22–52)adrenomedullin Shifts Cytokine Balance from Th1 to Th2, Reduces IL-17A Expressions and Modulates Treg Cells in Collagen-Induced Arthritis. Marie-Dominique Ah Kioon[5], Carine Asensio[5], Korng Ea[5], Sandrine Rullé[1], Géraldine Falgarone[1], Corinne Collet[4], Jean-Marie Launay[3] and Frederic P. Liote[2]. [1]EA 4222, Paris 13 University, Bobigny, France, Metropolitan, [2]Hopital Lariboisiere, Paris, France, [3]Paris 5 University, Paris, France, Metropolitan, [4]Paris 5 University, Bobigny, France, Metropolitan, [5]UMR-S606 Inserm, Paris Diderot University, Paris, France, Metropolitan

Purpose: Rheumatoid arthritis is an inflammatory disease characterized by an increase in pro-inflammatory cytokine production due to activated Th1 and Th17 cells, and Treg dysregulation. Depending on cell types, adrenomedullin (AM) acts as a pro- or anti-inflammatory peptide in vitro. It exerts anti-inflammatory effects in vivo: AM reduces IL-1, IL-6 and TNF-α in septic mice and reduces collagen-induced arthritis (CIA) by up-regulating Treg cells. (22–52)AM, a fragment peptide which binds to AM receptors, acts also as an antagonist or agonist of ADM in vitro but its in vivo effects are unknown. Our aim was to evaluate effects of (22–52)AM on arthritis score, seric and articular cytokines expression in CIA.

Methods: CIA DBA/1 mice were treated with 1.2 μg/g (22–52)AM or saline (control) as soon as arthritis occurred. Animals were sacrificed at day 45 (D45), joints were processed for histology and protein studies and spleens for Treg expression. Expression of cytokines (ELISA) was studied in joint tissues and in sera.

Results: At D24 post-immunization, control CIA saline-treated mice started to develop arthritis as shown by arthritic score (ranging from 2 to 11 from D24–45). At sacrifice, (22–52)AM had decreased arthritic score compared to saline (5.8±2 vs 11±3, respectively; $p<0.05$). Incidence of arthritis was reduced by 25 % with (22–52)AM. Histological scores were decreased with (22–52)ADM compared to control (0.56±0.04 vs 3.78±0.26, $p<0.05$). Compared to naïve mice, saline-treated CIA mice had significantly higher serum levels of the proinflammatory cytokines TNF-α, IL-6, IL-17A). (22–52)AM completely abrogated this increase The broad systemic antiinflammatory activity of AM and (22–52)AM was accompanied by down-regulation of Th1 (TNF-α, IL-6) and Th17 (IL-17A) cytokine expression in knee extracts and up-regulation of anti-inflammatory cytokines (IL-10, IL-4). Furthermore, the number of Treg cells expressing CD4+CD25+Foxp3 was decreased in control CIA mice vs naïve mice. (22–52)AM had no effect on number of Treg cells as compared to CIA control mice but, (22–52)AM treatment significantly increased serum IL-2 level in CIA mice.

Conclusions: (22–52)AM, along with reduced clinical and histological arthritis score in CIA, dramatically decreased serum and articular pro-inflammatory cytokines and triggered a robust increase in anti-inflammatory cytokines in CIA mice. (22–52)AM did not modulate the number of CD4+CD25+Foxp3 Treg cells but, increased Treg functions, as evidenced by increased IL-2 production, a marker of Treg activity.

A New Humanized Mouse Model for Experimental Erosive Arthritis: A Possible Role of Epstein-Barr Virus (EBV) for Experimental Erosive Arthritis That Resembles Rheumatoid Arthritis (RA). Yoshikazu Kuwana[5], Masami Takei[5], Misako Yajima[3], Hirotake Inomata[6], Masaaki Shiozaki[7], Natsumi Ikumi[7], Takamasa Nozaki[7], Hidetaka Shiraiwa[7], Noboru Kitamura[7], Shigemasa Sawada[7], Hiroyuki Masuda[7], Naoki Yamamoto[3], Norio Shimizu[4], Mamoru Ito[1], Ken-ichi Imadome[2] and Shigeyoshi Fujiwara[2]. [1]Central Institute for Experimental Animals, Kawasaki, Japan, [2]Department of Infectious Diseases, National Research Institute for Child Health and Development, Tokyo, Japan, [3]Department of Microbiology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, [4]Department of Virology, Division of Medical Science, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan, [5]Division of Hematology and Rheumatology, Department of Medicine, Nihon University School of Medicine, Itabashi Tokyo, Japan, [6]Division of Hematology and Rheumatology, Department of Medicine, Nihon University School of Medicine, Itabashi Tokyo, Japan, [7]Division of Hematology and Rheumatology, Department of Medicine, Nihon University School of Medicine, Tokyo, Japan

Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease of unknown etiology characterized by destructive synovitis and systemic immunologic abnormalities. In this study, whether Epstein-Barr virus (EBV) infection could result in erosive arthritis that resembles RA in NOD/Shi-*scid*/IL-2R^{null} (NOG) mice was examined.

Methods: NOG mice, a highly immunodeficient mouse strain, in which the functional human immune system is reconstituted when they receive hematopoietic stem cell (HSC) transplants, were used. Human CD34$^+$ HSCs were obtained from cord blood using a magnetic-activated cell sorting (MACS) direct CD34 Progenitor Cell Isolation Kit. These CD34$^+$ cells (1×10^4 to 1.2×10^5 cells/mouse) were injected intravenously into 6–10-week-old, female, NOG mice. The NOG mice were inoculated intravenously through the tail vein with EBV (10^0-10^3 TD_{50}) on days 106 to 180 after stem cell transplantation. EBV DNA in peripheral blood was quantified by a real-time quantitative polymerase chain reaction (PCR) assay based on the TaqMan system (Applied Biosystems) 1 to 4 months after inoculation. One, two, six, and twelve months after being inoculated with EBV, the humanized NOG mice were sacrificed, and their joints were examined pathologically. The joint tissues were stained with hematoxylin-eosin (H-E) stain, and immunostaining and EBV in situ hybridization were performed.

Results: The joint tissues of the mice revealed pannus invading bone tissue, synovial membrane proliferation, and inflammatory tissues infiltrating the bone marrow (BM) space. Human CD4$^+$ T cells were seen proliferating to the synovium and the BM near joints. Migration of large multinuclear giant cells, thought to be osteoclasts, was also evident in the pannus site. EBV-infected cells were mainly conformed within the BM of the EBV-inoculated NOG mice, but there were few EBV-infected cells in the synovium.

Conclusions: In this study, bone erosion accompanied by pannus and synovial membrane proliferation was confirmed at the joints of EBV-inoculated NOG mice. Further, some EBV-inoculated NOG mice revealed BM erosion as a result of the inflammatory cell infiltration. The results of this study suggest that EBV-inoculated NOG mice develop erosive arthritis that resembles RA.

ASC Plays a Role in the Priming Phase of the Immune Response to Type II Collagen in Collagen-Induced Arthritis. Hideshi Yamazaki[1], Michiko Takeoka[1], Masato Kitazawa[1], Takashi Ehara[2], Naoki Itano[1], Hiroyuki Kato[2] and Shun'ichiro Taniguchi[1]. [1]Shinshu University Graduate School of Medicine, Matsumoto, Japan, [2]Shinshu University School of Medicine, Matsumoto, Japan

Background: Although rheumatoid arthritis (RA) is an autoimmune disease of unknown etiology, the role of TNF-a, IL-1β, IL-18, and IL-6 in the pathogenesis of RA has been well established. IL-1β and IL-18 are generated via cleavage of their pro-forms in the presence of the apoptosis-associated speck-like protein containing a caspase recruit domain (ASC), which is an adaptor protein that activates procaspase-1. We therefore investigated the involvement of ASC in RA progression and assessed the phase at which ASC exerts effects using ASC-deficient mice models of collagen-induced-arthritis (CIA) and collagen antibody-induced arthritis (CAIA).

Method: CIA was developed in ASC-deficient (ASC$^{-/-}$) and wild-type (ASC$^{+/+}$) mice by four back-crosses to the DBA/1J background. CAIA was induced in ASC$^{-/-}$ and ASC$^{+/+}$ mice using a mouse monoclonal anti-type II collagen five clone antibody cocktail. Histological findings and expression of pro-inflammatory cytokines in knee joints were then compared and disease severity in joint sections was graded using a scoring system. Analysis of IL-1b and IL-18 expression was also performed by immunohistochemistry.

Results: Histological examination and scoring of arthritic knee joints from ASC$^{+/+}$ and ASC$^{-/-}$ CIA mice revealed that infiltration of inflammatory cells and cartilage/bone destruction were significantly decreased in ASC$^{-/-}$ mice compared with ASC$^{+/+}$ mice. Conversely, no differences were observed between ASC-deficient mice and controls for CAIA. In CIA knee joints, IL-1β and IL-18 expression were lower in ASC$^{-/-}$ mice compared with ASC$^{+/+}$ mice, whereas these cytokines were expressed at similar levels in the knee joints of ASC$^{+/+}$ and ASC$^{-/-}$ CAIA mice.

Conclusion: We demonstrated that ASC-deficient mice were comparably susceptible to CAIA as normal mice, but were protected from disease severity in CIA. Thus, ASC is believed to be involved in early CIA development and may play a role in the priming phase of the immune response to type II collagen.

Asymmetric Arthritic Flare in the Knees of TNF-Tg Mice Is Mediated by Expansion of CD23+/CD21hi B Cells and Ipsilateral Collapse of Lymph Nodes in Series. Jie Li, Igor Kuzin, Christopher Ritchlin, Ignacio Sanz, Andrea Bottaro, Lianping Xing and Edward Schwarz. University of Rochester

Purpose: The efficacy of TNF antagonists and anti-CD20 therapy has demonstrated a critical role for TNF and B cells in the pathogenesis of rheumatoid arthritis (RA). However, the mechanism underlying arthritic flare and asymmetric arthritis in particular joints is still unknown. Previously, we used contrast-enhancement (CE) MRI and near infrared (NIR) indocyanine green (ICG) lymphatic imaging to evaluate arthritis in TNF-Tg mice, and demonstrated that arthritic progression from the ankle to the knee joint occurs following a sudden decrease in lymphatic flow from the lower limb to the adjacent popliteal lymph node (PLN). This decrease in lymphatic flow to "expanding" PLNs with high lymphatic drainage capacity (LNcap) lead to a "collapsed" PLN phenotype characterized by a marked decreases in LNcap, and translocation of CD23+/CD21hi B cells in inflamed nodes (Bin) from the follicles into the sinus space. Interestingly, this pathology is asymmetric in time to occurrence and incidence, and some TNF-Tg mice never develop bilateral knee arthritis. Since lymph from the ankle drains to PLN and lymph from knee joint drains to the iliac lymph node (ILN), we hypothesized that the correlation of PLN collapse and arthritic flare in the adjacent knee is caused by inhibited lymph drainage of the lower limb due to simultaneous collapse of ipsilateral PLN and ILN, and tested this in our murine model.

Methods: 5–7 month old TNF-Tg mice with expanding or collapsed PLNs were identified by longitudinal CE-MRI, and their knees were phenotyped for arthritic flare (defined as synovial volume $>3mm^3$). PLNs ($n>10$) and ILNs ($n>10$) were harvested from the TNF-Tg, and their WT littermate controls, for flow cytometry or immunohistochemistry (IHC) to quantify Bin and their location within the node. Lymphatic draining function of PLN and ILN were measured by NIR of ICG injected into the footpad or knee cavity, respectively.

Results: Flow cytometry of ILNs revealed a significant ($p<0.05$) 2.8-fold expansion of the Bin population from 7.2% in WT to 19.8% in TNF-Tg, which was consistent with the significant ($p<0.05$) 3.3-fold increase from 10% to 33.2% observed in WT and TNF-Tg PLN respectively. While Bin numbers were similar in both expanding and collapsed PLNs, IHC revealed that ILN ipsilateral to collapsed PLN have similar lymphoid architecture in which Bin are depleted from the follicular region, and reside in paracotical LYVE+ lymphatic sinuses. NIR-ICG imaging revealed that lymph flow to ILN ipsilateral to expanding PLNs (S-max=255) is 1.7-fold greater than that of ILN ipsilateral to collapsed PLNs (S-max=151.4).

Conclusion: Our results showed that ipsilateral ILN and PLN function in series. The decrease of lymphatic flow from the lower limb and Bin translocation from the follicles into lymphatic sinuses of draining LNs occur simultaneously. This finding supports a novel mechanism of the asymmetric arthritic flare that is triggered by Bin translocation in draining LN, which results in decreased afferent lymph flow from the inflamed joint. Future studies aimed establish this Bin "clogging" phenomena in mice and RA patients will be discussed.

CD44 Involvement in Arthritis: The Role of cd44-Splice Variants in Development of Collagen-Induced Arthritis in Mice. Celia Menckeberg[3], Marjolein van Maanen[4], Ronald van der Neut[2], Steven T. Pals[2], Margriet Vervoordeldonk[3] and Paul P. Tak[1]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Department of Pathology, Amsterdam, The Netherlands, [3]Division of Clinical Immunology and Rheumatology, Amsterdam, The Netherlands, [4]Division of Clinical Immunoly, Amsterdam, The Netherlands

Objective: CD44 comprises a family of type I transmembrane glycoproteins with a wide tissue distribution including expression on leukocytes, fibroblasts, as well as epithelial and endothelial cells, and is capable of binding to several ligands, its preferred ligand being hyaluronic acid (HA). There have been several reports suggesting a role for CD44 and HA in rheumatoid arthritis (RA). Interestingly, it is now clear that alternative splicing and selective tissue distribution of CD44 variants confer specific functions to the CD44 molecule. Specifically, it has been shown that distinct CD44 splice variants differ in their ability to interact with extracellular matrix molecules (ECM) and with cytokines/growth factors. The role of these molecules in rheumatic diseases has been rarely studied so far, although it has for example been shown that CD44v3 is overexpressed on synovial fibroblasts, which carry an increased invasive capacity in vitro. In contrast, overexpression of CD44v8-v9 was described to correlate negatively with the invasive capacity of fibroblast-like synoviocytes. Therefore, we explored the role of CD44 splice variants in an animal model of RA by using a unique series of CD44 knock-out-knock-in mice that selectively express CD44 variants, differing in their capacity to interact with hyaluronan, chemokines/cytokines, and growth factors.

Methods: In C57BL6 mice collagen-induced arthritis (CIA) was induced at day 0 by an intradermal injection with chicken type II collagen at the base of the tail followed by the same injection on day 20. CIA was induced in wild-type (WT) mice, CD44 knock-out mice (KO), expressing none of the isoforms, and knock-out-knock-in strains CD44s/s (able to bind HA but not growth factors, chemokines), CD44v3-v10 (carrying the heparan sulphate (HS) side chains), and CD44v4-v10 mice (similar to CD44-v3-v10 but missing the HS attachment site). All mice were viable and did not show any detectable deficiencies. Mice were sacrificed on day 56 after induction of disease. Disease progression was monitored by visual clinical scoring and measurement of paw swelling. In addition, inflammation and joint destruction were examined by histology and radiology. Serum levels of anti-collagen type II antibodies were measured by enzyme-linked immunosorbent assay

Results: There was a significant decrease in the incidence and severity of arthritis in KO, CD44s/s, KO, and CD44v4-v10 mouse strains ($P<0.05$), accompanied by reduced synovial inflammation ($P< 0.05$) and bone destruction, compared to WT mice. In contrast, the CD44v3-v10 mice showed a delayed onset of disease but the clinical scores reached similar levels as those in WT. Moreover, we found a specific decrease in the collagen-specific 'Th1-associated' IgG2a response ($P<0.01$) in mice with reduced arthritis activity, but not in CD44v3-v10 mice.

Conclusion: The results suggest the involvement of the CD44 v3 region in the development and expression of arthritis.

Counter-Regulatory Role of Interferon Regulatory Factor 7 in Serum Transfer K/BxN Inflammatory Arthritis. Susan E. Sweeney[1] and Trevor B. Kimbler[2]. [1]University of California San Diego, La Jolla, CA, [2]University of California San Diego

Purpose: Innate immune response pathways play a role in synovial activation and cell recruitment into the rheumatoid joint. Viral-stress inducible proteins such as type I interferon (IFNα and IFNβ), IP-10, and RANTES are produced through the activation of NF-κB, MAP kinases, and IFN-regulatory factors (IRF) as a result of innate sensor recognition of dsRNA. The IRF family not only regulates the IFN response, but also cell differentiation, cell cycle, and apoptosis. This study examines the effect of genetic deficiency of IRF7 in regulation of the type I IFN response in murine synoviocytes, macrophages, and a passive K/BxN serum transfer model of arthritis.

Methods: Fibroblast-like synoviocytes (FLS) and peritoneal macrophages isolated from IRF7$-/-$ mice were stimulated overnight with poly (I-C) followed by Q-PCR to evaluate gene expression. Passive K/BxN serum transfer arthritis was induced in IRF7$-/-$ mice and additional groups were treated with IFNβ or poly (I-C). Clinical arthritis scores were measured and synovial tissue Q-PCR was performed. Mouse serum was analyzed for IFNβ, IL-10, and IL-1RA by ELISA.

Results: Poly (I-C) stimulation of murine IRF7$-/-$ FLS resulted in increased induction of pro-inflammatory gene expression of RANTES (5.2-fold, $p<0.01$), MIP1α (1.8-fold, $p<0.05$), and MMP-3 (2.7-fold, $p<0.05$) compared with C57BL/6 wild type FLS. In contrast, IRF7$-/-$ macrophages stimulated with poly (I-C) showed significantly less induction of inflammatory cytokine gene expression, including IFNβ, IP-10, MIP1α and IL-6 (8.8-fold, $p<0.01$; 11.2-fold, $p<0.01$; 5.3-fold, $p<0.05$; 21.7-fold, $p<0.005$ respectively). In the K/BxN passive in vivo model, arthritis severity in IRF7$-/-$ mice was significantly increased (day 12 score 8.8 vs. 3.9; $p<0.01$) compared with wild type K/BxN. Gene expression of IFNβ, RANTES, MIP1α, and IL-6 was decreased in IRF7$-/-$ synovial tissue compared with K/BxN control synovium (3.9-fold, $p<0.05$; 2.2-fold, $p<0.05$; 2.4-fold, $p<0.04$; 1.7-fold, $p<0.05$ respectively). The serum IFNβ level in IRF7$-/-$ mice was also significantly decreased compared with control K/BxN serum (2.8-fold, $p<0.04$). IRF7$-/-$ mice injected with IFNβ had a decrease in paw score (ΔPaw score = 1.8) similar to wild type mice (ΔPaw score = 2.9), suggesting that the increased arthritis might be partially due to decreased IFNβ. Poly (I-C) treatment diminished arthritis severity (17% change, $p<0.05$) in IRF7$-/-$ mice and increased serum IFNβ levels (1.6-fold, $p<0.05$).

Conclusion: These data suggest that IRF7 contributes to regulation of the type I IFN response and cytokine production in cell-specific manner in macrophages (pro-inflammatory) and synovioctyes (anti-inflammatory). IRF7 plays an anti-inflammatory role in passive transfer K/BxN arthritis possibly through regulation of IFNβ. IRF7 also partially contributes to poly (I-C)-mediated inhibition of arthritis in this model. Our data suggest that TLR agonists that induce IRF7 might represent a novel therapeutic approach in the treatment of inflammatory arthritis.

Dectin-1 and NOD2 Mediate Zymosan-Induced Arthritis in Mice. Holly L. Rosenzweig[1], Jenna S. Clowers[4], Gabriel Nunez[3], James T. Rosenbaum[2] and Michael P. Davey[5]. [1]Oregon Health & Science University/VA Medical Ctr, Portland, OR, [2]Oregon Health Science Univ, Portland, OR, [3]University of Michigan Medical School, Ann Arbor, MI, [4]VA Medical Ctr, [5]VA Medical Ctr/Oregon Health & Science University, Portland, OR

Purpose: Rheumatoid arthritis (RA) remains a disease of unknown etiology. Genetics, the environment and specific features of diarthroidial joints are presumed to play contributory roles. Receptors of the innate immune system within diarthroidial joints may contribute to arthritis by detecting components of infectious agents, a hypothesis often implicated in the etiology of RA. We sought to elucidate the role of innate immune receptors within the Toll-like receptor (TLR), NOD-like receptor (NLR) and C-type lectin receptor (CLR) families in the well-established murine model of zymosan-induced arthritis (ZIA).

Methods: Arthritis was elicited by intra-articular injections of zymosan or fungal cell wall components: curdlan, laminarin and mannan. The extent of disease within the joint was assessed by NIR-fluorescence imaging and histology. The contribution of individual immune receptors or a signaling molecule (CR3, TLR2, MyD88, Dectin-1, Dectin-2, NOD1, or NOD2) was assessed using knock-out mice or blocking antibodies. For fungal infection, mice were infected with *Candida albicans* and the presence of fungi and joint inflammation were assessed by PAS/green staining and NIR-imaging.

Results: Systemic fungal infection caused mild arthritis in mice that coincided with the presence of fungi within the joint. As previously demonstrated, intra-articular injection of zymosan triggered arthritis in mice at 3 days following injection. This response was dependent on Dectin-1, a member of the CLR family. Dectin-2 also contributed to ZIA, but to a lesser extent than Dectin-1. However, deficiency in TLR2, MyD88 or CR3 did not significantly alter ZIA. Injection of curdlan, laminarin or mannan (the individual components of zymosan) showed that curdlan alone was the arthritogenic component of zymosan and the effect was dependent on Dectin-1. Somewhat surprisingly, we found that ZIA was dependent on NOD2 as NOD2 KO mice were resistant to disease. In contrast to NOD2, we found that NOD1 deficiency did not alter arthritis.

Conclusion: The present study elucidates the receptors involved in mediating ZIA. Together, Dectin-1 and NOD2 are essential receptors of the innate immune system in the arthritogenic effects of zymosan. This is the first association of NOD2 with innate immune responses to fungal components and points to a regulatory role for NOD2 in the normal physiology of diathroidial joints. Given that mutations in NOD2 cause of an inherited form of arthritis (Blau syndrome), our findings further implicate NOD2 as an important protein within diarthroidial joints contributing to inflammatory arthritis.

Dendritic Cell-Based Immunotherapy Combined with Low-Dose Methotrexate Is Effective in the Treatment of Advanced Collagen-Induced Arthritis in Mice. Mi-Sun Kang[4], Jung-Wook Lee[4], Hyun-Soo Lee[4], Chan-Bum Choi[1], Hye-Soon Lee[3], Sang-Cheol Bae[2] and Yong-Soo Bae[5]. [1]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Republic of Korea, [2]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic of, Korea [3]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, [4]Research Institute for DC Immunotherapy, CreaGene Inc., [5]Research Institute for DC Immunotherapy, CreaGene Inc., Department of Biological Science, Sungkyunkwan University

Objectives: We have previously demonstrated that semi-mature dendritic cells (smDC)-based immunotherapy was effective in the treatment of early stage collagen-induced arthritis (CIA). This work was initiated to determine the efficacy of combination therapy with smDC and methotrexate (MTX) in advanced stage of CIA mice.

Methods: CIA mice in arthritis score 2–3 (5–6 weeks after primary CII inoculation) were treated with MTX and collagen-loaded smDCs (CII-smDC) in three consecutive therapeutic cycles. Each therapeutic cycle was completed by administration of MTX three times on days 2, 4 and 6, followed by administration of CII-smDC on day 7. Footpad thickness and the disease severity of each mouse were measured once or twice a week for 90 days after completion of three therapeutic cycles. Foxp3-positive regulatory T cell (Treg) populations, Th1/Th2 immune response, and cytokine profiles were assessed in the spleen and lymph nodes.

Results: Combination therapy with low-dose (0.5mg/kg) MTX and CII-smDC was more effective than high or low dose MTX alone or combination of high dose MTX and CII-smDC in inhibiting disease progression. Treatment with CII-smDC alone also showed comparable effect. $CD4^+Foxp3^+$ Treg populations were markedly increased in mice treated with the combination therapy compared to mice treated with CII-smDC alone as well as other treatments. IL-10 secretion also increased in proportion to the level of induced Treg. The combination therapy reduced the secretion of interferon gamma (IFN-γ), but did not affect or slightly increased the IL-4 secretion in the mixed lymphocyte reaction with spleen or lymph node T cells. Treg induced by combination therapy were effective in inhibiting CII-specific T cell proliferation. However, total CD4+ T cell populations were not significantly changed by the combination therapy.

Conclusion: Combination therapy with low-dose MTX and smDC, or smDC alone, was efficacious in the treatment of advanced arthritis mice by inducing antigen-specific Treg population, rather than changing Th1/Th2 immune deviation, followed by blocking autoreactive T cell proliferation, resulting in disease control.

Histone Deacetylase Inhibitor (HDAi) Ameliorates Chronic Arthritis in SKG Mice by Altering Conventional Dendritic Cells (cDCs) Phenotype into Tolerogenic DCs. Kenta Misaki[2], Akio Morinobu[2], Jun Saegusa[2], Yoshiaki Miyamoto[2], Shinpei Kasagi[2] and Shunichi Kumagai[1]. [1]Clinical Immunology and Pathology, Kobe University, Kobe, Japan, [2]Clinical Immunology and Pathology, Kobe University, Japan

Background & Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory polyarthritis, leading to joint destruction. CDCs contribute to pathogenesis of RA by triggering the immune responses. HDAi plays a significant role of controlling gene transcription, and has been reported to regulate immune responses. Here we examined the therapeutic effects of HDAi (Trichostatin A: TSA) on the RA model mice and cDCs.

Methods: SKG mice were injected with Zymosan A (ZyA) to induce chronic arthritis. DMSO or TSA was daily administrated to SKG mice. Cell surface molecules and cytokine production in splenic cDCs, clinical arthritis scores, histological arthritis scores were evaluated in each group. The effects of TSA on bone marrow cells-derived cDCs treated with ZyA (BMcDCs-ZyA) were assessed by flow cytometry, ELISA, real-time PCR (RT-PCR) and the allo-mixed lymphocyte reaction (allo-MLR) *in vitro*.

Results: Clinical arthritis scores and histological arthritis scores in SKG mice treated with TSA were significantly lower than those with DMSO. CD80 and CD86 expression of splenic cDCs in TSA group were notably down-regulated compared to those in DMSO group. IL-17A production in CD4 positive splenocytes was also decreased in TSA group. *In vitro*, IL-12p70, IL-12p40, IL-6 secretions and CD80, CD40 levels of BMcDC-ZyA were reduced in BMcDC-ZyA with TSA by flow cytometry and ELISA, respectively. Indoleamine 2,3-dioxygenase (IDO) expression in BMcDC-ZyA with TSA was much higher than those in BM-cDC-ZyA determined by RT-PCR. Pretreatment of BMcDCs with ZyA+TSA resulted in significantly reduced naïve CD4 positive T cell proliferation compared to that with BMcDCs-ZyA in allo-MLR.

Conclusions: TSA has notable anti-arthritis effects on SKG mice by modulating functions of cDCs. TSA alters DC function into tolerogenic DC, such as decreased expression of co-stimulatory molecules and pro-inflammatory cytokines, increased IDO expression, and reduced T cell proliferation. This is the first report that HDAi ameliorates the disease activity of SKG mice.

IDO Expressed CD11c+CD11b+ Dendritic Cells Enhance the Differentiation of Ag Inducible CD4+CD25+ Regulatory T Cells in Induction of Oral Tolerance under the Inflammatory State. Min Jung Park[2], Yong-Geun Jung[2], Su-Jin Moon[2], Ji-Min Kim[2], Seung-Ki Kwok[2], Ji-Hyeon Ju[2], Kyung-Su Park[2], Hyun Sil Park[2], Mi-La Cho[2], Sung-Hwan Park[2] and Ho-Youn Kim[1]. [1]Kang Nam St Marys Hospital, Seoul, Korea, Republic of, [2]Kang Nam St Marys Hospital

Repeated oral administration of an antigen is known to induce immunological hypo-responsiveness to that specific antigen, which is called oral tolerance. The mechanism of oral tolerance is believed to involve regulatory T cells (Tregs), tolerogenic dendritic cells (DCs) and several immune-regulatory molecules. Indoleamine 2,3-dioxygenase (IDO) which is expressed by DCs suppress T cell responses by catabolizing tryptophan and generating Tregs. In this experiment, we tried to identify which DC subsets in spleen express IDO and are involved in the generation of CD4+CD25+ Tregs during oral tolerance induction in murine collagen-induced arthritis (CIA) model.

We separated CD11c+ CD11b+ DCs from CIA mice after repeated oral administration of type II collagen (CII). The splenic CD11c+CD11b+ DCs produced IL-10 and TGF-β which are preferentially involved in the oral tolerance induction. In addition, splenic CD11c+CD11b+ DCs from CII fed mice expressed higher level of IDO than those from PBS fed CIA mice did. We compared the CII oral tolerance-induced IDO expression by and Treg inducing effect of CD11b+ DCs from CII-immunized CIA mice with those from un-immunized control mice. IDO expression in CD11b+ DCs as well as the proportion of Foxp3+ T cells in spleen and Peyer's Patch was significantly higher in CII-fed CIA mice (infalmmatory state) than in CII-fed non-immunized mice. Our data suggest that the immunoregulatory effect of CD11b+ DCs is more prominent in CII fed CIA(inflammation) condition. CD11c+CD11b+DCs from tolerized mice suppressed CII-specific T cell response and down-regulated proinflammatory cytokine production in an IDO-dependent manner. Notably, IDO-expressing $CD11c^+CD11b+$ DCs converted CD4+CD25-T cell into CD4+CD25+ Foxp3+ regulatory T cells with regulatory property.

Our results demonstrated that after repeated CII administration the specialized, tolerogenic DC subset, such as CD11b+ DCs can induce the peripheral differentiation of Tregs, prominently in inflammatory condition. Our data suggest that IDO-expressing CD11c+CD11b+ DCs play a crucial role in oral tolerance through an IDO-dependent pathway in inflammatory state and may be a candidate cell population for therapeutic modality in the treatment of autoimmune arthritis.

Immunisation with Citrullinated Human and Porphyromonas Gingivalis Enolase Induces Rapid Onset Arthritis in HLA DR4 Transgenic Mice. Andrew J. Kinloch[2], William Brintnell[5], David Yue[5], Lillian Barra[5], Natalia Wegner[1], Karin Lundberg[1], David A. Bell[3], Ewa Cairns[4] and Patrick J. Venables[1]. [1]Imperial College London, [2]Imperial College London, London, United Kingdom, [3]SJHC, London, ON, Canada, [4]Univ Western Ontario, London, ON, Canada, [5]University of Western Ontario

Background: Antibodies to citrullinated (cit) proteins/peptides are specific for RA, and predict more severe disease. Well-documented specific cit protein antigens include cit-fibrinogen and, more recently, cit-a-enolase. HLA DR4 alleles are genetic risk factors for antibodies to both antigens, with a preferential link with antibodies to an immunodominant peptide (CEP-1) of cit-a-enolase (Mahdi et al, Nature Genetics, 2009). The CEP-1 sequence is conserved in the enolase orthologue of *Porphyromonas gingivalis*, a bacterium which also expresses an active deiminase, which can citrullinate both a-enolase and fibrinogen. This suggests that antigens generated by this bacterium could breach immunological tolerance. Hill et al. (J Exp Med, 2008) demonstrated that mice expressing the human *0401* gene (DR4-IE transgenic mice) immunised with cit-fibrinogen developed chronic arthritis after 40 days and that this arthritis was dependent on the *0401* transgene. Given that the link with *0401* is particularly strong for anti-CEP-1 in human disease, the purpose of this study was to examine the arthritogenicity of cit-enolase in the same DR4-IE transgenic mouse model.

Methods: Recombinant human and *P gingivalis* enolase were citrullinated *in vitro* with rabbit PAD2 and used to immunise DR4-IE mice and control mice (MHC class II knockout and C57BL/6). Arthritis was quantified by measuring ankle swelling in the hind paws. The joints were examined by histopathology. Serum IgG reactivity with enolase and cit- enolase was assayed by Western blotting and ELISA. IgG antibodies to CEP1 and the arginine-bearing control (REP1) were measured by ELISA.

Results: All DR4-IE mice immunised with cit-enolase, both from human and *P gingivalis*, developed significant ankle swelling (mean 0.98 +/− 0.05 mm) in both hind paws, which peaked at day 20 whereas none of the other groups developed arthritis (swelling < 0.2 mm) $p < 0.0001$ (Student's *t*-Test). Pathology of arthritic joints showed synovial hyperplasia, but a relative paucity of leukocyte infiltration. IgG antibodies reacting with both cit- and non-cit-enolase, and also CEP1 and REP1 were detectable in all groups apart from the relatively immunodeficient MHC class II knockout group.

Conclusions: Both human and *P gingivalis* cit-enolase induce arthritis in DR4-IE mice. The arthritis was restricted to the group with the *0401* transgene, whereas the antibody response to both cit and non-cit antigens was not MHC-dependent. These data support recent epidemiologic evidence in humans that cit-enolase is an antigen of etiologic importance in RA in the context of DR4 risk alleles, and provides a novel model for investigating an etiologic role for *P gingivalis* in RA.

JNK1 Deficiency Limits Macrophage Mediated Antigen Induced Arthritis. Monica Guma[1], Gary S. Firestein[2], Michael Karin and Mary Corr[2]. [1]UCSD, [2]UCSD School of Medicine, La Jolla, CA

Objective: To elucidate the non-redundant roles of JNK1 and JNK2 in antigen-induced arthritis.

Methods: Mice that were genetically disrupted in Jnk1 or Jnk2 were primed with mBSA in complete Freund's adjuvant and then given an intraarticular challenge with mBSA in the knee on day 21. Bone marrow chimeras were generated and similarly treated. Joints were harvested and prepared for histological assessment. T cell responses were verified by proliferation response and relative immunoglobulin responses were measured by ELISA. Cytokine mRNA expression levels were measured by Q-PCR. Peritoneal macrophages and neutrophils were elicited by thioglycollate. Macrophage migration was tested in vitro. The peptide inhibitor D-JNKi was injected daily starting four days after intraarticular mBSA injection in wild type (WT) mice and inflammation was histologically scored.

Results: JNK1-deficient but not JNK2-deficient mice, had a marked reduction in inflammatory infiltration and bone erosion. This effect was restricted to hematopoetic cells, but B and T cell responses were preserved in mBSA injected mice. JNK1-deficient macrophages produced cytokines and chemokines comparably to WT counterparts. However, macrophage migration was impaired in vivo and in vitro. Targeting JNK with the peptide inhibitor D-JNKi dramatically reduced inflammation and joint destruction in WT mice.

Conclusions: Antigen-induced arthritis is dependent on JNK1, but not JNK2. JNK1 is a promising molecular target for reducing autoimmune inflammation as its inhibition impairs macrophage migration.

Loss of Integrin alpha2beta1 Suppresses Joint Inflammation and Cartilage Destruction in Mouse Models of Rheumatoid Arthritis. Marvin A. Peters[4], Doreen Wendholt[6], Simon Strietholt[6], Svetlana Frank[6], Adelheid Korb[5], Leo A. B. Joosten[2], Wim B. Van Den Berg[8], George Kollias[7], Elena Neumann[3], Beate Eckes[1], Ulf Muller-Ladner[9] and Thomas Pap[10]. [1]Department of Dermatology, University of Cologne, [2]Department of General Internal Medicine, Radboud University Nijmegen Medical Centre, [3]Department of Internal Medicine and Rheumatology, Justus-Liebig-University Giessen, Kerckhoff Clinic, Bad Nauheim, Germany, [4]Department of Internal Medicine and Rheumatology, Justus-Liebig-University Giessen, Kerckhoff Clinic; Institute of Experimental Musculoskeletal Medicine, University of Muenster, Bad Nauheim, Germany, [5]Department of Internal Medicine D, University of Muenster, [6]Institute of Experimental Musculoskeletal Medicine, University of Muenster, Muenster, Germany, [7]Institute of Immunology, Biomedical Sciences Research Center, [8]Radboud Univ Nijmegen Med Cntr, Nijmegen, The Netherlands, [9]Univ.Giessen/Kerckhoff-Clinic, Bad Nauheim, Germany, [10]University Hospital Münster, Münster, Germany

Background: Integrins are the main receptors for cell-matrix interactions, and integrin signaling is critical for a variety of cellular functions such as adhesion, cell spreading and inflammatory responses. Alpha2beta1 integrin acts as major receptor for type I collagen on a number of different cells, including inflammatory cells and fibroblasts. Although alpha2-deficient mice appear normal apart from mild platelet dysfunction, it was shown that alpha2 contributes to the induction and activation of MMPs in tissue remodeling. Based on the hypothesis that under stress conditions such as chronic inflammation alpha2beta1 integrin may be involved in the activation of synovial cells, we investigated its role in inflammatory arthritis.

Methods: The role of alpha2 was examined in two different murine models of arthritis, (i) alpha2-deficiency during antigen-induced arthritis (AIA), and (ii) alpha2-deficient mice crossed with arthritic human TNFalpha transgenic (hTNFtg) mice. Clinical signs of arthritis, weight and histological scores of synovitis and cartilage destruction were investigated using standard clinical evaluation and histomorphometric analysis. In addition, we analyzed MMP expression in tissue sections, serum and fibroblast-like synociocytes (FLS) from all genotypes and analyzed changes in proliferation and ERK phosphorylation. The role of the alpha2 subunit in the attachment of FLS to healthy and IL-1 damaged articular cartilage was analyzed using an established *in vitro* assay.

Results: At day 5 after AIA induction, alpha2(−/−) mice showed a decrease of joint inflammation (−57%) and proteoglycan loss (−54%) compared to wildtype mice. In addition, MMP3 levels were significantly lower in tissue sections of alpha2(−/−) mice. In hTNFtg mice, the loss of alpha2 integrin resulted in improved clinical signs and symptoms. hTNFtg/alpha2(−/−) mice had less paw swelling (1.80 vs. 2.38), increased grip strength (−1.71 vs. −2.42) and a less pronounced weight loss compared with hTNFtg mice. The histological analysis revealed that alpha2(−/−) mice had a decreased cartilage erosion (−48,5%) and significantly reduced attachment of FLS to cartilage (−55,5%). MMP-3 expression was reduced in the serum and in FLS of alpha2(−/−) mice. Additionally, the proliferation of alpha2(−/−) FLS was decreased *in vitro* and we demonstrated that this is mediated through ERK signaling pathways. Futhermore, attachment of alpha2-deficient FLS was reduced, particularly after induction of proteoglycan loss in IL-1 treated articular cartilage *in vitro*.

Conclusions: The results support the hypothesis that alpha2 deficiency is an important factor in inflammatory cartilage destruction by interfering with fibroblast attachment and proliferation as well as by modulating MMP expression.

Lung Inflammation and Pulmonary Function Alterations in Collagen-Induced Arthritis and in the Absence of Interferon-gamma Signaling. Evelien Schurgers[1], Freya Mertens[2], Jeroen Vanoirbeek[3], Tania Mitera[2], Stéphanie Put[2], Benoit Nemery[3] and Patrick Matthys[2]. [1]Laboratory of Immunobiology, Rega Institute, Katholieke Universiteit Leuven, Leuven, Belgium, [2]Laboratory of Immunobiology, Rega Institute, Katholieke Universiteit Leuven, Leuven, Belgium, [3]Research Unit of Lung Toxicology (Laboratory of Pneumology), Katholieke Universiteit Leuven, Leuven, Belgium

Background: Rheumatoid arthritis (RA), a systemic inflammatory disease affecting the joints, is regularly associated with extra-articular symptoms. Lung complications are one of these manifestations and have a profound impact on patient well-being and survival. There are no reports on pulmonary complications in collagen-induced arthritis (CIA), a widely used animal model for RA. We investigated potential lung inflammation and changes in pulmonary functions during CIA, using both wild type and interferon-gamma (IFN-γ) receptor knock-out (IFN-γR KO) mice, which develop a more severe form of arthritis.

Methods: CIA was induced in mice by a subcutaneous injection of collagen type II in Freund's adjuvant. At various time points after induction, cytokine and chemokine expression in the lungs and in synovial tissues were analysed by qPCR. Cell influx in the airways and inflammation in lung tissue were determined by broncheoalveolar lavage (BAL) and histology, respectively. To analyse the impact of arthritis on lung physiology, lung function measurements were assessed via the invasive forced oscillation technique of the flexiVent system. Resistance and elastance of the whole lung and more specific, the large airways and the alveoli were measured.

Results: Upon induction of CIA, the onset of arthritic symptoms was accompanied by induction of interleukin-1β (IL-1β) and the neutrophil chemokine Granulocyte Chemotactic Protein 2 (GCP-2) in the synovial tissues of both wild type and IFN-γR KO mice. In the lungs of wild type mice, IL-1β levels became detectable at day 10, before the onset of arthritis. In arthritic IFN-γR KO mice, lungs expressed GCP-2 and other chemokines such as KC and Monocyte Chemotactic Protein 1 (MCP-1). BAL fluid of arthritic wild type and IFN-γR KO mice contained elevated numbers of cells as compared to their respective naïve counterparts. The increase in cell numbers was caused by influx of macrophages and lymphocytes. BAL fluid of immunized IFN-γR KO mice showed an additional influx of neutrophils. On histological examination, lungs of arthritic IFN-γR KO mice demonstrated a perivascular lymphocytic infiltration into the lung tissue which was absent in arthritic wild type mice and in naïve animals. When lung function measurements were performed, tissue elasticity (H) and resistance (Rn) of the lungs were significantly elevated in arthritic IFN-γR KO mice as compared to naïve mice. No such effects could be observed in wild type mice.

Conclusions: Lung manifestations, as evident from expression of pro-inflammatory cytokines and chemokines in lung tissue and from cell influx in BAL, were detectable in both wild type and IFN-γR KO mice after induction of CIA. Perivascular infiltration into the lung tissue was exclusively present in arthritic IFN-γR KO mice and these changes negatively influenced the function of the lungs since these mice presented with a more rigid lung tissue. These results demonstrate that pulmonary manifestations do exist in CIA, and become more manifest upon deletion of one single gene (in this case IFN-γ). Therefore, CIA may prove a useful animal model to study the association between inflammation in the joints and in the lungs, as seen in RA patients.

1721

Macrophage Migration Inhibitory Factor Plays an Important Role in Inflammatory Arthritis. Mohammad A. Amin[2], Jeffrey H. Ruth[2], Bradley J. Rabquer[2], Phillip L. Campbell[2], Solhee Lee[2], John R. David[1] and Alisa E. Koch[3]. [1]Harvard School of Public Health, [2]University of Michigan, [3]VA Medical Service and University of Michigan Medical School, Ann Arbor, MI

Purpose: Macrophage migration inhibitory factor (MIF) is a proinflammatory cytokine which plays an important role in chronic inflammatory diseases such as rheumatoid arthritis (RA). We have previously shown that MIF mediates angiogenesis via phosphatidylinositol 3 kinase (PI3K) and mitogen activated protein kinase, and upregulates the expression of vascular cell adhesion molecule-1 and intercellular adhesion molecule-1 in monocytes via Src, PI3K, and NFκB. In this study, we examined the contribution of MIF to experimental inflammatory arthritis using K/BxN serum induced arthritis by employing MIF null and wild type (wt) mice.

Methods: We induced serum transfer K/BxN arthritis in MIF null and wt mice to examine the role of MIF in mouse inflammatory arthritis. We injected 150 μl of pooled K/BxN serum on days 0 and 2. Mice were scored clinically and ankle circumference was measured with a caliper before the induction of arthritis and then every day by an observer blinded to the experimental groups. We used enzyme linked immunosorbent (ELISA) assays to determine cytokine levels in arthritic MIF null ankle homogenates compared to wt mouse ankle homogenates. We also performed immunohistochemistry (IHC) to determine the inflammatory response in MIF null and wt mouse ankle sections. To further elucidate the contribution of MIF in an animal model of arthritis, we subjected MIF null and wt mice to sublethal total body irradiation. We performed bone marrow transfer experiments. In these experiments, irradiated MIF null mice received wt bone marrow cells (10^6 cells in 100 μl of PBS) and vice versa. After 12 weeks of bone marrow transplant, we induced K/BxN arthritis in these mice and collected ankles.

Results: MIF null mice had significantly less arthritis, showing a significant decrease in ankle circumference and articular index compared to wt mice. Mouse ankles were harvested on day 9 (day of maximal arthritis). Some of ankles were snap frozen for homogenization and cytokine analysis, while others were frozen in OCT for histology. While there was no difference in interleukin-1β in mouse ankle joint homogenates, monocyte chemoattractant protein-1 (MCP-1/CCL2) was significantly decreased in MIF null mouse arthritic ankle homogenates compared to wt mouse arthritic ankles. This decrease was ~ 2 fold, suggesting an important role of MIF in the regulation of MCP-1/CCL2). IHC of MIF null ankle sections revealed reduced inflammation compared to wt mice. There was a marked decrease in MCP-1/CCL2 levels in irradiated wt mice injected with bone marrow harvested from MIF null mice compared to irradiated MIF null mice which received wt bone marrow, further confirming the significance of MIF in inflammatory arthritis.

Conclusions: These data suggest an important role for MIF in induction of MCP-1/CCL2 in mouse inflammatory arthritis. MIF may be a potential therapeutic target for the treatment of chronic inflammatory diseases like RA.

Matrix Components Influence the Aggressive Behavior of Rheumatoid Arthritis Synovial Fibroblasts. Stephanie Lefevre[2], Birgit Zimmermann[3], Matthias Geyer[3], Angela Lehr[5], Henning Stürz[4], Jürgen Steinmeyer[1], Stefan Rehart[5], Ulf Müller-Ladner[3] and Elena Neumann[3]. [1]Dept Experimental Orthopedics, Justus-Liebig-University Giessen, [2]Dept Internal Medicine and Rheumatology, Justus-Liebig University Giessen, Bad Nauheim, Germany, [3]Dept Internal Medicine and Rheumatology, Justus-Liebig University Giessen, [4]Dept Orthopedics and Orthopedic Surgery, Justus-Liebig-University Giessen, [5]Dept Orthopedics and Trauma Surgery, Markus-Hospital, Frankfurt

Background: Central mediators in joint destruction in rheumatoid arthritis (RA) are activated synovial fibroblasts (SFs). They adhere to and invade into human cartilage but the molecular details of this disease-specific behavior are known only to a limited extent. As we could show the migratory potential of RASFs in the SCID mouse model of RA, in the present study we addressed the role of extracellular matrix (ECM) regarding RASF adhesion and migration.

Methods: Chemotactic effects of finely ground cartilage were analyzed *in vitro*. After (membrane-) coating with Matrigel, growth factor-reduced Matrigel or collagen type II and adding RASFs, adhesion (after 30min) and transmigration (after 16h) of RASFs were analyzed. Isolated RASFs or whole synovial RA tissue were coimplanted with healthy human cartilage (ipsilateral; I) subcutaneously into SCID mice. Cartilage without RASFs was inserted contralaterally (Co). To analyze potential effects of the ECM, bovine or murine cartilage or cartilage without vital chondrocytes was implanted. ECM components were analyzed *in vivo* by coating the carrier matrices in various combinations (either the ipsilateral or the contralateral carrier matrix or both) with the following factors: Matrigel, fibronectin, aggrecan, growth factor-reduced Matrigel, collagen type II, PuraMatrix Peptide Hydrogel. Histological analyses of implants followed after 60 days.

Results: RASFs invaded the coimplanted cartilage directly and migrated to and invaded into the cartilage inserted contralaterally independent of the species background and the source of RASFs (isolated or whole RA synovium). Cartilage inserted into carrier matrices coated with growth factor-reduced Matrigel showed a reduced invasion (invasion score I (non-coated carrier-matrix): 1.7±0.5, Co (coated carrier matrix): 0.2±0.3; I (coated carrier matrix): 0.9±0.6, Co (non-coated carrier matrix): 2.0±0) compared to cartilage in uncoated matrices (control; I: 2.1±0.6; Co: 1.5±0.4). A concentration-dependent increase of the chemotactic effect of finely ground cartilage regarding RASF migration was demonstrated *in vitro*. Transmigration and adhesion of RASFs were decreased *in vivo* after coating with growth factor-reduced Matrigel compared to coating with Matrigel or collagen type II (up to 86fold or 49fold resp.).

Conclusion: The ECM as well as matrix associated components such as growth factors influence RASF migration from the ipsilaterally to the contralaterally implanted cartilage. Accordingly, adhesion of RASFs to growth factor-reduced Matrigel was decreased compared to other coatings. In contrast, chondrocyte vitality and species background of the cartilage appear

not to be crucial for RASF migration. Taken together, matrix components play a central role in RASF migration, transmigration, adhesion to cartilage and following joint destruction.

Monocytes Are Required for Progression but Not for Initiation of Arthritis in Mouse Model of Autoantibody-Mediated Arthritis. Alexander Misharin[1], Evan Weber[1] and Harris R. Perlman[2]. [1]Division of Rheumatology, Northwestern University, Chicago, IL, [2]Northwestern University, Chicago, IL

Background: Monocytes and macrophages play essential role in pathogenesis of rheumatoid arthritis. However their role in initiation vs. perpetuation of inflammatory arthritis in rodent models is unclear. K/BxN serum-transfer model is a commonly used model for studying the effector phase of arthritis in mice. Role of the neuthrophils and mast cells in this model has been studied in details and it is now clear that these cells are essential for initiation of arthritis. Thought there are no doubts that monocytes and macrophages play very important role arthritis, it is less well studied. Previous studies have shown that mice depleted of macrophages by clodronate liposome treatment are completely resistant to K/BxN serum-induced arthritis and that reconstitution of these mice with macrophages from naïve animals reverses this resistance. However effect of clodronate is long-term and irreversible and it does not allow assessing role of monocytes and macrophages in different steps of effector phase of arthritis. Therefore we decided to take advantage of a conditional ablation system mediated by diphtheria toxin (DT) receptor (human hbEGF) expressed under CD11b promoter to study the effects of monocytes and macrophages depletion on the course of serum transfer arthritis.

Methods: Bone marrow from transgenic mice (C57Bl/6) expressing DTR under CD11b promoter was transferred into irradiated hosts. Six weeks after reconstitution all mice received injection of K/BxN serum and the severity of arthritis was assessed by measuring ankle width and clinical score for each limb on day 0, 2, 4, 7, 9, 11 and 14. Additionally mice were divided into three groups: arthritis only or control group – did not receive DT treatment; initial monocytes depletion—received DT on days −1 and 0; and continuous monocytes depletion—received DT on days −1, 0 and every 48 hours till the end of experiment (days 2, 4, 6, 8, 10 and 12). To assess the effects of DT peripheral blood was obtained on day −6, day 0 and day 14 and analyzed by flow cytometry.

Results: Single injection of DT did not affect T and B cells populations, but induced profound decrease of monocytes in peripheral blood (from 10.7% to 1.4% and from 13.2% to 1% for initially and continuously depleted mice, respectively). At the end of study levels of monocytes in mice that received only two injections of DT returned to baseline values and did not differ from control group (11.0% and 15.7%, correspondingly), while in mice that received continuous treatment with DT levels were significantly lower (3.87%). There was no decrease in neutrophils in DT-treated mice. All mice developed arthritis initially, however only mice continuously treated with DT failed to display progression of arthritits.

Conclusions: Continuous depletion of monocytes and macrophages prevents further progression of arthritis but not of initiation of K/BxN serum transfer arthritis. Taken together with recent findings about role of neutrophils in the effector phase of inflammatory arthritis, our work suggest that monocytes are necessary for its progression and bone damage while neutrophils are required for initiation of arthritis.

Overexpression of RORγt Attenuated Collagen Induced Arthritis (CIA). Zhaojin Yao[2], Yuya Kondo[2], Masahiro Tahara[2], Satoru Takahashi[1], Isao Matsumoto[2] and Takayuki Sumida[3]. [1]Department of Anatomy and Embryology, Biomolecular, and Integrated Medical Sciences, Graduate School of Comprehensive Human Sciences, University of Tsukuba, [2]Division of Clinical Immunology, Major of Advanced Biochemical Applications, Graduate School of Comprehensive Human Science, University of Tsukuba, Ibaraki, Japan, [3]Univ of Tsukuba/Inst Clin Med, Tsukuba City, Japan

Background: IL-17 producing CD4+ T cells such as Th17 cells play a crucial role in the generation of collagen induced arthritis (CIA). However, it is unclear how Th17 specific master regulator RORγt contributes to the development of arthritis. The purpose of the present study is to determine the role of RORγt overexpression on T cells in the generation of subpopulation with CIA.

Methods:

1) RORγt transgenic (RORγt Tg) mice were generated in C57BL/6 (B6) mice background under the promoter of CD2 gene. RORγt Tg and B6 mice were immunized with type II collagen (CII) emulsified with complete Freud's adjuvant (CFA).

2) Cells in draining lymph nodes were harvested on day 10 after immunization of CII and they were analyzed for the proportion and number of T cell subsets by flow cytometry.

3) After these cells were cultured in vitro with CII for 72 h, the expression of RORgt and Foxp3 in CD4+ cells was analyzed by intracellular staining method.

4) Cytokine production (IL-17, IFN-γ, IL-21, IL-6, and IL-4) by CD4+ T cells was analyzed by intracellular cytokine staining method, and levels in supernatants were measured by enzyme-linked immunosorbent assay (ELISA).

5) CII specific IgG antibodies (Abs) in sera on day 56 after immunization were measured by ELISA.

Results:

1) The incidence and severity of arthritis was significantly suppressed in RORγt Tg mice.

2) The number of total T cells in the draining lymph node after immunizations was not significantly different between RORγt Tg mice and B6 mice.

3) The RORγt expression in CD4+ T cells in RORgt mice was increased compared to B6 mice. Whereas, foxp3 expression was not changed.

4) Flow cytometry analyses shows that the number of IL-17 producing cells increased in RORγt Tg mice. ELISA assay also revealed the increase of IL-17 in supernatants.

5) CII specific IgG Abs production was significantly suppressed in RORγt Tg mice.

Conclusion: Overexpression of RORγt in T cells suppresses the development of autoimmune arthritis, in spite of the induction of antigen-specific Th17 responses. Low level of antigen specific IgG Abs production might be one of the factors for reduction of CIA in RORγt Tg mice.

Paradoxical Decrease in Collagen Induced Arthritis Severity in Gadd45β Deficient Mice. Yubin Luo[2], David L. Boyle[1] and Gary S. Firestein[1]. [1]UCSD School of Medicine, La Jolla, CA, [2]UCSD School of Medicine

Purpose: Growth arrest and DNA damage inducible 45b (Gadd45β) is involved in stress responses, cell cycle regulation, and oncogenesis. The mechanism of action for many functions relates to the ability of Gadd45β to block c-Jun amino terminal kinase (JNK) activity by binding to its upstream kinase MKK7. Gadd45β−/− mice have increase JNK activation and greater disease severity in models of innate immunity (passive K/BxN arthritis) and adaptive immunity (experimental allergic encephalomyelitis). We examined the role of Gadd45β in collagen-induced arthritis, which is a more complex model that includes an initial adaptive immune response to an autoantigen followed by an immune complex mediated effector phase.

Methods: CIA was induced in wild type DBA/1 (WT) and Gadd45β−/− DBA/1 mice by immunizing with type II collagen in complete Freund's adjuvant. Arthritis severity was assessed by clinical arthritis scores (maximum score=16) and histological evaluation of synovitis, bone erosion, extra-articular inflammation and proteoglycan damage (max score=16). Serum anti-collagen antibodies were measured by ELISA. Cytokine and matrix metalloproteinase (MMP) expression in joint and spleen extracts was determined by quantitative PCR. Phospho-JNK (P-JNK) in the joints was measured by Western blot analysis.

Results: The initiation onset and peak arthritis severity were similar in Gadd45β−/− and WT mice (Day 34 WT=13±1; Gadd45β−/−=12±2; P>0.5) Unexpectedly, the resolution phase was accelerated in Gadd45β−/− mice (Day 55 clinical scores: WT=11±1; Gadd45β−/−=6±1; P=0.03). Histology scores and joint damage were also significantly lower in the Gadd45β−/− mice (Day 55 WT=9±1; Gadd45β−/−=5±2; P=0.04).

However, serum anti-collagen antibody levels were similar in the two groups. Consistent with histologic evidence of joint damage, MMP3 and MMP13 expression was 4-fold higher in WT mice compared with Gadd45β−/− mice (P=0.01). Despite higher synovial MMP expression P-JNK levels in Gadd45β−/− and WT were similar (P>0.1). mRNA levels for synovial IL-1, IL-6, and TNF were similar in WT and Gadd45β−/− mice. Spleen qPCR demonstrated 2-fold higher levels of IFNγ and IL-10 mRNA in Gadd45β−/− compared with WT (P<0.05).

Conclusions: Gadd45β deficiency is usually associated with increase JNK activation and disease severity in murine inflammation models. Surprisingly, Gadd45β−/− mice had normal onset and peak severity of CIA but had accelerated resolution of arthritis. Adaptive immune responses were normal, as judged by autoantibody production. These data suggest that Gadd45β plays a complex role in immune responses. Enhanced resolution of arthritis could be due to altered cytokine balance in central lymphoid organs, such as increased IL-10 production.

Protection from Collagen-Induced Arthritis in a CX3CR1-Deficient Mouse Strain. Grainne Murphy[1], Arun Kumar[2], Fergus Shanahan[1], Sinead Harney[1], Michael Molloy[1] and Noel Caplice[2]. [1]Cork University Hospital, Cork, Ireland, [2]University College Cork, Cork, Ireland

Background: Fractalkine(FKN), is up-regulated in RA and has been implicated in the immunological dysfunction associated with this disease. FKN interacts specifically with its receptor, CX3CR1 and lacks the redundancy characteristic of many other chemokine partnerships. The role of the FKN-CX3CR1 interaction in the initiation of RA is however unknown.

Objective: To compare the incidence and severity of collagen-induced arthritis(CIA) in a CX3CR1 homozygote deficient transgenic mouse strain with that of wild-type and competent heterozygote mice.

Methods: We used a transgenic mouse model, on a C57/B6 background, where one or both copies of the CX3CR1 gene were replaced by enhanced Green Fluorescent Protein (eGFP), generating the homozygote functionally deficient or competent heterozygote state. The incorporated GFP construct facilitated the direct tracking of peripheral and bone marrow (BM) derived CX3CR1+ cells. CIA was induced in homozygotes (11), heterozygotes (9) and wild-type mice (9) using 2 intra-dermal injections of a 1:1 ratio of chick collagen and Freunds adjuvant (5mg/ml Mycobacterium TB). Circulating and bone marrow derived CX3CR1+ cells were analysed by flow cytometry. Following sacrifice, joints were analysed by H&E and immunohistochemistry to characterize the inflammatory infiltrate. Serum was collected on Day 40 for analysis of the IgG2a and IgG2b anti-collagen antibody responses.

Results: Homozygote mice had a significantly delayed onset of a very mild clinical phenotype in 18% compared with 77% in both the heterozygote and wild-type strains (p<0.001). Histologically, homozygotes had significantly milder synovial hyperplasia (p.0.01) with no evidence of bone or cartilage destruction. Analysis of the inflammatory infiltrate in the heterozygote and wild-type strains demonstrated a significant accumulation of F4/80+ macrophages, 95% of which co-expressed CX3CR1. BM and peripheral CX3CR1+ cells were expanded in both the hetero- and homozygotes. Moreover although strains were comparable in IgG2a responses, IgG2b was significantly higher in hetero- than homo-zygotes, an isoform thought to be of pathologic significance in the C57/B6 strain

Conclusion: Despite the lack of clinical disease in homozygote CX3CR1 deficient mice, peripheral CX3CR1+ cells were similarly mobilized compared to heterozygotes. This implies that while the expansion of this leukocyte population is FKN independent, the FKN-CX3CR1 interaction is crucial for the trafficking of inflammatory cells into synovium, thus initiating CIA. These findings demonstrate that monocytes are central to the initiation of CIA and that the FKN-CX3CR1 interaction is critical in their egress from PB to ST.

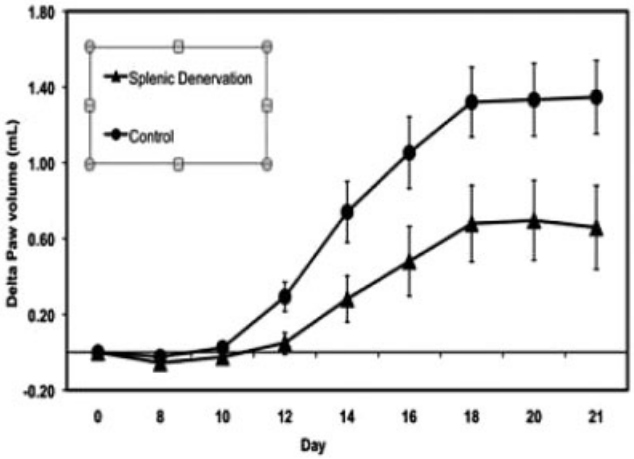
Role of the Central Nervous System (CNS) in Peripheral Inflammation: Sympathetic Innervation of the Spleen Regulates Inflammatory Arthritis. David L. Boyle[1], Meghan Edgar[2], Linda Sorkin[2] and Gary S. Firestein[1]. [1]UCSD School of Medicine, La Jolla, CA, [2]UCSD School of Medicine

Purpose: The CNS has been identified as a key regulator of peripheral inflammatory and immune responses, especially spinal reflexes and the vagus nerve. However, the sympathetic nervous system can also modulate inflammation in animal models of arthritis, with counter-balancing pro-inflammatory and anti-inflammatory effects at different times during the course of the model. The mechanism of sympathetic influence on immune regulation in arthritis is unknown. Because the spleen is a secondary lymphoid organ exclusively innervated by sympathetic fibers, we explored the role of splenic denervation on adjuvant arthritis in the rat.

Methods: Surgical splenic denervation of male Lewis rats was performed by dual transection and removal of the intervening segment of the splenic nerve and confirmed by norepinephrine assay of the spleen. Adjuvant arthritis was induced by injecting 1mg complete complete Freund's adjuvant at the base of the tail. Arthritis severity was measured by hind-limb plethysmometry. Hind-limb radiographs were scored on a 0–6 point scale. Splenic mRNA expression was determined by QPCR and expressed as relative expression units (REU).

Results: Splenic denervation (SD) decreased paw swelling by 48% compared with controls (C) (SD 0.65±0.2ml versus C 1.34±0.1ml; p<0.0001). Radiographic analysis showed that SD significantly decreased bone destruction (SD 1.1±0.4; C 2.20±0.2; p<0.03).



Splenic norepinephrine levels in C animals were 3.1±0.4ng/mg tissue at baseline (day 0) and trended to higher levels in active arthritis (day 12, 4.8±1.1ng/mg), and decreased to below baseline levels at the end of the model (day 21, 0.9±0.1ng/mg; p<0.0001 compared to baseline). Denervation reduced splenic norepinephrine to 0.48±0.34 ng/mg at all time points. TNF expression in arthritic animals was also reduced in denervated spleens (0.258±0.03 REU in SD vs 0.48±0.12 REU in SH; p<0.02). IL-1, GRO/CINQ1, IFNγ, IL-2 and TGF-β were not affected. Spleen mass was indistinguishable between SD and C groups in the presence or absence of arthritis, although spleen mass was doubled in arthritic animals compared with non-arthritic.

Conclusion: The sympathetic nervous system regulates the immune response in acute and chronic inflammation. Surprisingly, sympathetic innervation of the spleen is a key mechanism for neuro-regulation of inflammatory arthritis and is required for full expression of synovitis and matrix destruction. The mechanisms might include direct effects of neurotransmitters on immune cells via β adrenergic receptors, such as macrophages, with reduced splenic TNF production.

SapC-DOPS Agents in Imaging Arthritis. Sherry Thornton[1], Malinda Pinkerton[2], Monica DeLay[2], Tristan Bourdeau[2], Rachel Mason[2], Zhengtao Chu[2], Matthew Flick[2] and Xiaoyang Qi[1]. [1]Cincinnati Children's Research Foundation, Cincinnati, OH, [2]Cincinnati Children's Research Foundation

Rheumatoid arthritis (RA) is a chronic inflammatory disease that affects about 1% of the population worldwide. The devastating endpoint of RA pathology is the destruction of cartilage and bone ultimately leading to loss of joint function. Early detection and intervention of disease represents the best hope for successful treatment and preservation of joint

mobility and function. To date, reliable and non-invasive techniques that accurately measure arthritis onset and progression are largely lacking. Here we investigate a novel method of disease assessment that has the advantages of being (i) non-invasive, (ii) highly sensitive, and (iii) both qualitative and quantitative. We recently developed an agent, composed of the membrane-associated lysosomal protein Saponin C incorporated into 1,2-Dioleoyl-sn-Glycero-3-Phospho-L-Serine lipid nanovesicles (SapC-DOPS). SapC-DOPS has a high affinity for phosphatidylserine (PS)-rich domains on cellular surfaces, and fuses with PS-rich membranes on target cells. SapC-DOPS is tracked by labeling with a CellVue Maroon fluorophore (CVM). Since PS is normally present only on the inner leaflet of plasma membranes but is "flipped" to the outer leaflet upon cell damage, we hypothesized that the SapC-DOPS-CVM could be used to detect local tissue damage in inflammatory arthritis. To test this concept, two animal models of arthritis, K/BxN and collagen-induced arthritis (CIA) were utilized. Both of these models exhibit histological changes similar to RA including mononuclear cell infiltration, pannus development, fibrin deposition, and cartilage and bone erosion. SapC-DOPS-CVM was administered to arthritic and non-arthritic mice and detected by in vivo optical imaging (IVIS®). Our data indicate localization of SapC-DOPS-CVM to arthritic paws with 100% penetrance in both animal models; however, SapC-DOPS-CVM was not observed in non-arthritic paws. Flow cytometry analyses of total cells harvested from paws demonstrate that SapC-DOPS-CVM localized to approximately 20% of the joint cells from arthritic mice while less than 2% of cells from non-arthritic paws were CVM-positive. Preliminary studies indicated that in K/BxN arthritis, SapC-DOPS localized primarily to CD11b+ cells that are CD11c- and CD8-, with additional studies being performed to further characterize the cell types that are targeted by SapC-DOPS in each arthritis model. Results from the current studies provide support for the use of SapC-DOPS-CVM in imaging arthritis onset and progression in live subjects. Furthermore, this imaging strategy provides a novel method for tracking cells involved in inflammatory processes during arthritis.

Systemic, Lentiviral Gene Delivery of the Stress Protein BiP (Binding Immunoglobulin Protein) Improves Clinical, Histological and Immunological Parameters of Collagen-Induced Arthritis Via Suppression of IL-17. Adrian M. Shields[2], Paul H. Wooley[3], Rana Alyahya[2], Gabriel S. Panayi[1], Stephen J. Thompson[2] and Valerie M. Corrigall[2]. [1]King's College London, London, United Kingdom, [2]King's College London, [3]Via Christi Reg Medical Ctr, Wichita, KS

Introduction: Rheumatoid arthritis is an autoimmune disease principally manifesting as an autoimmune polyarthritis in the small diarthrodial joints. It is also characterised by multiple systemic sequelae.

Gene therapy offers a novel therapeutic approach to multisystem inflammatory diseases by permitting highly specific and disease-response, temporal and spatial expression of therapeutic genes.

The endoplasmic reticulum (ER) stress protein BiP (Binding immunoglobulin Protein) has demonstrated profound anti-inflammatory activity in human myeloid lineage cells and impressive therapeutic efficacy in multiple animal models of inflammatory arthritis. This study investigated the therapeutic potential of lentiviral gene therapy using BiP in the murine collagen-induced arthritis (CIA) model.

Methods: The murine BiP gene was manipulated to facilitate efficient protein secretion from transduced cells and cloned into a 3rd generation, self-inactivating HIV-1 lentiviral vector backbone containing the CMV immediate-early promoter and the WPRE stabilisation element (Lenti-BiP). An equivalent vector containing the GFP gene was produced as a control (Lenti-GFP). CIA was established in DBA/1 mice and lentiviral vectors were administered intraperitoneally at arthritis onset. Clinical, histological and immunological parameters of disease were studied.

Results: 2×10^{-7} infectious viral particles encoding the murine BiP gene significantly suppressed clinical disease scores compared to Lenti-GFP treated animals when delivered at disease onset (Fig. 1) (day 55: Lenti-GFP - 8.6±0.6 vs. Lenti BiP – 5.1±0.7, p=0.001).

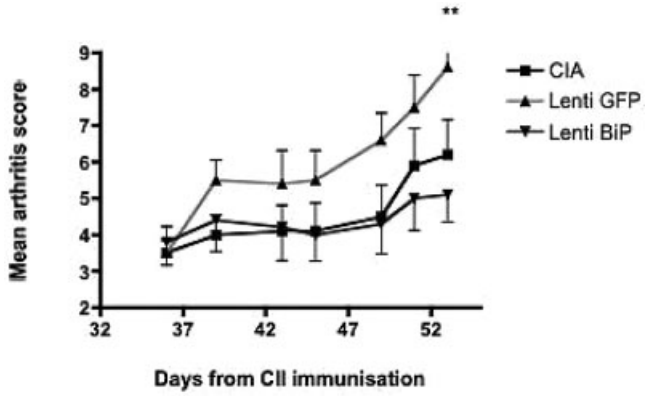

Figure 1. Lenti-BiP modulates collagen induced arthritis.

Lower doses of Lenti-BiP ($1\times10\hat{7}$) also suppressed clinical and histological manifestations of disease, but not signficantly. The mechanism of Lenti-BiP mediated disease suppression depends on the inhibition of IL-17. The splenocytes of Lenti-BiP treated animals produced significantly less IL-17 in response to collagen-II restimulation compared to Lenti-GFP treated animals (Lenti-GFP - 3819±1502pg/ml vs. Lenti-BiP – 2087±722pg/ml, $p<0.05$). Furthermore, Lenti-BiP treatment facilitated the development of regulatory cells; in admixing experiments, splenocytes from Lenti-BiP treated animals significantly suppressed IL-17 production from CII primed responder cells compared to Lenti-GFP treated animals (Lenti-GFP - 6119±689pg/ml vs. Lenti BiP – 2697±444pg/ml, $p<0.05$). This was associated with significantly greater IL-10 secretion in co-cultures containing Lenti-BiP treated cells (Lenti-GFP – 519±18pg/ml vs. Lenti BiP – 662±49pg/ml, $p<0.05$)

Conclusion: Lentiviral delivery of the murine BiP gene modulates clinical, histological and immunological parameters of CIA. Further experiments are underway to examine the mechanism of Lenti-BiP mediated suppression and to target anti-inflammatory gene expression using stress-responsive promoters.

Targets of Innate and Adaptive Immunity in a Humanized Arthritis Model: Research Value of the RA Synovium SCID Mouse Model. Marije I. Koenders[3], Shahla Abdollahi-Roodsaz[4], Renoud J. Marijnissen[4], Franco E. Di Padova[2], John Dulos[1], Annemieke M. H. Boots[1] and Wim B. van den Berg[4]. [1]MSD, Oss, The Netherlands, [2]Novartis Pharma AG, Switzerland, [3]Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, [4]Radboud University Nijmegen Medical Centre, The Netherlands

Target discovery and drug development is a very time consuming and expensive process, which is partly due to the fact that preclinical findings from animal models cannot always be translated to the clinical situation. To provide an intermediate step between classical arthritis models and clinical trials, the RA synovium SCID mouse model could be a valuable tool during preclinical research. In this study, the validity of this humanized mouse model was investigated.

SCID.CB17 mice were engrafted with two standardized pieces of human RA synovial tissue subcutaneously on the back, and subsequently the therapeutic effect of various biologicals on these grafts was assessed. After an engraftment period of seven days, mice were systemically treated with anti-TNF (Abalimumab), anti-IL-1, CTLA4-Ig (Abatacept), anti-CD20 (Rituximab), or isotype control antibodies at an excess dose of 10 mg/kg. In addition, this RA SCID model was used to study two new potential therapeutic targets, using the TLR4 antagonist B. quintana LPS, and anti-hIL-17A antibodies. As readout, serum levels of human cytokines and chemokines were analyzed by Luminex, and the synovial grafts were isolated for histological analysis.

Anti-TNF treatment significantly reduced serum levels of IL-6 and IL-8, and histological analysis demonstrated that this coincided with a clear reduction in the inflammation scores of the grafts and suppressed expression of TNF and IL-1 in the synovium as demonstrated by immunohistochemistry. In contrast, anti-IL-1 therapy did not show any effect. Since Adalimumab also

shows great efficacy in the clinics, anti-TNF antibodies were used as positive control throughout our further SCID studies.

The potential of the RA SCID model for T and B cell-related therapies was investigated using CTLA4-Ig and anti-CD20 respectively. Abatacept treatment was not effective in this RA SCID model, despite pre-screening of the synovial tissue for the presence of CD3+ T cells and the B7 molecules CD80/86 that provide costimulatory signals for T cell activation. In contrast, anti-CD20 treatment did reduce serum cytokines and histological scores, suggesting that this model is more sensitive to B cell than T cell-related therapies.

Our recent studies in IL-1Ra-deficient mice and collagen-induced arthritis suggested an important role for TLR4 in recognition of both exogenous and endogenous ligands that contribute to the pathological process during arthritis. Also for anti-IL-17 treatment great therapeutic potential was observed in mice, but additional proof was needed in more translational models. While our TLR4 inhibitor showed therapeutic effects comparable to anti-TNF treatment, IL-17 blocking seemed to be selectively effective in cases where high numbers of CD3+ T cells were present in the synovium.

In conclusion, the human RA synovium SCID mouse model seems a powerful tool in preclinical research. Using this model, further evidence was obtained that TLR4 and IL-17 might indeed be interesting therapeutic targets in RA. Further characterization of the RA patients' individual synovial profile is of great importance to achieve tailor-made therapy.

1731

The Role for TIM-2 in Collagen-Induced Arthritis. Toshio Kawamoto[2], Hisaya Akiba[1], Yoshiyuki Abe[2], Shinji Morimoto[2], Ken Yamaji[2], Naoto Tamura[2] and Yoshinari Takasaki[2]. [1]Department of Immunology, Juntendo University School of Medicine, [2]Department of Rheumatology, Juntendo University School of Medicine

Introduction: T cell Ig and mucin domain-2 (TIM-2) has been shown to regulate CD4 T cell activation. TIM-2-deficient mice developed more severe airway inflammation under Th2-polarizing condition.Thus, it seems likely that TIM-2 is a negative regulator of Th2 immune responses. However, the immunological function of TIM-2 under Th1-polarizing condition is still unclear. This study therefore examined the contribution of TIM-2 to the development of collage typeII (CII)-induced arthritis (CIA), which is a Th1-polarized disease model, by administering a newly generated anti-TIM-2 mAb.

Methods: In this study, we investigated the effects of anti-TIM-2 monoclonal antibodies in a collagen-induced arthritis (CIA), which is a mouse model of rheumatoid arthritis, to determine whether TIM-2 contributes to the development of pathogenic Th1 or Th17 cells and joint inflammation. A murine model of CIA can be induced by injection of CII emulsified with adjuvant in genetically susceptible DBA/1 mice. Mice were examined daily for the onset of CIA. The swelling of four paws was graded from 0 to 4,each paw was graded, and the four scores were totaled so that the maximal score per mouse was 16. Draining lymph node cells were isolated and pooled, and cultured in the presence or absence of indicated dose of denatured bovine CII. All cultures were pulsed with 3H-thymidine for the last 6h of a 72h or 96h culture and harvested. To determine the production of cytokines, cell-free supernatants were collected at 72h or 120h and assayed for INF-γ or IL-17 were measured by ELISA. Serums were collected and titers of anti-CII IgG Abs were measured by ELISA.

Results: Administration of anti-TIM-2 mAbs in early phase, but not late phase, significantly exacerbated the development of CIA. Although anti-TIM-2 mAbs treatment did not affect the development of Th1 or Th17 cells in the draining lymph node, the serum levels of anti-type II collagen Abs were significantly increased in the anti-TIM-2 mice. TIM-2 expression was found on splenic B cells and further up-regulated by anti-IgM, anti-CD40, and IL-4 stimulation. In contrast, CD4 T cells did not express TIM-2 even when stimulated with both anti-CD30 and anti-CD28 mAbs. Intrestingly, anti-TIM-2 mAbs enhanced proliferation and Ig production of activated B cells in vitro.

Conclusions: These results suggest that the exacerbation of CIA by anti-TIM-2 mAbs is caused by enhancement of B cell activation and Ab production.

The TNF-Ligand APRIL Can Control CIA by Regulating Antibody-Production and Stimulating Anti-Inflammatory IL-10 Producing B Cells. Leticia Fernandez[5], Cecilia Rocha[5], Carla Carvalho-Pinto[6], Jan Paul Medema[2], Bernard G. Combe[3], Dominique Baeten[1], Jacques Morel[4] and Michael Hahne[5]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Academic Medical Center, University of Amsterdam, [3]Hopital Lapeyronie, Montpellier, France, [4]Hopital Lapeyronie, [5]Institut de Génétique Moléculaire de Montpellier, [6]Universidade Federal Fluminense/UFF, Niteroi

Background: TNF family members are frequently implicated in inflammation and autoimmunity. Increased levels of the TNF-ligand APRIL (A Proliferation Inducing Ligand) were found in synovial fluid and serum of patients with inflammatory arthritis pointing to a pro-inflammatory role of APRIL. APRIL can bind to BCMA and TACI, two receptors of the TNF family, which can also bind the B cell activating factor (BAFF). In the collagen-induced arthritis (CIA), administration of TACI-Ig was found to prevent disease progression and to lower disease scores, compared with controls. As TACI binds both APRIL and BAFF, it remained to be determined, whether this effect was due to the capacity of TACI to block just one or both ligands.

Methods: CIA was induced in APRIL-transgenic (Tg) DBA/1 mice and littermates. Severity of disease was scored for each paw using a scale 0–4. In addition, mice were analyzed for histological signs of arthritis. Anti-collagen antibody titers were determined by ELISA. Lymphocyte populations in draining lymph nodes, spleen and peritoneum were analyzed by FACS. In another experimental setting mice were exposed to the collagen antibodies induced arthritis (CAIA). In addition, we employed the contact hypersensitivity model (CHS). For this, APRIL Tg and control mice were sensitized and challenged at the ear with oxazolone. Ear swelling and histological alterations were monitored.

Results: APRIL Tg (n=14) mice displayed in contrast to littermates (n=16) a lower disease score (maximal score at day 38 after first immunization: 4.9+/−0.9 versus 1.0+/−0.5), a lower incidence of arthritis ($p<0.01$), and also produced less collagen specific antibodies ($p<0.001$, at day 41 after first immunization). Joints of littermates had higher IgG levels. One of the main effector mechanisms of anti-collagen antibodies in arthritis is the activiation of mast cells by immune-complexes. Indeed we detected decreased number of degranulating, thus activated, mast cells in the joints of Tg mice. To confirm that the decreased IgG levels developed in the CIA model in APRIL Tg mice are directly linked to the less severe disease development, we employed the model of CAIA. In fact, disease development in CAIA was similar in APRIL Tg and control mice. In addition, we detected a significantly increased IL-10 production of peritoneal B cells in APRIL Tg mice in the CIA model (n=8 for each group, $p<0.05$). Evidence is accumulating that IL-10 producing B cells can regulate autoimmune diseases including arthritis. The regulatory role of APRIL by modulating activity of mast cells and IL-10-producing B was confirmed in the CHS model.

Conclusion: Our results show that APRIL can control inflammation in two disease models, i.e. arthritis and CHS. This suggests a therapeutic potential of APRIL agonists to down-regulate inflammatory diseases such as rheumatoid arthritis.

Towards Personalized Arthritis Gene Therapy: Screening of Computationally-Designed Promoters in an In Vivo Mouse Model and in Human Synovial Fibroblasts. Fons A. J. van de Loo, Eline Vermeij, Onno J. Arntz, Miranda B. Bennink, Jeroen Geurts and Wim B. van den Berg. Department of Rheumatology, Radboud University Nijmegen Medial Centre, Nijmegen, The Netherlands

Introduction: Chronic synovial inflammation is a hallmark of the autoimmune disease rheumatoid arthritis (RA). The synovial membrane is regarded as the primary target tissue for local gene therapeutic treatment of arthritic joints. RA is a truly heterogeneous disease, which is supported by gene expression analyses of RA tissues that have revealed molecularly distinct inflammatory subtypes. Therefore, personalized gene therapy using

disease inducible promoters might be a good approach to fine-tune supply of biologicals in an offer-meets-demand fashion, increasing safety and efficacy.

Methods: Previously, we developed a computational approach for selecting suitable promoters from endogenous genes differentially regulated in the inflamed synovium of collagen-induced arthritis mice. Based on this approach, we constructed lentiviral luciferase reporters containing proximal promoter regions that were predicted to be predominantly regulated by the transcription factors NFκB (*Cxcl1, Cxcl5, Il1β*), AP-1 (*Mmp3, Mmp13, Timp1*) or C/EBPβ (*Saa3, Chi3l1, Has1*).

Results: Next, we investigated kinetics and strength of these promoters as compared to a strong constitutive promoter (*PGK*) in experimental arthritis with two relapsing flares of inflammation. Surprisingly, only *Saa3* and *Cxcl1* were strongly upregulated (10–50 fold) during the first challenge, while a second challenge induced strong luciferase expression for all constructs (10–200 fold). The *Saa3* promoter activity showed a clear correlation with joint edema as measured by ^{99m}Tc uptake. Interestingly, in the absence of a second flare the *Cxcl1* promoter activity still increased whereas the *Saa3* promoter activity returned to basal levels. Promoter analysis suggested that hypoxia-response elements in the *Cxcl1* promoter are likely causative for this difference in expression profile with *Saa3*. Finally, we characterized the response of computationally-defined promoters in RA synovial tissue of varying inflammatory subtypes. *Saa3, Cxcl1, Cxcl5* and *Il1β* promoters could be induced by stimulation of RA synovial fibroblasts with pro-inflammatory stimuli. Uniquely, relative *Saa3* promoter responses to cytokines and a TLR4 agonist were significantly higher in fibroblasts with an inflammatory genetic imprint both as a group as in individual samples. Relative *Cxcl1* promoter responses did not discriminate between inflammatory synovial fibroblast subtypes.

Conclusion: These data demonstrate that computational design of promoters is of great value for the development of disease-regulated gene therapy, Towards personalized arthritis gene therapy, the *Saa3* promoter appears an excellent candidate for sensing the extent of joint inflammation and responding differentially in human arthritic synovium according to their inflammatory phenotype.

A Longitudinal Trivariate Model of Disease Activity Score, Physical Function and Radiographic Damage: Results from SONORA Study. Maggie Chen[1], Xiuying Li[1], Pooneh Akhavan[2] and Claire Bombardier[3]. [1]University Health Network, [2]University of Toronto, University Health Network, [3]University of Toronto, University Health Network, Mount Sinai Hospital, Toronto, ON, Canada

Purpose: Rheumatoid arthritis (RA) affects approximately 1% of adults in North America. Active disease leads to radiographic damage and poor physical function. The purpose of this study is to demonstrate the use of a novel longitudinal trivariate model to identify simultaneously common significant predictors for three important outcomes in RA: Disease Activity Score (DAS); physical function measured with the Health Assessment Questionnaire (HAQ) and radiographic damage (Sharp Score).

Method: 994 Patients diagnosed as having new onset RA (symptoms ≥3 but ≤12 months) by a board-certified rheumatologist were recruited from 98 rheumatology practices. Clinical, laboratory, X-ray and health questionnaire data were collected by the enrolling rheumatologist at baseline, year 1 and year 2. A trivariate longitudinal model of DAS28, HAQ and sharp score was constructed and estimated using pooled cross sections for two years period, adjusting the significant predictors from the univariate analysis at the same time allowing for the latent individual-level effect. Different covariance structures were tested for the assumptions among these three outcomes in the model.

Results: The mean age of patients was 53 years (SD, 14.8), with 72% female and 90% Caucasian. The mean RA symptom duration was 170 days (180). The DAS28, HAQ and Sharp score were 4.4(1.32), 1(0.73) and 5.01 (7.28) at baseline, 3.4(1.38), 0.82(0.71) and 6.19(8.73) at year 1, 3.2(1.34), 0.77(0.72) and 6.39(9.25) at year 2, respectively. Partial correlation adjusting for time point showed that DAS, HAQ and Sharp score are significantly correlated (all p-values <0.001). The longitudinal trivariate model showed that only higher baseline DAS, HAQ or Sharp Score value ($P<0.0001$), higher 28 swollen joint count ($P<0.0001$), longer disease duration ($P=0.002$) and lower house hold income ($P=0.015$) were significant predictors for these three combined outcomes.

Conclusion: This innovative method identified the significant common predictors for three outcomes which related to the different aspects of RA patients. This method can help us better understand the longitudinally complex relationship between different aspects from a broader view of the disease. These identified factors can help rheumatologists to identify the patients who are at greater risk of worsen disease, physical function and radiographic damage and make treatment decisions for RA patients at the early stage.

A Randomized Controlled Trial of Rheumatologist Education Impacting on Systematic Measurements and Treatment Decisions in Rheumatoid Arthritis (RA): Results of the Metrix Study. Janet E. Pope[3], J. Carter Thorne[2], Alfred A. Cividino[1] and Kurt Lucas. [1]McMaster University, Hamilton, ON, Canada, [2]Southlake Regional Health Care, Newmarket, ON, Canada, [3]St Joseph Health Care London, London, ON, Canada

Objective: The Metrix study was an investigator initiated pilot study where consenting rheumatologists in Ontario were randomized either to an IRB approved, accredited educational intervention over 6 months or no intervention and involved 2000 RA patient-encounters to determine if an intervention could result in behavioral change.

Methods: Twenty rheumatologists participated (all of whom who did a prospective chart audit of 50 consecutive RA patients at the beginning and again 50 consecutive RA patients at end of 6 months) and 10 rheumatologists were randomized to intervention. Only the intervention group was aware of the results of their practice audit including the frequency of measurements they were performing and outcomes of their patients compared to the others in both the intervention and control groups (comparative data of their practice to others). Interventions were monthly web-based conferences on the value of systematic assessments in RA and barriers to care with recent evidence based information, journal club, surveys and improvements on forms used in daily practice to collect data.

Results: 1000 serial RA charts were audited at 0 and another at 6 months with no between groups differences in patient characteristics (mean disease of 10 years and 77% women, 74% RF positive and mean DAS 3.7); 68% on current Mtx, 14% on steroids and 27% on biologics. At 6 months, there were significantly different within and between groups changes in how often many variables were measured and changes in treatment. The intervention group collected more patient global assessments (53% pre vs 66% post intervention and MD globals 51% vs 60%; $p<0.05$) and HAQs collected went from 37% to 42%; whereas control group had no change in outcomes collected. For the intervention group there was a 32% increase in calculable composite scores (such as DAS, CDAI, SDAI) ($p<0.05$) and no change in the control group. There was more targeting to a low disease state. For those with SDAI between 3.3 and 11, the % receiving a change in Rx (injection, or change in DMARD) was 66% in intervention and 36% in control group ($p<0.05$); similarly in DAS between 2.4 and 3.6; 57% of intervention and 38% of control group made changes to treatment ($p<0.05$). Table shows within and between groups differences.

Table. Between and Within Groups Differences for Intervention and Control Groups: Changes in Practice (Performing Measurements and Making Treatment Changes)

	Intervention	Control
Swollen Joint Count	Pre 96%	Pre 94%
	Post 98%	Post 93%
Tender Joint Count	Pre 80%	Pre 93%
	Post 79%	Post 92%
CRP	Pre 69%	Pre 69%
	Post 74%	Post 73%
HAQ	Pre 37%	Pre 42%
	Post 42%	Post 44%
Patient global frequency	Pre 53% $p < 0.05$	Pre 66% $p < 0.05$
	Post 62% (within group)	Post 59% (within group) (frequency decreased)
MD global frequency	Pre 50% $p < 0.01$	Pre 71% $p = 0.17$
	Post 60% (within group)	Post 66% (within group)
CDAI > 2.8 but <10 receiving joint injection or DMARD change	44%	33% $p = 0.44$*
SDAI > 3.3 but <11 receiving joint injection or DMARD change	56%	26% $p < 0.01$*
DAS28 > 2.4 but <3.6 receiving joint injection or DMARD change	57%	38% $p < 0.01$*

*Between groups differences

Conclusions: Despite a good baseline systematic assessment and many patients in a low disease state, there was improvement in the intervention group that surpassed the control group in both the frequency of performing assessments and the number of treatment changes when patients were not in remission. This is the first RCT of RA rheumatologist education where a result of a change in behavior has been linked directly to an intervention (comparative practice and education) as the control group did not change behavior. Small group learning with feedback from practice audits is an inexpensive way to improve outcomes in RA.

A Simple Fatigue Severity Scale Predicts Poor Health Outcomes, Frailty and Death in the Long-Term Follow-Up of Patients with Rheumatoid Arthritis. Gisela Westhoff and Angela Zink. German Rheumatism Research Centre Berlin, Berlin, Germany

Background: Rheumatoid arthritis (RA) patients highlighted fatigue as permeating every sphere of life. The EULAR/ACR task force recommended that fatigue should be implemented in an RA outcome measure core set. We investigated the association between baseline fatigue severity and 8-year outcomes in an early RA inception cohort.

Methods: Data from 1,057 RA patients with a disease duration <24 months at inclusion were used. Self reports of functional capacity, pain, global health (GH) and fatigue, measured by 11-point numerical rating scales (NRS 0–10), were collected for up to 8 years. Reasons for drop out were investigated thoroughly. Clinical and self-reported baseline parameters were compared between patients who attained the 8th year in favorable GH (0–6) and those who did so with unfavorable outcomes, i.e. they attained the 8th year in poor GH (7–10), had stopped participation without specifying reasons, had dropped out due to frailty or had died. Multivariate logistic regression analyses were performed to identify baseline predictors of adverse outcomes.

Results: At inclusion, 42.6% of the patients reported no or mild fatigue, 36.2% reported moderate fatigue and 21.2% reported severe fatigue. At 8 years, 12.7% of the patients had died, 7.0% had terminated participation due to frailty, 6.2% had withdrawn without specifying reasons, 3.2% were lost to follow-up and 13.2% reported poor GH (7–10). Three baseline parameters were significantly associated with unfavorable outcomes in the multivariate analyses. Besides higher age and substantial functional limitations, severe fatigue almost doubled the risk for adverse outcomes (adjusted OR 1.82; 95% CI 1.21–2.75). Furthermore, severe fatigue at inclusion was the only parameter predicting each individual type of drop-out, i.e. drop-out without specifying reasons (OR 2.8; CI 1.4–5.3), drop-out due to frailty (OR 2.3; CI 1.2–4.5) or death (OR 2.3; CI 1.3–4.2). Acute phase reactants, DAS28, erosiveness, rheumatoid factor and pain were not predictive of unfavorable outcomes.

Conclusions: Severe fatigue in early RA is indicative of poor long-term outcomes; it outranges all other baseline parameters taken into consideration. Therefore, fatigue should be implemented in an RA outcome measure core set, and, equally important, high attention should be paid to RA patients suffering from substantial fatigue.

Age, Sex, RF Antibodies, Baseline HAQ and DAS28 Score—But Not the Type of Initial Treatment—Are Predictive of Clinical Remission at 1 Year in Early Inflammatory Arthritis. Bindee Kuriya[9], Boulos Haraoui[4], Gilles Boire[2], Carol A. Hitchon[7], Janet E. Pope[6], J. Carter Thorne[5], Diane S. Ferland[3], Ed C. Keystone[8] and Vivian P. Bykerk[1]. [1]Brigham and Women's Hospital, Toronto, ON, Canada, [2]CHUS-Sherbrooke University, Sherbrooke, QC, Canada, [3]Hospital Maisonneuve Rosemount, LaSalle, QC, Canada, [4]Institut de Rhumatologie, Montreal, QC, Canada, [5]Southlake Regional Health Care, Newmarket, ON, Canada, [6]St Joseph Health Care London, London, ON, Canada, [7]University of Manitoba, Winnipeg, MB, Canada, [8]University of Toronto, Toronto, ON, Canada, [9]University of Toronto, Brookline, MA

Background: Aggressive DMARD therapy is more effective when given early in the disease course and the goal of treatment is remission. Factors associated with remission have been inconsistently reported in studies of early inflammatory arthritis (EIA). In Canada, access to biologics is reserved for those who have failed ≥ 2 DMARDs. Identifying those who will achieve remission can facilitate decisions to prevent over/under-treatment with limited resources. Our aim was to identify baseline and early treatment predictors of DAS28 remission at 1 year.

Methods: As of November 2009, 893 subjects were recruited to the Canadian ArThritis CoHort (CATCH). Patients are >16 years old, have symptoms between 6 weeks–12 months, have ≥ 2 swollen joints or 1 swollen MCP or PIP joint and ≥1 of: positive RF, anti-CCP, morning stiffness, response to NSAID or painful MTP squeeze test. Patients are assessed every 3 months and therapy is adjusted to minimize disease activity. Baseline demographic and clinical characteristics were analyzed via logistic regression.

Results: 363 subjects had ≥ 1 year of follow-up. Over this time, 288 (79%) patients met criteria for RA and 75 (21%) remained undifferentiated or fulfilled other diagnoses. Overall, 147 (41%) achieved DAS28 remission at 1 year. In univariate analyses, patients who experienced remission were younger, male, had lower HAQ scores, lower ESR and lower disease activity at baseline. Physical examination findings and radiographic erosions did not discriminate between the two groups. The presence of RF antibodies was less frequent among those who experienced remission but anti-CCP antibodies did not differ. The use of DMARDs early in the disease course was variable; methotrexate monotherapy was used less, while combination DMARD therapy was used more frequently in patients achieving remission. No patients were commenced on biologics during the first 3 months. After adjusting for significant univariate predictors ($p<0.10$), the multivariate model revealed 5 factors to be associated with remission: age, sex, RF, HAQ score and DAS28 score (Table, $p<0.05$).

Conclusion: Clinical remission was achievable in 41% of EIA patients. Predictors that favorably impacted this response included younger age, male sex, absent RF, low HAQ, and low disease activity at baseline. While sustained treatment with DMARDs has favorable long-term outcomes, DMARD use during the first 3 months alone or in combination did not accurately predict remission at 1 year.

Table. Multivariate analysis of baseline predictors for DAS28 remission at 1 year.

Characteristic	OR (95% CI)	*p*-value
Age*, years	0.98 (0.9–1.01)	0.03
Female sex	0.44 (0.25–0.78)	0.01
RF positive	0.78 (0.47–0.99)	0.04
HAQ score*	0.66 (0.44–0.98)	0.04
DAS28 score	0.06 (0.44–0.98)	0.03
ESR*, mm/hr	0.99 (0.98–1.01)	0.77
MTX monotherapy	0.59 (0.29–1.21)	0.15
Combination DMARD therapy	1.52 (0.84–2.75)	0.16

Algorithm Using Genome-Wide SNP Analysis for Prediction of Progression of Joint Destruction in RA Patients from Multiple Medical Cohorts. Tsukasa Matsubara[4], Satoru Koyano[7], Yoshitada Sakai[1], Keiko Funahashi[7], Takafumi Hagiwara[5], Takako Miura[4], Kosuke Okuda[4], Akira Sagawa[8], Takeo Sakurai[2], Hiroaki Matsuno[6], Tomomaro Izumihara[3] and Eisuke Shono[9]. [1]Himeji Dokkyo University, Himeji, Japan, [2]Inoue Hospital, Takasaki, Japan, [3]Izumihara Rheumatic and Medical Clinic, Kagoshima, Japan, [4]Matsubara Mayflower Hospital, Kato, Japan, [5]Matsubara Mayflower Hospital, Kato, Japan, [6]Matsuno Clinic for Rheumatic Diseases, Toyama, Japan, [7]Research Institute of Joint Diseases, Kobe, Japan, [8]Sagawa Akira Rheumatology Clinic, Sapporo, Japan, [9]Shono Rheumatology Clinic, Fukuoka, Japan

Purpose: Although not yet fully possible, ideally, the prediction of progression of joint destruction would be pivotal in establishing a strategy of treatment for individual RA patient since patients with rapidly progressing joint destruction need tight initial control. We have developed an SNP algorithm with the aim of enabling the prediction of progression of joint destruction with genome-wide SNP analysis by using multiple medical cohorts.

Patients and Methods: One-hundred and twenty-seven RA patients whose disease duration was within 5 years were enrolled in this study from 6 hospitals in different regions of Japan. All patients were treated with biologics after the failure of DMARDs therapy. RA joint destruction was estimated by Sharp score. Forty-five patients had a Sharp score of >100 (severe joint destruction), 30 had a score of 100-50 (intermediate joint destruction) and 52 had a score of <50 (mild joint destruction). Genome-wide SNP genotyping was performed by Illumina HumanHap300K chip. Case-control analyses between 278,347 SNPs and joint destruction (severe vs. mild) were examined by Fisher's exact tests. We selected 10 SNPs associated with joint destruction ($p < 0.0001$). We then scored relationship between each SNP and progress of joint destruction, the estimated total score of 10 SNPs (estimated scoring in each SNP was as follows: homo allele in the majority in severe joint destruction group: +1 point, hetero allele: 0 point, and homo allele in the majority of mild joint destruction group: −1 point), and examined relationships between the severe and mild group, and the total score.

Results: Accuracy ((true positive+true negative)/total), specificity (true negative/(false positive+true negative)) and sensitivity (true positive/(true positive+false negative)) of the algorithm for distinguishing the severe destruction group from the mild destruction group ranged from 92–97%. It is therefore suggested that the SNP algorithm may enable the prediction of rapidly progressing severe joint destruction.

Conclusion: This highly accurate algorithm using SNP analysis may be useful in initially distinguishing severe joint destruction, and, in this way, may contribute to establishing a strategy of treatment for individual RA patients.

1739

An Algorithm Using Genome-Wide SNP Analysis for Prediction of Interstitial Pneumonia in RA Patients. Takeshi Nakamura[3], Satoru Koyano[5], Keiko Funahashi[5], Takafumi Hagiwara[3], Takako Miura[3], Kosuke Okuda[3], Akira Sagawa[6], Takeo Sakurai[1], Hiroaki Matsuno[4], Tomomaro Izumihara[2], Eisuke Shono[7] and Tsukasa Matsubara[3]. [1]Inoue Hospital, Takasaki, Japan, [2]Izumihara Rheumatic and Medical Clinic, Kagoshima, Japan, [3]Matsubara Mayflower Hospital, Kato, Japan, [4]Matsuno Clinic for Rheumatic Diseases, Toyama, Japan, [5]Research Institute of Joint Diseases, Kobe, Japan, [6]Sagawa Akira Rheumatology Clinic, Sapporo, Japan, [7]Shono Rheumatology Clinic, Fukuoka, Japan

Purpose: Interstitial pneumonia (IP) is a serious complication for collagen diseases such as RA and is strongly associated with the prognosis of the disease. The presence of IP also limits the selection of medication. There is, however, no method for prediction of the risk of occurrence of IP. We established an algorithm based on genome-wide SNP analysis for prediction of IP (usual interstitial pneumonia: UIP; non-specific interstitial pneumonia: NSIP) in RA patients.

Patients and Methods: The first population sample included 215 RA patients, the second included 115 patients: a total of 330 patients from 6 hospitals in different regions of Japan. Classification of IP was determined by three doctors (one physician and two radiologists) according to UIP and NSIP criteria. The first population included 14 UIP (average disease duration: 9.8 years), 27 NSIP (average disease duration: 11.7 years) and 174 non-IP (average disease duration: 10.7 years) patients, and the second included 10 UIP (average disease duration: 10.5 years), 16 NSIP (average disease duration: 11.5 years) and 89 non-IP (average disease duration: 11.0 years) patients. Genome-wide SNP genotyping was performed by HumanHap300K chip. Case-control analyses between 285,548 SNPs and classification of IP were examined by Fisher's exact tests. We selected 10 SNPs associated with IP, UIP, or NSIP, which were common in analyses of both the first and second population ($p < 0.02$). We then scored the relationship between each SNP and classification of IP, the estimated total score of 10 SNPs (estimated scoring in each SNP was as follows: homo allele in the majority in IP: +1 point, hetero allele: 0 point, and homo allele in the majority of non-IP: −1 point), and examined the relationships between IP and non-IP, and the total score.

Results: Accuracy ((true positive+true negative)/total), specificity (true negative/(false positive+true negative)) and sensitivity (true positive/(true positive+false negative)) of the algorithm for UIP ranged from 86–91%. For NSIP, accuracy, specificity and sensitivity of the algorithm ranged from 87–93%. It is therefore suggested that the SNP algorithm can distinguish IP (UIP and NSIP) in individual RA patients.

Conclusion: This highly accurate algorithm using SNP analysis may be useful for the prediction of UIP and NSIP in individual patients, and, in this way, can contribute to establishing a strategy of treatment such as the selection of medication and prevention of IP in treated patients.

1740

Anti-Citrullinated Protein Antibodies Are Detected in a Significant Proportion of Patients with Anti-CCP-Negative, Early RA: Implications for Improved RA Diagnosis and Guided Therapy. Reuven Bromberg[3], Jeremy Sokolove[2], Piyanka Chandra[3], Aarat Patel[8], Stacy Cofield[7], Theresa McVie[5], S. Louis Bridges[4], Larry W. Moreland[6] and William Robinson[1]. [1]Stanford Univ School of Med, Stanford, CA, [2]Stanford University, Mountain View, CA, [3]Stanford University, [4]Univ of Alabama-Birmingham, Birmingham, AL, [5]Univ of Alabama-Birmingham, [6]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [7]University of Alabama-Birmingham, [8]University of Pittsburgh, Pittsburgh, PA

Purpose: The presence of anti-cyclic citrullinated peptide (CCP) antibodies, as detected by the anti-CCP2 test, is highly specific for the diagnosis of rheumatoid arthritis (RA). However, anti-citrullinated protein antibodies (ACPAs)—only some of which recognize CCP—collectively target many different antigens, and the anti-CCP2 test may therefore fail to detect the entire population of patients with anti-citrulline reactivity. We profiled ACPA reactivity in a cohort of patients with early RA by using a novel multiplex autoantigen array and compared our array results with those obtained using the commercial anti-CCP2 ELISA.

Methods: We performed multiplex autoantibody profiling using the Bio-Plex System to evaluate the presence of 16 ACPA specificities in serum from untreated patients with early RA who were enrolled in the Treatment of Early Aggressive RA (TEAR) trial and in serum from 80 non-RA controls. Bead arrays were used to profile antibodies targeting citrullinated epitopes derived from fibrinogen, vimentin, histone 2B, clusterin, biglycan and other candidate synovial antigens. Values that were 3 SD above the median value in controls were considered positive. Diagnostic sensitivity and specificity, as well as negative and positive predictive values, were calculated for seropositivity for 2, 3, or 4 different ACPAs, and the results were compared to those obtained with the commercial anti-CCP2 ELISA.

Results: Of 360 patients with early RA, 270 (75%) were positive for anti-CCP antibodies. Of the 90 anti-CCP-negative patients, 30 (33.3.1%), 16 (17.8%), and 11 (1.22%) had 2, 3, or 4 ACPAs, respectively. Diagnostic sensitivity of anti-CCP2 was 75%, whereas sensitivity of >/= 2, 3, or 4 ACPAs was 81.1%, 73.9%, and 67.2%, respectively. Diagnostic specificity was maintained even when the presence of only a small number of ACPAs was used for diagnosis: specificity was 91.3%, 97.6%, and 97.6% when using a threshold of 2, 3, or 4 ACPAs, respectively. Combining detection of ACPAs and anti-CCP improved diagnostic sensitivity over that achieved with anti-CCP alone with minimal decrease in diagnostic specificity.

Conclusion: We demonstrate the presence of >/=2 ACPA in 33.3% of patients designated seronegative by the commercial anti-CCP2 ELISA. Given that anti-CCP positivity has been shown to be a marker of more aggressive disease and potentially an indication for the need for earlier and more

aggressive intervention, our data suggest that an additional subpopulation may benefit from the use of a broader panel of ACPA biomarkers in the diagnosis and treatment of RA. Profiling of other ACPAs in addition to those detected by the current anti-CCP assay could yield greater sensitivity in the diagnosis of RA.

1741

Anti-Cyclic Citrullinated Peptide Antibodies: Beyond Rheumatoid Arthritis. Dolors Grados, Melania Martinez-Morillo, Susana Holgado, Sonia Mínguez, Anna Moltó, Beatriz Tejera, Lourdes Mateo, Xavier Tena, Anna Marín, Iñaki Salvador, Eva Martínez-Caceres, Estíbaliz Ruiz and Alejandro Olivé. Hospital Universitari Germans Trias i Pujol

Background: The determination of anti-cyclic citrullinated peptide antibodies has diagnostic and prognostic value in rheumatoid arthritis, with a sensitivity similar to that of the rheumatoid factor and of greater specificity.

Objectives: To describe the clinical characteristics of a cohort of patients with positive anti-cyclic citrullinated peptide antibodies.

Methods: The retrospective study was done at the university hospital with a reference population of 700,000 between 2007 and 2009. We reviewed the medical records of patients with anti-cyclic citrullinated peptide antibodies (citrullinated vimentin peptides) greater than or equal to 20 U/ml excluding those cases without clinical information. Technique used: ELISA anti-CMV (Orgentec, Freiburg, Germany).

Results: We carried out 1222 determinations, of which 418 (34%) were positive. We analyzed 320 patients: 103 men (32%) and 217 women (68%). In 234 cases (73%) patients had an associated rheumatic disease.

Table 1.

	20–50 U/ml	51–100 U/ml	101–500 U/ml	>500 U/ml	Total
Rheumatoid arthritis	21	19	36	51	127
Elderly-onset arthritis	5	3	5	2	15
Non-titrated arthritis	18	4	2	1	25
Connective and vasculitis	30	2	2	2	36
Stills disease	1	2	1	0	4
Palindromic rheumatism	1	3	1	2	7
Miscellaneous	15	3	1	1	20

64.5% of patients with rheumatoid arthritis, who had values above 100 U/ml, where seropositive and erosive forms. In the cases of vasculitis and connective tissue disease the values were between 20 and 50 U/ml. They were above 50 U/ml only in six patients: 3 with SLE and 3 with Sjogren syndrome. The distribution in Still's disease, palindromic rheumatism and elderly-onset arthritis was similar for all values. 72% of the non-filiated arthritis had values between 20 and 50 U/ml. In the miscellaneous group (psoriatic arthritis, microcrystalline arthritis, polymyalgia rheumatica, sarcoidosis, arthritis associated with inflammatory bowel disease and postinfectious arthritis), 75% had values less than 50 U/ml. The value of 100 U/ml was only exceeded in a case of polymyalgia rheumatica and a case of chondrocalcinosis.

In 86 cases (27%) the patients did not have any associated rheumatic disease.

Table 2.

	20–50 U/ml	51–100 U/ml	101–500 U/ml	>500 U/ml	Total
Endocrinology and nephropathy	16	2	2	0	20
Lung disease	9	0	2	0	11
Hematology and infections	18	4	2	0	24
Miscellaneous	28	3	0	0	31

Fifteen patients (17%), two of whom were smokers, had values above 50 U/ml. In six cases the values were greater than 100: 2 with nephropathy, 2 with lung disease (pulmonary hypertension and idiopathic pulmonary fibrosis), 1 with autoimmune hemolytic anemia and 1 case of drepanocytosis.

Conclusion: Although anti-cyclic citrullinated peptide antibodies are highly specific for rheumatoid arthritis, they have also been described in other rheumatic diseases. Values above 100 U/ml usually relate to rheumatoid arthritis. Values between 20–50 U/ml without articular simptoms, must be considered negative, so this determination must be valued only in the context of rheumatic disease.

1742

Assessment of Nontraditional Prognostic Markers in Patients with Rheumatoid Arthritis. Bozena Targonska-Stepniak and Maria Majdan. Department of Rheumatology and Connective Tissue Diseases, Medical University of Lublin, Lublin, Poland

Background: Rheumatoid arthritis (RA) is associated with patients' shortened life expectancy. Premature deaths are mostly due to accelerated cardiovascular disease (CVD) which cannot only be explained by the presence of traditional CV risk factors. The search for early markers of poor prognosis seems to be crucial. N-terminal pro-BNP (NT-proBNP) concentrations are increased in CVD and predict the risk of CV events. Renal involvement worsens both the course of RA and CVD. Cystatin C (Cys-C) is used as an endogenous, precise marker for glomerular filtration rate. Carotid intima-media thickness (cIMT) assessed by ultrasound reflects early stages of atherosclerosis and is a strong predictor of CV events.

The purpose of the study was to assess the value of chosen prognostic markers in patients with RA in association with markers of disease activity.

Methods: The study population consisted of 140 RA patients (111 women and 29 men); with the mean (SD): age 50.3 (10.9) years and disease duration 120.6 (89.8) months. Disease Activity Score in 28 joints (DAS28) was calculated as a primary outcome measure. High disease activity (DAS28≥5.1) was observed in 42 patients (30%), erosive form of RA in 117 (83.6%). Plasma NT-proBNP concentration was assessed in patients and 20 healthy controls with chemiluminescent immunometric method. Serum Cys-C concentration was assessed with quantitative enhanced immunonephelometry method (normal range 0.53– 0.95 mg/l). cIMT was measured in patients and 31 healthy controls using high-resolution B-mode ultrasonography.

Results: The mean (SD) concentration of NT-proBNP was significantly higher in RA patients than in controls [120.1 (212.3) pg/ml vs 30.8 (30.6) pg/ml ($p< 0.0001$)], as well as cIMT [0.75 (0.17) mm vs 0.59 (0.12) mm] ($p< 0.0001$)]. The mean (SD) serum Cys-C concentration was 0.78 (0.3) mg/l (range 0.42–3.37).

The three markers correlated positively with each other (NT-proBNP and cIMT: $R=0.29$; $p=0.0005$; NT-proBNP and Cys-C: $R=0.34$; $p=0.00003$; Cys-C and cIMT: $R=0.44$; $p=0.00001$). There were significant associations with metabolic variables: between cIMT and cholesterol (total and LDL), atherogenic index, glucose, body mass index; between Cys-C concentration and triglycerides, atherogenic index.

The value of cIMT, Cys-C, NT-proBNP correlated positively with the patients' age and inflammatory markers (ESR, fibrinogen). Both NT-proBNP and Cys-C were also significantly associated with markers of RA: immunological (ACPA) and functional (HAQ). Only Cys-C concentration showed significant correlation with markers of disease activity (DAS28, CRP, morning stiffness, VAS patient's global assessment of disease activity).

Conclusions: The values of Cys-C, NT-proBNP and cIMT in RA patients were associated with the age and metabolic parameters, but also with markers of the disease activity. These nontraditional prognostic markers may be helpful in early diagnosis of complications associated with the course of RA.

1743

Baseline ADAMTS5 Expression Could Sort the Prediction of Response to Infliximab or Adalimumab in Patients with Rheumatoid Arthritis. Kensei Tsuzaka[1], Yuka Itami[2], Naoshi Shinozaki[2] and Tetsuo Morishita[2]. [1]Tokyo Dental College Ichikawa General Hospital, Ichikawa, Chiba, Japan, [2]Tokyo Dental College Ichikawa General Hospital, Ichikawa, Chiba, JAPAN

Objective: We have reported a disintegrin and metalloproteinase with thrombospondin motifs 5 (ADAMTS5) as a candidate marker for predicting the efficacy of infliximab (IFX) in RA patients in the last ACR meeting. In this paper, we investigate ADAMTS5 as a predicting marker for the

adalimumab (ADA) treatment in RA to certify the sorting of ADA or IFX by baseline ADAMTS5 expression.

Methods: Forty-eight and one hundred active RA patients were treated with ADA and IFX, respectively. Peripheral blood samples were collected at baseline and ADAMTS5 mRNA was quantified using real-time PCR.

Results: Baseline ADAMTS5 mRNA levels ($\times$ 10-4) in the ADA good responder (GR) (3.54 $\pm$ 2.18) were significantly ($p=0.003$) higher than that in the ADA moderate and non-responder (NGR) (2.02 $\pm$ 1.23) at 12 weeks' ADA treatment. The DAS28 at 12 weeks' ADA treatment was significantly lower in the baseline High-ADAMTS5 ($\geq 4.90 \times$ 10-4) groups than in the Low-ADAMTS5 groups, respectively (Fig.1). We observed high positive predictive value (PPV) of the baseline High-ADAMTS5 ($\geq 4.90 \times$ 10-4) for predicting ADA GR and ADA remission (DAS28<2.6 at 12 weeks) as shown in Table 1.

On the other hand, baseline ADAMTS5 mRNA level ($\times$ 10-4) in the IFX GR (1.82 $\pm$ 1.31) was significantly ($p=0.004$) lower than that in the IFX NGR (2.78 $\pm$ 1.77) at 14 weeks' IFX treatment. The DAS28 at 14 weeks' IFX treatment was significantly lower in the baseline Low-ADAMTS5 ($<1.12 \times 10^{-4}$) group than in the High-ADAMTS5 group (Fig. 1). We observed high positive predictive value (PPV) of the baseline Low-ADAMTS5 ($<1.12 \times 10^{-4}$) for predicting IFX GR and IFX remission (DAS28<2.6 at 14 weeks) as shown in Table 1.

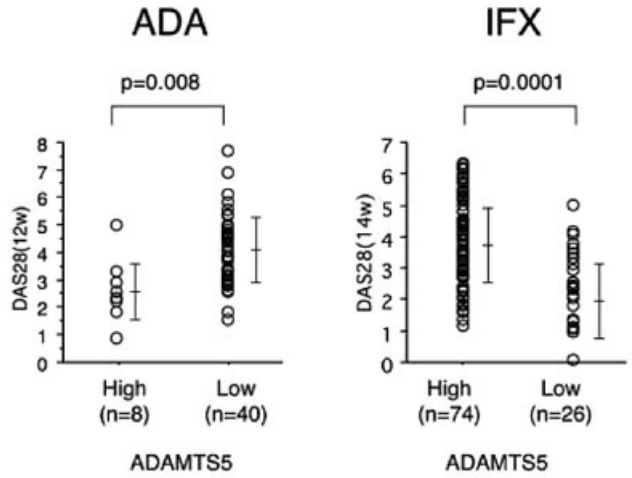

Fig. 1.

Table 1. Prediction of response to adalimumab or infliximab using ADAMTS5

	Prediction by High-ADAMTS5[b]		Low-ADAMTS5[c]	
	ADA GR	ADA Remission	IFX GR	IFX Remission
PPV (%)	75.1	61.5	70.4	62.5
NPV (%)	66.7	78.4	68.5	90.1

ADA: Adalimumab, IFX: infliximab, GR: good responder
High-ADAMTS5[b]: ADAMTS5 $\geq 4.90 \times 10^{-4}$
Low-ADAMTS5[c]: ADAMTS5 $< 1.12 \times 10^{-4}$
PPV: Positive prediction value, NPV: negative prediction value

Conclusion: Baseline Low-ADAMTS5 mRNA level ($< 1.12 \times 10^{-4}$) could predict good response to IFX while High-ADAMTS5 ($\geq 4.90 \times 10^{-4}$) could predict respectable reaction to ADA, suggesting ADAMTS5 could sort the prediction of response to these two anti-TNFα biologics.

Classification of Rheumatoid Arthritis—Comparison of the 1987 ACR and 2010 ACR/EULAR Criteria. M. P. M. van der Linden, R. Knevel, T. W. J. Huizinga and A. H. M. van der Helm-van Mil. Department of Rheumatology, Leiden University Medical Center, Leiden, The Netherlands

Objective: New criteria to classify RA have been derived in order to increase the specificity and sensitivity for early RA compared to the 1987 criteria. This study evaluated differences in classification between the 1987 ACR criteria and 2010 ACR/EULAR criteria and determined the test characteristics of the 2010 ACR/EULAR criteria.

Methods: 2258 early arthritis patients included in the Leiden Early Arthritis Clinic cohort between 1993 and February 2009 were studied. Fulfilment of the 1987 and 2010 criteria for RA was determined at baseline. Also the diagnosis at the 1 year visit was assessed. The sensitivity and specificity of the 2010 criteria were determined using three outcome measures: initiation of metrotrexate therapy or any DMARD therapy during the first year of followup and having persistent arthritis over 5 years. Persistent arthritis was defined as the absence of remission, which was defined by the absence of arthritis for at least one year after the cessation of eventual DMARD-therapy.

Results: At first presentation, 1090 patients fulfilled the 2010 criteria and 726 patients fulfilled the 1987 criteria for RA. 85 of the 726 patients (12%) that fulfilled the 1987 criteria did not fulfill the 2010 criteria at the same time point.

		2010 ACR/EULAR Classification Criteria		
		RA at baseline	no RA at baseline	*Total*
1987 ACR classification Criteria	RA at baseline	641	85	*726*
	no RA at baseline	449	1083	*1532*
	Total	*1090*	*1168*	*2258*

68% of the patients that fulfilled the 1987-criteria during the first year of the disease but not at baseline did fulfill the 2010 criteria at baseline. This indicates that the 2010 criteria indeed classify RA in an earlier stage of the disease. The sensitivity and the specificity were 0.90 and 0.56 with initiation of methrotrexate therapy as outcome and 0.83 and 0.74 respectively with use of any DMARD as outcome. When taking arthritis persistency over 5 years as outcome, the sensitivity and specificity were 0.70 and 0.63.

	2010 ACR/EULAR Classification Criteria		
Outcome Measure	Sensitivity	Specificity	AUC
MTX-use	0.90	0.56	0.73
DMARD-use	0.83	0.74	0.78
Persistency over 5 years	0.70	0.63	0.66

Conclusion: Compared to the 1987 criteria, the 2010 criteria classify more patients with RA and in an earlier phase of RA. The discriminative ability of the 2010 criteria is reasonable.

Disclosure: M. P. M. van der Linden: None; **R. Knevel:** None; **T. W. J. Huizinga:** None; **A. H. M. van der Helm-van Mil:** None.

1745

Clinical Utility and Validity of Self Assessed Joint Involvement in Rheumatoid Arthritis (RA) Patients with Low Active Disease. Helga Radner[4], Tanja Alexandra Stamm[3], Johannes Grisar[2], Josef S. Smolen[1] and Daniel Aletaha[3]. [1]Krankenhaus Lainz, Vienna, Austria, [2]Medical Universitiy Vienna, [3]Medical University of Vienna, Vienna, Austria, [4]Medical Universty Vienna, Vienna, Austria

Background: Joint swelling and tenderness are essential clinical manifestations of RA disease activity. Especially in patients in low disease activity states without significant joint involvement regular performance routine visit are usually less frequent. In these patients, self assessment of joints, and potentially, the use of a purely patient derived disease activity score might be an acceptable alternative. As a first step, we evaluated the validity of patient self assessed joint counts and a composite disease activity scores calculated from patient derived scores.

Methods: 212 patients with established RA were instructed to perform self-assessment of joints regarding swelling and tenderness on the 28 joint count (SJC28, TJC28) before an independent routine assessment by a trained evaluator. A randomly chosen subgroup of patients (n=79) received short training of joint assessment by a physician.

Based on patient derived joint counts a composite index of disease activity was calculated (patient clinical disease activity index CDAIp = TJC28 patient + SJC28 patient + patient global assessment (PGA) in cm) and correlated with the standard CDAI (CDAIe) via Spearman Correlation. Furthermore we calculated the concordance of CDAI states and differences in swollen and tender joint counts between the two different assessors using Wilcoxon test. Subsequently patients were divided into their level of disease activity defined by CDAIe and agreement was analyzed in the 4 subgroups.

Last, differences of agreement for trained and untrained subgroups were calculated separately to investigate the effect of training.

Table 1. Wilcoxon test comparing patient and evaluator derived swollen and tender joint counts (SJC28p, TJC28p; SJC28e, TJC28e) as well as the clinical disease activity index calculated by patient derived values (CDAIp) compared to the standard one (CDAIe) in the total cohort and subgroups defined by CDAI

Wilcoxon Test	TOTAL	REM	LDA	MDA	HAD
SJC28p>SJC28e	76	7	39	21	9
SJC28p<SJC28e	75	4	39	25	7
ties	61	26	26	7	2
TJC28p>TJC28e	86	10	45	26	5
TJC28p<TJC28e	45	3	22	12	8
ties	81	24	37	15	5
CDAIp>CDAIe	36	7	22	7	0
CDAIp<CDAIe	47	0	23	15	9
ties	129	30	59	31	9
total	212	37	104	53	18

Results: We found a significant correlation ($p<0.01$) of patient and assessor derived SJC28 ($r=0.42$), TJC28 ($r=0.71$) and CDAI ($r=0.79$). Wilcoxon test showed good accordance of CDAI level between CDAIp and CDAIe (ties=129 of 212) and slightly lower agreement of SJC28 (ties= 61) and TJC28 (ties=81). In different subgroups of CDAI-level we found a high concordance of patient and evaluator derived values using Wilcoxon test (see table) and significant ($p<0.01$) correlation of CDAI in all subgroups of disease activity except HDA (REM $r=0.61$; LDA $r=0.50$; MDA $r=0.38$; HDA $r=0.36$ $p=0.13$).

Comparing trained and untrained patients we found no significant differences between these two subgroups regarding Spearman correlation of CDAIp and CDAIs (trained $r=0.74$; untrained $r=0.83$) or Wilcoxon test (ties CDAI level trained =48 of 79, untrained =81 of 133).

Conclusion: Patients self assessment of joints show good correlation with those performed by specialists, regardless of training. To improve effective follow-up, especially in patients with REM or LDA, a purely patient derived disease activity index seems valid and might be a helpful tool in daily clinical practice.

1746

Comparing the Validity of the EuroQol-5D, Short Form-6D and the Well-Being Preference-Based Scores Using the Mean Short Form-36 Health Dimension Scores in Patients with Rheumatoid Arthritis and in Healthy Controls.

Fausto Salaffi[1], Marina Carotti[2], Stefania Gasparini[1], Alessandro Ciapetti[1] and Walter Grassi[1]. [1]Department of Molecular Pathology and Innovative Therapies, Division of Rheumatology, University of Ancona (Politecnica delle Marche), Italy, [2]Department of Radiology, University of Ancona (Politecnica delle Marche), Italy

Background: Over the years, the interest of the preference-based generic instruments, used to measure the health-related quality of life in a general population or in rheumatoid arthritis (RA) patients, have been increased. However, the several instruments have several discrepancies in terms of utility of results.

Objective: To compare the validity of the EuroQol-5D (EQ-5D), Short Form-6D (SF-6D) and the well-being preference-based scores (RS) using the mean Short Form-36 health dimension scores in patients with rheumatoid arthritis and in healthy controls.

Methods: A cross-sectional study was carried out among 511 patients with RA (384 women, 127 men) who were attending at Rheumatology Department. Each patient was asked to complete EQ-5D, SF-6D and the RS questionnaires. The SF-6D was derived from the Short-Form 36 health dimension (SF-36) questionnaire. SF-6D utility scores were calculated using the eight mean SF-36 scores by algorithms developed from the UK general population. Agreement between the utility instruments was assessed by comparing their score distributions, medians, interquartile range (IQR), intraclass correlation coefficients (ICCs) and a Bland-Altman plot. Interrelationship of the EQ-5D, SF-6D and RS with Disease Activity Score, 28 joint (DAS28), radiographic damage score (by Sharp v van der Heijde score method), disease duration and socio-demographic factors (age, gender and educational level) were also assessed.

Results: Baseline scores from all measures were not normally distributed (Kolmogorov–Smirnov test, all $p < 0.001$). The median baseline values have different locations in their respective scoring ranges: the median EQ-5D score was located in the top quarter and the median SF-6D and RS scores in the middle part. Median (IQR) EQ-5D utility score was 0.43 (0.34–0.55), the median (IQR) SF-6D utility score was 0.56 (I0.52–0.64) and the median (IQR) RS utility score was 0.50 (0.42–0.60). All measures were able to discriminate between patients and controls ($p < 0.001$). Agreement among measures was poor, with an ICC that range from 0.45 to 0.51. The Bland-Altman plot showed proportional error, and wide limits of agreement. Instrument correlated equally with disease activity and demographic characteristics. The SF-6D showed smaller average differences in utility between patients with better and worse disease compared with the EQ-5D and the RS. Damage score showed weak correlation with HRQL measures.

Conclusions: Although EQ-5D, SF-6D and the RS exhibited satisfactory psychometric properties for use among patients with RA, the EQ-5D and SF-6D appeared to be quite different. The low agreement and the differences in median values and scoring range show that the EQ-5D and SF-6D yield incomparable scores in patients with RA Moreover, measures of damage were weakly correlated with these instruments, suggesting that HRQL is an important complementary source of information about patients with RA. Further research is required to fully understand the respective roles of the above mentioned instruments and to examine their implications for estimates the impact of health care interventions in RA.

Disclosure: F. Salaffi: UCB, Inc., 2; **M. Carotti:** UCB, Inc., 2; **S. Gasparini:** UCB, Inc., 2; **A. Ciapetti:** UCB, Inc., 2; **W. Grassi:** UCB, Inc., 2.

1747

Computer Assisted Patient Reported (PR) Versus Physician Generated (PG) Joint Count (JC) and DAS28 Scores for Rheumatoid Arthritis (RA) Patients.

Norman B. Gaylis[2], Jeffrey Scott[3], Sue North[3], Marty True[3], Guss Savloff[1] and Barry V. Fortner[3]. [1]Arthritis & Rheumatic Disease Specialties, [2]Arthritis & Rheumatic Disease Specialties, Aventura, FL, [3]P4 Healthcare

Background: JCs and the DAS scores are established clinical indicators of disease severity, treatment response, and outcome measurement for RA. The purpose of this study was to evaluate the similarity and difference between JCs and corresponding DAS scores generated by computer assisted patient self-report or through clinical interview.

Methods: An electronic homunculus was created allowing RA patients to rate the severity of tenderness (TEN) and swelling (SW) for indicated joints through touch screen computer tablets. PG JCs were generated through normal clinical interview. A clinician interface allowed the same JC information to be recorded electronically by medical staff. JCs were combined with erythrocyte sedimentation rates (ESR) to calculate DAS28 scores using PR and PG data respectively using accepted scoring methodology. The clinician was not formally blinded to the PR scores and the order of completion was determined by clinical circumstance. The analysis design is an anonymous, retrospective, within subject correlational design testing the convergent validity PR JCs and PR DAS28 scores with corresponding PG scores. The primary hypothesis was that the PR JCs and DAS28 scores would be similar to and not different from PG JCs and DAS28 scores.

Results: At the time of this report, 51 RA patients (M[SD] age = 59.3 [11.2]; 86% female) had available PR and PG JCs and DAS28 scores on the same day. PR and PG SWJCs were significantly correlated ($R = 0.52$, $p < .001$) and were not significantly different (M[SD] PRSWJC = 3.2 [6.0], M[SD] PGJC = 4.5 [5.1], paired samples t-test, $t(df) = 1.1$ (48), $p > .1$). PR and PG TENJCs were significantly correlated ($R = 0.56$, $p < .001$) and trended toward being higher when PG (M[SD] PRJC = 2.8 [5.2], M[SD] PGJC = 4.4 [6.7], paired samples t-test, $t(df) = 1.9$ (48), p.07). PRDAS28 scores PGDAS28 scores were significantly correlated ($R = 0.75$, $p < .001$) and not significantly different (M[SD] PRDAS28 = 3.6 [1.6], M[SD] PGDAS28 = 3.7 [1.8], paired samples t-test, $t(df) = 0.8$ (50), $p < 0.4$). As shown in the table, PRTENJC, PRSWJC, and PRDAS28 scores were significantly correlated with RAPID3, RAPID4, and PGDAS28. An exploratory principal components factor analysis was performed on PRTENJC, PRSWJC, PGTENJC, PGSWJC, RAPID4, and ESR. Two components were extracted (Eigenvalues >1) accounting for > 73% of the variance. Component 1 (Symptomatology) was characterized by PRTENJC, PRSWJC, PGTENJC, PGSWJC, and RAPID4. Component 2 (Inflammation) was characterized by ESR PRTENJC, PRSWJC, and PGSWJC.

Conclusions: This study suggests that a computer assisted PR JCs are valid and may be used to produce DAS28 scores comparable to PGDAS28 scores. Initial evaluation suggests the PRJCs are related to both RA symptomatology and inflammation. Future evaluations will also compare PR JCs

and DAS scores to other available RA measures, such as radiologic indices, and will examine test-retest reliability. The primary study limitations are that PR and PG JCs were blinded and the post hoc nature of the hypothesis.

1748

Concurrent Depressive or Anxiety Disorders Significantly Worsen the Health-Related Quality of Life of Patients with Rheumatoid Arthritis. Eugenia Y. C. Lok[1], Chi Chiu Mok[2], Fuk Chi Cheung[1] and Chi Wai Cheng[1]. [1]Castle Peak Hospital, [2]Tuen Mun Hospital

Objectives: To study the effects of depressive or anxiety disorders on the health-related quality of life (HRQOL) of patients with rheumatoid arthritis (RA).

Methods: Consecutive Chinese patients who fulfilled the ACR criteria for RA were recruited from an out-patient rheumatology clinic. Written consent was obtained from these patients who were interviewed by a psychiatrist for the presence of depressive and anxiety disorders using the Chinese-bilingual Structured Clinical Interview for DSM-IV Axis I disorders, Patient research version (CB-SCID-I/P). HRQOL was measured by the validated Chinese version of the MOS 36-item Short Form Health Survey (SF-36) questionnaire. Socio-demographic and clinical data (age, gender, duration of RA, disease activity scores (DAS28), family income, education level) at the time of interview were also collected.

Results: Between July 2007 and June 2008, 200 patients with RA were studied (79% women, mean age 51.4±10.5 years; median RA duration 4.0 years [IQR 2.0–9.0]). 47 (23.5%) patients were diagnosed to have a current psychiatric disorder (depressive disorders 14.5%, anxiety disorders 13.0%). There were no statistically differences in the age, sex distribution, education level, marital status, disease activity scores and duration of RA in patients who had either depressive or anxiety disorders compared to those without any psychiatric disorders (univariate analysis). However, RA patients with either depressive ($p=0.002$) or anxiety disorders ($p=0.02$) had significantly lower family income than those without psychiatric disorders. The mean scores (out of 100) of the eight subscales of SF-36 of RA patients with depressive disorders were 34.8±21.7 (physical functioning), 11.2±22.7 (role physical), 26.4±16.9 (bodily pain), 17.8±15.0 (general health), 22.1±17.5 (vitality), 34.6±24.5 (social functioning), 3.4±18.6 (role emotional) and 34.5±16.4 (mental health), respectively. The mean scores of the eight subscales of SF-36 of RA patients with anxiety disorders were 45.2±16.2 (physical functioning), 11.5±25.7 (role physical), 34.0±15.9 (bodily pain), 23.6±12.5 (general health), 27.9±14.8 (vitality), 50.2±27.4 (social functioning), 11.5±26.6 (role emotional) and 45.7±15.4 (mental health), respectively. The scores of each of the eight subscales of SF-36 of patients with either depressive or anxiety disorders were significantly lower than those of RA patients who did not have any psychiatric disorders ($p<0.001$ in both cases). In linear regression models, both depressive disorders and anxiety disorders were independently and inversely associated with the total SF-36 scores after adjustment for socioeconomic and demographic variables ($P<0.001$ in both models). A lower family income was another independent factor for lower SF-36 scores.

Conclusion: The presence of concomitant depressive or anxiety disorders in patients with rheumatoid arthritis is associated with a significant worsening of the HRQOL, which is independent of demographic and socioeconomic factors.

Construct Validity and Reliability of the Quick Disability of the Arm, Shoulder and Hand Questionnaire in Rheumatoid Arthritis Based on IORRA Cohort Study. Asami Tokita[1], Takuji Iwamoto[2], Ryo Hiroshima[2], Yu Sakuma[2], Koichiro Yano[2], Kosei Kawakami[2], Katsunori Ikari[2], Atsuo Taniguchi[2], Hisashi Yamanaka[2] and Shigeki Momohara[2]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Kawada-cho, Shinjuku-ku, Tokyo, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Japan

Background: The Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire and the QuickDASH, which is a shorter version, are used for clinical research involving upper extremity musculoskeletal disorders. The purpose of this study is to test the reliability and validity of the Japanese Society for Surgery of the Hand Version of the QuickDASH in patients with rheumatoid arthritis (RA).

Methods: For the validation, we examined the correlation between DASH and Quick DASH was examined in RA patients who have the upper extremity disorders. The correlation between DASH, QuickDASH and Cooney's wrist score were also examined in patients with wrist disorders. Reliability was tested by a test-retest method for an average of 9.9 days interval in other patients. Moreover, the correlation between QuickDASH and Japan Health Assessment Questionnaire (J-HAQ), Visual analog scale (VAS), Disease Activity Score (DAS28) were investigated on 5,191 patients who participated in the Japanese RA cohort project (Institute of Rheumatology RA cohort: IORRA). Validity was tested using a Pearson correlation analysis.

Results: The QuickDASH was calculated for 85 out of 94 patients (90.4%). The mean of QuickDASH score was 36.25 (0–89). DASH and QuickDASH showed extremely high correlation ($r=0.97$).

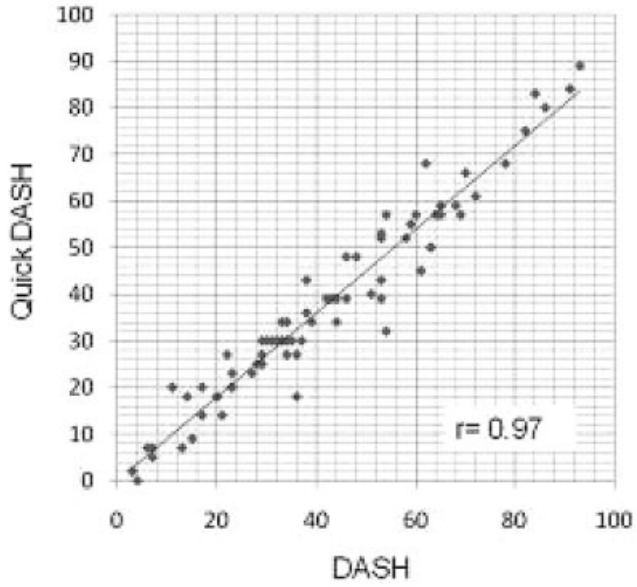

Fig. 1. DASH—Quick DASH.

The Cooney's wrist score correlated strongly with the DASH ($r=-0.79$) and the QuickDASH ($r=-0.7$). Reliability of the DASH and QuickDASH was excellent. The intraclass correlation of DASH was 0.96, and QuickDASH was 0.95. In the IORRA cohort study, the QuickDASH could be calculated for 4,946 out of 5,192 patients (95.3%). The mean of QuickDASH score was 19.9 (0–97.7). The QuickDASH and J-HAQ also showed high correlation ($r = 0.88$).

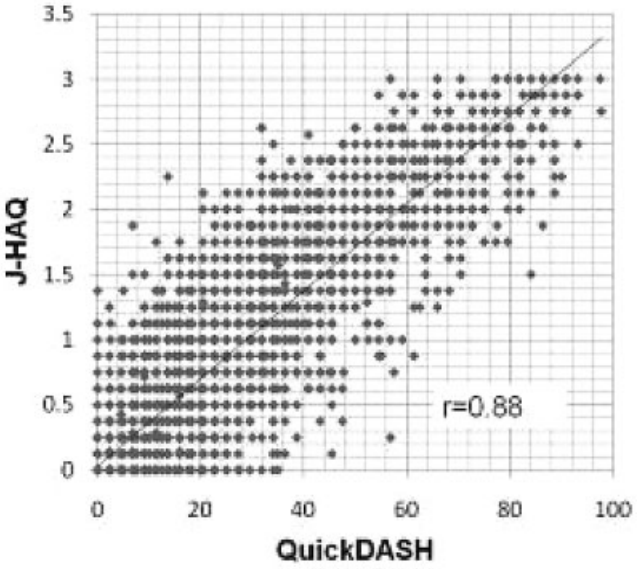

Fig. 2. QuickDASH—J-HAQ.

The clinical scores had relatively low correlations with the QuickDASH (VAS, r=0.63; DAS28, r=0.53).

Conclusions: The QuickDASH is a valid and reliable instrument for measuring the functional status of RA patients, and it is useful for large cohort study because of its high response rate.

1750

Contribution of the Rheumatoid Arthritis Impact of Disease (RAID) on Disease Activity in Rheumatoid Arthritis (RA). Till Uhlig[1], Turid Heiberg[3], Cathrine Austad[2] and Tore K. Kvien[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Oslo University Hospital, Oslo, Norway

Purpose: The RAID score is a new patient reported outcome developed through a EULAR task force (1). The OMERACT (Outcome Measures in Rheumatoid Arthritis Clinical Trials) group recently put on its research agenda a need to explore how RAID relates to disease activity in RA. Currently, patient global assessment of disease activity (PatGlob) is the patient reported variable included in DAS28.

Objectives: To provide data on validity of RAID and contribution to assessment of disease activity in a large data set from a population based RA registry 2009 (ORAR).

Methods: In a population based RA registry in Oslo, Norway, 868 patients aged 20–79 years (mean (SD) age 59.9 (12.3) years, disease duration 13.0 (10.8) years, 77.1% females, 57.0 % RF+ or CCP+) responded in 2009 to a mailed questionnaire (response rate 60.6%). RAID score (0–10) is calculated from seven domains, perceived by patients to be particularly important: pain, functional disability, fatigue, sleep problems, emotional and physical well-being, coping. The Rheumatoid Arthritis Disease Activity Index (0–10) was used to assess disease activity. Other patient reported outcomes separately assessed included pain, fatigue and PatGlob on 100 mm visual analogue scales, modified HAQ, SF-36 with physical (PCS) and mental component summary (MCS) (low scores=poor health), and SF-6D derived utility.

Pearson correlation coefficients are reported between RAID and measures of disease activity. We further used linear regression analysis to calculate the explained variance of RAID and of PatGlob for disease activity in RA.

Results: RAID was mean 3.35 (SD 2.16), disease activity (RAID) was 3.20 (SD 1.71) and both were strongly correlated (r=0.82). RAID was also highly or substantially correlated to other core measures of disease activity: pain (r=0.81), patients global (r=0.84), for physical function HAQ (r=0.67) and PCS (r=0.72), and also to fatigue (r=0.68), mental health (MCS) (r=0.52) and SF-6D derived utility (r=0.78).

RAID explained 67% of the variance in disease activity, PatGlob explained 71%, and both together explained 77%.

Conclusion: RAID was highly and substantially related to core measures and to an index (RADAI) of disease activity. PatGlob explained only slightly more than RAID of the variation in disease activity. These results support that RAID as a global composite of disease is closely related to disease activity in RA.

CXCL2 as a Potential Biomarker of Disease Activity in Rheumatoid Arthritis. Kichul Shin[2], Ji Ah Park[3], Jun Wan Kim[3], Hong Hee Kim[1], Eun Bong Lee[3] and Yeong Wook Song[3]. [1]Department of Cell and Developmental Biology, BK21 and DRI, Seoul National University School of Dentistry, Seoul, Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic of, [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea

Background: The diverse role of chemokines in rheumatoid arthritis (RA) includes enhancement of leukocyte migration, angiogenesis, and osteoclastogenesis in the synovium. CXCL2 is a chemokine produced by activated macrophages and acts as a mediator for chemotaxis of neutrophils, regulation of transmigration and extravascular tissue accumulation of leukocytes. We recently demonstrated that CXCL2 contributes in osteoclastogenesis and bone erosion *in vivo*. We investigated the relationship between serum CXCL2 concentration and clinical and radiological parameters in RA patients.

Methods: Eighty one RA patients who visited the rheumatology outpatient clinic participated in this study. All patients fulfilled the 1987 ACR classification criteria for RA. Serum CXCL2, CRP levels and blood ESR were measured. Clinical parameters including DAS28, visual analog scale (VAS) of physician's and patient's global assessment, pain, fatigue, and health assessment questionnaire (HAQ) score as well as simple erosion narrowing score (SENS) were evaluated at the time point obtaining the samples. In additional 19 patients treated with infliximab, sera at pre- and post-treatment (5 infusions) were obtained.

Results: Demographic data of 81 RA patients (female ratio 79 %) included mean age of 51 years, mean disease duration of 9.7 years, and DAS28(ESR) of 4.8 ± 1.8 (mean ± standard deviation). The serum level of CXCL2 in RA patients and healthy controls were 963.3 ± 42.1 vs. 505.0 ± 40.7 pg/ml (p= 0.002) respectively. Among the clinical parameters, a positive correlation was shown between DAS28(ESR) and CXCL2 levels (r= 0.235, p= 0.035). ESR and CRP levels also showed positive correlation with CXCL2 (r= 0.310, p= 0.005 and r= 0.540, p< 0.001, respectively). SENS did not correlate with CXCL2 levels. Serum CXCL2 levels tended to decrease compared with baseline in 19 RA patients after receiving 5 infusions of infliximab (p= 0.055).

Conclusion: Serum CXCL2 levels correlated well with DAS28(ESR), and ESR, CRP levels in RA patients. CXCL2 may be a potential biomarker of disease activity of RA.

Development by the STPR Group of the Flare Instument, a New Tool To Identify Flare in Rheumatoid Arthritis (RA) in Clinical Practice. Jean-Marie Berthelot[4], Michel De Bandt[2], Jacques Morel[1], Arnaud Constantin[3], Philippe Gaudin[3], Xavier Le Loët[3], Jean-Francis Maillefert[3], Olivier Meyer, Thao Pham, Alain Saraux, Elisabeth Solau-Gervais, Daniel Wendling, Elisabeth Spitz, Bruno Fautrel and Francis Guillemin. [1]Montpellier, France, [2]Aulnay Sous Bois, France, [3]France, [4]Rheumatology Unit CHU Nantes, Nantes, France

Introduction: Rheumatoid arthritis (RA) patients may have stable disease activity at two determinations but flares may occur between two scheduled evaluations, not captured by any activity score. There is no measure for such flares in RA patients, although they could impact on radiographic and functional outcome.

Objectives: To explore the concept of flare (transient or lasting exacerbation of disease activity) in clinical practice in RA, from both patient's and rheumatologist's perspectives, and to develop a self-administered questionnaire enabling the prospective or retrospective detection of flare(s) in the timeframe between two medical visits.

Methods: To capture the patient perspective, 105 established RA patients from 12 rheumatology centres were proposed to participate in an individual, semi-structured interview scheduled to record their feeling about flare. Content analysis was used to identify verbatim and derive candidate items. The most representative and frequently reported items were selected. To explore the physician perspective, 13 RA-experienced physicians from the STPR (Strategy of Treatment in Patients with Rheumatoid arthritis) panel, participated to a Delphi exercise. They were asked to list the signs or symptoms best reflecting RA flare(s) from their point of view. The items listed were reduced in a 5-round Delphi process in which all items cited by at least 75% were definitively selected and those cited by less than 25% of the respondents were excluded.

Results: In the patient perspective, 10 items were selected: swollen joints, fatigue, unbearable pain, pain-killer intake, night awakening, being restricted to inaction, need for help, wish to be alone, drop in mood, irritability. They were integrated in a self-administered questionnaire presenting items with Likert scale-type response frame. In the physician perspective, 9 items were identified: morning stiffness, night awakening, joint swelling, raise in ESR or CRP, worsening of nightly or morning pain, deterioration in arthritis, increase in corticosteroid intake, increase in pain-killer intake, feeling of a flare. They

were presented with discrete answers. Four dimensions were common to physicians and patients: joint swelling, pain, sleep disturbance, increase in pain killer intakes.

Conclusion: The study enabled the identification of 15 different items and will allow the construction of a self-administered questionnaire potentially able to detect flares between two medical evaluations in clinical practice, regardless any disease activity index.

1753

Development of a Multi-Biomarker Test for Rheumatoid Arthritis (RA) Disease Activity (Vectra™ DA). Marije F. Bakker[8], Yijing Shen[3], Johannes W. J. Bijlsma[7], Johannes W. G. Jacobs[8], Floris P. J. G. Lafeber[8], Guy Cavet[3], Michael Centola[4], Doug Haney[3], Lyndal K. Hesterberg[3], David Chernoff[3], John Carulli[1], Nancy A. Shadick[2], Michael E. Weinblatt[2], Max I. Hamburger[6], Roy M. Fleischmann[5], Jeffrey R. Curtis[9] and Ed C. Keystone[10]. [1]Biogen Idec, [2]Brigham & Womens Hospital, Boston, MA, [3]Crescendo Bioscience, Inc., [4]Oklahoma Med Research Foundation, Oklahoma City, OK, [5]Rheumatology Associates, Dallas, TX, [6]Rheumatology Associates of LI, Dix Hills, NY, [7]University Medical Ctr Utrecht, Utrecht, The Netherlands, [8]University Medical Ctr Utrecht, [9]University of Alabama-Birmingham, Birmingham, AL, [10]University of Toronto, Toronto, ON, Canada

Background: Increasing emphasis on tight control in RA management relies on efficient, quantitative monitoring of disease activity. Given the heterogeneous biology of RA, we sought to develop a quantitative, objective, multi-protein test of RA disease activity. To develop this test, we used a stepwise approach, starting with a broad survey of RA biology, to reach a final set of biomarkers and algorithm to combine them into a single, easy-to-interpret score.

Methods: 25 serum protein biomarkers were previously selected from 137 candidates based on their relationship with disease activity in prior studies: SAA, IL-6, TNF-RI, VEGF-A, PYD, MMP-1, ICAM-1, calprotectin, YKL-40, MMP-3, EGF, IL-1RA, VCAM-1, leptin, resistin, CRP, IL-8, ApoAI, ApoCIII, CCL22, IL-1B, IL-6R, IL-18, keratan and ICTP. Biomarker assays were systematically optimized for analytical performance. Biomarkers were analyzed in 512 serum samples from Index For Rheumatoid arthritis Measurement (InFoRM), a multi-center observational study of North American RA patients, and 167 from the Brigham and Women's Rheumatoid Arthritis Sequential Study (BRASS). Algorithms combining multiple biomarkers were trained to derive a single clinical disease activity measure with scores between 1 and 100; models were developed using ordinary least squares, Lasso and Elastic Net regression, and Curds and Whey, as well as combinations of these approaches. Performance was evaluated by Pearson correlation (r) and area under the ROC curve (AUROC), a measure of classification performance, comparing to the DAS28CRP. Evaluation used cross-validation within the training dataset to guard against over-fitting. A final algorithm was developed and assessed in an independent cohort, i.e. patients from the CAMERA tight control study (testing dataset), to determine performance.

Results: Concentrations of the 25 biomarkers were cross-sectionally measured in 512 patient samples from InFoRM. Associations between concentrations and multiple measures of disease activity were used to prioritize 15 top biomarkers which were subsequently measured in 167 BRASS patient samples. The combined set of 679 patients was diverse in geographic location, ethnicity, age, and RA disease activity. Multiple algorithms were developed; the algorithm with the best performance included 12 biomarkers and used an algorithm similar to the DAS calculation, with different subsets of the biomarkers used to estimate SJC28, TJC28 and patient global. The 12-biomarker algorithm (DA Test) was assessed in the CAMERA cohort, an independent test set, where it achieved r of 0.73 with DAS28CRP and AUROC of 0.87. The DA Test score decreased significantly between the baseline and 6 month study visits, reflecting patients' clinical response to therapy. The DA Test was advanced into independent validation in other cohorts.

Conclusion: An objective test (DA Test) integrating multiple serum biomarkers representing diverse RA pathophysiology has been derived and tested; it can quantify RA disease activity. Once validated in an independent cohort to confirm its performance and additional value, this test has the potential to enhance clinical assessment of RA patients.

1754

Evaluation of Patients with Rheumatoid Arthritis in Clinical Remission with 12 Joints Ultrasonography. Preliminary Results. José M. Senabre[1], José C. Rosas[2], Carlos Santos-Ramírez[2], Gregorio Santos-Soler[2], Xavier Barber[3], Nuria Llahí[2], Catalina Cano[2] and Rosa Riestra[2]. [1]Hospital Marina Baixa, Villajoyosa, Alicante, Spain, [2]Hospital Marina Baixa, [3]University Miguel Hernández

Objective: To assess wether gray scale and power Doppler (PD) ultrasound of 12 joints can detect disease activity in rheumatoid arthritis (RA) patients classified as clinical remission by DAS28-ESR and / or DAS28-CRP <2.6.

Material and Methods: We included prospectively RA patients in clinical remission (DAS28-ESR and / or DAS28-CRP <2.6) from the Rheumatology Clinic of the Hospital Marina Baixa and within 30 days of clinical evaluation a gray scale and PD ultrasound scan (Esaote, MyLab25 Gold) was performed, by the same rheumatologist who was unaware of the clinical data. We evaluated the presence of joint effusion and PD signal: elbows (anterior and posterior), wrists, 2nd and 3rd MCPs joints (dorsal and palmar aspects), knees (suprapatelar, medial and lateral recesses) and ankle (anterior). The effusion was scored from 0 to 3 points (OMERACT) and the patients were classified into 2 groups (> or <10 points) under the joint global summation.

Results: We analyzed 33 consecutive RA patients in clinical remission, 73 % were women and the mean age was 60 ± 16 years. The average time course of RA was 88 ± 80 months (median 60). PD signal was detected in any joint in 52% of patients. Some degree of joint effusion was detected in 88% of patients. 22% of patients were in group A with effusion > 10 points and 78% in group B with effusion < 10 points. The mean time since diagnose of AR was 81 in group B vs 114 months in the group A. Presence of erosions was 27% in group B vs 57% in group A. No significance was detected in the statistical analysis.

	DOPPLER SIGNAL					
	ABSENCE			PRESENCE		
	Mean	Standard deviation	Median	Mean	Standard deviation	Median
Time in remission (months)	21	21	11	19	25	9
RA Diagnose (months)	81	71	56	94	89	60
DAS28-ESR	1,25	0,45	1,00	1,59	0,507	2,000
DAS28-CRP	1,13	0,35	1,00	1,18	0,39	1,00
Age (years)	54,81	16,1	50,00	64,59	13,72	67,0

Conclusions: 1—Ultrasonographic inflammatory activity (presence of PD) was detected in 52% of RA patients (in clinical remission). 2—22% of patients were in group A with effusion > 10 points. 3—In this group a greater percentage of erosions was detected (57% vs 27%).

1755

Feasibility of Online Registration of Physical Functioning by RA Patients in the Out Patient Clinic. Rosanne Koevoets[3], N. A. de Glas[3], I. Speyer[1], A. A. Schouffour[3], T. W. J. Huizinga[3], Thea P. M. Vliet Vlieland[2] and Cornelia F. Allaart[2]. [1]Bronovo Hospital, The Hague, [2]Leiden University Medical Centre, Leiden, The Netherlands, [3]Leiden University Medical Centre, Leiden, The Netherlands

Background: Monitoring functional ability is important to assess efficacy of treatment in rheumatoid arthritis (RA), however implementation of routine assessment of functional ability in daily practice remains difficult.

Purpose: To assess the feasibility of and patients' opinion about autonomic online health assessment questionnaire (HAQ) registrations by RA patients in our out patient clinic

Methods: RA patients visiting the out patient department were given an oral instruction and asked to fill in a computerized HAQ in METEOR, a free web based program designed for monitoring both functional ability and disease activity. The time needed to fill in the HAQ and any problems arising were registered. Next, patients answered questions on computer access, the usefulness of the HAQ and the METEOR program. Answers were filled in on a 5 point Likert scale with a high score representing a positive answer and a low score a negative one.

Results: Of 111 consecutive patients, 92 agreed to participate, and 78 patients completed the whole evaluation, while 14 patients stopped early because of time constraints. Seventy-seven percent of the participants were female, and the average age was 58.4 years (range 25–78). Mean (SD) disease duration was 10.4 (8.7) years and mean (SD) HAQ score at the time of assessment was 1.01 (0.72). Of all participants, 84% had personal computer access and 73% reported frequent (daily or weekly) computer use. The mean time patients needed to fill in their own HAQ was 6 minutes, which 99% of patients reported as reasonable or good. Patients felt they had not needed much assistance when filling in the HAQ, although the investigator had noted that some assistance (mainly concerning technical computer problems) was needed in 78% of all patients. Average scores on questionnaire items are presented in table 1. Ninety-five percent of patients said they would be willing to fill in the computerized HAQ at the next visit and 83% was prepared to come to the hospital earlier to fill in the HAQ there, 73% of patients would like the option of filling in the HAQ at home. Twenty percent of patients felt there were missing subjects in the HAQ, in particular work-related activities, social activities and sports, as well as registration of fatigue and psychological problems. Ninety-four percent reported that the subjects included in the HAQ were all relevant. According to patients discussing problems in daily functioning is important, however it is not always part of the out patients visit to the rheumatologist (table1).

Table 1. Results of patients survey questions.

	Mean	Sd
1. What was your opinion about filling in the HAQ on the computer? (1=very difficult 5=very easy)	4.5	1.1
2. Would you be capable of filling in the HAQ independently the next visit? (1=definitely not 5=definitely)	4.2	1.3
3. Did you appreciate filling in the HAQ on the computer in the waiting room? (1=no, not at all 5=yes, very much)	4.0	1.2
4. How important is it discuss about problems in daily functioning with you rheumatologist? (1=not important at all 5=very important)	4.0	1.1
5. How often are problems in daily functioning discussed with the rheumatologist? (1=never 5=always)	3.5	1.3
6. Do the questions in the HAQ give an accurate representation of your abilities and limitations in daily functioning? (1=not at all 5=very much)	3.9	1.2

Conclusion: Independent computerized registration of physical functioning by RA patients in the out patient clinic is feasible and is appreciated by patients. Filling in the HAQ using the METEOR tool before seeing the rheumatologist may stimulate to discuss functional (dis)ability during the consultation, which patients find important, but is not always done.

1756

Identification of a Novel Marker of Radiological Damage in RA. A. Kleszcz, M. Teare, D. Moore, J. Worthington, A. Barton and G. Wilson. The University of Sheffield

Introduction: Recent genome-wide meta-analysis association studies have identified 10 new risk loci for rheumatoid arthritis: *CD2 and CD58, PRDM1, PTPRC, TAGAP, FCGR2A, CD28, C5orf30, RBPJ, CCR6, and PXK*. The aim of this study was to determine whether RA risk variants were also associated with disease severity as assessed by modified Larsen scores in patients with established rheumatoid arthritis.

Methods: Modified Larsen scores of radiographic damage were determined in a cross-sectional population of patients with established rheumatoid arthritis (n=946). Rheumatoid factor and anti-cyclic citrullinated antibody levels were assayed using nephelometry and ELISA respectively. The Kruskal-Wallis nonparametric test was used to compare median Larsen scores for each genotype, followed by Nonparametric Trend Test.

Results: Of the 10 risk loci, an allele-dose association with increased radiological damage was found for rs26232 ($P = 0.001$) in C5orf5, with the common genotype CC having the highest median modified Larsen score. Stratification by antibody status suggests that the association is strongest for in RF and anti-CCP positive RA ($P = 0.005$), however the number of antibody negative patients was relatively small.

Conclusions: The data indicates that rs26232 is strongly associated with severity of radiological joint damage in patients with rheumatoid arthritis. The SNP rs26232 is located at chromosome 5q21 within the intron of the predicted gene C5orf30 where no obvious biological candidate gene has been found. Similar to DRB1 and TNFAIP3 alleles, this marker is associated with both risk and severity of RA.

1757

Improvement of Serological Rheumatoid Arthritis Diagnostics by Autoantibody Profiling. Karsten Conrad[2], Dirk Roggenbuck[1] and Kirsten Lüthke[3]. [1]Generic Assays GmbH, Dahlewitz, Germany, Germany, [2]Institute of Immunology, Medical Faculty of the Technical University of Dresden, Germany, [3]Rheumatological Practice, Dresden, Germany, Germany

Appropriate treatment at a sufficiently early stage can have a favourable effect on progression and serious clinical complications of rheumatoid arthritis (RA). CCP antibodies are used as specific markers for RA but are detectable in less than 80%. Therefore, a multiparametric analysis of RA-associated autoantibodies (RA-AAB) may increase the diagnostic sensitivity.

Sera of 349 patients with definite rheumatoid arthritis (RA) and 535 patients with various diseases other than RA were tested for rheumatoid factors (IgM and IgA-RF) and antibodies to RA33 (HUMAN GmbH, Germany), CCP (GA Generic Assays GmbH, Germany), mutated citrullinated vimentin (MCV) (ORGENTEC Diagnostika GmbH, Germany), and citrullinated protein (CPA) (HUMAN GmbH, Germany). The diagnostic sensitivity and specificity as well as the receiver operating characteristics were analyzed for these autoantibodies. The cut-off values were determined, at which the diagnostic specificity reaches >98% (optimized cut-off). 76.8% of RA patients were positive for CCP antibodies. In 22 of the CCP antibody negative RA patients, at least one of the other RA-AAB could be found at the optimized cut-off. Hence, the diagnostic sensitivity for RA can be increased to 83.7% by parallel or sequential determination of RA-AAB without loss of diagnostic specificity.

In conclusion, the serological diagnosis of RA can be improved by varying cut-off values to increase diagnostic specificity of certain RA-AAB and by determination of RA-AAB profiles to increase diagnostic sensitivity. A further improvement depends on the discovery of novel RA-AAB with high specificity and high predictive values as well as on methodological aspects (e.g., multiplex analyses).

In Patients with Rheumatoid Arthritis Who Are in a Low Disease Activity State or Remission, Does Lack of Fatigue Relate to Better Function and Damage Scores. George A. Wells[2], Tracy Li[1] and Maarten Boers[3]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]Univ of Ottawa Faculty of Med, Ottawa, ON, Canada, [3]VU University Medical Center, Amsterdam, The Netherlands

Purpose: With current treatment options for patients with rheumatoid arthritis (RA), low disease activity (LDA) and remission are reasonable treatment goals. Most criteria for LDA and remission are based on physician-reported measures and traditional patient-reported outcomes (PRO). The Outcome Measures in Rheumatology (OMERACT) initiative has recently recommended fatigue be assessed in all clinical trials. The importance of fatigue in relation to response and disease activity criteria on function and damage scores needs to be evaluated. To evaluate the added affect of fatigue on function and radiography in patients with RA meeting response, LDA and remission criteria.

Methods: The active RA patients under study were from a 12-month,

randomized, double-blind, placebo controlled trial (AIM trial) comparing abatacept (n=433) to placebo (n=219) on a background of MTX. Assessments at 12 months included: function (HAQ), radiography (erosions, joint space narrowing, total), fatigue (100mm visual analog scale) and core set measures used to derive response (ACR20, ACR50, ACR70), LDA (DAS28<3.2, SDAI≤11, CDAI≤10) and remission (DAS28<2.6, SDAI≤3.3, CDAI≤2.8) criteria at 6 months. The following patient groups are of interest at 1 year: criteria not met (NC) and criteria met (C); and within the latter, those with high (>10; C-hiF) and low fatigue levels (≤10; C-loF). These 4 groups will be compared on their function and radiography.

Results: The results for function (HAQ) are given in the table. Except for SDAI remission criteria, the HAQ is significantly lower in the patients that met the criteria and fatigue was low (≤10) compared to patients that met the criteria and fatigue was high (>10). For NC vs C and for NC vs C-loF, p<0.0001 for all criteria. For radiography, there was no significant difference between low and high fatigue for patients meeting the criteria.

Table. HAQ-functional progression (mean ± SD)

Criteria	Criteria Not Met (NC)	Criteria Met (C)	Criteria Met + Fatigue > 10 (C-hiF)	Criteria Met + Fatigue ?10 (C-loF)	p-value C-loF vs C-hiF
ACR 20	1.50 ± 0.65 (n=154)	0.90 ± 0.66 (n=412)	1.05 ± 0.63 (n=307)	0.43 ± 0.45 (n=101)	<0.0001
ACR 50	1.36 ± 0.64 (n=315)	0.69 ± 0.59 (n=251)	0.86 ± 0.60 (n=165)	0.36 ± 0.38 (n=86)	<0.0001
ACR 70	1.23 ± 0.67 (n=429)	0.54 ± 0.52 (n=137)	0.74 ± 0.56 (n=70)	0.32 ± 0.37 (n=67)	<0.0001
DAS28 <2.6	1.14 ± 0.68 (n=496)	0.47 ± 0.49 (n=58)	0.65 ± 0.48 (n=28)	0.29 ± 0.44 (n=30)	0.0043
DAS28 <3.2	1.17 ± 0.68 (n=467)	0.53 ± 0.52 (n=87)	0.76 ± 0.54 (n=44)	0.29 ± 0.39 (n=43)	<0.0001
CDAI ?2.8	1.12 ± 0.68 (n=522)	0.38 ± 0.50 (n=44)	0.57 ± 0.60 (n=14)	0.28 ± 0.43 (n=30)	<0.0001
CDAI ?10	1.24 ± 0.67 (n=388)	0.68 ± 0.61 (n=178)	0.90 ± 0.62 (n=106)	0.36 ± 0.41 (n=72)	<0.0001
SDAI ?3.3	1.11 ± 0.68 (n=530)	0.38 ± 0.54 (n=36)	0.61 ± 0.64 (n=11)	0.27 ± 0.46 (n=25)	0.0756
SDAI ?11	1.23 ± 0.66 (n=392)	0.68 ± 0.62 (n=172)	0.90 ± 0.64 (n=103)	0.36 ± 0.41 (n=71)	<0.0001

Conclusions: For patients meeting various response and remission criteria, there is a significantly better function among patients with low fatigue, but no effect on radiography. As it relates to function, fatigue is an important factor to be considered in clinical practice and treatment evaluati

Is Exclusion of Joints of the Feet in a Disease Activity Index like DAS28 a Clinical Problem When Assessing the Individual RA Patient? M. F. Bakker[2], J. W. G. Jacobs[2], P. M. J. Welsing[1], F. P. J. G. Lafeber[2] and J. W. J. Bijlsma[2]. [1]Rheumatology & Clinical Immunology, Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, The Netherlands, [2]Rheumatology & Clinical Immunology, University Medical Center Utrecht, The Netherlands

Background: The disease activity of RA patients is often assessed with the DAS28, in clinical trials as well as in daily practice. However, the DAS28 has not been validated for use in individual patients and joints of feet are not included. The aim of this investigation was to study whether this last drawback could be a clinical problem.

Methods: Patients within the CAMERA trial were divided into 3 'damage progression' groups according to local radiographic progression rates: 1) primarily progression of the feet, 2) similar progression of hands and feet, and 3) primarily hand progression. This was done for radiographic progression within the first 2 years, between 2 and 5 years and from 0 until 5 years. Time-averaged DAS28, its individual components (TJC, SJC, ESR, and VAS-GH), and tender and swollen joints of feet were compared between the 3 groups within the first 2 time periods. The longitudinal relation of DAS28 with radiographic damage (total SHS score) over the 5 year period was investigated within the 3 'damage progression' groups with RF-status, baseline joint damage as well as the SJC and TJC of the feet as covariates using longitudinal regression analysis (mixed model analysis).

Results: After 2 and 5 years of treatment, respectively 145 (55%) and 66 (33%) patients had no radiographic progression, 30 (11%) and 33 (16%) primarily feet progression, 60 (23%) and 69 (35%) similar progression and 30 (11%) and 32 (16%) primarily hand progression. Over the first two years the primarily feet and hand progression groups (group 1 and 3) had a similar mean (SD) DAS28: 4.0 (1.0) vs. 3.9 (0.9), respectively. However, compared to the primarily hand group, the primarily feet group had more tender and swollen joints of the feet: 3.4 (2.2) vs. 1.5 (1.3), p<.001 and 2.8 (1.9) vs. 1.1 (1.2), p<.001, respectively. This statistically significant difference was not present in the 2 until 5 year period. In both time periods, the 'similar progression' group (group 2) had lower disease activity scores and involvement of the feet in between those of groups 1 and 3.

On group level there was a longitudinal relation between the DAS28 and radiographic progression. The 'damage progression' groups modified the relation between the DAS28 and radiographic progression, with the 'primarily foot progressors' (group 3) showing more (change in) radiographic progression with the same (change in the) DAS28 as compared to the other groups (interaction term DAS28*primarily foot progressors: β=1.2, 95%CI: 0.6–1.9, p<.001). In other words, in the 'primarily foot progressors' the disease activity when assessed by the DAS28 seems to be underestimated. In the primarily foot progressors the joint counts for the feet were also longitudinally related to radiographic progression.

Conclusions: In a subgroup of RA patients the DAS28 underestimates the total joints involved (especially during the first 2 years of the disease) and the expected joint damage. This could particularly be a problem in tight control, using the DAS28 remission or low disease activity definition. For follow-up of individual patients, assessment of all for RA relevant joints seems indicated.

1760

Level of Agreement of 1987 ACR and 2010 ACR/EULAR Classification Criteria: An Analysis Based on the ESPOIR Cohort Data. Bruno Fautrel[3], Nathalie Rincheval[4], Bernard G. Combe[1], Maxime Dougados[2] and ESPOIR Scientific Committee. [1]Hopital Lapeyronie, Montpellier, France, [2]Hospital Cochin, Paris, France, [3]Pitie Salpetriere Hospital, Paris, France, [4]UIRC Montpellier

New rheumatoid arthritis (RA) classification criteria have been developed conjointly by the ACR and EULAR in 2010 to replace the 1987 ACR ones. However, information is lacking to determine in what extent the "old" and "new" sets identify similar patients as having RA.

Objective: To assess the agreement between 1987 ACR and 2010 ACR/EULAR criteria and the source of potential disagreement of the 2 sets, based on the ESPOIR cohort data.

Patients and Methods: 813 patients with early arthritis (EA) were included into the cohort between 2002 and 2005 and followed every 6 months during the first 2 years. Inclusion criteria were: 18 to 70 years old; more than 2 swollen joints for more than 6 weeks and less than 6 months; with suspected RA diagnosis.

The agreement between the 2 criteria sets was based on Kappa coefficient calculation.

Results: Data on 811 patients were available with main characteristics as follows: female 77%; mean age 48 ±13 years; mean HAQ 1.0 ± 0.7; swollen joint count 7.2 ±5; tender joint count 8.4 ±7; DAS28 5.2 ±1.5; ESR 29 ±25 mm/1 hr; CRP 22 ±34 mg/L, IgM RF+ 47 %, anti-CCP+ 39 %; structural damage on X-ray 22 %. 579 (71.4%) patients met the 1987 ACR criteria and 641 (79.0 %) met the 2010 ACR/EULAR ones at baseline. 168 patients were discordant, 115 only satisfying the 2010 criteria and 53 only the 1987 ones. The concordance between the 2 sets was fair with a Kappa coefficient of 0.45 [95% CI: 0.38; 0.52]. Main sources of disagreement are indicated in the table below.

Patients meeting:	Both sets (n=526)	Only 2010 set (n=115)	Only 1987 set (n=53)
Tender joints, mean ± sd	10.4 ± 7.2	7.2 ± 6.2	3.8 ± 2.7
4 to 10 involved small joints, n(%)	91 (17.3)	31 (27.0)	38 (71.7)
≥ 10 involved joints, n (%)	421 (80.0)	61 (53.1)	1 (1.9)
Swollen joints, mean ± sd	9.1 ± 5.5	3.9 ± 3.2	5.2 ± 2.6
≥3 synovitis, n (%)	503 (95.6)	52 (45.2)	51 (96.2)
Symmetrical arthritis, n (%)	486 (92.4)	42 (36.5)	52 (98.1)
Morning stiffness ≥60 min, n (%)	497 (94.5)	74 (64.4)	53 (100)
RF +, n (%)	309 (58.7)	58 (50.4)	3 (5.7)
ACPA +, n (%)	274 (52.1)	39 (33.9)	2 (3.8)
RA diagnosis certainty at inclusion on a 0–10 VAS	7.9 ± 1.8	5.0 ± 2.4	6.2 ± 2.1
RA diagnosis certainty at 2 years on a 0–10 VAS	8.1 ± 2.7	6.3 ± 3.6	6.4 ± 3.5

The concordance of the 2010 set with the 1987 ACR criteria at 2 years was also tested since 1987 criteria perform better at that time point (Saraux et al. Arthritis Rheum 2001;44:2485). Kappa coefficient remained fair: 0.42 [95% CI: 0.33; 0.51].

Conclusion: 2010 criteria identify more patients than 1987 criteria as having RA. However, the 2010 set failed to identify as RA patients with symmetrical sero-negative arthritis with limited joint involvement.

Levels of Soluble CD163 Is Associated with Disease Activity and Radiographic Progression in Early Rheumatoid Arthritis. Stinne R. Greisen[6], Malene Hvid[4], Kristian Stengaard-Pedersen[1], Merete L. Hetland[2], Kim Hørslev-Petersen[7], Holger J. Møller[3] and Bent Deleuran[5]. [1]Arhus University Hospital, Aarhus, Denmark, [2]Copenhagen Univ Hosp Hvidovre, Hvidovre, Denmark, [3]Department of Clinical Biochemistry, Aarhus University Hospital, Denmark, [4]Institute of Medical Microbiology and Immunology, University of Aarhus and Department of Dermato-venerology Aarhus University Hospital, Denmark, [5]Institute of Medical Microbiology and Immunology, University of Aarhus, and Aarhus University Hospital, Denmark, [6]Institute of Medical Microbiology and Immunology, University of Aarhus, Denmark, [7]King Christian X Hospital for Rheumatic Disease, University of Southern Denmark

Background: The macrophage is the predominant cell type in the cartilage-panus junction, and is strongly associated with joint destruction in rheumatoid arthritis (RA). Resident macrophages exclusively express the scavenger receptor CD163, which is also present in plasma and joint fluid in a soluble form (sCD163).

Objective: The aim was to investigate the degree of macrophage activity by the presence of solouble and cell surface CD163. Soluble CD163 was investigated for its association with core parameters for disease activity including radiographic progression in early RA, and cell surface CD163 was examined for its co-expression with the known monocyte/macrophage marker CD14.

Methods: In a longitudinal sample set of early RA patients (n=34) we measured plasma levels of sCD163 at baseline and after 9 months of treatment, and correlation levels with disease activity in 28 joints (DAS28), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), and total Sharp score (TSS). In a transverse sample set of chronic (>8 years of disease) RA patients (n=24) we measured paired plasma and joint fluid levels of sCD163 by ELISA. We also examined the cellular expression of CD163 and CD14 by flow cytometry. Statistical correlations were assessed by Spearman's rho, and data are expressed as median with IQR in parenthesis.

Results: In early RA, patients had significantly higher plasma levels of sCD163 (1.69 mg/L (1.42–2.10)) at baseline, than after 9 months of treatment (1.28 mg/L (0.963–1.66) p=0.001). Plasma levels of sCD163 at baseline were strongly correlated with sCD163 at 9 months, (r2=0.672, p=0.00001). At baseline sCD163 correlated with DAS28, CRP and ESR. Interestingly sCD163 at 9 months, but not at baseline, was associated with radiographic progression (TSS) between year 2 and 3 (r2=0.468, p =0.02). Chronic RA patients had higher plasma levels of sCD163 than early RA patients (3.05 mg/L (1.84–6.04)), p<0.001). The levels in joint fluid were even higher (8.32 mg/L (6.04–10.65)) and correlated with sCD163 in plasma (r2=0.4, p=0.05).

Cell surface CD163 was almost exclusively detected on synovial macrophages, compared with cells in peripheral blood (p=0.02), and all CD163+ cells co-expressed CD14.

Conclusion: Plasma levels of sCD163 are associated with core parameters for disease activity and radiographic progression, and decreases significantly after 9 months of effective treatment. The observation that sCD163 in the synovial fluid correlates with plasma levels, and that CD163 is highly expressed by synovial macrophages, supports that resident macrophages are important for the joint destruction in early RA, and that plasma sCD163 reflects the macrophages population within the inflamed joint. This supports the role of sCD163 as a biomarker of disease activity and joint destruction.

Liver Injury in Patients with Rheumatic Diseases and Inflammatory Syndrome: A Case-Control Prospective Analysis Using Biomarkers (FibroTest, ActiTest and SteatoTest). Cécile Gaujoux-Viala[2], Mathilde Benhamou[2], Mona Munteanu[1], Yen Ngo[1], Djamila Messous[1], Françoise Imbert-Bismut[1], Vlad Ratziu[1], Pierre Bourgeois[2], Thierry Poynard[1], Bruno Fautrel[2] and SAFE-T DILI-GHPS Study Group. [1]Paris 6–Pierre et Marie Curie University; Hepatology, Pitié-Salpêtrière Hospital, Paris, France, [2]Paris 6– Pierre et Marie Curie University; Rheumatology, Pitié-Salpêtrière Hospital, Paris, France

Background: Several drugs used in chronic rheumatic diseases (RHU) can induce liver damage. Few studies on consecutive cohorts are available because of the limitations of liver biopsy.

The aim was 1) to use validated biomarkers to evaluate the presence of fibrosis (Fibrotest), necroinflammatory activity (Actitest), and steatosis (Steatotest) and associated risk factors among RHU subjects hospitalized in a rheumatology department 2) to evaluate the impact of inflammatory syndrom estimated by C-reactive protein (CRP) on FibroTest parameters.

Methods: 211 prospective RHU were compared to 211 healthy controls without known liver disease (CTR), matched for age, gender, self-declared alcohol intake (SDA) and body mass index. Standard thresholds were: Fibrotest<0.27 for no/minimal fibrosis (METAVIR F0) and Fibrotest>0.48 for advanced fibrosis (AF, METAVIR>F2); Actitest<0.29 for no/minimal activity (METAVIR A0); Steatotest<0.38 for no steatosis.

Results: Among RHU (36.4% male, age 48 years, median [range] CRP 4g/L[4–72]), 96 had rheumatoid arthritis (RA), 57 ankylosing spondylitis (AS), 14 psoriatic arthritis (PsA) and 50 other diagnoses; 36.5% were treated with methotrexate (MTX), 22.7% with corticosteroids, 22.8% with non-steroid anti-inflammatory, 8.1% with infliximab (IFX), 29.4% with paracetamol. Median [range] number of treatments per subject was 3[0–11]. The mean (SE) SDA in PsA compared with others was 12g/d (7.7) vs. 5g/d (0.7) (p=0.02).

The prevalence of presumed lesions in RHU versus CTR in overall population and according to etiology was presented in the table.

	RHU	CTR	p
Fibrosis %	10.9	7.2	0.17
- RA	7.3	5.2	NS
- AS	8.8	5.3	NS
- PsA	21.4	7.1	NS
AF	2.4	0.1	0.025
Activity %	10.4	4.3	0.015
		OR=2.61 [1.17–5.82]	
- RA	11.5	3.1	0.026
		OR=4.012 [1.082–14.88]	
- AS	8.8	1.8	0.09
- PsA	21.4	14.3	NS
Steatosis%	38.5	30.2	0.048
		OR=1.44 [0.95–2.17]	
- RA	41.2	33.7	NS
- AS	30.2	34	NS
- PsA	64.3	28.6	0.058

Steatosis was more prevalent in patients treated with MTX or IFX than in CTR (40.3% vs 29.9%, p<0.0001; 52.9%vs17.6%, p=0.031 respectively). The prevalence of other lesions was not different according to treatment regimen.

CRP was not correlated [Spearman correlation coefficient (SCC)] with alpha2-macroglobulin (SCC= 0.01, p=0.89) and was correlated only with haptoglobin (SCC= 0.71, p<0.0001) without impact on FibroTest results (SCC=−0.07, p=0.36).

Conclusions: Compared with CTR, RHU had a higher prevalence of necroinflammatory activity and steatosis presumed with biomarkers. The subjects with RA had greater presumed activity, and subjects with PsA more frequent steatosis. The presumed steatosis was associated with treatments with MTX and IFX. Haptoglobin and not alpha2macroglobulin was correlated with inflammatory syndrom without impact on final FibroTest results.

1763

New 2010 ACR-EULAR Rheumatoid Arthritis Classification Criteria Are Highly Sensitive in Patients with Early Rheumatoid Arthritis. Sarang Chitale[2], Nicola J. Goodson[2], David W. Sharpley[2], Robert N. Thompson[1], Robert J. Moots[2] and Cristina Estrach[2]. [1]Academic Rheumatology Department, University Hospital Aintree, Liverpool, Merseyside, United Kingdom, [2]Academic Rheumatology Department, University of Liverpool, Liverpool, Merseyside, United Kingdom

Background: Rheumatoid Arthritis (RA) requires early recognition & treatment with disease modifying anti-rheumatic drugs (DMARD) to prevent erosive damage and long-term disability. Many patients with early RA (eRA) do not satisfy the 1987 ACR classification criteria [1] at initial presentation. Other revised criteria have been proposed to improve the identification of such patients [2].

ACR and EULAR have jointly formulated new RA classification criteria, to facilitate early recognition of patients likely to have persistent and progressive disease and require DMARD therapy [3].

Aims: To explore whether a cohort of patients with symptom duration ≥12 months, diagnosed with eRA (based on the opinion of the rheumatologist) and started on DMARDS, met ACR-EULAR criteria at the initial assessment.

And to compare the percentage of patients diagnosed with RA at baseline by using 4 sets of criteria [1–3].

Methods: Baseline data on patients with eRA attending between May 2006 and March 2010 were examined & included symptom duration, joint involvement (small & large), symmetry, early morning stiffness in minutes, swollen and tender joint counts out of 44 joints, radiographic changes, anti-CCP & rheumatoid factor (RF) status and titre and ESR & CRP at initial presentation. All patients had at least 1 clinically swollen joint at baseline.

1987 ACR criteria, ACR tree criteria [1], anti-CCP revised criteria and the new ACR-EULAR 2010 RA classification criteria were applied. A score of ≥6 out of 10 by the ACR-EULAR criteria equals definite RA. Analysis was repeated for patients presenting with very early RA (veRA: defined as symptom duration ≤3 months).

Results: 208 patients with eRA were identified, with mean age 58.7 years (SD 15.7 years) and median symptom duration of 16 weeks, IQR [9.5, 28 weeks]. 130 (62.5 %) were female, 123 (59%) tested positive for both RF & anti-CCP and 28 (13%) had radiographic erosive disease at baseline. 91 (44%) presented with veRA.

171 (82%) with eRA & 74 (81%) with veRA had definite RA by the ACR-EULAR RA classification criteria. Proportion of eRA & veRA patients satisfying each of the four sets of RA classification criteria at their initial rheumatology assessment is shown in Table 1.

Table 1. Number of eRA & veRA patients satisfying RA criteria at baseline rheumatology assessment

	eRA patients n=208		veRA patients n=91	
	n	%	n	%
ACR 1987 criteria	121	58	48	53
ACR Tree format	142	68	61	67
Anti-CCP revised criteria (CCP-6)	166	80	68	74
ACR-EULAR Definite RA (≥6 points)	171	82	74	81

Conclusion: This study demonstrates that the ACR-EULAR criteria are more sensitive for identifying RA at the initial rheumatology assessment than the other RA and eRA classification criteria in this EAC cohort.

This difference was most marked in those patients presenting with veRA, with the highest sensitivity for ACR-EULAR criteria. Applying these criteria in the EAC setting should facilitate more rapid initiation of DMARD therapy and has the potential to improve long-term outcomes for RA patients.

Novel Multiplex Technology for Diagnostic Characterization of Rheumatoid Arthritis. Piyanka E. Chandra[4], Jeremy Sokolove[3], Berthold G. Hipp[1], Heike Eberl[1], Ursula Klause[1] and William Robinson[2]. [1]Roche Diagnostics, [2]Stanford Univ School of Med, Stanford, CA, [3]Stanford University, Mountain View, CA, [4]Stanford University

Purpose: To develop a clinical-grade, automated, multiplex system for the diagnosis and molecular stratification of rheumatoid arthritis (RA).

Methods: We profiled autoantibodies, cytokines, and bone-turnover products in sera from 120 patients with a diagnosis of RA of <6 months' duration, as well as in sera from 27 patients with ankylosing spondylitis, 28 patients with psoriatic arthritis, and 25 healthy individuals. We used a bead-based commercial assay to measure cytokine levels, and developed an array-based assay using a novel multiplex technology research platform (Immunological Multi-Parameter Chip Technology) to evaluate autoantibody reactivities and bone-turnover markers. Positive values were defined as 2 standard deviations above that of healthy controls. Data were analyzed by Significance Analysis of Microarrays and hierarchical clustering software. Prediction rules were generated

Results: We developed a highly reproducible, automated, multiplex biomarker assay that can reliably distinguish between RA patients and healthy individuals or patients with other inflammatory arthritides. Multiplex measurement of a subset of the differentiating biomarkers provided high sensitivity and specificity for the diagnostic discrimination of RA. Identification of distinct biomarker signatures enabled molecular stratification of early-stage RA into clinically relevant subtypes.

Conclusions: The multiplex biomarker assay described herein has the potential to diagnose RA with greater sensitivity and specificity than do current clinical tests. Its ability to stratify RA patients in an automated and reproducible manner paves the way for the development of assays that can guide RA therapy.

Table 1. Performance characteristics of multiplex-assay autoantibody profiles in the diagnosis of rheumatoid arthritis.

Biomarker panel	PPV	NPV	Sensitivity	Specificity
1+ markers	79.5%	92.6%	96.7%	62.5%
2+ markers	91.8%	89.7%	93.3%	87.5%
3+ markers	95.3%	79.8%	84.2%	93.8%
4+ markers	95.9%	61.1%	59.2%	96.3%

Patient Questionnaire Scores for Physical Function and Pain Are More Likely Than Erythrocyte Sedimentation Rate (ESR) To Document a Quantitative Abnormality in New Patients with Rheumatoid Arthritis (RA). Theodore Pincus[1] and Christopher J. Swearingen[2]. [1]New York University Hospital for Joint Disease, Hastings-on-Hudson, NY, [2]University of Arkansas for Medical Sciences, Little Rock, AR

Purpose: To analyze the capacity of 3 quantitative measures—erythrocyte sedimentation rate (ESR), physical function on a multidimensional health assessment questionnaire (MDHAQ-FN) and pain (PAIN) on a 0–10 visual analog scale (VAS)—to document an abnormality at presentation of 413 new patients with RA seen between 1982 and 2006, by comparing the proportions with normal versus abnormal results.

Methods: All new patients seen at a weekly academic rheumatology clinic complete an MDHAQ with scores for MDHAQ-FN and PAIN. Patients with RA also had assessment of ESR. Complete data for ESR, MDHAQ-FN and PAIN scores were available for 413 new patients with RA seen between 1982 and 2006. Abnormal values were ESR ≥28 mm/h (clinical trial inclusion criterion), MDHAQ-FN >2 on a 0–10 scale (>0.6 on a 0–3 scale), and PAIN >2 on a 0–10 VAS. The proportions of patients with abnormal and normal values at presentation were compared, using descriptive statistics.

Results: Of the 413 patients, 192 (46%) had normal ESR <28 mm/h (54% had ESR ≥28), 122 (30%) had normal MDHAQ-FN scores ≤2 (70% had MDHAQ-FN >2), and 44 (11%) had normal PAIN scores ≤2 (89% had PAIN >2). Patients with ESR <28 were more likely to have MDHAQ-FN or

PAIN score ≤2. Nonetheless, among the 192 patients with a normal ESR of <28, 112 (58%) had an abnormal MDHAQ-FN score of >2, and 161 (84%) had an abnormal PAIN score of >2. A normal score for MDHAQ-FN, PAIN, and ESR was seen in only 26 patients, 14% of those with ESR <28, and 6% of all patients.

	Number (%) normal*	Number (%) abnormal*	Number (%) of normal ESR with abnormal MDHAQ scores**
ESR (< vs ≥28 mm/h)	192 (46%)	221 (54%)	NA
MDHAQ-FN (≤2 vs >2)	122 (30%)	291 (70%)	112 (58%)
PAIN (≤2 vs >2)	44 (11%)	369 (89%)	161 (84%)

*Percentage of all 413 patients. **Percentage of 192 patients with ESR <28 mm/h.

Conclusion: Among new patients with RA, 54% had an abnormal ESR, while 94% had at least one of 3 abnormal measures: ESR, MDHAQ-FN or PAIN. Patient self-report questionnaire scores for physical function and pain are more likely than ESR to document an abnormality in patients with RA at presentation. An abnormal quantitative baseline measure is desirable to assess changes over time. Scores for physical function and pain can be collected easily in the infrastructure of usual clinical care to improve quality and document quantitatively responses to therapies.

Preliminary Rheumatoid Arthritis (RA) Flare Assessment for Randomized Clinical Trials (RCTs): An Outcome Measures in Rheumatology (OMERACT) Data-Driven, Patient-Centered, and Consensus-Based Initiative. Clifton O. Bingham[3], Ernest Choy[4], Rieke Alten[6], Maarten Boers[11], Peter Brooks[9], Vivian Bykerk[1], Robin Christensen[5], Dan Furst[8], Sarah Hewlett[10], Amye Leong[2], James May, Christof Pohl[6], Tessa Sanderson[10], Vibeke Strand[7] and Thasia Woodworth. [1]Brigham and Women's, [2]Healthy Motivation, [3]Johns Hopkins University, Baltimore, MD, [4]King's College, [5]Parker Institute: Musculoskeletal Statistics Unit Copenhagen University Hospital, [6]Schlosspark Klinik University Charite, [7]Stanford University, [8]UCLA, [9]University of Queensland, [10]University of the West of England, [11]Vu University Medical Center

Background: There is no established definition of flare in RA, a potentially disabling disease feature that can impair function, confidence, and productivity. Patients (pts) use "flare" to describe episodes of disease worsening, but the magnitude, quality and duration of symptoms leading to a change of therapy have not been studied. Our objective was to establish a framework for the assessment of RA flare in RCTs which could serve to develop new efficacy parameters and/or facilitate tapering strategies and tight disease control.

Methods: An international multidisciplinary group of health care providers (HCPs), outcomes researchers, and pts established that RA flare would be anchored by worsening or return of disease activity of sufficient duration and intensity to result in (re)initiation or/and change of therapy. Qualitative research in RA pts utilizing detailed thematic analysis identified potential relevant domains. Additional candidate domains were obtained from literature search, face-to-face meetings, teleconferences, and stakeholder survey. Parallel HCP and pt research partner Delphi exercises identified and ranked potential domains as essential, important, or not important. To evaluate measurement properties of these items, standardized response means (SRMs) were derived from LOS and RCT databases. At the OMERACT 10 conference approximately 120 HCPs and pt experts participated in data review, in depth discussions, and consensus voting regarding domains to detect and measure flare. In consensus voting analysis, "don't know" responses were imputed conservatively as "no", and descriptive statistics used for reporting.

Results: HCPs and researchers (>100) and 78 pts identified >20 potential domains and participated in online Delphi exercises prior to OMERACT10 with strong agreement regarding importance of pain, function, patient global assessment (PtGA), swollen joints (SJC) and tender joints (TJC) (core domains). Analyses of LOS and RCT showed that instruments assessing most potential domains are available and moderately sensitive to change. There was >90% agreement that the above core domains and investigator global assessment (MDGA) should be included in a preliminary flare core set. Respondents also identified fatigue (80%), stiffness (70%), and laboratory features (eg ESR/CRP, 66%) as domains of potential importance. 75% affirmed the importance of symptom persistence, and 74% that pt self report of flare should be measured. Other important areas included systemic features (60%), participation (57%), and self-management (58%).

Conclusions: Developing a common set of items to prospectively capture RA flare in RCTs is needed. Qualitative research and stakeholder consensus identified the existing RA core set of SJC, TJC, pain, function, PtGA, MDGA, and acute phase response to define RA flare. In addition, fatigue and stiffness were identified as requisite domains and systemic features, participation, and self-management as desirable to include. A preliminary flare assessment tool will be incorporated in upcoming RCTs and LOS for refinement and validation. Ongoing data analysis and a third Delphi will inform a final consensus based definition.

1767

Preliminary Validation for the Short Version of the Valued Life Activities Questionnaire (S-VLA). Afton L. Hassett[5], Diane C. Radvanski[3], Anagha Nadkarni[1], Steven Buyske[2], Sam A. Schiff[3], Moti L. Tiku[3] and Patricia P. Katz[4]. [1]Bristol-Myers Squibb Co, Princeton, NJ, [2]Rutgers University, New Brunswick, NJ, [3]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ, [4]University of California, San Francisco, CA, [5]University of Michigan Medical School, Ann Arbor, MI

Background: Individuals with rheumatoid arthritis (RA) often experience a decreased ability to participate in valued life activities, such as working, traveling, gardening and attending social events. Many will make accommodations in order to continue participating in these activities. Such accommodations may be associated with the progression of disability in RA. To assess this important domain, including the need for accommodations, a short form of the Valued Life Activities Questionnaire (VLA) was developed and its initial reliability and validity demonstrated using item response analysis[1]. The short form of the VLA (S-VLA) is a 14-item self-report questionnaire with scores that range from 0 to 4, with higher scores indicating greater disability. A large validation trial is currently underway to evaluate the psychometric properties of the S-VLA for patients with RA. The results from the first 100 participants are reported here.

Methods: In the S-VLA validation trial, patients meeting ACR criteria for RA completed a series of questionnaires, including the S-VLA, Rheumatoid Arthritis Disease Activity Index (RADAI), Health Assessment Questionnaire-Disability (HAQ-D), Short Form-36 (SF-36) Health Survey, Satisfaction with Activities and Well-being Scale (SAWS) and the Activity Participation Questionnaire (APaQ). Data from the first 100 patients were analyzed using Cronbach's alpha for internal consistency reliability. Test–retest reliability was also calculated for a randomly selected subset of patients. Next, item statistics were calculated to assess the correlations between individual items and the total score on the S-VLA, while also correcting for overlap and scale reliability. Lastly, correlations between the S-VLA and the other measures were used to evaluate convergent and discriminant validity.

Results: 100 of 150 patients have been enrolled. Mean (standard deviation) age was 55.01 (14.8) years, duration of RA was 12.5 (10.0) years and 71.0% were female. Test–retest reliability was 0.92 based on the responses of a random subset of 25 patients. Cronbach's alpha for the S-VLA was 0.93, and none of the 14 items were associated with improved alpha coefficients when omitted. All items were strongly correlated with the S-VLA total score. Item-total correlations ranged from 0.59 to 0.79. As anticipated, the total score for the S-VLA was highly positively correlated with patient-reported disease activity (RADAI [$r=0.71$; $p\leq0.001$], the HAQ-D [$r=0.77$; $p\leq0.001$], SAWS total score [$r=0.77$; $p\leq0.001$], SAWS satisfaction with abilities subscale [$r=0.77$; $p\leq0.001$] and APaQ days with activity limitations [$r=0.61$; $p\leq0.001$]). As hypothesized, the S-VLA was significantly inversely correlated with SF-36 Physical Component Summary score ($r=-0.76$; $p\leq0.001$) and the SF-36 subscales: Physical Functioning ($r=-0.75$; $p\leq0.001$), Role Physical ($r=-0.68$; $p\leq0.001$) and Social Functioning ($r=-0.71$; $p\leq0.001$).

Conclusions: The S-VLA is a new instrument for the measurement of valued life activities in RA. Data from the initial cohort of 100 patients from the larger validation trial lend support to its reliability and validity.

1768

Presence and Predictors of Poor Functional Outcomes in US Hispanics with Rheumatoid Arthritis (RA). George A. Karpouzas[4], Soha Dolatabadi[1], Rosalinda C. Moran[3], Perry Nicassio[5] and Michael H. Weisman[2]. [1]Cedars Sinai, Los Angeles, CA, [2]Cedars-Sinai Medical Center, Los Angeles, CA, [3]Harbor UCLA, Carson, CA, [4]Harbor-UCLA, Long Beach, CA, [5]UCLA

Background: Functional outcomes of Hispanics (H) with RA in the US have been under-reported and their predictors remain largely unknown. Prior works suggest worse function, pain, and global assessment scores in H despite a seemingly appropriate control of disease measures. We address self-reported outcomes, their relationships and determinants in a recently established cohort of H with RA from a single center in the US.

Methods: We describe the first 193 of 349 H fullfiling 1987 ACR criteria for RA and with regular follow-up. Demographic, serologic (RF, a-cyclic citrullinated peptide Ab-ACPA), radiographic parameters and treatments were recorded. Irreversible articular damage (IAD: ankylosis, sublaxation, arthrodesis, prosthesis) and joint replacement surgeries (JRS) were tracked. Patients (pts) were evaluated quarterly and Disease Activity Score (DAS2–v-ESR), disability (HAQ-DI), pt-reported pain by visual analogue scale (pain-VAS: 0–3), and depression scores (PHQ-9 scales) were collected. Exploratory linear regressions with forward selection were performed followed by hierarchical multivariate regression to identify independent predictors of disability as reported by HAQ-DI. Data was analyzed with STATA 10.

Results: Median (IQR) DAS28 was 3.28 (2.5–4.1) and low disease activity (DAS28≤3.2-LDAS) was present in 46%. RF was seen in 93% and ACPA in 85%. Overall, 51% had HAQ-DI≥1.5 and 67% ≥1. In the LDAS group in particular, 42% had HAQ-DI≥1.5 and 58% had DI≥1. Generally, 36% of pts had PHQ-9≥10, consistent with clinical depression. Pain-VAS, JRS, disease activity, depression, age and IAD were univariate determinants of disability (table). RF or ACPA status, erosions, biologics and number of DMARDs did not predict disability. In a multivariate model, pain-VAS was the most robust predictor of disability (standardized regression coefficient =0.4), followed by DAS28 (0.22), JR (0.21), depression (0.17) and age (0.12).

Conclusion: The majority of H report poor functional outcomes and high level of disability despite well controlled disease by physician standards. Pt-reported pain is the cardinal independent predictor of this disability, followed by disease activity, JR, and depression. The directionality for these relationships is being explored with a focus on future intervention.

Progression Patterns of Radiographic Damage: Results from SONORA Study. Maggie Chen[1], Xiuying Li[1], Pooneh Akhavan[2] and Claire Bombardier[3]. [1]University Health Network, [2]University of Toronto, University Health Network, [3]University of Toronto, University Health Network, Mount Sinai Hospital, Toronto, ON, Canada

Purpose: Identifying progression patterns and its characteristics for radiographic damage is important to understand early rheumatoid arthritis (RA). Data from the SONORA (study of new-onset rheumatoid arthritis) was analyzed to explore patterns of radiographic progression in early RA patients.

Methods: A total of 529 patients diagnosed as early RA (symptoms ≥3 and ≤12 months) and with hand radiographs at baseline, year 1 and 2 were included in this study. The radiographs were scored according to original Sharp method (range 0 to 280) in random order per patient. Radiographic progression was defined by a change of at least 3.5 in total Sharp score within a year. Four patterns of radiographic progression were identified; never progressed, progressed at year 1 only, progressed at year 2 only and progressed at both year 1 and year 2. Demographic and clinical characteristics were compared across these four patterns using ANOVA for continuous outcomes and Chi-square test for categorical outcomes.

Results: Among these four patterns, 86% subjects never had radiographic progression, 3.4% progressed in the first year only, 7.6% progressed in the second year only and 2.6% progressed in both year 1 and year 2 (table 1). There were significant differences ($p < 0.05$) between the patients in the four patterns of progression, for, sharp score, CRP, anti-CCP and RF positive. Subjects who had no radiographic progression in two years were those who are younger, had less swollen joint counts, lower DAS score, lower sharp score, lower CRP, anti-CCP negative and RF negative at baseline.

Table 1.

	No progression N=457	Progression at year 2 only N=18	Progression at year 1 only N=40	Progression at year 1 and 2 N=14	P-value
Age	52 (13.79)	60 (14.45)	53 (14.15)	57 (18.33)	0.05
Baseline swollen joint count	4.89 (6.09)	2.61 (3.32)	6.75 (7.40)	8.29 (6.66)	0.02
Baseline tender joint count	4.88 (6.38)	3.89 (5.32)	5.90 (7.17)	6.35 (6.50)	0.55
Baseline DAS	3.85 (1.34)	3.64 (1.14)	4.17 (1.18)	4.63 (1.06)	0.03
Baseline HAQ	1.38 (0.74)	0.83 (0.66)	1.46 (0.83)	1.36 (0.47)	0.06
Baseline Sharp score	4.06 (5.57)	9.33 (11.17)	8.28 (8.47)	14.0 (19.97)	<0.0001
Baseline CRP	2.70 (3.17)	4.3 (3.69)	3.91 (3.94)	4.36 (3.70)	0.009
Disease duration (days)	160 (123)	124 (82)	146 (93)	148 (82)	0.55
Anti-CCP positive	49.72%	61.54%	80.77%	81.82%	0.0003
Male	23.41%	11.11%	32.50%	21.43%	0.57
Rheumatoid factor positive	58.72%	66.67%	70%	78.57%	0.04
Ever smoking	57.74%	41.18%	58.82%	50%	0.57

Conclusion: The majority of the early RA subjects in routine practice do not have radiographic progression within the first two years of the disease. Very few subjects continuously progressed within 2-year period. Baseline sharp score is the best indicator of whether the subject will progress or not followed by anti-CCP positive, CRP and swollen joint count. These identified indicators can help clinicians to identify the subjects who are at high risk of continuous radiographic progression.

Quantification of Periarticular Osteopenia in Rheumatoid Arthritis. Inhye E. Ahn[3], Ji Hyeon Ju[1], Kwi Young Kang[2], Seung-Ki Kwok[1], Kyung-su Park[1], Sung-Hwan Park[1] and Ho-Youn Kim[1]. [1]Department of Internal Medicine, Division of Rheumatology, Catholic University of Korea, Seoul, Korea, Republic of, [2]Department of Internal Medicine, Division of Rheumatology, Chungbuk University, Cheongju, Korea, Republic of, [3]Department of Internal Medicine, The Methodist Hospital, Houston, TX

Objectives: By quantifying localized hand bone mineral density (BMD), we aimed to validate a new diagnostic method for evaluating the periarticular bone damage in rheumatoid arthritis (RA).

Methods: The study enrolled 195 patients with polyarthritis and was conducted in three steps.

Table 1. Clinical and demographic features of patients and controls.

	RA	Non-RA	P^a
N (total=195)	*45*	*150*	
Sex (female/male)	40/5	113/37	0.881

Others		2 Systemic sclerosis 1 Raymonds disease 1 Stills disease 5 Unspecified	

Abbreviations: SD: standard deviation. BMI: body mass index
[a] Mann-Whitney rank sum test for unpaired differences p under 0.05 was considered statistically significant.

First, inter-observer agreement of periarticular osteopenia in the conventional hand x-ray was evaluated. Second, BMDs of periarticular and non-periarticular regions were quantified by digital x-ray radiogrammetry (DXR). BMD ratios were calculated out of eight designated areas on proximal phalanges and compared between RA (n=45) versus non-RA (n=149) groups. Third, medical records of RA patients were retrospectively reviewed to identify clinical conditions predisposing to the loss of juxta-articular bone minerals.

Results: The interpretation of periarticular osteopenia on x-ray reached a moderate degree of inter-observer agreement among four physicians (kappa 0.47, $p<0.001$). On DXR-assisted BMD quantification, we designed three types of mathematical formulae; the ratio of non-periarticular to periarticular BMD, the mean of ratios, and the ratio of sums.

Table 2. Periarticular osteopenia in RA versus non-RA patients

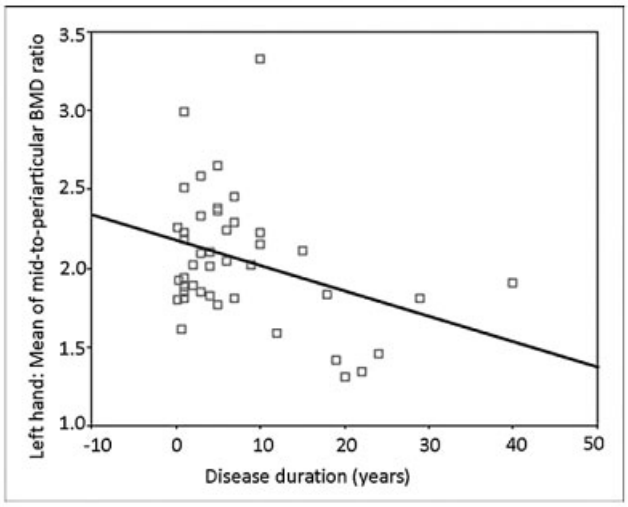
[a]Independent t-test to compare means of non-RA patients versus one of the three groups; all RA patients, RA under 10 years, RA for and over 10 years.
An asterisk (*) indicates a statistically significant difference with p value under 0.05 when compared to the non-RA group. Other unlabled values were not significant. Values are the mean (SD) in g/cm^2.

These values were significantly higher in patients with RA for less than 10 years than in non-RA group ($p<0.05$). RA for 10 years or longer blunted the BMD ratios, and the disease duration was inversely correlated to the ratio (correlation coefficient −0.35).



Cut-off values were within 2.10–2.15 (sensitivity 36.67–80.64%, specificity 52.17–86.42%). In bivariate analysis, body mass index, the duration of steroids and c-telopeptide showed correlation with BMD ratios ($p<0.05$).

Conclusion: In DXR-assisted localized quantification and proportional calculation, periarticular osteopenia is a distinctive feature of RA under 10 years of duration.

Radiological Progression in Very Early Rheumatoid Arthritis, Results of the DREAM Remission Induction Cohort. Marloes Vermeer[3], Ina H. Kuper[3], Monique Hoekstra[1], Hein J. Bernelot Moens[4], Piet L. C. M. van Riel[2] and Mart A. F. J. van de Laar[3]. [1]Isala Klinieken, Zwolle, The Netherlands, [2]Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, [3]University of Twente and Medisch Spectrum Twente, Enschede, The Netherlands, [4]Ziekenhuisgroep Twente, Almelo/Hengelo, The Netherlands

Background: Previous studies suggest that disease activity at baseline and even stronger disease activity over time are related to radiological progression in rheumatoid arthritis (RA) (1, 2). This emphasizes the importance of controlling inflammatory activity and inducing remission rapidly. The objective of this study was to assess the relationship between disease activity and radiographic progression after 1 year in a remission induction cohort of patients with very early RA.

Methods: Data of the Dutch Rheumatoid Arthritis Monitoring (DREAM) remission induction cohort were used. Inclusion criteria were: a clinical diagnosis of RA, age ≥ 18 years, duration of symptoms ≤ 1 year and no previous treatment with DMARDs and/or prednisolone. DMARD medication was adjusted based on 4–8 weekly DAS28 measurements, aiming at remission (DAS28 < 2.6). The treatment protocol started with methotrexate (MTX), addition of sulfasalazine in case of inefficacy, followed by MTX + anti-TNF. Radiographs of hands and feet were obtained at baseline, after 6 and 12 months and evaluated in chronological order by two observers (consensus score) according to the Sharp-van der Heijde Score (SHS). An increase in SHS ≥ 5 U/year was regarded as clinically relevant radiological progression (3). Primary outcome was the association of the area under the curve (AUC) of the DAS28 (0, 3, 6, 9 and 12 months) and radiological progression after one year. This was analyzed in a logistic regression model with correction for confounders, in case of missing values the principle of last observation carried forward was applied. Secondary outcome was the percentage of patients without radiological progression after one year.

Results: One year radiological data were available for 143 patients. After one year, observed DAS28 levels were: 61.5% (88/143) remission (DAS28 < 2.6), 16.1% (23/143) low (2.6 ≥ DAS28 ≤ 3.2), 19.6% (28/143) moderate (3.2 < DAS28 ≤ 5.1) and 2.8% (4/143) high (DAS28 > 5.1). Median (IQR) SHS was 5.0 (2.0–10.0) and median (IQR) progression of SHS was 2.0 (1.0–5.0). Hundred of the 143 patients did not show radiological progression (69.9%). In the remission group, there were more patients without radiological progression than in the group with active disease (DAS28 > 3.2): 72.7%

(64/88) vs. 59.4% (19/32). The majority of patients achieved remission on conventional DMARD therapy. A higher AUC of DAS28 over the first year was associated with radiological progression (p=0.054, corrected for baseline SHS).

Conclusion: In very early RA, disease activity over time is associated with radiological progression. In this very early RA cohort, radiological progression was limited. Patients in remission showed less radiological progression than patients with persistent disease activity.

Retinal Vascular Caliber Is Altered in Patients with Rheumatoid Arthritis: A Biomarker of Disease Activity and Cardiovascular Risk? Sharon Van Doornum[3], Gemma Strickland[2], Ryo Kawasaki[3], Jing Xie[3], Lauren Hodgson[3], Ian Wicks[1] and Tien Wong[3]. [1]Royal Melbourne Hospital, Melbourne, Australia, [2]Royal Melbourne Hospital, [3]University of Melbourne

Introduction: Examination of the retinal vasculature is a novel method for assessing cardiovascular (CV) risk. Changes in retinal vascular caliber (narrowing of arteriolar caliber and/or widening of venular caliber) have been independently associated with CV risk factors and also with an increased risk of CV events. Retinal venular dilatation has also been associated with elevated biomarkers of inflammation.

Methods: 51 RA patients and 51 age and gender matched population controls had retinal photographs taken according to a standardized protocol. The digital images of all subjects were analysed by a single trained assessor using a validated computer program. The caliber of arterioles and venules were summarised as central retinal arteriolar equivalent (CRAE) and central retinal venular equivalent (CRVE) respectively. Disease activity in RA patients was classified according to the 28 joint Disease Activity Score (DAS).

Results: Demographic characteristics and mean CRVE and CRAE of the RA patients and controls are shown in

Table 1. Demographic and clinical details and retinal vascular caliber measurements in RA and control patients

	RA (n=51)	Controls (n=51)	p value
Female	34 (67)	34 (67)	NS
Age (years)	59.5 ± 12.5	59.5 ± 12.5	NS
Systolic blood pressure (mmHg)	131 ± 19	132 ± 22	NS
Diastolic blood pressure (mmHg)	77 ± 11	69 ± 11	0.002
Diabetes mellitus	5 (9.8)	6 (11.8)	NS
Smoking status			
Current smoker	7 (13.7)	2 (3.9)	NS
Ex-smoker	8 (15.7)	14 (27.4)	NS
Never smoker	36 (70.6)	35 (68.6)	NS
Body mass index	29.7 ± 5.6	29.2 ± 5.3	NS
Total cholesterol (mmol/l)	5.2 ± 1.2	5.3 ± 1.1	NS
HDL cholesterol (mmol/l)	1.6 ± 0.	1.3 ± 0.4	0.012
LDL cholesterol (mmol/l)	2.9 ± 0.9	3.3 ± 0.9	NS
Triglycerides (mmol/l)	1.4 ± 0.6	1.5 ± 0.8	NS
RA disease duration in years (median (range))	9.4 (0.3–55)	N/A	
DAS (median (range))	3.4 (1.2–7.9)	N/A	
No. of DMARDs (median (range))	2 (0–4)	N/A	
Central retinal arteriolar equivalent (μm)	152.3 ± 15.3	143.7 ± 13.9	0.004
Central retinal venular equivalent (μm)	235.9 ± 24.6	211.6 ± 21.0	<0.00001

Data are n (%) or mean±SD unless otherwise indicated. HDL high density lipoprotein, LDL low density lipoprotein, DAS disease activity score, DMARD disease modifying anti-rheumatic drug

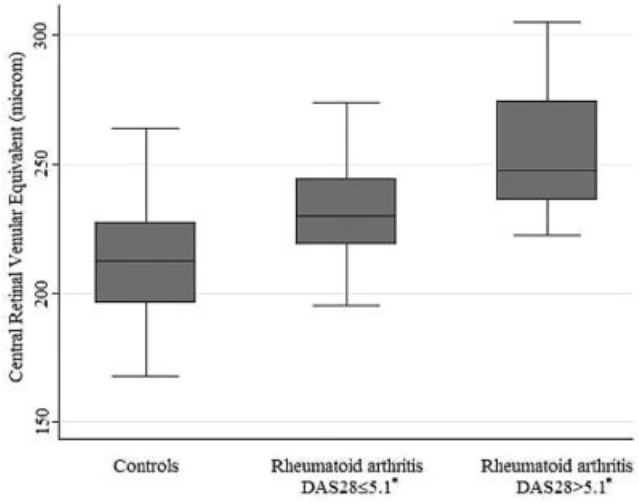
Table 2 shows the relative difference in CRAE and CRVE between RA patients and controls in an unadjusted comparison and after adjustment for relevant clinical variables. In the unadjusted analysis both CRAE and CRVE were significantly wider in the RA group compared with controls. After adjustment for all relevant variables the CRVE remained significantly larger in the RA patients (mean CRVE 20.3 mm greater in RA vs controls, 95% CI 10.4–30.3) whereas CRAE was not different between the groups.

Table 2. Difference in CRAE and CRVE in RA patients as compared with matched Controls

	Unadjusted analysis (mean, 95% CI)	Adjusted analysis* (mean, 95% CI)
CRAE in RA relative to controls, μm	8.6 (2.8–14.4)	2.4 (−4.3–9.1)
CRVE in RA relative to controls, μm	24.3 (15.2–33.2)	20.3 (10.4–30.3)

CRAE central retinal arteriolar equivalent CRVE central retinal venular equivalent
*Adjusted for age, gender, body mass index, systolic and diastolic blood pressure, lipid levels, diabetes status, smoking status and companion vessel calibre.

We also investigated the relationship between CRVE and inflammation. Figure 1 compares CRVE in controls and in the RA patients grouped according to disease activity. CRVE in the RA patients with high disease activity was greater than the controls and remaining RA patients, and this difference remained significant after adjusting for potential confounders.



RA rheumatoid arthritis; DAS28 28 Joint Disease Activity Score
*DAS28≤5.1 = moderate or lower disease activity; DAS28>5.1 = high disease activity

Figure 1. Central retinal venular equivalent in controls and RA patients.

Conclusion: To our knowledge this is the first report of retinal vascular caliber measurement in patients with RA. We have demonstrated increased CRVE in RA patients and a relationship between RA disease activity and CRVE. Longitudinal studies correlating CRVE with subsequent CV events will be required to further evaluate this relationship and to examine the predictive role of CRVE measurement in this patient group.

Serum Undercarboxylated Osteocalcin Levels in Patients with Rheumatoid Arthritis. Kuninobu Wakabayashi, Kumiko Otsuka, Michihito Sato, Ryo Takahashi, Tsuyoshi Odai, Takeo Isozaki, Nobuyuki Yajima, Yusuke Miwa and Tsuyoshi Kasama. Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan

Purpose: Elevated serum levels of undercarboxylated osteocalcin (ucOC) is indicative of vitamin K (VK) deficiency in bone and increased risk of osteoporotic fracture. We assessed serum ucOC levels in patients with rheumatoid arthritis (RA).

Methods: Serum ucOC levels were measured in 100 RA patients, and the relationships between ucOC levels and age, sex, C-reactive protein (CRP) levels, erythrocyte sedimentation rate (ESR) and prednisolone (PSL) dosage, with or without bisphosphonate (BP), were assessed. Patients whose usOC levels were above a cut-off value of 4.5 ng/ml were treated with menatetrenone (vitamin K_2), and ucOC levels before and after the treatment were compared. Serum ucOC levels were measured using an electrochemiluminescence immunoassay (ECLIA).

Results: Serum ucOC levels were elevated in 37 of the RA patients tested, and the ucOC-positivity rate was higher among female patients than among male patients ($p<0.05$). We observed a significant negative correlation between serum ucOC levels and PSL dosage ($p<0.001$).

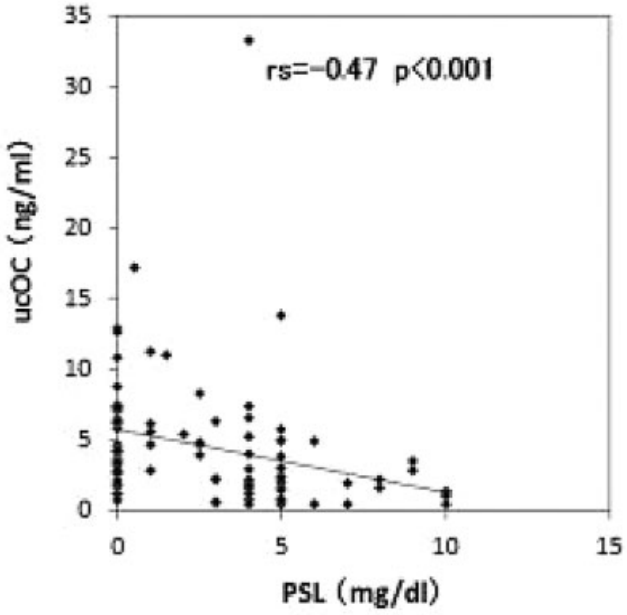

Figure 1.

Thus ucOC levels were significantly lower in RA patients treated with PSL 5–10 mg/day than in patients treated with PSL <5 mg/day ($p<0.01$) or in untreated patients ($p<0.001$).

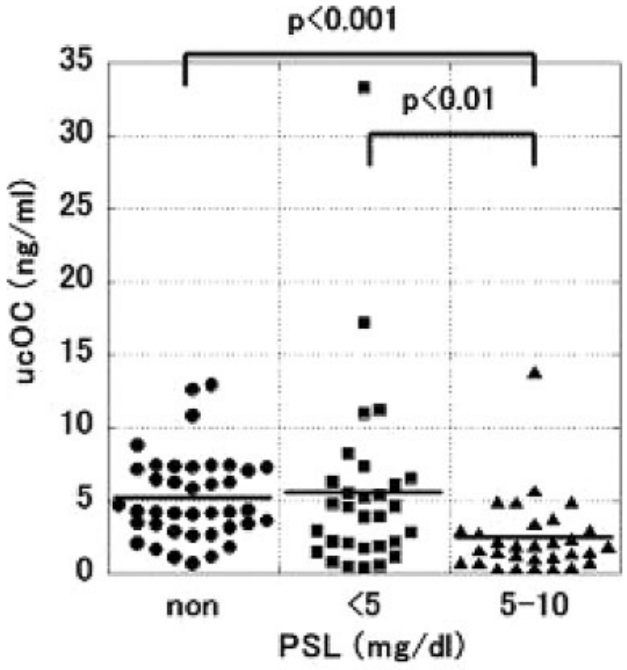

Figure 2.

Moreover, those also receiving BP showed lower ucOC levels than those not receiving BP ($p<0.02$). Twenty-four patients with high ucOC levels were treated with menatetrenone (vitamin K_2), which significantly reduced ucOC levels after 3 months of treatment ($p<0.001$). There was no correlation between serum ucOC levels and age, CRP or ESR.

Conclusion: PSL is known to inhibit bone formation and osteocalcin production. We suggest that levels of vitamin K, which is necessary for γ-carboxylation of the glutamate residues in osteocalcin, are reduced in RA patients treated with PSL >5 mg/day. In RA patients treated with PSL <5 mg/day and whose serum ucOC levels are above a cut-off value of 4.5 ng/ml, menatetrenone (vitamin K_2) treatment is effective against osteoporosis.

The 2010 ACR/EULAR Criteria for Rheumatoid Arthritis Perform Well in Prediction of Clinical RA Diagnosis at 6 Months in Very Early Arthritis Patients: Longitudinal Data from the NOR-VEAC Cohort.

Maria D. Mjaavatten[3], Desiree M. Van Der Heijde[8], Till Uhlig[5], Anne J. Haugen[1], Halvor Nygaard[6], Olav Bjørneboe[9], Nils G. Arvidson[7], Hans C. Gulseth[2] and Tore K. Kvien[4]. [1]Østfold Hospital, Moss, Norway, [2]Betanien Hospital, Skien, Norway, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Diakonhjemmet Hospital, Oslo, Norway, [5]Diakonhjemmet Hospital, Oslo, Norway, [6]Hospital for Rheumatic Diseases, Lillehammer, Norway, [7]Innlandet Hospital, Kongsvinger, Norway, [8]Leiden University Medical Center, Meerssen, The Netherlands, [9]Martina Hansen's Hospital, Sandvika, Norway

Background: The new ACR/EULAR criteria for rheumatoid arthritis (RA) were designed to predict risk of RA development at an early stage. The algorithm yields a score from 0–10 points where a patient needs >= 6 points to be classified as RA. The criteria need validation in cohorts of early arthritis patients.

Methods: Patients in the Norwegian Very Early Arthritis Clinic (NOR-VEAC) (swelling in>=1 joint with duration <=16 weeks, 18–75 years) were followed for 6 months and assessed for development of RA (clinical diagnosis). Only patients that did not contribute with data to Phase 1 of the criteria development were included to minimize overfitting of data. Sensitivity, specificity and likelihood ratios (LR) for different cut-offs were calculated and overall discriminatory ability was assessed with a receiver operating characteristics (ROC) curve.

Results: 298 patients (50 % females, median age 46.6 years, median duration of joint swelling 39 days, anti-CCP/IgM rheumatoid factor positives 18.5 %/14.2 %) were included in the analyses. After 6 months, 72 (24.2 %) patients had RA by the judgement of a rheumatologist (seropositive RA 45 (62.5 %)). Median (range) ACR/EULAR score at inclusion in RA/non-RA patients was 7(3–10)/3(0–9). Area under the ROC curve (95% CI) was 0.93 (0.90–0.96). The proposed cut-off of 6 points for RA classification showed a good combination of sensitivity, specificity and LRs (table). All seropositive RA patients had a score >=6, while 19/27 (70.4 %) seronegative clinical RA patients fulfilled the new criteria.

Conclusion: The new ACR/EULAR RA classification criteria performed well for prediction of clinical RA diagnosis in a cohort of very early arthritis patients. This validation supports the use of these criteria in clinical practice.

Table. Sensitivity, specificity and likelihood ratios for clinical RA diagnosis for different cut-offs for the 2010 ACR/EULAR RA criteria.

Cut-off (points)	Sensitivity (%)	Specificity (%)	LR+	LR−
3	100	36.3	1.57	0.00
4	98.6	58.8	2.39	0.02
5	91.7	76.5	3.90	0.11
6	88.9	83.2	5.29	0.13
7	63.9	93.4	9.68	0.39
8	47.2	99.4	78.67	0.53

LR+: positive likelihood ratio; LR-:negative likelihood ratio.

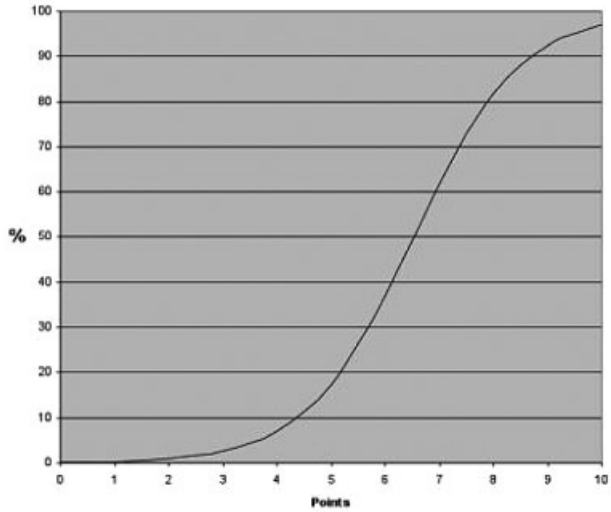

Figure. Predicted probability of RA development for increasing number of points in the algorithm.

1775

The ACR/EULAR 2010 Criteria as Well as Other Predictive Algorithms for Rheumatoid Arthritis Show Good Diagnostic Performance. Celina Alves[2], Jolanda Luime[1], Jendé van Zeben[4], Margriet Huisman[4], Angelique Weel[3], Pieternella Barendregt[3] and Johanna Hazes[1]. [1]Erasmus MC, [2]Erasmus MC, Rotterdam, The Netherlands, [3]Maasstad Ziekenhuis, [4]Sint Franciscus Gasthuis

Background: The ACR/EULAR devised new diagnostic criteria to improve early diagnosis of rheumatoid arthritis. The criteria were developed as a diagnostic algorithm for persistent and/or erosive disease, what was previously considered to be rheumatoid arthritis. Several other diagnostic algorithms already exist [1,2].

Objectives: To evaluate the diagnostic performance of the ACR/EULAR 2010 criteria, van der Helm algorithm [1] and Visser algorithm [2] to identify persistent arthritis at 1 year using different patient sets and 2 outcomes.

Methods: Eligible patients in the Rotterdam Early Arthritis CoHort presented with inflammatory arthritis or ≥ 2 inflammatory tender joints and symptom duration less than 12 months. Diagnostic algorithms were tested on discrimination using ROC-curves and calibration by calibration plots. Robustness was tested using different (sub) sets of patients: (i) all patients (n=736) (ii) classified and unclassified arthritis (n=532), and (iii) undifferentiated arthritis (n=301). Two outcomes evaluated were: (a) persistence, defined as arthritis or the need for DMARDs and (b) the 1987 ACR criteria for rheumatoid arthritis.

Results: Patients (n=736) had mean age 51 yr (sd 14), median ESR 15 (0–121), RF+ 21%, Anti-CCP+ 20%, median SJC 2 (0–44), median TJC 6 (0–38), erosions 5% at baseline. Table 1 shows discrimination performance for each algorithm per patient set (i;ii;iii) and for outcome (a) and (b). The algorithms had comparable performance on discrimination and calibration, with better performance the ACR/EULAR 2010 and van der Helm algorithm on discrimination. The ACR/EULAR 2010 criteria and van der Helm algorithm performed best in sample (i). Figure 1 shows ROC-curves and calibration plots for the algorithms in patient set (i).

Table 1. AUCs (95% CI) for all algorithms in 3 patient subsets with either the outcome persistent arthritis or the *1987 ACR criteria* (in italic).

	ACR/EULAR 2010	Van der Helm	Visser
(i)	0.83 (0.79–0.86)	0.81 (0.77–0.85)	0.74 (0.69–0.78)
(ii)	0.78 (0.73–0.83)	0.76 (0.71–0.82)	0.79 (0.74–0.84)
(iii)	0.73 (0.66–0.80)	0.74 (0.66–0.82)	0.73 (0.65–0.80)
(i)	*0.83 (0.79–0.87)*	*0.83 (0.79–0.87)*	*0.78 (0.73–0.83)*
(ii)	*0.77 (0.72–0.82)*	*0.77 (0.71–0.82)*	*0.76 (0.70–0.82)*
(iii)	*0.61 (0.51–0.70)*	*0.60 (0.50–0.71)*	*0.59 (0.50–0.69)*

(i) all patients; (ii) (un-) and classified arthritis; (iii) undifferentiated arthritis

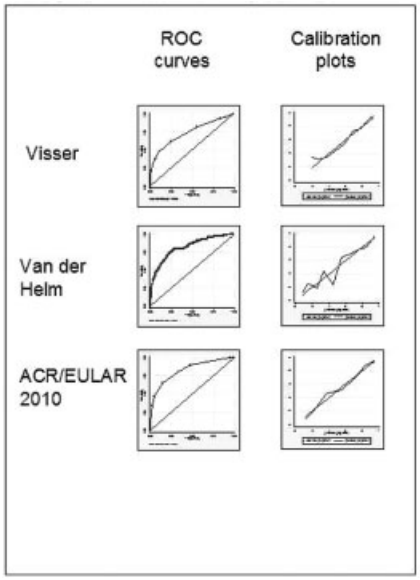

Figure 1. ROC-curves and calibration plots for patient set (i) and outcome persistence.

Conclusion: The algorithms had comparable performance. However, on discrimination the ACR/EULAR and the van der Helm algorithm performed best in the full patient set. The well performing algorithms enable use in different settings (e.g. primary and specialized care) and suggests that any of these models will improve early diagnosis of patients at risk for rheumatoid arthritis.

1776

The Diagnostic Performance of the ACR/EULAR 2010 Criteria If One of Its Parameters Is Not Available. Results from the Rotterdam Early Arthritis CoHort (REACH). Celina Alves[2], Jolanda Luime[1], Jendé van Zeben[4], Margriet Huisman[4], Angelique Weel[3], Pieternella Barendregt[3] and Johanna Hazes[1]. [1]Erasmus MC, [2]Erasmus MC, Rotterdam, The Netherlands, [3]Maasstad Ziekenhuis, [4]Sint Franciscus Gasthuis

Background: Recently, criteria were developed for the diagnosis of RA to improve early diagnosis of RA, devised as a predictive algorithm for persistent and/or erosive arthritis. They contain 4 domains: joints, serology, acute phase reactants (APR) and duration. However, in daily clinical practice components may not be available due to various reasons. Therefore we set out to evaluate the diagnostic value of the ACR/EULAR criteria if one of its parameters is not available.

Methods: Eligible patients for REACH presented with synovitis or ≥ 2 tender joints and symptom duration less than 12 months. The outcome used was persistent disease, defined as synovitis or the need for DMARDs at 1 year. Statistical analysis was done using ROC-curves for discriminative power and sensitivity and specificity when using the proposed cut off of 6 or higher. Data were analysed for the full model and 9 models with a missing or modified parameter: (i) use of swollen joint count (SJC) instead of SJC and tender joint count (TJC) for joints, (ii) missing RF, (iii) anti-CCP, (iv) ESR or (v) CRP and (vi, vii, viii, ix) serology low or high values were replaced by a binary result attaching 2 or 3 points if the biomarker was present.

Results: Patients (n=736) had mean age 51 yr (sd 14), median ESR 15 (0–121), RF+ 21%, Anti-CCP+ 20%, median SJC 1 (0–38), median TJC 6 (0–42), erosions 5% at baseline. Complete information was not obtained for 36 patients. Figure 1 shows the ROC-curves for the full criteria set and all modified criteria sets. The model with only SJC provided the best AUC was 0.82 (95%CI 0.79–0.85) while the lack of anti-CCP provided the poorest model (AUC 0.71 (95%CI 0.68–0.75)). Table 1 shows sensitivity and specificity for the full set and all modified sets. All models performed well in identifying the non-diseased (specificity), but moderate performance was shown for identifying those who were ill (sensitivity).

Conclusion: The ACR/EULAR 2010 criteria are robust against missing values shown by a consistent diagnostic performance. However, the model with all 4 variables available but only swollen joints taken into account performed better than the original criteria including tender joints.

Table 1. AUC (95% CI), sensitivity and specificity. Sensitivity and specificity were calculated for the proposed cut-off of 6 or higher. (n=700)

	AUC, 95% CI	Sensitivity	Specificity
(0) ACR/EULAR 2010 criteria	0.73 (0.70–0.77)	0.53	0.80
(i) ACR/EULAR 2010 criteria with only SJC	0.82 (0.79–0.85)	0.37	0.97
(ii) ACR/EULAR 2010 criteria; RF missing	0.73 (0.70–0.77)	0.49	0.81
(iii) ACR/EULAR 2010 criteria: Anti-CCP missing	0.71 (0.68–0.75)	0.49	0.80
(iv) ACR/EULAR 2010 criteria: ESR missing	0.73 (0.70–0.77)	0.52	0.80
(v) ACR/EULAR 2010 criteria: CRP missing	0.73 (0.69–0.77)	0.51	0.80
(vi) ACR/EULAR 2010 criteria: no value for RF, RF pos (2 points)	0.73 (0.70–0.77)	0.52	0.81
(vii) ACR/EULAR 2010 criteria: no value for anti-CCP, anti-CCP pos (2 points)	0.73 (0.69–0.76)	0.52	0.80
(viii) ACR/EULAR 2010 criteria: no value for RF, RF pos (3 points)	0.73 (0.69–0.77)	0.53	0.79
(ix) ACR/EULAR 2010 criteria: no value for anti-CCP, anti-CCP pos (3 points)	0.73 (0.70–0.77)	0.53	0.79

1777

The Performance of the Hospital Anxiety and Depression Scale for Screening of Depressive and Anxiety Disorders in Patients with Rheumatoid Arthritis (RA). Eugenia Y. C. Lok[1], Chi Chiu Mok[2], Fuk Chi Cheung[1] and Chi Wai Cheng[1]. [1]Castle Peak Hospital, [2]Tuen Mun Hospital

Objectives: To evaluate the performance of the Hospital Anxiety and Depression Scale (HADS) for screening of depressive and anxiety disorders in patients with rheumatoid arthritis.

Methods: 200 consecutive Chinese patients who fulfilled the ACR criteria for RA were recruited from an out-patient rheumatology clinic. Written consent was obtained from these patients who were then interviewed by a psychiatrist for the presence of depressive disorders and anxiety disorders using the Chinese-bilingual Structured Clinical Interview for DSM-IV Axis I disorders, Patient research version (CB-SCID-I/P). Patients were invited to complete a validated Chinese version of the HADS questionnaire (depression sub-score 0–21; anxiety sub-score 0–21) before the psychiatric interview. Socio-demographic and clinical data such as age, gender, duration of RA, disease activity scores (DAS28), pain, income and education level at the time of interview were also collected. The sensitivity and specificity of the cut-off scores of the HADS depression and anxiety subscale for the clinical diagnosis of depressive or anxiety disorders was evaluated by the receiver operating curve (ROC) analysis.

Results: Between July 2007 and June 2008, 200 patients with RA were studied (79% women, mean age 51.4±10.5 years; median RA duration 4.0 years [IQR 2.0–9.0]). 47 (23.5%) patients were diagnosed to have a current psychiatric disorder (depressive disorders 14.5%, anxiety disorders 13%). Major depressive disorder was the commonest current mood disorder whereas generalized anxiety disorder was the most common current anxiety disorder. The mean depression sub-score of HADS in RA patients who were diagnosed to have depressive disorders was 13.1±3.1, which was significantly higher than that in patients without depressive disorders (5.7±3.5; $p<0.001$). On the other hand, the mean anxiety sub-score of the HADS in patients with anxiety disorders was also significantly higher than those without anxiety disorders (11.2±3.4 vs 5.4±3.9; $p<0.001$). Using ROC analysis, the optimal cut-off score of the HADS depression subscale was 10 for the presence of depressive disorders, yielding a sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of 90%, 85%, 50% and 98%, respectively (area under the ROC: 93%). The optimal cut-off score of the anxiety subscale of HADS was 8 for the presence of anxiety disorders, with a sensitivity of 89%, specificity of 74%, PPV of 34% and NPV of 98% (area under the ROC: 87%).

Conclusion: As a screening tool, the HADS perform better for depressive disorders than anxiety disorders in patients with RA. A cut-off of 10 points in the HADS depression subscale yields a good sensitivity and specificity for picking up depressive disorders.

1778

The Role of Objective Measures vs. Patient Reported Outcomes (PROs) as a Reflection of Flares in Patients with RA: Results from the Brigham RA Sequential Study (BRASS). Vivian Bykerk[1], Daniel Hal Solomon[5], Clifton O. Bingham[6], Michelle Frits[3], Christine Iannaccone[4], Michael E. Weinblatt[5] and Nancy A. Shadick[5]. [1]Brigham & Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Jamaica Plain, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham and Women's Hospital, MA, [5]Brigham and Womens Hospital, Boston, MA, [6]Johns Hopkins University, Baltimore, MD

Background: Worsening of disease activity or RA flare can be severe enough to warrant a change of therapy. Little is known about how frequently flares occur in RA or which measures best reflect a flare of RA.

Objective: To describe the frequency of self-reported flares in a population of patients with RA and determine which variables best relate to patients' recall of flare in the prior 6 months.

Methods: Data were collected in a prospective, observational, single- academic center cohort of RA patients treated according to preference of their rheumatologist. Patients were questioned every 6 months if they'd had a flare of their disease, what the duration was and how they'd treated it. Variables analyzed included patient reported outcomes, composite indices of disease activity and laboratory measures. Univariate logistic regression analyses using generalized estimating equations (GEE) were performed to determine possible predictors of flare. Disease measures with a $p \leq 0.10$ were included in a multiple logistic regression model using GEE. Additional multiple logistic regression models were performed, with patient reported measures and with objective measures.

Results: Of 1095 RA patients, 567 with ≥ 3 yrs follow-up reporting on flares were included for this analysis. Baseline characteristics included mean age: 57 ±13 yrs; 85% female, 93% Caucasian, mean disease duration14 years. 75% reported flares at baseline, 59% at 6 months and 55 % reported flares every 6-months thereafter. 30% reported flares lasting > 2 weeks, 27% lasting 1–2 weeks & 43% lasting ≤ 3 days. Variables significantly associated with current flare in the multivariate analysis overall, were pain, physician global, tender joint count (TJC), and age (figure 1). The TJC dropped out in the model containing just objective measures (figure 1). For predicting a flare within the next 6 months, pain, emotional distress, physician global, AM stiffness, and age were statistically significant (figure 2). Patient reported treatment during a flare included increases or changes in: prednisone by 35%, DMARDs by 32%, NSAIDs by 27%, biologics by 6%, narcotics by 5%, other pain meds by 13%.

Current flare analyses indicates variables that are associated with a recent flare as reported by the patient. (Odds Ratios from GEE)

Variables significantly associated with a current flare (Multivariate Regression)
All Measures:

Variable	Odds Ratio	Lower 95% CI	Upper 95% CI	P value

Total MRI Inflammatory Score Correlates with Disease Activity Measures after Aggressive Treatment of Rheumatoid Arthritis. Veena K. Ranganath[3], David A. Elashoff[4], Paul Maranian[4], Kambiz Motamedi[4], Espen Haavardsholm[2], Fiona M. McQueen[5], Theresa McVie[7], Stacey S. Cofield[7], Larry W. Moreland[6], Weiling Chen[4] and Harold E. Paulus[1]. [1]Encino, CA, [2]Diakonhjemmet Hospital, [3]UCLA, Los Angeles, CA, [4]UCLA, [5]Univ of Auckland Sch of Med, Auckland, New Zealand, [6]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [7]University of Birmingham

Purpose: MRI is a sensitive imaging modality to investigate "inflammation" in rheumatoid arthritis (RA) joints. Tenosynovitis, synovitis, and bone edema independently correlate with disease activity measures in RA and suggest radiographic progression. The purpose of this study was to evaluate the relationship of clinical disease activity measures with two composite total MRI inflammatory score measures and their components, after 2 or more years of aggressive treatment of RA.

Methods: MRI with gadolinium contrast (1.5 Tesla) of the dominant wrist was obtained in 118 early (RA duration 4.1 ± 10.8 months) seropositive or erosive RA patients after completing the TEAR 2-year controlled clinical trial comparing various combinations of MTX, etanercept, HCQ, and SSZ. Clinical disease activity measures were recorded every 12 weeks during the trial and at the time of MRI. MRIs were scored for tenosynovitis (T: range 0–30), synovitis (S: 0–9), and bone marrow edema (BME: 0–42) using published RA MRI(RAMRIS) and tenosynovitis scoring methods. One method of calculating the total MRI inflammatory score was by: T+ S + BME. Another method produced a weighted measure, by taking the actual values of T, S, and BME and dividing by the range for each component. These values were then added together to give the weighted total MRI inflammatory score.

Results: After 2 years of aggressive RA treatment, the patients' average age was approximately 51 years. The mean DAS28 and clinical disease activity index (CDAI) fit into the mild disease activity categories, 2.9 and 9.2 respectively. More clinical core set measures correlated significantly with the weighted and unweighted total MRI inflammatory score than with the individual components of the scores (T, S, and BME), and the Rho values were also higher. T correlated significantly with only the physician global and swollen joint count. S correlated with CDAI, physician global, patient global, ESR, pain, stiffness, and arthritis severity. BME correlated with age, CDAI, physician global, stiffness, and swollen joint count. No single correlation coefficient was greater than >0.4. Weighting the MRI inflammatory score components did not improve the correlations.

Conclusions: The total composite MRI inflammatory score was shown to correlate better than the individual components of the MRI scores, with residual disease activity as assessed by standard core set measures and patient self-reported pain and stiffness.

Towards a Data-Driven Evaluation of the 2010 ACR/EULAR Criteria for Rheumatoid Arthritis: Is It Sensible To Look at Levels of Rheumatoid Factor? M. P. M. van der Linden[4], M. R. Batstra[1], L. E. Bakker-Jonges[1], J. Detert[2], H. Bastian[2], H. U. Scherer[2], G. R. Burmester[2], M. D. Mjaavatten[3], T. K. Kvien[3], R. E. M. Toes[4], T. W. J. Huizinga[4] and A. H. M. van der Helm-van Mil[4]. [1]Department of Medical Laboratories, Reinier de Graaf Group, Delft, The Netherlands, on Behalf of SKML-HIM (WGHAS), [2]Department of Rheumatology and Clinical Immunology, Charité University Medicine Berlin, Berlin, Germany, [3]Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway, [4]Department of Rheumatology, Leiden University Medical Center, Leiden, The Netherlands

Objective: The classification criteria for Rheumatoid Arthritis (RA) have been recently updated. The diagnosis of RA requires achieving ≥6 points; anti-citrullinated protein/peptides antibodies (ACPA) or Rheumatoid Factor (RF) presence yields 2 points and high levels 3 points. High RF level has an increased specificity for RA compared to RF-positivity, however the same holds for ACPA-positivity. This study evaluated the prognostic performance of high RF levels compared to the presence of ACPA (as determined by anti-CCP antibodies) for the development of RA. The predictive ability for the severity of RA was also assessed.

Methods: Three independent cohorts with a total of 972 undifferentiated arthritis patients were studied for RA-development (according to the 1987 ACR criteria) and arthritis persistency. Positive and negative predictive values (PPV, NPV) and likelihood ratios (LR) were compared for different levels of RF with the presence of anti-CCP antibodies. A similar comparison was made in 686 RA-patients for the rate of joint destruction during 7 years of follow-up and achievement of sustained DMARD-free remission. The variation in RF levels obtained by different measurement methods in the same RF-positive sera was explored.

Results: Presence of anti-CCP had a better balance between LR+/LR- and PPV/NPV than high RF levels for RA-development. The additive value of anti-CCP assessment after high level RF-testing was higher than vice versa. High level RF was less strongly associated with RA severity than anti-CCP antibodies. The RF level obtained by different methods in the same patients' sera varied considerably.

Conclusion: Level determination of RF is subject to large variation; high level RF has limited additive prognostic value compared to anti-CCP-positivity.

Ultrasound Evaluation Reveals the Reason for High Interrater Variability in Joints of the 66/68 Joint Count. Matthias Nikolaus Witt[2], Monika Ronneberger[1], Amelie Schnez[3], Ruediger Laubender[4], Matthias Engelbrecht[1], Arthur Kavanaugh[6], Hendrik Schulze-Koops[5] and Mathias Grunke[3]. [1]Department of Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Division of Rheumatology, Ludwig-Maximilians-University, Munich, Germany, [3]Division of Rheumatology, Ludwig-Maximilians-University, Munich, Germany, [4]Institute of Medical Informatics, Biometry and Epidemiology (IBE), Ludwig-Maximilians-University, Munich, Germany, [5]Ludwig-Maximilians-University, Munich, Germany, [6]University of California-San Diego, La Jolla, CA

Background: In patients with rheumatoid arthritis, joint counts are the key outcome parameter in clinical trials as well as in daily clinical practice. It has been shown, however, that there is a huge variability between different assessors of the same patient. In a previous paper we have shown, that this can be reduced by a standardised training of the EULAR examination technique. We have also shown, however, that the effect of standardisation is worse for the 66/68 than for the 28 joint count.

Objectives: To evaluate the reason for the higher interrater disagreement in the assessment of the 68/66 in contrast to the 28 joint count. Is it the greater difficulty in assessing the joints of the lower extremity and can this be ruled out by ultrasonography?

Methods: Participants of joint examination seminars evaluated a given RA patient before and after they were made familiar with the EULAR examination technique. Joints were rated positive or negative for tenderness and swelling without graduation. The amount of tender and swollen joints as well as the variability between the examiners (groups of 4–6 trainees per patient) before and after the training were compared. For every single joint, the degree of agreement was calculated using the Fleiss-Kappa test. In a subgroup of 40 patients, the clinical results were compared to an independent ultrasound examination of the MTP joints.

Results: 340 health professionals participating in standardised joint assessment trainings were evaluated. 256 were instructed in the 68/66, 84 in the 28 joint count. For both joint counts, the disagreement between different examiners was higher for the dimension of joint swelling than for tenderness. After the training of the EULAR examination technique, there was a significant reduction of interrater variability, which was more pronounced in the 28 than in the 68/66 joint count. Comparisons between manual and ultrasound assessment revealed, that concerning the dimension of swelling manual examination has a very low sensitivity and high variability in the joints of the feet.

Conclusion: Standardisation of the joint examination technique significantly reduces variability. The relatively better performance of the 28 joint count is partly due to the higher number of examined joints in the 68/66 joint count. Another reason is, that the joints of the feet, although they are more often rated negative by manual than by ultrasound evaluation, tend to imply a higher disagreement between different assessors.

Validation of a Multi-Biomarker Test for Rheumatoid Arthritis (RA) Disease Activity (Vectra™ DA) in a Multi-Cohort Study. Jeffrey R. Curtis[9], Doug Haney[3], Annette H. M. van der Helm[5], Yijing Shen[3], Rachel Knevel[5], Guy Cavet[3], Linda Dirven[5], Cornelia F. Allaart[4], Thomas W. J. Huizinga[5], Michael Centola[6], Lyndal K. Hesterberg[3], David Chernoff[3], John Carulli[1], Nancy A. Shadick[2], Michael E. Weinblatt[2], Max I. Hamburger[8], Roy M. Fleischmann[7] and Ed C. Keystone[10]. [1]Biogen Idec, [2]Brigham & Womens Hospital, Boston, MA, [3]Crescendo Bioscience, Inc., [4]Leiden Univ Med Ctr, Leiden, The Netherlands, [5]Leiden Univ Med Ctr, [6]Oklahoma Med Research Foundation, Oklahoma City, OK, [7]Rheumatology Associates, Dallas, TX, [8]Rheumatology Associates of LI, Dix Hills, NY, [9]University of Alabama-Birmingham, Birmingham, AL, [10]University of Toronto, Toronto, ON, Canada

Background: Regular measurement of disease activity enables more effective management of rheumatoid arthritis (RA). DAS28CRP is a validated tool for assessment of disease activity, but it requires enumeration of tender and swollen joints, which are subject to significant inter- and intra-assessor variability, and is not routinely performed by all physicians. A test based on serum protein biomarkers involved in RA pathophysiology has the potential to provide quantitative, objective and reproducible information that has not previously been available to clinicians. A 12-biomarker test of RA Disease Activity (DA Test) has recently been developed in a series of clinical studies. Here we show in a prospectively-designed study that the biomarker-based DA Test validly quantifies RA disease activity as compared to the DAS28CRP.

Methods: 230 RF+ and/or anti-CCP+ patients were selected from participants in the Index for Rheumatoid Arthritis Measurement (InFoRM), Brigham and Women's Hospital Rheumatoid Arthritis Sequential Study (BRASS), and Leiden Early Arthritis Clinic studies. To ensure test validity across a wide range of disease activity, patients representing all levels of disease activity were selected. The concentrations of 12 serum biomarkers (IL-6, EGF, VEGF-A, Leptin, SAA, CRP, VCAM-1, MMP-1, MMP-3, Resistin, YKL-40, and TNF-RI) were measured and combined in a pre-specified algorithm to generate DA Test scores ranging from 1–100. The DA Test score was calculated from an equation similar to that for DAS28CRP where scores for TJC28, SJC28, and Patient Global were individually modeled using serum biomarkers. To calculate area under the ROC curve (AUROC), a DAS28CRP cutoff of 2.67[i] was used to assign cases to low vs moderate/high disease activity. A separate, longitudinal analysis of patients from the InFoRM study with significant changes in DAS28CRP was undertaken to understand whether changes in DA Test score were associated with changes in DAS28CRP.

Results: The AUROC for DA relative to the DAS28CRP cutpoint of 2.67 was 0.77 (CI: 0.70 – 0.83; $p < 0.001$); the correlation between DA and DAS28CRP was 0.56 (CI: 0.46 – 0.64; $p < 0.001$). Decomposition of the DA Test into a non-CRP DA Test score and a CRP term demonstrated that the non-CRP DA Test score was an independent predictor of DAS28CRP ($p < 0.001$) in multivariate analysis (after controlling for CRP). In longitudinal analysis, there was a significant association between change in DA Test score and change in DAS28CRP ($p<0.01$). Exploratory analysis suggests the DA Test may more accurately detect low disease activity than CRP (Fig. 1).

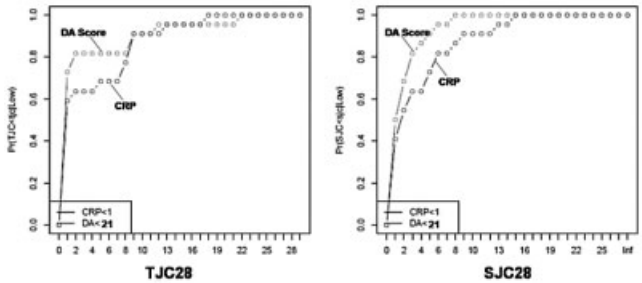

Fig. 1. Proportion of patients with joint counts below a threshold for those with low CRP or DA test score.

Conclusion: The DA Test has been validated as a quantitative, objective, biomarker-based test of RA disease activity. It could be used to optimize clinical care and provide an objective measure of treatment response in observational analyses or randomized trials.

1783

Validation of New Classification Criteria for Rheumatoid Arthritis in Japanese Population. Hisanori Shimizu[1], Hiromichi Tamaki[3], Eishi Uechi[3], Mitsumasa Kishimoto[2], Ken-ichi Yamaguchi[3] and Masato Okada[1]. [1]St. Luke's International Hospital, Tokyo, Japan, [2]St. Luke's International Hospital, Chuo-ku, Tokyo, Japan, [3]St. Luke's International Hospital

Background: The Classification Criteria of Rheumatoid Arthritis has been revised by ACR/EULAR joint committee in 2009. The new criteria is aimed to establish the diagnosis earlier to initiate appropriate disease modifying anti-rheumatic drugs without delay in the current era when complete remission before joint damage becomes a realistic goal with the advance of medical treatment.

Objectives: We performed retrospective validation of the new criteria in patients with undifferentiated arthritis who were later diagnosed as rheumatoid arthritis based on 1987 ACR classification criteria.

Methods: We reviewed electronic medical records of all the patients who were referred to St. Luke's International Hospital-Tokyo from October 2007 to November 2009 as undifferentiated arthritis before institution of any diseases modifying anti-rheumatic drugs (DMARDs). We applied the new ACR/EULAR criteria for all the patients to determine in which points they could be diagnosed as rheumatoid arthritis if the new criteria was utilized instead. We also compare patients who had delayed diagnoses based on the old criteria to patients whose time of the diagnoses did not differ, to analyze the clinical characteristics and also prognosis of the joints.

Results: There were two hundreds six patients who were referred to our institution without definitive diagnoses of rheumatoid arthritis over the period. We excluded all the patients who had been prescribed any DMARD for any purpose in other institution. There were eighteen patients without definitive diagnoses at the time of chart review and none of them was classified as rheumatoid arthritis even with the new criteria.

For the rest of fifty eight patients who were later diagnosed as definitive rheumatoid arthritis based on 1987 ACR classification criteria, we applied the new ACR/EULAR criteria. The average age was 54.0, and 50 of them were female and 8 were male. Rheumatoid factor were positive in 39 (67%), and anti-CCP antibody (second generation) was significantly elevated in 46 patients (79%). Bone erosions were already detectable in 11 patients at their first visits. In seventeen patients (group 1), the definitive diagnoses could be established significantly earlier with the new criteria and the average difference was 63.1 days. In forty one patients (groups 2), the diagnoses was not delayed even with the old criteria. Overall, the durations of days from the first visits to diagnoses were 36.2 days and 17.7 days with the old and new criteria, respectively. Biologics were eventually prescribed in two of seventeen patients (group 1) and eight of forty one patients (group 2).

Conclusion: The new ACR/EULAR Classification Criteria was effective to establish the diagnoses of rheumatoid arthritis significantly earlier in substantial percentage of patients, who eventually require intensive medical treatment such as biologics.

Table 1. Baseline characteristics of patients who were diagnosed as definitive rheumatoid arthritis based on 1987 ACR classification criteria (n=58)

Age	**54.0**
Female, n. (%)	50 (86)
No. of joint involvement*	
- Total joints	7.3
- Small joints	5.1
DAS-CRP (ESR)*	4.22 (4.90)
RF positive, no. (%)	39 (67)
Anti-CCP positive, no. (%)	46 (79)
Duration of synovitis (≥6 weeks), no. (%)	55 (95)
Bone erosions, no. (%)	11 (19)
No. of days from the first visit to the diagnosis	36.0
Treatment	
- DMARDs alone, no.(%)	30 (52)
- MTX, no. (%)	23 (40)

Validity of Clinical Associations of Biomarkers in Translational Research Studies: The Case of Systemic Autoimmune Diseases. Maria Tektonidou[2] and Michael Ward[1]. [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, [2]National University of Athens

Objective: Validity of biomarkers may be impacted if studies do not include certain features in their design. We evaluated if translational research studies of potential biomarkers incorporated design features important for valid clinical associations.

Methods: We searched 10 journals for translational studies in 6 systemic autoimmune diseases published in 2004–2009. We included studies that reported associations between laboratory markers and the presence of disease, measures of disease activity, or prognosis. We examined the following design features: age-, sex- and race-matching; control for effects of treatment on expression of the biomarker; inclusion of both patients with early and late disease, or both active and inactive disease; longitudinal or cross-sectional design; and use of validated activity and damage measures.

Results: Among 170 articles, 156 articles examined potential biomarkers for diagnosis, 37 for disease activity assessment and 9 for prognosis; 67 were studies of rheumatoid arthritis (RA), 48 of systemic lupus erythematosus, and 41 of other diseases. Gene expression profiles were the most commonly examined potential biomarkers (N =51). Less than one-half of studies incorporated study design features important for valid clinical associations. Only 47.4% of studies of biomarkers for diagnosis had groups that were age-matched, 45.5% were sex-matched, and 35.3% controlled for treatment. Studies that examined biomarkers in histological samples and studies of RA were less likely to include important design features.

Conclusion: Less than one-half of translational studies of potential biomarkers incorporated design features needed for valid interpretation of clinical associations. Attention to these features could reduce false-positive and false-negative associations.

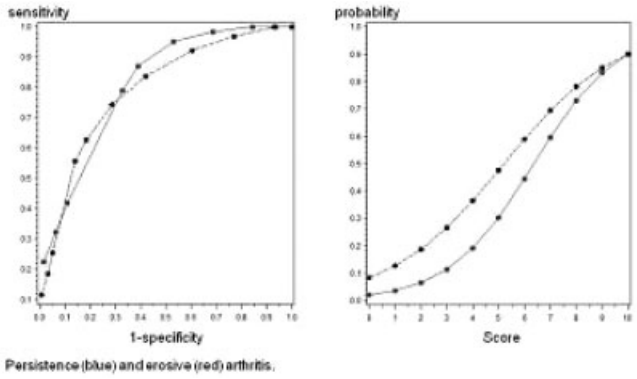
Validity of the Revised ACR/EULAR Classification Criteria for Rheumatoid Arthritis: Predicting Persistent Arthritis and Joint Erosions after 2 Years in Patients with Early Undifferentiated Arthritis. Jaap Fransen[3], Mieke Hazes[2] and Henk Visser[1]. [1]Alysis Hospital, Arnhem, The Netherlands, [2]Erasmus Medical Centre, Rotterdam, The Netherlands, [3]Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands

Background: The revised ACR/EULAR criteria for the classification of RA were developed to enable a more timely diagnosis. With the criteria the probability of developing persistent inflammatory or erosive arthritis that is considered to be 'RA' is calculated. However, the revised criteria were not validated against these two outcomes.

Objective: To study the revised ACR/EULAR criteria for the ability to correctly predict persistent arthritis and joint erosions after 2 years in patients with early undifferentiated arthritis.

Methods: Data were used from an existing cohort of patients with early arthritis (N=566) [1]. Patients with undifferentiated arthritis were included for the current analysis if at baseline they had: synovitis in at least 1 joint (N=561/566), arthritis not explained by another diagnosis (N=396/561), no joint erosions on X-ray (N=322/396), completed 2 year follow-up (N=286/322). Patients had been clinically assessed at baseline, including joint involvement, RF and ACPA, symptom duration, ESR and CRP. Scoring for joint involvement was slightly modified because small joint swelling was registered in Ritchie units. The 'risk' score (0–10) of the revised classification criteria was applied to the baseline data, persistent arthritis and joint erosions on X-ray at year 2 were the outcomes.

Results: At year 2, 45% (129/286) had persistent arthritis and 48% (62/129) of them had erosions. At baseline, the median (P25-P75) number of swollen joints was 2 (1–4), 23% were RF positive and 18% ACPA positive, median symptom duration was 13 weeks, median (P25-P75) ESR was 26 (13–44). Height of the 'risk' score (0–10) was significantly associated with persistent arthritis, OR (95%CI) 1.6 (1.4–1.8), and erosions, OR (95%CI) 1.8 (1.5–2.3), with areas under the ROC curve of.79 and.81, respectively. Patients with a 'risk' score of ≥6 at baseline had a.74 probability to develop persistent arthritis at year 2 and given persistence there was a.68 probability to develop erosions. The proposed cut point for 'definite RA' may be held at ≥6, while ≥3 may be an appropriate cut point for 'probable RA'. The diagnostic criteria of Visser et al. [1] performed slightly better, the list version of the 1987 ACR classification criteria was outperformed by both the other criteria.



Graph. Discrimination and calibration.

Conclusion: The revised ACR/EULAR classification criteria for RA are valid to predict future persistent arthritis and joint erosions in patients with early undifferentiated arthritis.

Vitamin D Levels Do Not Correlate with Disease Activity, Erosions, or Inflammatory Markers in Patients with Active Rheumatoid Arthritis. Joshua Baker[2], Daniel G. Baker[1], Gary Toedter, Justine Shults and Mary B. Leonard. [1]Centocor Inc, Malvern, PA, [2]University of Pennsylvania, Philadelphia, PA

Introduction: Evidence supports vitamin D deficiency as a potential risk factor for autoimmune disease. Small studies have yielded controversial data with regard to an association between vitamin D and disease activity measures among patients with RA.

Methods: Vitamin D levels were performed at baseline on 500 randomly selected patients with rheumatoid arthritis from the golimumab RCT. Participants met ACR criteria for the diagnosis, had active disease, and were naïve to both methotrexate and to other biologic therapies. Spearman correlations and multivariable linear regression were performed to assess associations between vitamin D levels and demographic and disease activity measures.

Results: 83% of patients had vitamin D levels <30 ng/mL, while 48% had levels <20 ng/mL. Vitamin D level did not correlate with the DAS28 score, ESR, CRP, or erosion score at baseline (Table 1). Vitamin D levels correlated with age ($p=0.005$), sex ($p=0.009$), BMI ($p=0.02$), HAQ scores ($p=0.02$), and patient reported health ($p=0.03$) (Table 1). The 6 black patients also had significantly lower vitamin D levels ($p=0.03$). Disease activity was similar across quartiles of vitamin D in a multivariable linear regression model. Age was the most important confounder of the non-significant trend between vitamin D and disease activity in the unadjusted model (Table 2). Disease activity was significantly decreased in the 22 patients with a vitamin D level >40 ng/mL. Age, race, BMI, and disease duration alone helped significantly to predict vitamin D levels in a predictive regression model.

Conclusions: Vitamin D levels do not correlate cross-sectionally with disease activity measures, erosion scores, or inflammatory markers in a large sample of patients with RA. Overall, vitamin D correlated with HAQ scores and patient reported health, but these were not independent predictors of vitamin D level in a predictive model including age, race, and BMI. Limitations include unknown geographic area and a study population that was selected for high disease activity. Overall, these data do not support a contribution of vitamin D in the activity of rheumatoid arthritis.

Table 1.

Variable	Spearman's Rho	P value

Work Disability in Early Rheumatoid Arthritis: Prognostic Factors after Two Years of Follow-Up. Fausto Salaffi[1], Gianfranco Ferraccioli[3], Marina Carotti[2], Alessandro Ciapetti[1], Stefania Gasparini[1] and Walter Grassi[1]. [1]Department of Molecular Pathology and Innovative Therapies, Division of Rheumatology, University of Ancona (Politecnica delle Marche), Italy, [2]Department of Radiology, University of Ancona (Politecnica delle Marche), Italy, [3]School of Medicine, Catholic University of the Sacred Heart, Rome, Italy

Objective: Premature work disability in rheumatoid arthritis (RA) patients is a serious problem that needs to be addressed. The aims of the study was to explore the prevalence of work disability (WD) and to identify socio-demographic and disease-related factors that can predict future WD in patients with early RA over a 2-year period.

Methods: Two hundred and eleven working-age patients with early (<1 year) RA were evaluated every 3 months for a period of 2 years. At baseline Health Assessment Questionnaires (HAQ) were administered to each patient and socio-demographic data (age, gender, status of living, educational level), the presence of anti-cyclic citrullinated peptide (anti-CCP) antibodies and/or rheumatoid factor and comorbidities were recorded. The current occupations were categorized into four groups: predominantly mental demands, a combination of physical and mental effort, light physical demand and heavy physical demands. Radiological damage was evaluated by using the Sharp/van der Heijde score–SHS). The cumulative inflammatory burden was estimated by the evaluation of time-integrated values (area under the curve - AUC) of Disease Activity Score–28 joints (DAS28). The association between risk factors and WD was assessed using multiple logistic regression analysis (with Wald statistic as measures of WD risk).

Results: Among the 211 patients work disability rates were 2,8% and 8.1% at 12 months and after 24 months, respectively. Time-integrated values of DAS28 (Wald test = 10.82; $p<0.001$) and the work status (Wald test = 6.72; $p<0.01$) were identified as independent predictors variables of increased risk for new WD in the final logistic regression model. The strength of association of the model were Cox and Snell R^2 0.240 and Nagelkerke R^2 0.558. In the stratified analyses, the use of an anti-Tumor Necrosis Factor (TNF) drug revealed to protect against work disability among subjects with shorter disease duration.

Conclusions: Work demands and disease activity significantly and independently contributes to WD. Since WD frequently occurs within the first 2 years of disease adequate therapeutic interventions are advisable to start early in the course of RA.

A Study To Evaluate the Effectiveness and Safety of the Interleukin-6 (IL-6) Receptor Antagonist Tocilizumab (TCZ) after 4 and 24 Weeks in Patients with Active Rheumatoid Arthritis (RA)—Final Effectiveness Results of the TAMARA Study. Eugen Feist[1], Andrea Rubbert-Roth[2], Jürgen Braun[6], Jörg Kaufmann[4], Herbert L. Kellner[7], Reiner Kurthen[3], Jürgen Wollenhaupt[5] and Gerd R. Burmester[1]. [1]Campus Charité Mitte, Med. Klinik Abt. Rheumatologie u. Klin. Immunologie, Berlin, Germany, [2]Klinik I für Innere Medizin, Uniklinik Cologne, Cologne, Germany, [3]Praxis für Innere Medizin und Rheumatologie, Aachen, Germany, [4]Praxis für Innere Medizin und Rheumatologie, Ludwigsfelde, Germany, [5]Rheumatologikum Hamburg, Schön-Klinik Hamburg-Eilbeck, Hamburg, Germany, [6]Rheumazentrum Ruhrgebiet, St. Josefs-Krankenhaus, Herne, Germany, [7]Schwerpunktpraxis fuer Rheumatologie und Gastroenterologie, Munich, Germany

TAMARA was a multi-center, open-label, single-arm (TCZ 8 mg/kg iv q4w), Phase IIIb study over 24 weeks (wks) to confirm the effectiveness and safety of TCZ in a treatment setting close to real-life medical care in Germany. Pts. with moderate/severe RA in spite of treatment with conventional (c)DMARDs and/or Biologics were enrolled at 70 sites; inclusion criteria included baseline DAS28 >3.2, ESR ≥28mm/h or CRP ≥1mg/dL, and previous treatment with at least 1 cDMARD continued during the study. Primary endpoint was the proportion of pts. achieving DAS28 "low disease" (LDAS, ≤3.2) at Wk24. Secondary effectiveness variables included ACR responses, CDAI, SDAI, inflammatory markers, and patient-reported outcomes such as HAQ-DI and FACIT-F (fatigue). Additional analyses considered several subgroups, e.g. based on rheumatoid factor (RF) at Baseline (RF^+ vs. RF^-), inadequate response (IR) to previous antirheumatics (TNFα-IR vs. cDMARD-IR), or Baseline DAS28 (>4.1-≤5.1 vs. >5.1).

Results: 286 pts. (ITT; median age: 55 yrs., 75.5% women, Baseline DAS28: 6.0±1.0) received TCZ; 239 pts. (71.6%) completed the 24wk treatment. 119 pts. (41.6%) had previously received TNFα-blockers; 163 (57.0%) cDMARDs only. 81 pts. (28.3%) were considered RF^- and 184 pts. (64.3%) RF^+. 47 pts. (16.4%) showed a Baseline DAS28 4.1-≤5.1 whilst 217 pts. (75.9%) had DAS28 >5.1.

At Wk24, 57% of the ITT pts. (95%-CI: [51.0; 62.8]) had achieved LDAS, ACR20/50/70 response rates were 65.0%/50.7%/33.9%. "Good" and "moderate" EULAR response was seen in 54.9% and 20.3% of pts., respectively. A clinically significant DAS28 reduction from Baseline (by ≥1.2) was seen in 74.5% of pts.; 47.6% achieved DAS remission (<2.6). The mean course of continuous effectiveness variables is provided in Table 1 (relevant improvements were seen as early as Wk4).

Table 1. Results (continuous data) of the Week 24 effectiveness analyses (ITT, LOCF)

	Baseline mean ± SD (N obs.)	Week 24/Early withdrawal mean ± SD (N obs.)	Mean Change mean ± SD (N obs.)
Single variables			
SJC (n)	9.6 ± 5.4 (286)	2.6 ± 3.7 (286)	−7.0 ± 5.5 (286)
TJC (n)	12.6 ± 6.8 (286)	4.3 ± 6.1 (286)	−8.3 ± 6.6 (286)
VAS-Disease Activity (mm)	62.2 ± 20.2 (286)	26.3 ± 25.4 (286)	−35.9 ± 30.2 (286)
ESR (mm/h)	37.4 ± 22.1 (274)	7.1 ± 9.5 (286)	−30.3 ± 21.7 (274)
CRP (mg/L)	23.1 ± 30.7 (274)	3.0 ± 7.7 (286)	−20.1 ± 29.9 (274)
Composite measures			
DAS28	6.0 ± 1.0 (274)	2.6 ± 1.5 (286)	−3.4 ± 1.4 (274)
CDAI	34.7 ± 12.5 (284)	11.3 ± 11.5 (285)	−23.5 ± 13.3 (284)
SDAI	37.2 ± 13.1 (272)	11.6 ± 11.5 (285)	−25.9 ± 13.7 (272)
Patient-reported outcome (PRO) measures			
HAQ-DI	1.48 ± 0.65 (285)	1.00 ± 0.75 (286)	−0.48 ± 0.60 (285)
FACIT-F (fatigue)	28.8 ± 11.2 (283)	37.4 ± 12.2 (286)	8.6 ± 11.1 (283)

N obs.=number of observations, SD=standard deviation.

The proportions of subgroup pts. achieving LDAS or DAS remission at Wk 24 are summarized in Table 2.

Table 2. LDAS and DAS28 remission in several subgroups at Week 24

Baseline Characteristics	N (=100.0%)	LDAS n (%)	DAS28-Remission n (%)
Rheumatoid factor			
Positive	184	105 (57.1)	85 (46.2)
Negative	81	48 (59.3)	41 (50.6)
Previous RA treatment			
Conventional DMARD-IR	163	103 (63.2)	87 (53.4)
TNFα-IR	119	60 (50.4)	49 (41.2)
Baseline DAS28			
4.1 < DAS28 ≤5.1	47	34 (72.3)	27 (57.4)
DAS28 >5.1	217	115 (53.0)	95 (43.8)

Conclusions: In a clinical setting close to usual care the treatment with TCZ led to rapid and sustained improvement of RA symptoms, thereby indicating the therapeutic benefits of TCZ. This improvement was consistently observed in all applied outcome measures independent of the measure characteristics. Subgroup analyses showed numerically better outcomes (i.e., difference by >10.0 percentage points in both LDAS and DAS remission when compared with the complementary group) in cDMARD-IR vs. TNFα-IR pts. or pts. with baseline DAS28 4.1-≤5.1 vs. >5.1, whereas no such differences were seen between RF^+ vs. RF^- pts., thereby suggesting that RF seemed not to relevantly predict the outcome at Wk 24.

1789

Age at Onset and Comorbidities Correlate with the Health Assessment Questionnaire and Clinical Disease Activity Index (CDAI) Responses to Etanercept in Rheumatoid Arthritis Patients.

Man R. Shim[6], Harold E. Paulus[1], Sandeep Chaudhari[3], JingYaun Feng[2], David A. Elashoff[4] and Veena K. Ranganath[5]. [1]Encino, CA, [2]Amgen, [3]Kforce Clinical Research/Amgen, [4]UCLA, [5]UCLA School of Med Rehab 32–59, Los Angeles, CA, [6]UCLA/ VA Greater Los Angeles Healthcare System, Los Angeles, CA

Objective: To investigate the influence of age of onset of rheumatoid arthritis (RA) and comorbidities on the health assessment questionnaire and clinical disease activity index (CDAI) responses in patients with active RA after 6 months of treatment with etanercept (ETN).

Methods: A cohort of 1,960 RA patients enrolled in the RA Disease-Modifying Anti-Rheumatic Drug (DMARD) Intervention and Utilization Study (RADIUS) 2 met the following inclusion criteria: initiated ETN, continued therapy for at least 6 months, and were not in remission at baseline (CDAI ≤ 2.8). Seventeen patient-reported comorbidities were recorded at baseline, and patients were classified by five quintiles of age of onset, <32, 32–41, 42–48, 49–55, and >55 years. Changes in HAQ and CDAI scores over 6 months were analyzed across the age categories using ANOVA. Linear and logistic regression models were constructed to evaluate the independent association between age of onset and number of comorbidities with change in HAQ/CDAI scores or achieving low disease activity (CDAI<10) after accounting for other covariates.

Results: Seventy-seven percent of patients were female, average age was 44 yrs, mean disease duration was 8.6yrs and average CDAI was 35.6. Baseline tender joint count and CDAI were statistically different across the age quintiles (Bsl CDAI grp1 33.9, grp2 35.5, grp3 35.4, grp4 37.2, grp5 36.3), however not clinically different. HAQ, patient global, physician global, swollen joint count and pain visual analogue scales (VAS) were similar across the age groups at baseline. Improvement in HAQ and CDAI scores after at least 6 months of treatment was not clinically different across the age groups, although both were statistically different across age. The results of the multiple linear regression model demonstrated that younger age at onset, higher baseline HAQ/CDAI score, positive rheumatoid factor, shorter disease duration, male gender, and fewer comorbidities at baseline were independently associated with both improvement in HAQ and CDAI. Similarly, achieving CDAI low disease activity after treatment with ETN for at least 6 months, was associated with younger age of onset, lower baseline CDAI, shorter disease duration, male gender, and fewer comorbidities (Table 1).

Table 1. Regression Models for Change in HAQ, Change in CDAI and CDAI Low Disease Activity

	Change in HAQ		Change in CDAI		CDAI Low Disease Activity	
	Beta-Coeff (SE)	p-value	Beta-Coeff (SE)	p-value	OR (95% CI)	p-value
Age at onset (yrs)	0.01 (0.00)	<0.0001	0.06 (0.02)	0.0190	1.01 (1.00–1.02)	0.0027
Baseline CDAI/HAQ	−0.29 (0.02)	<0.0001	−0.68 (0.02)	<0.0001	1.04 (1.03–1.04)	<0.0001
Baseline Off Prednisone	0.02 (0.02)	0.5222	0.33 (0.58)	0.5704	1.09 (0.89–1.33)	0.4063
Baseline Negative RF	0.08 (0.03)	0.0095	1.79 (0.68)	0.0087	1.21 (0.96–1.53)	0.1105
Disease Duration	0.01 (0.00)	<0.0001	0.10 (0.04)	0.0079	1.02 (1.00–1.03)	0.0083
Gender (Female)	0.08 (0.03)	0.0083	1.22 (0.68)	0.0074	1.35 (1.07–1.71)	0.0116
# Comorbidities	0.05 (0.01)	0.0003	1.20 (0.32)	0.0002	1.18 (1.06–1.32)	0.0037
Race (Non-White)	0.00 (0.03)	0.8985	0.99 (0.76)	0.1933	1.23 (0.94–1.59)	0.1260

Conclusion: In a large prospective cohort of RA patients who received at least 6 months of ETN therapy, younger age of onset and fewer comorbidities were associated with HAQ/CDAI improvement and with CDAI low disease activity after adjusting for other clinically relevant variables. These results confirm the importance of the number of reported comorbidities and age of onset in impacting RA response to anti-TNF treatment, and suggest that physicians should consider these factors when initiating therapy.

1790

Assessment of Real Life Efficacy of Rituximab in Rheumatoid Arthritis: Predicting Factors of the Therapeutic Maintenance and Demonstration of a Corticosteroid Sparing Effect in the AutoImmunity and Rituximab Registry. Jacques-Eric Gottenberg[10], Philippe Ravaud[4], Thomas Bardin[6], Patrice Cacoub[5], Alain Cantagrel[11], Bernard Combe[8], Maxime Dougados[2], René-Marc Flipo[7], Bertrand Godeau[3], Loic Guillevin[2], Eric Hachulla[7], Xavier Le Loët[9], Thierry Schaeverbeke[1], Jean Sibilia[10], Gabriel Baron[4] and Xavier Mariette. [1]Bordeaux Hospital, [2]Cochin Hospital, [3]Henri Mondor Hospital, [4]Hotel Dieu Hospital, [5]La Pitié Hospital, [6]Lariboisière Hospital, [7]Lille Hospital, [8]Montpellier Hospital, [9]Rouen Hospital, [10]Strasbourg Hospital, [11]Toulouse Hospital

Objectives: Registries might provide useful information on efficacy of biological agents, provided that the selected outcome criteria take into account the variability of the follow-up of hundreds of patients among a large number of centers. We therefore evaluated the real life efficacy of rituximab (RTX) in rheumatoid arthritis (RA) by analyzing its maintenance and its corticosteroid sparing effect.

Patients and Methods: The French Society of Rheumatology has developed an independent registry, named AutoImmunity and Rituximab (AIR), available on-line (www.air-cri.org), in which data of tolerance and efficacy of RTX in refractory RA and also other refractory autoimmune diseases are prospectively collected every 6 months during 5 years.

Results:

- Predicting factors of retreatment with RTX

Among the 2005 patients with RA included in AIR registry (median age: 58 years, median RA duration: 13 years), 1057 patients (52.9%) have been retreated by RTX (2 cycles: 570, 3 cycles: 273, 4 cycles: 141, 5 cycles or more: 73).

570 patients have a follow-up of at least 18 months, including 459 patients (80.5%) who were retreated by subsequent cycles of RTX and 111 patients (19.5%) who received only one cycle before RTX discontinuation, as indicated in the crf and/or by the initiation of a new biological DMARD. RTX was discontinued because of absence of efficacy (n= 92) or problem of safety (n= 19). On univariate analysis, a higher proportion of retreated patients had not received any previous TNF antagonists (22% versus 13.7% in patients who received a single cycle, P=0.05), were RF-positive (82.1 vs 66.3%, P= 0.001) or anti-CCP positive (80.2% vs 61.7%, P<0.0001) or were RF or anti-CCP positive (91.9% vs 77.4%, P=0.04). In multivariate analysis, retreatment with RTX was significantly associated with anti-CCP positivity.

- Corticosteroid sparing effect

The proportion of patients treated with oral corticosteroids decreased from 79.1% at cycle 1 to 73.9% at cycle 2, 69.2% at cycle 3 and 69.4% at cycle 4 ($P< 0.0001$). Median dosage of corticosteroid decreased from 10.0 mg at 1st cycle to 6.0 mg at cycle 2, and 5.0 mg at cycle 3 and cycle 4 ($P< 0.0001$).

Conclusion: These results from the AIR registry show that anti-CCP positivity is a predicting factor of therapeutic maintenance in real life. These data also demonstrate the corticosteroid sparing effect of RTX in patients with RA.

Background: The optimal treatment approach to achieve and sustain low disease activity (LDA) with TNF antagonists and methotrexate (MTX) in patients with early rheumatoid arthritis (RA) has not been resolved.

Methods: OPTIMA is an ongoing Phase 4, randomized, double-blind trial to determine the **O**ptimal **P**rotocol for **T**reatment **I**nitiation with **M**ethotrexate and **A**dalimumab (ADA) in MTX-naive patients with early RA. Subjects with RA <1 year, DAS28 >3.2, ≥6 SJC, ≥8 TJC, ESR ≥28 mm/h or CRP ≥1.5 mg/dL, and ≥1 of: >1 erosions or RF+ or anti-CCP+ were randomized 1:1 to ADA (40 mg eow) +MTX (titrated to 20 mg/wk by week 8) or placebo (PBO) +MTX for the first 26 weeks. ADA+MTX subjects achieving LDA (DAS28 <3.2) at weeks 22 & 26 were re-randomized to compare continued combination therapy versus ADA withdrawal for the 52-week Period 2; PBO+MTX subjects with LDA at weeks 22 & 26 remained blinded on MTX monotherapy. Any subject failing to meet LDA at week 22 and/or 26 was given open-label ADA+MTX. A high-field 1.5T MRI substudy was conducted on the metacarpophalangeal and wrist joints at baseline, week 26, and week 78.

Results: OPTIMA enrolled 1,032 subjects (PBO+MTX N=517, ADA+MTX N=515); a similar percentage of subjects discontinued prematurely in each treatment group (table). Baseline characteristics were comparable between groups: 74% female, 89% white, mean RA duration of 4.2 months, mean DAS28 of 6.0 with 81% having DAS28 ≥5.1, mean SDAI of 43.6, mean CDAI of 40.8, mean SJC66 of 18.1, mean CRP of 2.9 mg/dL, and mean HAQ disability index (HAQ-DI) score of 1.6. Subjects treated with ADA+MTX demonstrated a significantly more rapid response, with a greater proportion achieving clinical and functional improvements through 26 weeks compared with PBO+MTX subjects (table).

Table. Subjects' Disposition and Clinical Outcomes through 26 weeks of OPTIMA*

Subjects, n (%)	Randomized		Completed Period 1			
PBO+MTX	517		460 (89%)			
ADA+MTX	515		466 (91%)			
	Week 2		Week 12		Week 26	
	PBO+MTX	ADA+MTX	PBO+MTX	ADA+MTX	PBO+MTX	ADA+MTX
ACR 20/50/70, % pts	16/2/0	46/18/5	58/30/11	73/49/30	57/34/17	70/52/35
DAS28 <3.2, % pts	4	15	22	42	26	47
DAS28 <2.6, % pts	1	7	10	26	16	34
SDAI ≤3.3, % pts	0.4	2	5	14	10	20
CDAI ≤2.8, % pts	0.2	3	7	13	11	20
SJ (0–66), mean (SD)‡	14	11	9	7	8	5
CRP (mg/dL), mean (SD)‡	2.5	1	1.4	0.9	1.3	0.8
HAQ ≤0.5, % pts	10	25	30	41	33	45

*Results based on nonresponder imputation analysis unless otherwise noted; P <0.001 for all between-groups comparisons; ‡LOCF.

In the MRI sub-study, PBO+MTX (N=32) and ADA+MTX (N=27) subjects, respectively, had mean changes from baseline to week 26 in synovitis of −2.0 and -3.6 (P=0.003), in erosion of 1.4 and −0.8 (P=0.004), and in osteitis of 0.0 and −4.0 (P=0.006), suggesting more improvement of joint inflammation and damage in the ADA+MTX group. Serious adverse events occurred in 31 (6%) PBO+MTX and 36 (7%) ADA+MTX subjects. Serious infections occurred in 6 (1.2%) and 13 (2.5%) subjects in the PBO+MTX and ADA+MTX groups, respectively. There was 1 case of peritoneal TB in the ADA+MTX group, and opportunistic infections excluding TB occurred in 3 (0.6%) PBO+MTX and 1 (0.2%) ADA+MTX subjects. There were no cases of lymphoma or demyelinating disease. Six deaths occurred in the ADA+MTX group, 5 related to infection and 4 in subjects ≥65 years, compared with 1 death in the PBO+MTX group.

Conclusion: Treatment of early RA with ADA+MTX resulted in rapid, enhanced clinical and functional responses and improved MRI profiles, compared with MTX monotherapy through 26 weeks.

Clinical Response during Sequential Anti-Tumor Necrosis Factor Therapy in US Veterans Enrolled in the Veterans Affairs Rheumatoid Arthritis (VARA) Registry. Grant W. Cannon[4], Brian C. Sauer[5], Candace L. Hayden[5], Liron Caplan[2], Gail S. Kerr[7], J. Steuart Richards[8], Dannette S. Johnson[3], Ted R. Mikuls[6] and Andreas M. Reimold[1]. [1]Dallas VA and University of Texas Southwestern, Dallas, TX, [2]Denver VA and University of Colorado, Aurora, CO, [3]Jackson VA and University of Mississippi, Jackson, MS, [4]Salt Lake City VA and University of Utah, Salt Lake City, UT, [5]Salt Lake City VA and University of Utah, [6]Univ of Nebraska Med Ctr, Omaha, NE, [7]Washington VA and Georgetown and Howard Universities, Washington, DC, [8]Washington VA and Georgetown University, Washington, DC

Purpose: The linkage of pharmacy databases with objective clinical outcome measures provides an opportunity to evaluate rheumatoid arthritis (RA) therapies

in "real-world" clinical settings. Merging of data from the Veterans Affairs RA (VARA) registry, initiated in 2003, and the VA Pharmacy Benefits Management (PBM) database dating back to 1998 allowed the investigation of disease activity score (DAS28) in patients receiving anti-tumor necrosis factor (TNF) therapy with adalimumab (ADA), etanercept (ETA), and infliximab (INF).

Methods: VARA routinely collects DAS28 on RA patients in this prospective cohort study. For each anti-TNF prescription, PBM data was used to estimate duration of the prescription, total dose dispensed, and anticipated refill date. A treatment course duration was defined as time from the initial prescription until the expected refill date for the last treatment before a 90 day gap or discontinuation. The average DAS28 and ESR was calculated during each course of therapy greater than 90 days during the observation period from 90 days after initial prescription to the end of the course.

Patients with sequential treatment courses with either the same anti-TNF (no switch) or a different anti-TNF therapy (switch) were evaluated. EULAR response criteria were evaluated using average DAS28 in comparing the sequential therapies and reported as better (if good or moderate response criteria fulfilled), worse (if a reverse of the sequence fulfilled EULAR good or moderate response criteria), and no change if neither better or worse.

Results: Of the 1382 patients in the VARA cohort, 601 (44%) had received anti-TNF therapy in 1258 courses. Of these courses, 530 (42%) were of greater than 90 days in duration with at least one DAS28 recorded during the clinical observation period. Comparison of no switch patients (n=56) and switch patients (n=46) showed that the initial DAS28 score during the initial (first) and subsequent (second) evaluable courses were higher in switch patients ($p<0.001$) but no difference in ESR ($p=0.10$) were discernable. Compared to initial values, the sequential DAS28 scores and ESR measurements were not statistically significant by pair t-test. EULAR response measures for better, worse, and no change response also did not achieve statistical significance ($p=0.168$). Evaluations of the different combinations for switching or not switching for each anti-TNF were also not statistically significantly different.

Table 1. Use of Anti-TNF agents in the VARA cohort

	Initial anti-TNF (n=601)	Patients with any exposure (n=601)	Number of courses	Courses >90 days	Courses >90 days with DAS28
ADA	170 (28%)	309 (51%)	425	327	195
ETA	311 (52%)	349 (58%)	533	294	221
INF	120 (20%)	175 (29%)	300	159	122

Table 2. Patients switching and not switching anti-TNF therapy. Clinical outcome during initial (first) and subsequent (second) course

	EULAR response			DAS 28 during:		ESR during:	
Anti-TNF therapy	Better	No change	Worse	First anti-TNF	Second anti-TNF	First anti-TNF	Second anti-TNF
No Switch (n=56)	14 (25%)	31 (55%)	11 (20%)	3.6 ± 1.1	3.4 ± 1.1	28 ± 20	31 ± 21
Switch Rx (n=46)	18 (39%)	17 (40%)	11 (23%)	4.6 ± 1.2	4.4 ± 1.3	24 ± 22	23 ± 22

Conclusions: RA patients in the VARA registry who were switched to a second anti-TNF agent were more likely to have higher DAS28 scores than patients who were not switched. However, there was no evidence that a switch in anti-TNF therapy was associated with greater clinical improvement in patients who switched than patients who did not switch anti-TNF therapies, nor did any particular anti-TNF show superior efficacy.

Clinical, Structural and Functional Remission in the Treatment of Rheumatoid Arthritis with Tocilizumab in Daily Clinical Practice–REACTION-2 Study. Tsutomu Takeuchi[2], Yoshiya Tanaka[5], Kouichi Amano[1], Eri Sato[4], Masao Nawata[6], Hayato Nagasawa[1], Daisuke Hoshi[4], Masayoshi Saito[6], Syunsuke Fukuyo[6], Kentarou Hanami[6], Hideto Kameda[3], Takahiko Kurasawa[1] and Hisashi Yamanaka[4]. [1]Division of Rheumatology and Clinical Immunology, Department of Internal Medicine, Saitama Medical Center, Saitama Medical University, Saitama, Japan, [2]Division of Rheumatology, School of Medicine, Keio University, Tokyo, Japan, [3]Division of Rheumatology, School of Medicine, Keio University, Tokyo, Japan, [4]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [5]The First Department of Internal Medicine, School of Medicine, University of Occupational & Environmental Health, Kitakyusyu, Japan, [6]The First Department of Internal Medicine, School of Medicine, University of Occupational & Environmental Health, Kitakyushu, Japan

Purpose: Anti-IL-6 receptor monoclonal antibody, tocilizumab (TCZ), is increasingly recognized as a powerful biological agent for the treatment of rheumatoid arthritis (RA). Comprehensive effectiveness of TCZ in daily clinical practice, in which the patients are advanced and even refractory to TNF inhibitors, is not fully understood. In this report, we evaluated the effectiveness of TCZ in the three major rheumatology centers as judged by clinical, structural and functional remission at 52 weeks in the advanced RA patients.

Patients and Methods: From May 2008 to March 2009, a total of 255 RA patients were enrolled and received 8 mg/kg every four weeks of TCZ treatment. Disease activity was assessed using DAS28-ESR, joint damage using the van der Heijde modified total Sharp score (mTSS), and functional disability using the health assessment questionnaire (HAQ) score. Safety was assessed by identifying adverse events for which a causal relationship with TCZ could not be ruled out. The last-observation-carried-forward method was used in each of the analyses.

Results: The mean (± SD) of each parameter at baseline were as indicated below, age; 59.1 ± 13.3 years, duration of RA; 12.4 ± 11.1 years, mTSS; 140 ± 101, prior biologics user; 62.8%, concomitant methotrexate (MTX) user; 55.6% (the mean dose was 5.31 ± 4.8 mg/week), and concomitant corticosteroid user; 67.0% (the mean dose was 3.9 mg/day).

With the 52 weeks TCZ treatment, the mean DAS28-ESR was significantly improved from 5.72 at baseline to 3.2 at week 52, and clinical remission was achieved in 42% of patients, and 55% of the patients reached low disease activity criteria. The individual parameters of DAS28-ESR decreased significantly until 24 weeks after starting treatment with TCZ, and this efficacy was maintained until 52 weeks.

The estimated yearly progression of mTSS was also significantly improved from 26.0 at baseline to 1.1 at week 52 ($p<0.0001$). Cumulative probability analysis showed that progression of joint damage was inhibited in 61.7% of patients. Similarly, erosion was inhibited in 75.8% and joint space narrowing was inhibited in 71.1% of patients.

Based on the HAQ scores, extremely severe functional disability was evident before treatment, with a mean score of 1.56. After treatment with TCZ for 52 weeks, the HAQ score decreased to 1.29 with a gradual decline. Defined as HAQ score ≤ 0.5, functional remission was achieved by 26.4% of patients.

The 52-week retention rate was approximately 72%, independent of history of prior therapy with biologics. In contrast, the patients taking MTX achieved the higher continuation rate, compared to those without MTX.

Conclusions: This study showed that clinical remission was achieved in 42% of the patients with 12.4 years of disease duration and progression of joint damage is inhibited appreciably by treatment with TCZ in daily clinical practice. Given the results that functional remission was obtained about one fourth of the patients, which is apparently lower than that of clinical remission, early treatment with TCZ before irreversible and progressed disability by structural damage is important to achieve higher rate for all three remission criteria.

1794

Comparable Persistency and Effectiveness of Abatacept Versus Anti-TNF Agents in the Treatment of Biologic-Naïve Rheumatoid Arthritis Patients Using the CORRONA Registry. Leslie Harrold[3], George Reed[3], Lisa C. Rosenblatt[1], Monica Mody[1], Diane Moniz Reed[1] and Jeffrey Greenberg[2]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]NYU Hospital of Joint Diseases, New York, NY, [3]University of Massachusetts Medical School, Worcester, MA

Background: For RA patients who are new candidates for biologic treatment, there is limited observational data to guide physician decision making with respect to the relative merits of an anti-TNF as compared to a non-anti-TNF biologic, such as abatacept (ABA).

Objective: To examine the persistency and effectiveness of ABA versus anti-TNF agents among biologic-naïve RA patients in a multi-centered observational registry within the United States.

Methods: Using data from the Consortium of Rheumatology Researchers of North America (CORRONA) from 2/20/02–12/31/09, RA patients who initiated ABA or an anti-TNF and were not in remission (based on Clinical Disease Activity Index; [CDAI]) at the time of initiation were identified. Anti-TNF to ABA initiators (3 to 4:1) were matched based on age, RA

duration, MTX use at initiation, initiation time frame (at or prior to index visit) and baseline CDAI. Persistency was evaluated 24 mths post-initiation using Kaplan–Meier curves. The likelihood of discontinuation was examined using Cox proportional hazard models, adjusting for clustering by physician, matched clusters and concomitant medications (MTX and prednisone). Effectiveness was measured at ~1 yr (±3 mths) after initiation of biologics by patient global assessment and pain, using an intention-to-treat (ITT; including all initiators) analysis as well as a completers analysis (only included those who remained on drug). Regression models were performed to adjust for clustering by physician matched clusters and baseline differences.

Results: After matching, there were 57 ABA initiators and 213 anti-TNF initiators. Both groups were mostly female (77–81%) with a mean age of 64–66 yrs, mean disease duration of 9–10 yrs and a mean CDAI of 17.8. At baseline, there were no differences between ABA and anti-TNF initiators, in terms of swollen and tender joint count, physician and patient global assessment, and ESR. Unadjusted persistency for ABA at 6, 12 and 24 mths was 84, 72 and 56%, respectively. Among anti-TNF users it was 81, 67 and 55%, respectively. The adjusted hazard ratio for discontinuing ABA as compared with anti-TNF over the 24-mth period was 0.88 (95% CI: 0.51–1.52). Among patients with a follow-up visit at 1 yr (ABA=37; anti-TNF=149), the estimated change in patient global assessment was 4.07 more in ABA patients (–4.07 [95% CI: –13.09 to 4.95]) as compared with anti-TNF patients in adjusted analyses among those who remained on drug at follow-up (ABA n=30/37; anti-TNF 106/149) and 2.62 more (–2.62 [95% CI: –10.82 to 5.58]) in the ITT population. In adjusted analyses, the estimated change in patient pain was 5.09 more in ABA patients (–5.09 [95% CI: –13.82 to 3.64]) as compared to anti-TNF patients among those who remained on drug at follow-up (ABA n=30/37; anti-TNF 108/149) and 4.76 more (–4.76 [95% CI: –12.9 to 3.44]) in the ITT population.

Conclusions: In this small sample of RA patients in a real world setting, treatment with ABA was comparable in persistency or effectiveness to anti-TNFs. This study suggests similar effectiveness of ABA and anti-TNFs in biologic-naïve RA patients, and further research with a larger sample size should be undertaken to confirm these findings.

1795

Comparative Effectiveness of Biological Treatment Options Following Tumor Necrosis Factor α Inhibitor Failure in Rheumatoid Arthritis: Systematic Review and Indirect Pairwise Meta-Analysis. Monika Schoels[1], John B. Wong[2], Daniel Aletaha[3] and Josef S. Smolen[4]. [1]2nd Department of Internal Medicine, Hietzing Hospital, Vienna, Austria; Div. of Clinical Decision Making, Informatics and Telemedicine, Tufts University School of Medicine, Boston, MA, [2]Div. of Clinical Decision Making, Informatics and Telemedicine, Tufts University School of Medicine, Boston, MA, [3]Division of Rheumatology, Department of Medicine 3, Medical University of Vienna, Austria, [4]Division of Rheumatology, Department of Medicine 3, Medical University of Vienna, Austria; 2nd Department of Internal Medicine, Hietzing Hospital, Vienna, Austria

Background: The optimal treatment for rheumatoid arthritis (RA) patients who fail tumor necrosis factor α inhibitors (TNFi) remains uncertain; direct randomized controlled trials comparing therapeutic options are lacking. Therefore, we indirectly compared drug efficacy and safety of biologic agents following inadequate response to TNFi. Additionally, we investigated the dependence of success rates on the number of previously failed TNFi.

Methods: We performed a systematic literature search and retrieved randomized controlled trials (RCTs) that enrolled patients who had experienced TNFi failure. After assessing the heterogeneity of trial populations at baseline, we performed an indirect meta-analysis with pairwise comparisons of drug efficacy and safety using a random effects model. We used published clinical trial data on abatacept (ABA), rituximab (RTX), and tocilizumab (TOC) to perform the analyses; for golimumab (GOL), we obtained ACR20, 50 and 70 response rates in the subpopulation of patients treated with concomitant methotrexate (MTX) for 24 weeks to match the other trials. We derived odds ratios (OR) for ACR response and ascertained risk differences (RD) for adverse events, serious adverse events and infection rates. In sub-analyses, we investigated whether multiple previous TNFi failures diminished the clinical response when compared to the efficacy of biologicals after one TNFi.

Results: In four RCTs with 24 week follow-up, direct comparisons of abatacept, golimumab, rituximab, and tocilizumab versus placebo showed statistically significant mean odds ratios for ACR20 (point estimates ranging from 3.3–8.9), ACR50 (5.5–10.2) and ACR70 (4.1–13.5). The risk for adverse events, serious adverse events, and serious infections was non-significant compared with placebo. Indirect pairwise comparisons of the four biologic agents showed no statistically significant differences in ACR50 and ACR70 outcomes. Golimumab had a significantly lower ACR20 response (OR 0.56–0.59) but significantly fewer adverse events (RD 0.13–0.18). Drug efficacy outcomes following multiple previous TNFi failures did not differ significantly from patients with a history of 1 TNFi (data for comparison was available for golimumab and tocilizumab, Figure).

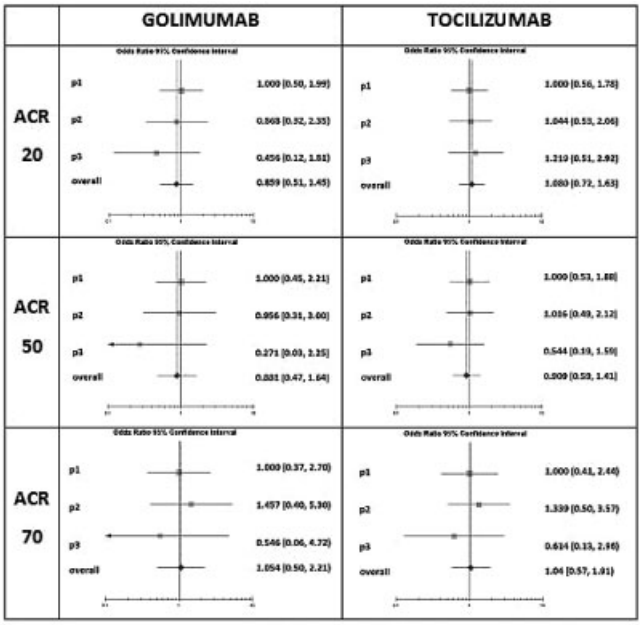

Figure. Response rates of GOL (left column) and TOC (right column). ACR20 (top panel), 50 (middle panel), and 70 (lower panel) of patients that had previously failed 2 (p2) and 3 (p3) TNFi, when compared to drug response rates after failure of 1 TNFi (p1).

Conclusions: In patients refractory to one or more TNFi, new biological agents provide significant improvement with good safety. In the absence of head-to-head trials, adjusted indirect meta-analysis enables evaluation of the comparative effectiveness and safety of biologics with each other and reveals similar effects of all biologicals.

1796

Comparative Effectiveness of Rituximab in Combination with Either Methotrexate or Leflunomide in the Treatment of Rheumatoid Arthritis. Javier Narvaez[4], César Díaz Torné[2], José Miguel Ruiz[3], Maria Victoria Hernández[1], Vicens Torrente[2] and Sergio Ros[3]. [1]Department of Rheumatology, Hospital Clinic, Barcelona, Spain, [2]Department of Rheumatology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [3]Department of Rheumatology, Hospital de Viladecans, Barcelona, Spain, [4]Department of Rheumatology, Hospital Universitario de Bellvitge, Barcelona, Spain

Background: Rituximab (RTX) has only been approved in combination with methotrexate (MTX) for patients with rheumatoid arthritis (RA) who have not responded to treatment with tumour necrosis factor (TNF) blocking agents. When MTX is contraindicated, RTX in combination with other DMARDs is increasingly used, despite a lack of specifically-designed, randomised clinical trials assessing these alternative combination therapies. In this context, real-world data on the effectiveness and safety of treatment combinations arising from observational cohort studies are the second-best source of evidence. One treatment option lacking sufficient supporting data is the combination of RTX with leflunomide (LEF). To date, only a small retrospective case series of ten patients has been published, with promising results.

Purpose: To compare the effectiveness of a combination of RTX with either MTX or LEF in the treatment of patients with active RA and inadequate response to anti-TNF agents or traditional DMARDs in a real-world setting.

Methods: Data from 77 consecutive unselected patients with active RA and treated with at least one cycle of RTX (1 g × 2 weeks) plus MTX or LEF were retrospectively collected. The primary endpoint of this retrospective analysis was the DAS28 response rate at month 6, according to the EULAR improvement criteria. Secondary efficacy endpoints included the percentage of patients in remission (DAS28 < 2.6) and with low disease activity (defined as DAS28 ≤ 3.2), the percentage of patients that fulfilled the ACR50 and ACR70 response criteria, and the variations in level of disability as established by the HAQ score. The ACR and EULAR response considered for the analysis was the maximal clinical response obtained between the end of month +4 and the end of month +6 of follow-up after the first cycle of RTX.

Results: Of the 77 patients, 45 received RTX+MTX and 32 RTX+LEF. At baseline there were no significant differences between the groups in terms of the main clinical and laboratory data, or in the number of previous DMARDs and anti-TNF agents used. The responses at six months are presented in the following table:

Treatment response rates at 6 months of therapy

	RTX+MTX (N=45)	RTX+LEF (N=32)	P
DAS28	4.24 (1.52)	3.85 (1.61)	0.2826[2]
Change in DAS 28	−1.68 (1.38)	−1.72 (1.43)	0.3103[2]
Change% in DAS28	−28.85 (−73, 35)	−26.41 (−92, 7)	0.7158[2]
EULAR response good-moderate	34 (75.5%)	25 (78.1%)	d=−2.6 CI: (020.5, 17.2) (>0.05)
Good	10 (22.2%)	8 (25%)	d=−2.8 CI: (−22.4, 15.5) (>0.05)
Moderate	24 (53.3%)	17 (53.1%)	d=0.2 CI: (−21.2, 21.8) (>0.05)
None	11 (24.4%)	7 (21.8%)	d=2.6 CI: (−17.2, 20.5) (>0.05)
DAS28 <3.2 (%)	11 (24.4%)	11 (37.3%)	0.3418[1]
DAS28 <2.6 (%)	4 (8.8%)	6 (18.7%)	0.303[4]
ACR50 responders (%)	6 (13.3%)	7 (21.8%)	0.324[1]
ACR70 responders (%)	1 (2.2%)	2 (6.2%)	0.3680[1]
HAQ	0.5 (0, 3)	0.75 (0, 3)	0.4612[3]
Change in HAQ	−0.68 (−3, 1)	−0.64 (−2, 2)	0.9149[3]
Change% in HAQ	−60.00 (−100, 100)	−50.00 (−94, 700)	0.2468[3]

Results are presented as mean (standard deviation), median (minimum, maximum) and counts and percentages. D=differences; CI=95%confidence interval.
[1]Chi-square, [2]t-test, [3]Median test, [4]Fisher test.

Minor adverse events occurred in 8.8% (4/45) of RTX+MTX patients and in 9.3% (3/32) of RTX+LEF patients. None of the patients had serious adverse events and none discontinued the treatment.

Conclusion: Current clinical practice is to use MTX as a first choice for combination with RTX. However, in a number of patients MTX has to be replaced by another DMARD. Our preliminary data support the view that LEF is a useful alternative if MTX is contraindicated, since its effectiveness and safety seem similar.

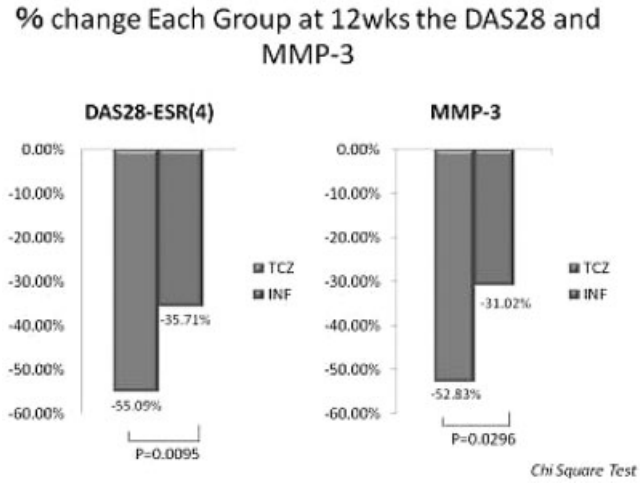
1797

Comparison of Tocilizumab and Infliximab Treatment for RA for a Duration of 12 Weeks, Based on MMP-3: Preliminary Report. Isamu Yokoe[1], Hitomi Kobayashi[2], Hiroshi Sato[2] and Shinya Nishio[2]. [1]Itabashi Chuo Medical Center, Tokyo, Japan, [2]Itabashi Chuo Medical Center

Purpose: MMP-3, an enzyme produced by synoviocytes, is a marker of synovitis, providing a more direct indication of actual joint destruction than CRP or ESR. It is potentially useful to detect synovitis at an early stage. A synergistic effect of IL-6 and either TNF or IL-1 induces MMP-3 production, and inhibition of IL-6 may alleviate synovitis by inhibiting both synergistic effects, but inhibition of only TNF or IL-1, only inhibits an additive effect. To measure this difference in RA treatments, infliximab (INF, an anti-TNF α antibody) and tocilizumab (TCZ, an anti-IL-6-receptor antibody) were given to groups of RA patients. Changes in MMP3 and improvement in the DAS were then compared between the INF and TCZ groups.

Methods: Consecutive Patients diagnosed with RA according to ACR criteria, were resistant to DMARDs, had moderate to severe activity, and complied with the Guideline for Biological Products of the Japanese College of Rheumatology, received either TCZ 8 mg/kg at Weeks 0, 4 and 8 or INF 3 mg/kg at Weeks 0, 2 and 6. Age, duration of illness, staging, classification, anti-CCP antibody, RF factor, PSL dose, mHAQ, DAS28 (ESR4), MMP-3, etc., were then compared between the 2 groups at baseline and after 12 weeks of administration. Chi-square test, Pearson test and Tukey-Kramer test were used to find statistical significance.

Results: TCZ and INF were respectively given to 20 and 24 patients, with a mean age of 60.2 ± 13.1 and 57.8 ± 12.4 years (P=0.40), and a mean duration of illness of 94.85 ± 93.5 and 70.0 ± 81.9 (P=0.45) months. Female ratio, staging, classification, anti-CCP antibody, RF factor, PSL dose (3 mg vs 4 mg, P=0.20), MTX dose (6 mg vs 7.3 mg, P=0.12), HAQ (0.675 vs 0.53, P=0.9) and MMP-3 (241 ng/mL vs 296 ng/mL, P=0.65) showed no significant differences between the 2 groups at baseline. In the TCZ group, 55% used MTX concomitantly, and 25% had not responded to TNF inhibitors previously. At baseline, the INF group included more patients with high disease activity than the TCZ group based on DAS28 (ESR4) (4.65 vs 5.33, P=0.027). After treatment, DAS28 (ESR4), mHAQ and MMP-3 values showed statistically significant improvement, but there were not significant differences between the 2 groups. The TCZ and IFX groups did, however, show significant changes in DAS28 score (−55% vs −36%, P=0.009) and MMP-3 level (−53% vs −31%, P=0.03).



MMP-3 and DAS28 (ESR4) were correlated in the 2 groups.

Conclusions: MMP-3 decreased earlier in the TCZ group than the IFN group, suggesting that TCZ can control progression of synovitis earlier than IFN. DAS28 also decreased in correlation with the MMP-3 value, so TCZ may suppress activity earlier than INF. However, the evaluated study population was very small and further study is required to draw a definite conclusion.

CTLA-4-Ig Fusion Protein (Abatacept) Modulate Inflammatory Activity of Cultured Synovial Macrophages from Rheumatoid Arthritis Patients. Maurizio E. Cutolo[6], Stefano Soldano[3], Paola Montagna[3], Alberto Sulli[3], Bruno Seriolo[3], Barbara Villaggio[4], Pier Franco Triolo[5], Paolo Clerico[5], Lamberto Felli[1], Luigi Molfetta[2] and Renata Brizzolara[3]. [1]Academic Orthopedic Department, University of Genova, Italy, [2]Orthopedic Unit, San Martino Hospital, Genova, Italy, [3]Research Laboratories and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Italy, [4]Research Laboratory of Nephrology, Department of Internal Medicine - University of Genova, Italy, [5]Rheumatoid Arthritis Unit – Orthopedic Surgery Department. CTO Hospital, Turin, Italy, [6]University of Genova, Genova, Italy

Background: CTLA-4-Ig, a biological agent employed in rheumatoid arthritis (RA) [1], is a fusion protein of the extra-cellular binding domain of human CTLA-4 with the Fc region of human IgG1. CTLA-4-Ig, like the native CTLA-4, binds more avidly than CD28 (T cells) to CD80(B7.1)/CD86(B7.2) on antigen presenting cells (APCs) [2], blocking CD28/B7 and CTLA-4/B7 interactions and downregulating immune activation in RA patients [3].

Our previous data in vitro demonstrated that CTLA-4-Ig blockade, in RA synovial macrophages/T cells co-cultures, resulted to induce anti-inflammatory effects [4].

The aim of this study was to investigate in vitro if CTLA-4-Ig directly affect the inflammatory activation of the cells of the monocytic lineage in monocultures of RA SM, in the absence of T cells.

Methods: RA SM were obtained from patients (5 females, 1 male; mean age 50±2 yrs; DAS28>5.2) who underwent therapeutic arthroscopic synoviectomy, after informed consent and in accordance with the local Ethical Committee. After 24 hours of culture, in the absence, as well as in the presence of CTLA-4-Ig at different in vitro concentrations (100, 500 μg/ml), RA SM were harvested and the expression of inflammatory cytokines (IL-6, TNFα, IL-1β) and TGFβ were evaluated by immunocytochemistry (ICC) (all mAbs diluited 1:100, Santa Cruz Biotechnology, Santa Cruz, CA, USA), with relative image analysis (Leica Q-Win image analysis system, Leica, Cambridge, UK) and western blot (WB) analysis. In addition, quantitative real-time PCR (qRT-PCR) analysis of mRNA was performed for IL-6, TNFα and IL-1β. Experiments were performed in triplicate.

Results: ICC image analysis revealed that the addition of CTLA-4-Ig 500 μg/ml in cultures of RA SM was able to significantly downregulate the cytokine expression ($p<0.001$ for IL-6 and TGFβ; $p<0.01$ for TNFα and IL-1β), compared to untreated RA SM. Moreover, the treatment with CTLA-4-Ig 100 μg/ml already showed a significant decrease for IL-6 ($p<0.001$) and IL-1β ($p<0.05$) and only TGFβ expression shown a significant variation for CTLA-4-Ig 100 μg/ml treatment compared to CTLA-4-Ig 500 μg/ml ($p<0.01$).

WB and qRT-PCR analysis confirmed these results and revealed a mild decrease in the amount of inflammatory cytokine production after CTLA-4-Ig 500 μg/ml treatment compared to untreated RA SM.

Conclusions: We provide evidence for a CTLA-4-Ig dose-dependent anti-inflammatory effect in vitro, in RA SM cultures. The addition of CTLA-4-Ig resulted in downregulating IL-6, TNFα, IL-1β and TGFβ production. Therefore, even if the best-defined mechanism of action of CTLA-4-Ig is the inhibition of the T cell co-stimulatory pathway, this study identifies the SM as further possibile target cells of CTLA-4-Ig treatment in RA.

1799

Dosing of Anti-Tumor Necrosis Factor Biologics (Anti-TNFs) for Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) in Clinical Practice in the United States. J. Timothy Harrington[5], Dimitrios A. Pappas[2], Susan Messing[4], Xin Tu[4], Rui Chen[4], Kimberly Kaukeinen[4], Timothy Pietras[4], Jeffrey D. Greenberg[1] and Joel M. Kremer[3]. [1]Millburn, NJ, [2]Johns Hopkins University, Baltimore, MD, [3]The Center for Rheumatology, Albany, NY, [4]University of Rochester Medical Center, [5]University of Wisconsin, Madison, WI

Background: RA and PsA patients experience variable responses to biologics, and recommended doses and frequency of administration vary among the alternative anti-TNFs. Accelerated dosing is approved for infliximab (INFL) infusions, but varies for the other individual anti-TNFs. Switching among anti-TNFs and to biologics with alternative therapeutic targets has also not been well studied in a US population. Insurers often deny higher dosing of anti-TNFs as experimental treatment, while at the same time, therapeutic acceleration is being recommended to achieve optimal disease control and long term outcomes, as for example in the Treat to Target initiative.

Objective: To study rheumatologists' current choices of biologic agents in clinical practice, and the dosing of anti-TNFs in patients with RA and PsA enrolled in the CORRONA observational registry (Consortium of Rheumatology Researchers of North America, Inc.)

Methods: Biologic drug use is collected during routine office visits for the CORRONA enrolled RA and PsA patient populations. Food and Drug Administration (FDA) approved doses and frequencies are specified on the questionnaires, and space to indicate other dosing is also provided. Golimumab was not specified previously. Other doses, and/or frequencies of ant-TNF administration were pooled for this abstract into lower or higher than the specified categories. These data were obtained from the most recent visit report for all enrolled patients.

Results: Current biologic treatments were reported for 8706 of 22973 RA enrollees (38%) and 1742 of 3604 PsA enrollees (48%). For RA, these included: INFL (2733/8706, 31%), ETAN (2819, 32%), ADAL (1935, 22%), and all other biologics (1219, 14%). For PsA, these included: INFL (460/1742, 26%), ETAN (768, 44%, ADAL (495, 28%), and all other biologics (19, 1%). Anti-TNFs account for 86% of biologic use for RA, and 99% for PsA. Anti-TNF dosing for INFL, ETAN, and ADAL is shown in Table 1. Higher doses and/or frequencies of administration than those recommended are commonly reported.

Table 1. Dosing of Anti-TNFs (Number RA/Number PsA)

Infliximab (mg)	<300	3–<600	6–<900	9–<1200	>1200
	332/34	1806/261	508/133	68/24	19/8
Etanercept (mg)	Lower	25/wk*	25 2x/wk*	50/wk*	Higher
	26/17	119/23	410/121	1839/485	20/21
Adalimumab (mg)	Lower	40/2wks*	40/1.5wks	40/wk	
	19/8	1532/397	24/7	354/82	

*recommended doses for etanercept and adalimumab

Conclusions: 1. Choices and dosing of biologic drugs vary greatly across these RA and PsA populations. 2. Higher doses of anti-TNFs are commonly prescribed, suggesting that dosage acceleration is being considered for patients who experience a partial response to initial doses. 3. Further studies are needed regarding clinical outcomes, relative safety, and cost effectiveness of higher dose biologic treatment. 4. The results of these studies will likely differ in the US and other countries where biologic drugs are less commonly prescribed.

Drug Free REmission after Cessation of Tocilizumab (Actemra) Monotherapy (DREAM Study). Norihiro Nishimoto. Wakayama Medical University, Ibaraki-City, Japan

Purpose: Tocilizumab (TCZ) has been demonstrated to frequently induce remission according to the DAS28 in patients with rheumatoid arthritis (RA). With long-term TCZ treatment reduced serum IL-6 levels have been observed in some patients, although TCZ does not directly act on IL-6, but inhibits the IL-6 receptor. It may be possible to discontinue TCZ in such patients without causing acute flare of the disease. We have previously reported that the serum IL-6 level correlates with actual in vivo IL-6 production and disease activity in patients with RA. Here we aimed to determine the rate of efficacy continuation at 52 weeks after cessation of TCZ treatment, and explore the factors that contribute to the duration of efficacy.

Methods: Patients who achieved DAS28<2.6 at the last observation of the previous Japanese TCZ clinical trials were enrolled and monitored for their disease activities without DMARDs. Patients with DAS28<3.2 were additionally enrolled to know if the disease activity at TCZ discontinuation might influence the efficacy duration. The loss of efficacy was defined as either DAS28>3.2 at two consecutive visits, initiation of additional RA treatments including increase in corticosteroid dose, or patient's request for retreatment. We estimated the efficacy continuation rate from Kaplan-Meier curves.

Results: A total of 187 patients were enrolled. Baseline characteristics of the patients were as follows: median disease duration, 7.8 years; median previous TCZ treatment for 4.0 years; median DAS28, 1.5 (remission rate 90%); 34.2% received corticosteroid and mean dose was 2.8 mg/day in these patients. The efficacy continuation rate was 35.1% at 24 weeks and 13.4% at 52 weeks. Efficacy continued in 24 patients as long as 52 weeks. Furthermore 19 patients were completely free from any drug. Multivariate Cox regression analysis revealed that baseline disease duration of the patients did not influenced efficacy duration after cessation of TCZ. However low serum IL-6 (<35 pg/mL) and normalization of MMP-3 level at TCZ discontinuation were identified as independent predictive markers for the longer efficacy duration. The estimated efficacy continuation rate in the patients both with serum IL-6 ≤12.9 pg/mL, which was calculated from receiver operating characteristic (ROC) curve, and with normal MMP-3 level was 70.6% at 24 weeks and 38.0% at 52 weeks, respectively. On the other hand, loss of efficacy among those with an IL-6 level higher than 35pg/mL was seen in 68.6% of patients within 12 weeks.

Conclusion: Efficacy continued after TCZ cessation without use of any DMRAD in 13.4% of the patients. Patients with normalization IL-6 and MMP-3 levels showed much longer duration of efficacy after cessation of TCZ.

1801

Effect of Rituximab Treatment on Il-15 and T Cell Subpopulations in Rheumatoid Arthritis Patients. Cesar Diaz-Torne[1], Maria A. Ortiz[1], Carme Geli[1], Josep M. Llobet[1], Elisabeth Cantó[1], Elena Perez[1], Hector Corominas[2], Candido Juarez[1], Cesar R. Diaz-Lopez[1] and Silvia Vidal[1]. [1]Hospital de la Santa Creu i Sant Pau, [2]Hospital Moises Broggi

Rituximab is a therapeutic anti-CD20 antibody used for in vivo depletion of B cells. However, the mechanisms of action are not fully understood because clinical responses do not always correlate with the extent and duration of B cell depletion. This study was conducted to examine the effect of B cell depletion on peripheral T cells from rheumatoid arthritis patients after the first infusion and to compare the results with consecutive infusions.

Methods: 26 active RA patients received rituximab (1000 mg) on days 1 and 15. Following infussions were done depending clinical evolution (Never before six months) Peripheral blood samples were collected at baseline and at 30, 90 and 180 days postinfusion. The phenotype of T cell subsets of peripheral blood from RA patients were examined by cytometry and cytokine production was determined by ELISA and flow cytometry. Results from four consecutive infusions were compared and correlated with DAS28 activity index. Linear regression analysis was used to associate cellular changes and disease activity.

Results: Mean age was 61,5±11,5 years. 92,3% were women. Mean RA evolution was of 18,2±11,9 years. Previous DMARDs and biological therapies were 3,17±1,32 and 1,49±0,85 respectively. 50% were treated just with rituximab and the other 50% on combination with a DMARD. 96,2% were also using glucocorticoids. 96,2% had a positive antiCCP and/or rheumatoid factor. 89,5% had an erosive arthritis and 42,1% had a history of rheumatoid nodules. Patients previous DAS28 to treatment was 5,64±0,98.

According to our previous results, peripheral B cell depletion was fully effective by 30 days. No changes in the percentage of CD3+, CD4+, CD8+ and NK cells were found in the first as well as the two following infussions. Similarly to our observations in the first infussion, there was a comparative progressive diminution of CD8+CD45RO+ cells with the recovery starting at 180 days. DAS28 significantly correlated with CD8+CD45RO+ cells in the first and subsquent rituximab infussions. Since CD8+CD45RO+ diminution was coincident with the clinical response measured as DAS28, we investigated whether IL-15 could be responsible for this population changes in rheumatoid arthritis patients. As expected there was significant levels of IL-15 in the serum RA patients (110 ± 31 pg/ml) compared to healthy donors (< 10 pg/ml). Rituximab treatment decreased IL-15 levels in serum from rheumatoid arthritis patients. Although, no significant correlation was observed between IL-15 in the serum and CD8+CD45RO+ cells, levels of IL-15 trans-presented on the surface of neutrophils from RA patients significantly correlated with CD8+CD45RO+ ($p<0.01$) cells and CD8+CD45RO+/RA+ ratio ($p<0.001$).

Conclusions: This study demonstrates for the first time that rituximab treatment is able to reduce IL-15 levels. This reduction could be responsible for the observed CD45RO+ changes during the follow-up of these patients.

1802

Effectiveness of Different DMARD Co-Therapies in Rituximab-Treated Rheumatoid Arthritis (RA) Patients–Results of a One-Year Follow Up Study from the CERRERA Collaboration. Cem Gabay[12], Katerina Chatzidionysou[11], Elisabeth Lie[5], Galina Lukina[9], Merete L. Hetland[2], Ulrik Tarp[3], Piet L. Van Riel[14], Dan Nordström[6], Juan J. Gomez-Reino[7], Karel Pavelka[1], Matija Tomsic[13], Evgeny L. Nasonov[8], Tore K. Kvien[4] and Ronald Van Vollenhoven[10]. [1]Charles Univ, Prague, Czech Republic, [2]Copenhagen Univ Hosp Hvidovre, Hvidovre, Denmark, [3]Copenhagen Univ Hosp Hvidovre, [4]Diakonhjemmet Hospital, Oslo, Norway, [5]Diakonhjemmet Hospital, Oslo, Norway, [6]Helsinki Univ Hosp, Helsinki, Finland, [7]Hospital Clinico Universitario, Santiago, Spain, [8]Institue of Rheumatology, Moscow, Russian Federation, [9]Institute of Rheumatology, Moscow, Russia, [10]Karolinska University Hospital, Stockholm, Sweden, [11]Karolinska, Stockholm, Sweden, Sweden, [12]Univ Hosp of Geneva, Geneva, Switzerland, [13]Univ Medical Center, Ljubljana, Ljubljana, Slovenia, [14]University Hosp Nijmegen, Nijmegen, The Netherlands

Background: Clinical trials have shown that rituximab (RTX) is efficacious in RA patients when prescribed in combination with methotrexate (MTX). However, some patients do not tolerate MTX, and are treated either with other DMARDs such as leflunomide (LEF) or without co-therapy. The purpose of this study was to compare the effectiveness and safety of rituximab alone or in combination with either MTX or LEF.

Methods: Ten European registries submitted anonymized datasets with baseline, 3, 6, 9 and 12 month clinical data for patients who had started RTX. Baseline and follow-up data included disease duration, number of previous biologic agents, disease activity (DAS28), functional disability (HAQ), concomitant DMARDs, corticosteroid use, and RTX retreatment. Patients were separated into three groups: RTX+MTX, RTX+LEF, and RTX alone. Patients receiving other DMARDs or combinations of DMARDs were excluded. Chi-square tests were used to compare the EULAR good response rates. Baseline values and mean changes were compared using ANOVA followed by Dunn/Bonferroni post-hoc testing. Logistic regression analyses were performed using co-therapies as independent variables.

Results: 2265 patients were analyzed: 1195 treated with RTX+MTX (mean dose (mg) of MTX was 14.4 ± 5.4 weekly), 177 with RTX+LEF, and 505 with RTX alone. At baseline, RTX alone patients were significantly older (55.2 ± 12.9 vs. 52.3 ±12.1 and 51.9 ±13.1), had longer disease (13.2 ± 10.1 vs. 11.4 ± 7.9 and 11.7 vs. 8.8), had more previous biological agents (1.1±1.1 versus 0.7±1.0 and 1.0±1.1) and previous DMARDs (2.8±1.8 versus 2.5±1.4 and 2.6±1.5) than RTX+LEF and RTX+MTX, respectively. Fewer patients on RTX+MTX were RF (74.5%) and anti-CCP positive (73.6%) than patients on RTX+LEF (77.6% RF+, 77.5% anti-CCP+) or RTX alone (78.8% RF+, 76.9% anti-CCP+).

Significantly more patients achieved a EULAR good response at 6 months when treated with RTX+LEF (29.1%) as compared to RTX+MTX (20.7%) and RTX alone (19.5%), P=0.04 and P=0.04, respectively. At 12 months an even greater percentage of good responders was observed in the RTX+LEF group (31.4%), while the percentage of good responders remained stable in the RTX+MTX and RTX alone groups (p=0.005 and p=0.01 respectively). RTX+LEF was significantly more often associated with a good EULAR response compared to RTX+MTX at 6 months (OR, 95% CI: 1.6, 1.0–2.5) and at 12 months (1.8, 1.2–2.8), P=0.04 and P=0.005, respectively. Similarly, RTX+LEF was also more often associated with a EULAR good response compared to RTX alone at 6 and 12 months (OR, 95% CI: 1.7, 1.0–2.8 and 1.8, 1.1–2.9, P=0.04 and P=0.01, respectively). Fewer patients with RTX + LEF were retreated during the first 12 months (19.2%) compared with RTX+MTX (27.9%) or RTX alone (21.8%). Adverse events occurred in 14.1%, 16.2%, and 16.4% of patients in RXT+LEF, RTX+MTX, and RTX alone, respectively.

Conclusion: The results of this large multinational cohort of patients show that LEF is effective and safe in combination with RTX. The finding that the efficacy of RTX in combination with LEF was greater than with MTX must be confirmed in further studies but suggests the possibility of a pharmacological synergism between the two agents.

1803

Effects of Anti-TNF Agents on the Lung Function of Patients with Rheumatoid Arthritis: A Prospective Study. Meryem Can[1], Sait Karakurt[3], Atilla Bulur[1], Pamir Atagündüz[1], Sule Yavuz[2], Haner Direskeneli[2] and Nevsun Inanç[2]. [1]Marmara University Medical School, Division of Rheumatology, Istanbul, Turkey, [2]Marmara University Medical School, Division of Rheumatology, [3]Marmara University Medical SchoolDepartment of Pulmonary and Critical Care, Istanbul, Turkey

Background: The current evidence argues for caution in using TNF-targeted therapies in rheumatoid arthritis (RA) patients with pre-existing lung disease. Although the etiology of interstitial lung disease (ILD) in RA is still unclear, several cytokines are believed to play important roles in the pathogenesis of ILD.

Objective: To investigate both beneficial and adverse effects of anti-TNFα agents on the lung function of patients with RA in a 6 months follow-up study, to determine whether high resolution computed tomography (HRCT) findings correlated with clinical and pulmonary function test (PFT) abnormalities and to identify whether serum cytokines levels have an association with ILD in RA.

Methods: Fourty RA patients (F/M:33/7) were enrolled to the study. Infliximab (n=9), etanercept (n=12) and adalimumab (n=19) were started according to current guidelines in Turkey. The rate of concomitant metotrexate usage was 70%. Disease activity was assessed by DAS28. HRCT, pulmonary function test (PFT) and diffusing capacity of the lung for carbon monoxide (DLCO) were performed in all patients before and after 6 months of anti-TNFα treatment. Serum cytokines were measured by multiplex ELISA assay (IL1, IL6, MCP, TNF, VEGF, IFN gamma, IL10, IL12, IL13) at baseline and at 6 month's visit.

Results: Mean(SD) age was 48.8(11.8) and mean disease duration was 8.4(4.9) years. Anti-CCP and RF positivity were 55,6% and 80% respectively. Mean DAS28(SD) score was 5.5(1.1) and 4.2(3.2) at baseline and at 6 months' follow-up visit, respectively. None of the patients had severe respiratory involvement after starting treatment with anti-TNF agents. Significant improvements have been observed on respiratory parameters both by HRCT (77,5% vs 66,7%, p=0.01) and PFT (35.3% vs 30.8%, p=0.03) at 6 months' visit, however without a significant change in DLCO findings (14.7% vs 19.2%, p=0.3). At both evaluations bronchiectasis and interstitial lung disease were the most common pulmonary complications. When compared to the baseline findings, the number of patients with bronchiectasis and ILD also decreased (n=16/ 9 vs 10/6, respectively) at 6 months' visit. When the relationship of interstitial pulmonary involvement with the baseline HRCT, serum cytokine levels and serologic findings (RF, CCP) were analyzed, higher levels of IL10 (p=0.025), IL1beta (p=0.03) and MCP (p=0.027) were found to be associated with interstitial lung disease in RA.

Conclusion: Our results suggest that HRCT is sensitive for monitoring pleuropulmonary changes in RA patients. Anti-TNF agents seem to improve the chances of recovery in interstitial lung disease.

1804

Effects of Subcutaneous and Intravenous Golimumab on Markers of Inflammation in Patients with Rheumatoid Arthritis. Mittie K. Doyle[4], Mahboob U. Rahman[4], Bart Frederick[2], Charles A. Birbara[6], Dick de Vries[1], Gary Toedter[3], Xiaoying Wu[3], Dion Chen[2], Mark Westerman[5] and Daniel E. Furst[7]. [1]Centocor B.V., Leiden, The Netherlands, [2]Centocor Research and Development, Inc., Malvern, PA, [3]Centocor Research and Development, Inc., [4]Centocor Research and Development, Inc./Univ. of Pennsylvania School of Medicine, Malvern, PA, [5]Intrinsic Life Sciences, [6]Univ. of Massachusetts City Campus, Worcester, MA, [7]University of California Los Angeles Medical School, Los Angeles, CA

Background: Treatment with the human anti-TNFα mAb golimumab, plus methotrexate, is effective in reducing the signs and symptoms of rheumatoid arthritis (RA). Elevated serum IL-6 and hepcidin have been associated with anemia of inflammation, common in RA pts, but the effects of golimumab on serum markers of inflammation and iron homeostasis are unknown.

Objectives: Assess early changes in inflammatory biomarkers, including CRP, IL-6, and hepcidin, in RA pts treated with golimumab (SC and IV).

Methods: In this phase 1, open-label study, pts ≥18 yrs with active RA for ≥3 months were randomized to receive SC injections of golimumab 100mg q4w through wk 20 or IV golimumab 2mg/kg at wks0&12. At wk24, the proportion of patients achieving ACR20/50/70 responses was determined. Blood samples for measuring serum levels of CRP, IL-6, SAA, TNFα, MMP-3, hyaluronic acid, ferritin, hepcidin, Hgb, and haptoglobin were collected at baseline, 24, 48, and 72 hrs, and at wks1, 2, 4, and 8. Urine hepcidin levels were measured at baseline, 48 hrs, and at wks2, 4, and 8.

Results: 49 pts were randomized to receive SC golimumab (n=33) or IV golimumab (n=16). Most patients were iron replete at baseline with mean ferritin >97ng/mL and mean transferrin saturations >22%. 5 pts (SC group) had mild anemia at baseline (Hgb=10.3–11.1 g/dL). For all pts, mean baseline CRP level was mildly elevated (1.1mg/dL), while mean hepcidin levels started and remained within normal ranges (17–286 ng/mL) throughout the study. Urine and serum hepcidin were positively correlated at all times. Overall, Hgb levels were maintained or increased. Mean serum CRP, IL-6, SAA, TNFα, MMP-3, haptoglobin, ferritin and hepcidin decreased rapidly within 2wks after the first golimumab administration and remained below baseline through wk8. Spearman's correlations showed decreases in serum hepcidin correlated with decreases in CRP and ferritin at most timepoints. At wk24, 62% of pts in SC group and 56% in IV group achieved ACR20, 31% and 25%, respectively, achieved ACR50, and 21% and 19%, respectively, achieved ACR70. Golimumab was generally well tolerated. Infections were the most common AEs (SC group, 39.4%; IV group, 31.3%). 2 pts in each group had SAEs, including noncardiac chest pain, pneumonia, and asthma; although none were considered related to golimumab therapy. There were no deaths in this study.

Conclusions: Both IV and SC golimumab were efficacious in reducing signs and symptoms of RA in this small phase 1 study. Very early decreases in mean serum levels of CRP, IL-6, SAA, TNFα, MMP-3, haptoglobin, ferritin, and hepcidin were evident. Decreases in CRP correlated with decreases in hepcidin, while concomitant decreases in ferritin were also observed, suggesting that golimumab treatment mobilized iron stores in these pts by reducing inflammation and in parallel, hepcidin levels. These observations support further study of hepcidin's role in RA and as a potential biomarker for clinical studies.

Efficacy and Safety of Certolizumab Pegol in a Clinically Representative Population of Patients (Pts) with Active Rheumatoid Arthritis (RA): Results of the REALISTIC Phase IIIb Randomized Controlled Study. Michael Weinblatt[2], Roy Fleischmann[8], Paul Emery[3], Niti Goel[11], Clifton O. Bingham[5], Janet Pope[9], Elena Massarotti[1], Ronald van Vollenhoven[6], Thomas W. J. Huizinga[7], Benjamin Duncan[10] and Maxime Dougados[4]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, [3]Chapel Allerton Hospital, Leeds, United Kingdom, [4]Hospital Cochin, Paris, France, [5]Johns Hopkins University, Baltimore, MD, [6]Karolinska Institute, Stockholm, Sweden, [7]Leiden University Medical Centre, Leiden, The Netherlands, [8]MCRC, University of Texas, Dallas, TX, [9]St. Joseph's Health Care, University of Western Ontario, London, ON, Canada, [10]UCB, Raleigh, NC, [11]UCB, Smyrna, GA

Background: Certolizumab pegol (CZP) is effective and well tolerated in pts with active RA when used with methotrexate (MTX) or given as monotherapy.[1–3] The objective of this study was to further investigate the safety and efficacy of CZP in a broader active RA population more closely resembling routine clinical practice.

Methods: REALISTIC (RA Evaluation in Subjects Receiving TNF Inhibitor Certolizumab Pegol) was a multicenter (North America and Western Europe) Phase IIIb trial in active RA pts with inadequate response to ≥1 DMARD including pts with prior TNF-inhibitor exposure (NCT00717236), stratifying by baseline (BL) MTX use, prior TNF-inhibitor use and disease duration. In the 12-wk double-blind (DB) phase, pts were randomized to CZP 400 mg at Wks 0, 2 and 4 and 200 mg at Wks 6, 8 and 10 or placebo injection (control) every 2 wks (Q2W) added to their current treatment. From Wk 12, open-label (OL) CZP 200 mg Q2W was given for ≥16 wks. Primary outcome was ACR20 at Wk 12. ACR responses were determined using NRI, and DAS28(CRP) and HAQ-DI using LOCF.

Results: Of the 1063 pts aged 19–86 (mean 55.1) years (78.0% female) who were randomized (CZP = 851; control = 212), 37.6% had prior TNF-inhibitor exposure. Mean HAQ-DI and DAS28(CRP) scores at BL were 1.50 and 5.71 for CZP and 1.61 and 5.71 for the control group. Duration of RA was 0.2–52.0 (mean 8.7, SD 8.8) years. Most pts (88.7% overall; CZP: 89.5%, n = 762; control: 85.4%, n = 181) completed 12 wks' therapy and entered the OL phase. The primary objective was met; ACR20 was achieved in 51.1% of CZP vs 25.9% of control pts (p<0.001) at Wk 12. Wk 12 ACR50 and ACR70 responses were 26.6% and 13.0% for CZP pts vs 9.9% and 2.8% for control pts (p<0.001 for both). CZP clinical responses were rapid; ACR20/50 responses were significantly superior to control (31.8% vs 8.5% and 9.6% vs 1.4%, p<0.001 for both) from first time point (Wk 2) onwards. Significant improvements in DAS28(CRP) were reported with CZP vs control from Wk 2 (–1.07 vs –0.42; p<0.001) through to Wk 12 (–1.64 vs –0.79, p<0.001). DAS28(CRP) remission (DAS28 <2.6) was achieved in 16.3% of CZP and 5.7% of controls (p<0.001) at Wk 12. CZP pts also reported rapid and significant improvements in HAQ-DI vs control: mean change from BL at Wk 2: –0.29 vs –0.12; p<0.001 to Wk 12: –0.43 vs –0.21; p<0.001. In CZP pts, BL use of MTX (yes vs no) did not markedly affect ACR20 responses (52.4% vs 48.3%), nor did prior use of TNF-inhibitor (47.2% vs 53.5%) at Wk 12. Similar ACR20 results were seen regardless of disease duration, activity and geographic region. Adverse and serious adverse

event rates were comparable between CZP and control groups (65.1% vs 59.3%, and 5.4% vs 6.2%), with no new safety signals and no cases of TB observed.

Conclusion: In a diverse group of RA pts reflecting those seen in daily clinical practice (including those with prior TNF-inhibitor use), addition of CZP to current therapy was associated with a rapid clinical response consistent in all strata, improved function and reduced disease activity with a favorable risk benefit profile.

Efficacy and Safety of Certolizumab Pegol Plus Methotrexate in Patients with Rheumatoid Arthritis (RA): 3-Year Data from the RAPID 2 Study.

Josef S. Smolen[4], Ronald F. van Vollenhoven[1], Arthur Kavanaugh[8], Niti Goel[7], Andreas Fichtner[6], Vibeke Strand[3], Jiri Vencovsky[5] and Desiree van der Heijde[2]. [1]Department of Rheumatology, Karolinska Institute, Stockholm, Sweden, [2]Department of Rheumatology, Leiden University Medical Center, Leiden University Medical Center, Leiden, Meerssen, The Netherlands, [3]Division of Immunology and Rheumatology, Stanford University School of Medicine, Palo Alto, CA, [4]Division of Rheumatology, Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [5]Institute of Rheumatology, Prague, Czech Republic, [6]UCB, Monheim, Germany, [7]UCB, Smyma, GA, [8]University of California-San Diego, La Jolla, CA

Background: Certolizumab pegol (CZP) every other week (EOW) + methotrexate (MTX) had rapid and sustained efficacy with an acceptable tolerability profile over 2 years (yrs) in patients (pts) with active RA despite MTX.[1–3] Here we evaluate the sustainability of improvements in RA signs and symptoms, inhibition of joint damage progression and tolerability of CZP + MTX over 3 yrs in pts who completed 24 weeks (wks) of double-blind treatment with CZP 200 or 400 mg EOW + MTX (completers) in RAPID 2, and entered an open-label extension (OLE) of CZP 400 mg EOW + MTX.

Methods: ACR responses, DAS28(ESR), HAQ-DI, pain VAS (0–100 mm scale) are shown over 3 yrs (148 wks) from RAPID 2 baseline (BL) for CZP completers who entered the OLE; modified Total Sharp Scores (mTSS) are shown over 2.5 yrs (128 wks). Pts who withdrew from the OLE for any reason or took rescue medication in the OLE had data imputed from that time point onward. For mTSS, linear extrapolation (Lin ext) was used. For DAS28, HAQ-DI, and pain VAS, last observation carried forward (LOCF) was used for any missing data. For ACR responses, both nonresponder imputation (NRI) and observed data are reported. AEs were assessed in all pts at each visit (after first study drug administration) from RAPID 2 BL. Safety analyses were based on the ITT population. AEs and serious AEs (SAEs)/100 pt-yrs are presented for all pts who received ≥1 CZP dose. RAPID 2: NCT00160602; RAPID 2 OLE: NCT00160641.

Results: Of 494 pts treated with CZP + MTX, 355 completed RAPID 2; of these, 342 (96%) entered the OLE. Completers entering the OLE had high disease activity at RAPID 2 BL (mean: DAS28: 6.8; HAQ-DI: 1.6; pain VAS: 60.7); mean mTSS at RAPID 2 BL was 33.6. After 3 yrs, 79% of CZP completers continued to receive OL CZP; only 2 pts withdrew due to lack of efficacy. ACR responses and improvements in DAS28, HAQ-DI and pain from BL were sustained in the OLE to 3 yrs in CZP completers (Table). Inhibition of progression of structural damage observed during the placebo-controlled phase was sustained up to the last x-ray evaluation at 2.5 yrs. The incidence of AEs by Wk 148 was 108.17 cases/100 pt-yrs, and SAEs 13.35 cases/100 pt-yrs. Most AEs were mild to moderate; no new safety signals were identified. Serious infections were reported at a rate of 5.46 cases/100 pt-yrs, and malignancies at 0.64 cases/100 pt-yrs.

Table. Efficacy of CZP+MTX over 3 yrs in RA pts

	Wk 24		Wk 100		Wk 148	
	NRI	Observed[a]	NRI	Observed[a]	NRI	Observed[a]
ACR50 % responders	46.6	51.3	44.9	60.4	39.1	60.2
ACR70% responders	19.1	21.0	22.9	30.8	20.5	31.6
DAS28, mean (SD)[b]	4.0 (1.2)		3.8 (1.2)		3.8 (1.2)	
DAS28 change from BL, mean (SD)[b]	−2.8 (1.3)		−3.0 (1.3)		−3.0 (1.4)	
HAQ-DI, mean (SD)[b]	0.96 (0.60)		0.93 (0.61)		0.94 (0.62)	
HAQ-DI change from BL, mean (SD)[b]	−0.64 (0.50)		−0.66 (0.56)		−0.65 (0.58)	
Pain VAS change from BL (0–100 mm), mean (SD)[b]	−30.0 (22.4)		−30.9 (25.1)		−29.2 (25.8)	
mTSS change from BL, mean (95% CI)[c]	0.61 (0–1.3)		0.58 (0.1–1.1)		0.75 (0.2–1.3)[d]	

[a]Wk 24: N=310; Wk 100: N=240; Wk 148: N=206. [b]LOCF. [c]Lin ext. [b,c]The actual number of subjects in the summaries varies slightly from N=342 due to nonimputable missing data for each parameter. [d]Wk 128.

Conclusion: In pts with active RA despite MTX, the addition of CZP provides clinical improvements that are sustained over 3 yrs, inhibits joint damage progression, and is well tolerated.

Background: The optimal regimen for treatment of RTX in RA has not yet been established. The purpose of this study was to analyze the efficacy of treatment and retreatment with RTX within 12 months after the first treatment and to identify predictors of response.

Methods: Ten European registries submitted anonymized datasets with baseline, 3, 6, 9 and 12 month data for patients who had started RTX. Heterogeneity between countries was analyzed by ANOVA. Predictors of response were identified by logistic regression analyses.

Results: Baseline data were available for 2265 patients. The mean (SD) age/disease duration of patients was 53.4 (13.2)/12.1 (9.1) years. 80.4% of them were female, 77.3% RF positive and 75.5% (574 out of 760 patients) were anti-CCP positive. The numbers of confirmed double seropositive and seronegative patients were 453 and 77 respectively. The mean (SD) numbers of previous DMARDs and biologics were 2.7 (1.6) and 1.1 (1.1) respectively. Significant heterogeneity was noted between countries for all baseline characteristics.

Significant reduction of DAS28 was observed at 6 [ΔDAS28 =1.92 (1.5)] and 12 months [ΔDAS28 =1.82 (1.5)]. HAQ was reduced from 1.63 (0.7) at baseline to 1.22 (0.7) and 1.27 (0.7) at 6 and 12 months, respectively. At 6

months 21.1% and 42.6% of patients were EULAR good and moderate responders, respectively; at 12 months the respective proportions are 20.8% and 40.6%. Seropositivity was associated with better response at 6 and 12 months (Table 1).

Table 1. Mean ± SD reductions in DAS28 at 6 and 12 months by serology.

	DAS28 improvement at 6 months (n=963)			DAS28 improvement at 12 months (n=539)		
	Positive	Negative	p	Positive	Negative	p
RF	1.95 ± 1.50	1.84 ± 1.50	NS	1.86 ± 1.49	1.67 ± 1.45	NS
ACPA	2.02 ± 1.52	1.42 ± 1.56	0.001	2.03 ± 1.45	1.58 ± 1.65	0.09
DOUBLE	2.02 ± 1.56	1.30 ± 1.47	0.006	2.0 ± 1.46	1.61 ± 1.66	NS

531 patients received retreatment by the end of 12 months. These patients achieved even higher DAS28 reductions at 12 months [ΔDAS28 =2.25 (1.4)] while for non-retreated patients a loss of effectiveness was observed [ΔDAS28 =1.46 (1.5)], (p<0.0001). A similar trend was observed in HAQ.

321 patients had an adverse event (AE) during the first year of treatment. The majority of the AE was infections and allergic reactions. 8 deaths occurred during the first year, 1 of them related to treatment (aspiration pneumonia). 193 patients discontinued RTX by the end of 12 months, 12 because of an AE, 92 because of inefficacy and the rest of the patients for other reasons. Retreatment was not associated with higher AE rate.

Predictors of EULAR Good Response at 12 months positive anti-CCP (p=0.002) and lower DAS28 at baseline (p=0.03).

Conclusions: RTX was effective and well tolerated for the majority of patients. Retreatment before 12 months lead to sustained efficacy and is generally safe. Anti-CCP positivity was associated with good response to treatment with RTX.

1808

Efficacy and Safety of Tocilizumab in Patients with Moderate to Severe Active RA and a Previous Inadequate Response to DMARDs: The ROSE Study. Yusuf Yazici[3], Jeffrey R. Curtis[6], Akgun Ince[4], Herbert Baraf[5], Raymond L. Malamet[1], Carol Y. Chung[2] and Arthur Kavanaugh[7]. [1]Genentech, a Member of the Roche Group, South San Francisco, South San Francisco, CA, [2]Genentech, a Member of the Roche Group, South San Francisco, CA, [3]NYU Hospital for Joint Diseases, New York, NY, [4]St. Louis University School of Medicine, St. Louis, MO, [5]The Center for Rheumatology and Bone Research, Wheaton, Wheaton, MD, [6]University of Alabama at Birmingham, Birmingham, AL, [7]University of California at San Diego, La Jolla, CA

Purpose: Early and aggressive treatment of RA has been associated with improved outcomes. The objective of the Rapid Onset and Systemic Efficacy (ROSE) study was to assess the efficacy of tocilizumab (TCZ) versus placebo in combination with DMARDs in reducing signs and symptoms during 24 weeks of treatment in patients with moderate to severe RA who have had inadequate clinical response to DMARDs.

Methods: 619 patients were randomly assigned to TCZ 8 mg/kg + DMARDs (TCZ, n=412) or placebo + DMARDs (control, n=207). The primary efficacy end point was ACR50 response at week 24. Efficacy parameters were assessed every 4 weeks through week 24. Disease activity was also assessed at 1 week for a subset of 62 patients. Safety and laboratory parameters were assessed throughout the study.

Results: Most patients were female (81%) and Caucasian (81%); mean age was 55 y, mean disease duration was 8.6 y, mean number of previous DMARDs was 1.2, and mean DAS28 was 6.5. At week 24, there was a significantly higher percentage of ACR50 responders (primary end point) in the TCZ group than in the control group (30.1% vs 11.2%; $p<0.0001$). Significantly higher percentages of patients in the TCZ group than in the control group achieved ACR20 and ACR50 responses from week 4 through week 24 and ACR70 responses from week 8 through week 24 (Table). Patients in the TCZ group had significant improvement in RAPID3 scores from week 4 through week 24 and in FACIT-Fatigue scores from week 8 through week 24 compared with control (Table). In the TCZ group, improvements in CRP and Hb levels occurred early (week 4) and were sustained through week 24; CRP improvement was significant at all time points ($p<0.0001$). In the subset, DAS28 and patients' pain and global assessment scores significantly improved, and CRP levels normalized 1 week after TCZ treatment ($p\leq0.01$ vs control). SAE rates/100 PY (95% CI) were 24 (17, 33) and 19 (11, 31) for the TCZ and control groups, respectively. Serious infections were reported in 2.9% and 0.5% of patients in the TCZ and control groups, respectively. Malignancies were reported in 0.7% and 1.5% of patients in the TCZ and control groups, respectively. ALT shifts from normal at baseline to >3× ULN occurred in 3.2% of TCZ patients and in 1.1% of control patients. Clinically significant (grade 3/4) decreases in neutrophil counts were reported in 2.9%/0% of TCZ patients; no grade 3/4 decreases were reported in control patients. There were no occurrences of decreased platelet counts to clinically significant values (grade 3/4).

Conclusions: TCZ led to significant improvements in disease activity, ACR responses, and CRP and Hb levels as early as week 4 and in DAS28 response as early as week 1; responses persisted through week 24. Safety findings were consistent with the known safety profile of TCZ. With early and sustained efficacy, TCZ is an effective treatment option for patients with RA who have failed DMARDs.

Percentages of ACR20, ACR50, and ACR70 Responders, Mean Change From Baseline in RAPID3 and FACIT-Fatigue Scores, and Mean CRP Levels by Visit (ITT population: TCZ group, n=409; control group, n=205)

Week	TCZ	Control	p	TCZ	Control	p	TCZ	Control	p
	ACR20, %			ACR50, %			ACR70, %

Efficacy of Abatacept and Tocilizumab in Rheumatoid Arthritis Patients Treated in Clinical Practice. Results from the Nationwide Danish DANBIO Registry. Henrik C. Leffers[4], Mikkel Ostergaard[4], Bente Glintborg[7], Niels Steen Krogh[10], Heidi Foged[6], Ulrik Tarp[1], Tove Lorenzen[9], Annette Hansen[3], Michael S. Hansen[2], Martin S. Jacobsen[8] and Merete L. Hetland[5]. [1]Aarhus University Hospital, Denmark, [2]Copenhagen University Hospital Gentofte, Denmark, [3]DANBIO Registry, and Copenhagen University Hospital Gentofte, Denmark, [4]DANBIO Registry, and Copenhagen University Hospital, Hvidovre and Glostrup, Hvidovre, Denmark, [5]DANBIO Registry, and Copenhagen University Hospital, Hvidovre and Glostrup, Denmark, [6]Frederiksberg Hospital, Denmark, [7]Holbæk Hospital, Denmark, [8]Randers Hospital, Denmark, [9]Vejle Hospital, Denmark, [10]Zitelab Aps, Denmark

Background: Abatacept (a selective T-cell costimulation modulator) and tocilizumab (an interleukin-6 (IL-6) receptor-inhibiting monoclonal antibody) have recently been approved for the treatment of rheumatoid arthritis (RA) based on their efficacy and safety in randomized controlled clinical trials. However, reports on their efficacy in clinical practice are scarce.

The aim of this study was to describe the disease activity, clinical response and drug survival in RA patients treated with abatacept or tocilizumab for the first time, based on prospectively registered data from the nationwide Danish DANBIO registry.

Methods: In the DANBIO registry we identified 150 and 178 RA patients treated with abatacept and tocilizumab, respectively. The clinical efficacy was assessed by changes in the 28 joints Disease Activity Score (DAS28), European League Against Rheumatism (EULAR) response rates after 24 and 48 weeks and drug survival. No imputation of missing values was done.

The small number of patients and the brief follow-up period did not allow for a direct comparison of the 2 drugs.

Results: Of the patients receiving abatacept and tocilizumab, respectively, 34%/42% (abatacept/tocilizumab) were male, median (interquartile range, IQR) age 54 (43–62)/56 (43–68) years, disease duration 8.5 (3–14)/9 (3–12) years and number of previous biological drugs 2 (2–3)/2 (2–3). Nearly all patients (95%/93%) had previously received ≥1 Tumor Necrosis Factor inhibitor (TNFi).

In the abatacept group, DAS28 was 5.3 (4.7–6.1), 3.4 (2.7–4.9) and 3.3 (2.5–4.3) at baseline, weeks 24 and 48, respectively, while 5.4 (4.7–6.2), 2.9 (2.3–4.0) and 2.5 (1.9–4.5) in the tocilizumab group. Changes in DAS28 variables over time seemed numerically very similar, except for C-Reactive Protein (CRP), which declined more rapidly in tocilizumab treated patients.

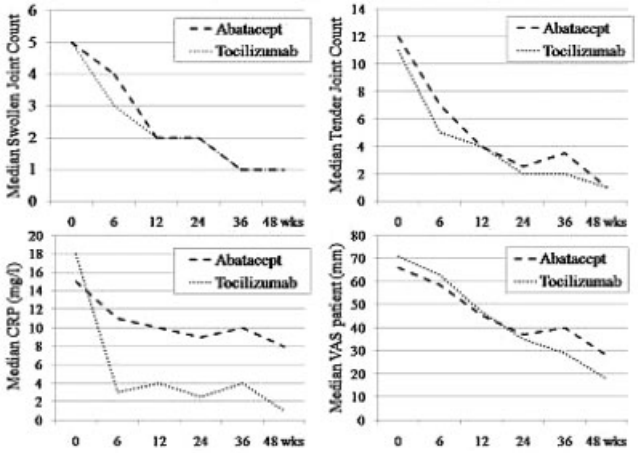

Figure 1. DAS28 variables. Time since treatment initiation (weeks).

DAS28 remission rates were 19% and 26% at week 24 and 48, respectively, in the abatacept group, while 39% and 58% in the tocilizumab group. Rates of EULAR moderate-/EULAR good response were 30%/40% and 32%/45% at week 24 and 48, respectively, in the abatacept group, while 43%/45% and 26%/58% in the tocilizumab group. After 1 year, 50% of abatacept patients and 60% of tocilizumab patients were still receiving the drug.

Conclusions: In RA patients (≥90% TNFi failures), abatacept and tocilizumab both significantly decreased the disease activity, and clinical response (EULAR good or moderate) were seen in the majority (≥70%) of patients. 50–60% of patients were still receiving the drug after 1 year. In the tocilizumab group, a steeper decline in CRP was observed than in the abatacept group, whereas changes in other outcome measures were similar.

Efficacy of Rituximab on Pulmonary Rheumatoid Nodules: Data of 10 Patients from the French AIR/PR Registry. Baptiste Glace[7], Jacques E. Gottenberg[13], Xavier Mariette[1], Antoine Roche[5], Jean-Marie Berthelot[11], Maxime Dougados[3], Eric Toussirot[6], Thao Pham[9], Yannick Allanore[2], Damien Loeuille[10], Liana E. Euller-Ziegler[4], Thierry Lequerré[12] and Martin Soubrier[8]. [1]Bicetre Hospital/Paris Univ, Le Kremlin Bicetre, France, [2]Hopitaux de Paris Cochin, Paris, France, [3]Hospital Cochin, Paris, France, [4]L'Archet Hospital (University), Nice, France, [5]Radiology Department, CHU Clermont-Ferrand, [6]Rheumatology Department, CHU Besançon, [7]Rheumatology Department, CHU Clermont-Ferrand, [8]Rheumatology Department, CHU Clermont-Ferrand, [9]Rheumatology Department, CHU Marseille, [10]Rheumatology Department, CHU Nancy, [11]Rheumatology Department, CHU Nantes, [12]Rheumatology Department, CHU Rouen, [13]Strasbourg Hospitals, Strasbourg, France

Background: Pulmonary rhumatoid nodules (PRN) occur in 5 to 20% of patients having rheumatoid arthritis (RA). DMARDs (methotrexate, leflunomide) and TNF blockers may accelerate pulmonary nodulosis. The presence of B CD 20 lymphocytes on their outer rim has raised the potential impact of Rituximab (RTX) as emphasized in a recent report [1].

Objectives: We assessed the outcomes of patients with PRN from the French autoimmunity and RTX registry (AIR).

Method: AIR is an independent registry under the aegis of the French society of Rheumatology. Standardized information was gathered every 6 months for 5 years by trained clinical nurses in each centre taking part. RA patients with pulmonary nodules observed on CT-scan at baseline and at follow up were included. Scanner readings were centralized (AR). The nodules were assessed according to their number and size (long axis).

Results: Of the 2573 patients from 85 centres reviewed, 30 had PRN. 10 of these patients fitted the inclusion criteria: 8 women with a mean age of 66.5 ± 59/79 years and 2 men with a mean age of 56 ± 51/61 years. All the patients had erosive, seropositive, anti CCP positive RA. Nine patients had sub-cutaneous nodulosis. The nodules were found while the patients were undergoing treatment with methotrexate (MTX) (n=3), MTX in combination with etanercept (n=3) or adalimumab (n=1), adalimumab alone (n=1) and leflunomide in combination with etanercept (n=2). RTX was administred with MTX (n=4), leflunomide (n=2), salazopyrine and hydroxychloroquine (n=1) or alone (n = 3). Nine patients were receiving corticosteroids (prednisolone) with a mean dose of 10.8 ± (5.20) mg. With a mean follow-up of 11.5±8.2 months, twenty one out of the 27 nodules studied improved (78%) and the mean long axis decreased from 14.4 ± 7.8 mm to 8.5 ± 9mm (p=0.001). Fourteen nodules had improved after a mean follow-up of 8.3±2.7 months (mean long axis from 14.4±9mm to 11.3±8.9mm). Seven nodules had disappeared after a mean follow-up of 19.5±17.6 months (mean long axis at baseline: 15.5±5.5mm). Six nodules worsened after a mean follow-up of 14.8±0.7 months (mean long axis from 14.8±10mm to 17.8±9.8mm).

Conclusion: RTX seems to be effective in treating pulmonary rheumatoid nodules.

Etanar® Therapy in Real-Life Patients with Rheumatoid Arthritis. Federico Rondon[11], Alain Bautista[4], Juan Carlos Salazar[1], Nohemí Casas[9], Pedro Santos[9], Francisco Vargas[6], Javier Márquez[2], Fredy Pumarejo[8], Fernando Fernández[3], Andrés Fernández[5], Rossana Mejía[1], Oscar Ruiz[1], Alberto Torrenegra[3], Jose Bernardo Martínez[7] and Rubén Darío Mantilla[10]. [1]CIREI, Bogota, [2]Hospital Pablo Tobon Uribe, Medellin, [3]Rheumatology, Barranquilla, [4]Rheumatology, Cucuta, [5]Rheumatology, Ibague, [6]Rheumatology, Medellin, [7]Rheumatology, Monteria, [8]Rheumatology, Valledupar, [9]Riesgo de Fractura-CAYRE IPS, Bogota, [10]Riesgo de Fractura-CAYRE IPS, Bogota, Colombia, [11]Universidad Nacional, Bogota

Objectives: Etanar®, a recombinant tumor necrosis factor receptor:Fc fusion protein, has been shown to be effective in suppressing disease activity in patients with rheumatoid arthritis (RA) who fail to respond to disease-modifying anti-rheumatic drugs (DMARDs). We present a 20-week analysis of the efficacy and safety of treating patients with long-standing, multi-DMARD resistant RA with Etanar® in a 'real-life' setting.

Methods: This multicenter observational before-after study enrolled patients with active RA despite treatment with DMARDs who started Etanar® treatment (25 mg s.c. injection twice weekly) and were followed for 20 weeks. Demographics and clinical characteristics including functional status (HAQ) and activity of disease (DAS28) were registered every 4 weeks.

Results: 110 patients were enrolled (82% women, mean age: 52.5 ± 14.5 yrs, mean duration of RA: 9.7 ± 8.9 yrs). Comorbidity was present in 43 (39.1%) patients with arterial hypertension, observed in 20 (18.2%) patients, being the most frequent. Methotrexate (MTX) was administered for 85.3% of the patients. Of the patients, 28.5% were receiving monotherapy and 71.5% were on combination therapy, MTX-Sulfasalazine and MTX-Leflunomide were the most frequently used in 21.5% and 20.6% respectively. DAS28 declined from 5.76 ± 0.81 to 3.48 ± 1.12 ($p < 0.001$, by Friedman test), and HAQ declined from 2.5 ± 1.1 to 1.1 ± 0.9 ($p < 0.001$). Side-effects were registered in 11 (10%) cases, and the main causes of discontinuation of anti-TNF therapy were lack of efficacy

(n=2), heart failure (n=2), nausea and dizziness (n=2), pneumonia (n=2) and asthma (n=1).

Conclusions: Etanar® can effectively control disease activity in real-life patients with active RA and poor responses to MTX but also other DMARDs. Safety and tolerability assessment indicates Etanar to be well tolerated.

1812

Etanercept (ETN) Plus Methotrexate (MTX) Combination Therapy Resulted in a Better Radiographic Outcome Than ETN Monotherapy Even in Patients with Active Rheumatoid Arthritis Despite MTX Treatment: 104-Week Results from the JESMR Study. Hideto Kameda[2], Katsuaki Kanbe[7], Eri Sato[7], Yukitaka Ueki[5], Kazuyoshi Saitoh[8], Shouhei Nagaoka[9], Toshihiko Hidaka[10], Tatsuya Atsumi[1], Michishi Tsukano[4], Tsuyoshi Kasama[6], Shunichi Shiozawa[3], Yoshiya Tanaka[8], Hisashi Yamanaka[7] and Tsutomu Takeuchi[2]. [1]Hokkaido University Graduate School of Medicine, [2]Keio University, [3]Kobe University Hospital, [4]Kumamoto Orthopaedic Hospital, [5]Sasebo Chuo Hospital, [6]Showa University School of Medicine, [7]Tokyo Women's Medical University Medical Center, [8]University of Occupational and Environmental Health, [9]Yokohama Minami Kyosai Hospital, [10]Zenjinkai Shimin-No-Mori-Hospital

Background: The radiographic superiority of the continuation of methotrexate (MTX) to its discontinuation at the commencement of etanercept (ETN) in patients with active rheumatoid arthritis (RA) despite MTX therapy has not been clarified.

Objectives: An important aim of the JESMR study is to compare the radiographic efficacy of continuation versus discontinuation of MTX at the commencement of ETN for two years in patients with active RA despite MTX therapy.

Methods: In total, 151 patients with active RA despite treatment with MTX were randomized to either ETN 25 mg twice a week with 6–8 mg/week of MTX (the E+M group), or ETN alone (the E group). The radiographic progression was assessed by van der Heijde-modified Sharp score at baseline, weeks 24, 52 and 104. The last observation carried forward and linear imputation were used for the analysis of clinical and radiographic efficacy, respectively, for missing data.

Results: Demographic and clinical features between groups at baseline were similar. The cumulative probability plot of ACR-N at week 104 clearly demonstrated the superior response in the E+M group to that in the E group. The ACR 20, 50 and 70 response rates at week 52 were 82.2%, 68.5% and 46.6%, respectively, in the E+M group, all of which were significantly greater than 59.4% (p=0.003), 39.1% (p=0.001) and 23.2% (p=0.005), respectively, in the E group. The mean progression in total score (ΔTSS) tended to be smaller in the E+M group than in the E group (1.2 versus 6.6, p=0.09), and a significant difference was observed in the erosion score change at week 104 (−0.5 versus 3.1, respectively, p=0.045). Furthermore, ACR-N < 50 predicted a risk for radiographic progression only in the E group.

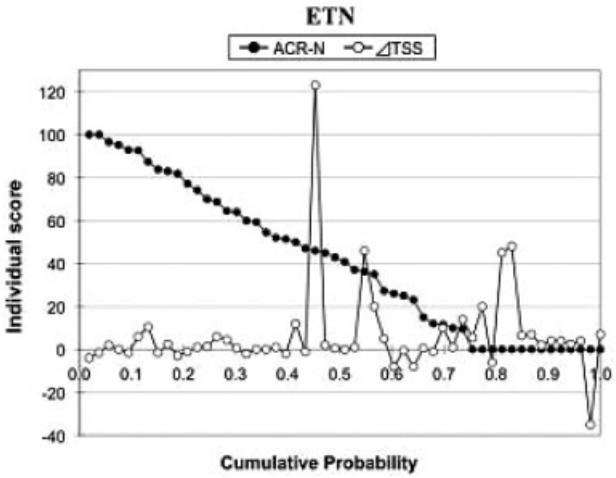

Figure 1.

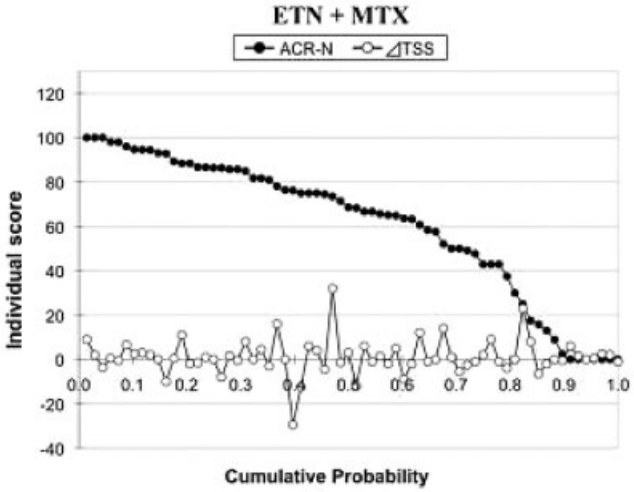

Figure 2.

Conclusion: The continuation of MTX at the commencement of ETN therapy is clinically and radiographically beneficial even in RA patients who had shown an inappropriate response to MTX.

1813

Etanercept Normalizes Systemic Bone Metabolism in Rheumatoid Arthritis Patients. Won Park[2], Mie Jin Lim[1], Seong Ryul Kwon[1], Ji Yeol Yoon[1], Chang Gi Moon[1] and Go Eun Ju[1]. [1]Inha University Hospital, Incheon, Republic of Korea, [2]Inha University Hospital, Choong-Gu Incheon, Korea, Republic of

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease accompanied by bone loss. Etanercept is soluble TNF-α receptor which is effective in suppressing RA activity.

Objective: Our aim is to assess bone metabolism in TNF naïve RA patients and to figure out effects of etanercept on bone turnover markers and inflammatory mediators.

Methods: Twenty-one RA patients (19 women and 2 men; age 46.29 ± 11.6 years) were included. They were required to be active RA, thus meeting the criteria of DAS28 ≥ 3.2 and either ESR ≥ 28 mm/hr or CRP ≥ 2.0 mg/dL and morning stiffness ≥ 45 minutes.

Age and sex matched control group were recruited.

Etanercept was administered at standard dose, twice a week.

Venous blood was drawn at baseline in both groups and at week 14–16 after etanercept use in RA patient. Bone metabolism was assessed using bone specific alkaline phosphatase (BSAP), osteoprotegerin (OPG), sclerostin for bone formation and receptor activator for nuclear factor κB ligand (RANKL), serum c-telopeptide (CTX) for bone resorption. Serum level of inflammatory mediators including ESR, CRP and IL-6 were also determined.

Differences between two groups were examined for statistical difference by Wilkoxon signed ranks test. A p value of less than 0.05 was denoted statistically significant.

Results: At baseline the sclerostin level was significantly decreased in RA patients than in control group while serum CTX was decreasing. However after etanercept use, both serum CTX and sclerostin markedly increased (Table 1).

Table 1. Bone metabolism in TNF naïve RA patients and changes observed after etanercept use

	Baseline	Week 14–16 after etanercept use	*p*
ESR (mm/hr)	39 ± 31.2	26 ± 25	0.013
CRP (mg/dL)	0.98 ± 0.866	0.43 ± 1.118	0.013
IL-6 (pg/mL)	3.58 ± 3.371	0.77 ± 0.726	0.001
OPG (pmol/L)	2.36 ± 1.081	2.2 ± 0.786	0.619
BSAP (U/L)	20 ± 6.97	20.3 ± 7.45	0.887
RANKL (pmol/L)	0.25 ± 0.37	0.22 ± 0.422	0.07

Table 2. Bone turnover markers and inflammatory mediators after etanercept administration in RA patients

	Age and sex matched control	RA patients baseline	*P* (control vs. RA patients baseline)	week 14–16 after etanercept	*P* (RA patients baseline Vs. Week 14–16)
Sclerostin (pg/mL)	2.2 ± 1.61	1.63 ± 2.26	0.03	2.95 ± 4.18	0.046
Serum CTX (ng/mL)	0.38 ± 0.18	0.28 ± 0.13	0.114	0.34 ± 0.17	0.048

BSAP and OPG were slightly affected by etanercept. RANKL mildly decreased after treatment.

Inflammatory mediators responded to the treatment as ESR, CRP and IL-6 all significantly decreased (Table 2).

Conclusions: Our study showed lower level of serum CTX and sclerostin in RA patients than in control group, which suggested slow bone resorption rate coupled with low bone production. However after etanercept use, bone turnover markers rose while inflammation was decreasing. Therefore we conclude that etanercept stimulates depressed bone metabolism in RA patients as it suppresses inflammation.

Golimumab, a Human Anti-TNFα Monoclonal Antibody Administered Subcutaneously Every Four Weeks as Monotherapy in Patients with Active Rheumatoid Arthritis Despite DMARD Therapy: 24-Week Results of Clinical and Radiographic Assessments. Tsutomu Takeuchi[5], Masayoshi Harigai[8], Yoshiya Tanaka[10], Hisashi Yamanaka[9], Naoki Ishiguro[7], Kazuhiko Yamamoto[11], Takuya Oba[4], Mahboob U. Rahman[1], Toru Yoshinari[6], Nobuyuki Miyasaka[2] and Takao Koike[3]. [1]Centocor Research and Development, Inc., Malvern, PA, [2]Graduate School of Medical and Dental Sciences, Tokyo, Japan, [3]Hokkaido University Graduate School of Medicine, [4]Janssen Pharmaceutical K.K., [5]Keio University, Toyko, Japan, [6]Mitsubishi Tanabe Pharma Corporation, [7]Nagoya University, [8]Tokyo Medical and Dental University, Tokyo, Japan, [9]Tokyo Womens Med Univ, Shinjuku-ku, Tokyo, Japan, [10]University of Occupational and Environmental Health, Kitakyushu, Japan, [11]University of Tokyo Graduate School of Medicine, Tokyo, Japan

Objective: To assess the efficacy and safety of golimumab (GLM) as a monotherapy in Japanese patients with active rheumatoid arthritis (RA) despite DMARD therapy.

Methods: In this multicenter, randomized, double-blind, placebo (PBO)-controlled study, patients with active RA with ≥6 swollen and ≥6 tender joints (SJC/TJC) despite treatment with DMARD were randomized to subcutaneous injections of PBO, GLM 50mg, or GLM 100mg administered q4 wks. Starting at wk 16, GLM 50mg was administered q4 wks to patients in the PBO group. The primary endpoint was the proportion of patients achieving ACR20 at wk 14. Secondary endpoints included the proportion of patients achieving ACR50, ACR70 response, DAS28 (ESR) response, and improvement in Health Assessment Questionnaire (HAQ) at wk 14, and change from baseline in van der Heijde/Sharp-Score (vdH-S) at wk 24. Data was analyzed using Full Analysis Set (modified Intent-To-Treat: all patients receiving one dose of study treatment included) population. The results of the non-parametric data analyzed using van der Waerden method is being reported.

Results: 308 patients received treatment (105 PBO, 101 GLM 50mg, and 102 GLM 100mg). Treatment groups were balanced for baseline demographic and disease characteristics [mean (SD) values for all patients: CRP 2.46(2.62) mg/dL, ESR 47.9(30.18) mm/hr, SJC 12.9(6.49), TJC 15.7(9.25), DAS 28(ESR) 5.89(1.04)]. The baseline vdH-S(TSS) for the GLM 50mg and 100mg groups were 44.05(50.80) and 56.66(56.74), respectively. At wk 14, the GLM 50mg and 100mg groups were significantly better than PBO in improving signs and symptoms of RA and physical function (Table). At wk 24, the GLM 100mg group significantly inhibited radiographic progression compared with PBO; the median and IQ ranges clearly showed better inhibition with the GLM 100 mg dose. Through wk 16, the overall incidence of adverse events (AEs) was 63.8%, 62.4%, and 59.8% in the PBO, GLM 50mg, and GLM 100mg groups, respectively; serious AEs occurred in 1.9%, 1.0%, and 2.0% of the patients in the PBO, GLM 50mg, and GLM 100mg groups, respectively. Serious infections occurred in 1.0%, 0%, and 1.0% of patients, respectively, in the PBO, GLM 50mg, and GLM 100mg. Injection site reactions occurred in 6.7%, 7.9%, and 7.8% of patients, respectively. There were no reports of tuberculosis or death.

Conclusion: Both doses of GLM significantly improved signs, symptoms, and physical function compared with PBO. In addition GLM 100 mg significantly inhibited progression of structural damage compared with PBO. Injection site reactions were mild and not increased compared with PBO. GLM monotherapy was well-tolerated with safety profile similar to other anti-TNF agents.

Tables. Efficacy at Wk 14 and Wk 24

Assessment	PBO	GLM 50 mg	GLM 100 mg
Patients treated (n)	105	101	102

Rahman[1], Toru Yoshinari[5], Nobuyuki Miyasaka[8] and Takao Koike[2]. [1]Centocor Research and Development, Inc., Malvern, PA, [2]Hokkaido University Graduate School of Medicine, [3]Janssen Pharmaceutical K.K., [4]Keio University, Toyko, Japan, [5]Mitsubishi Tanabe Pharma Corporation, [6]Nagoya University, [7]The University of Tokyo, [8]Tokyo Medical and Dental University, Tokyo, Japan, [9]Tokyo Womens Medical University, Shinjuku-ku, Tokyo, Japan, [10]University of Occupational and Environmental Health, Kitakyushu, Japan

Objective: To assess the efficacy and safety of golimumab(GLM) in Japanese pts with active RA despite MTX therapy.

Methods: In this multicenter, randomized, double-blind, placebo-controlled study, pts with active RA despite MTX therapy with ≥4 swollen and ≥4 tender joints (SJC/TJC) were randomized to receive subcutaneous injections of PBO, GLM 50mg, and GLM100mg administered q4wks. All pts received MTX 6–8 mg orally/wk. Pts with <20% improvement in SJC/TJC entered early escape at wk16 in a blinded manner, as follows: PBO+MTX → GLM50mg+MTX and GLM50mg+MTX → GLM100mg+MTX. Pts receiving GLM100mg+MTX remained on the same dose. The primary endpoint was the proportion of pts achieving ACR20 at wk14. Secondary endpoints were the proportion of pts achieving ACR20 at wk24, ACR50, ACR70 response at wks14 and 24, change from baseline in DAS28 (ESR) scores and improvement in Health Assessment Questionnaire (HAQ) at wks14&24, and change from baseline in van der Heijde/Sharp-Score(vdH-S) at wk24. Data was analyzed using Full Analysis Set (modified Intent-To-Treat:all pts receiving one dose of study treatment included) population. The results of the non-parametric data analyzed using van der Waerden method is reported.

Results: 261 pts received treatment (88 PBO+MTX, 86 GLM50mg+MTX, and 87 GLM100mg+MTX). Treatment groups were balanced for baseline demographic and disease characteristics [mean(SD) values for all pts: CRP 1.86(2.29) mg/dL, ESR 44.3(29.94) mm/hr, SJC 11.5(6.60), TJC 13.1(7.92), DAS 28(ESR) 5.52(1.05), vdH-S(TSS) 55.10 (58.09)]. Both doses of GLM+MTX were significantly better than PBO+MTX in improving signs and symptoms/physical function and in inhibiting radiographic progression (Table). Through wk24, 80.7%, 81.4%, and 82.8% of pts had ≥1 adverse event (AE) in the PBO + MTX, GLM 50mg + MTX, and GLM 100mg + MTX groups, respectively. Serious AEs occurred in 1.1%, 2.3%, and 3.4% of pts, respectively. Serious infections occurred in 0.0%, 0.0%, and 1.1% of pts, in the PBO+MTX, GLM50mg+MTX, and GLM100mg+MTX groups respectively. Injection site reactions occurred in 9.1%, 9.3%, and 11.5% of pts, respectively. One pt in the GLM50mg+MTX group had a bone neoplasm (thoracic vertebra tumor; hemangoendothelioma, of low malignancy potential). There were no reports of tuberculosis or deaths.

Conclusions: Both GLM+MTX doses had significantly greater improvement in signs and symptoms and physical function, as well as significantly better inhibition of progression of structural damage compared with PBO+MTX in pts with RA. Injection site reactions were mild and not increased compared with PBO+MTX. GLM+MTX was well-tolerated with safety profile similar to other anti-TNF agents.

Table. Efficacy results through Wk 14 and Wk 24

Assessment	PBO+MTX	GLM+MTX GLM 50 mg	GLM+MTX GLM 100 mg	GLM+MTX Combined

Impact of Abatacept on Circulating Dendritic Cells and Regulatory T Cells in Rheumatoid Arthritis Patients with Inadequate Response or Intolerance to TNF-alpha Blockers. Emilie Shipley[1], Christophe Richez[1], Thomas Barnetche[2], Cécile Contin-Bordes[2], Patrick Blanco[2] and Thierry Schaeverbeke[1]. [1]Hôpital Pellegrin, Bordeaux, France, Metropolitan, [2]Hôpital Pellegrin, France, Metropolitan

Objectives: To assess the variation of circulating dendritic cells (DCs) and T cell subsets, including regulatory T cells (Treg), in rheumatoid arthritis (RA) patients with inadequate response (IR) or intolerance to TNF blockers receiving abatacept and methotrexate for at least 6 months. To evaluate whether these variations correlate with EULAR response criteria and to identify predictive factors of response to abatacept.

Methods: Circulating DCs, including myeloid DCs (mDCs) and plasmacytoid DCs (pDCs), and different T-cell subsets were longitudinally evaluated (M0, M3 and M6) by flow cytometry. Wilcoxon's signed-rank test was used for the analyses of matched pairs. Correlation between cells numbers and activity markers were assessed using Spearman's rank. $P < 0.05$ was considered statistically significant.

Results: Seventeen RA patients with inadequate response or intolerance to TNF blockers initiated with abatacept + MTX, were assessed at baseline, 3 and 6 months. 86% were female. These patients had mean age 61 years, disease duration 13 years, DAS28 4.9 (+/−1.4) and CRP 1.4 mg/dl (+/−1.7). 75% were rheumatoid factor positive and 62.5 % were anti-CCP positive. RA patients were classified as either good or moderate EULAR responders (11pts, 65%) or non-responders (6pts, 35%) at 3 months.

At baseline, no correlation was found in the total population between disease activity and levels of different immune cells, whereas in the responders group, DAS28 negatively correlated with the absolute number of circulating T cells ($r = -0.90$, $p = 0{,}0003$, CD4+T cells ($r = -0.88$, $p = 0{,}0008$, Tregs ($r = -0.68$, $p = 0.03$), mDCs ($r = -0.87$, $p = 0.001$), pDCs ($r = -0.79$, $p = 0.006$) and activated mDCs ($r = -0.82$, $p = 0.02$).

Between M0 and M3, blood CD4+ T cells (595 +/− 362 × 10^3cells/ml at M0 vs. 743 +/− 523 × 10^3cells/ml at M3, p=0.04) and plasmacytoid DCs (3936 +/− 3466 cells/ml at M0 vs. 7277 +/− 5262 cells/ml at M3, p=0.02) levels increased substantially in RA patients treated by abatacept. Interestingly, EULAR responders showed a significant increase at M3 in their numbers of circulating CD3+ T cells (865 +/− 336 × 10^3cells/ml at M0 vs. 1045 +/− 428 × 10^3cells/ml at M3, p=0.02) and myeloid DCs (3177 +/− 2621 cells/ml at M0 vs. 9867 +/− 1145 cells/ml at M3, p=0.03).

Conclusion: Our data suggest that patients with active RA and responding to abatacept are characterized by a decrease at baseline in circulating DCs and T cells including Tregs, which are probably recruited in the target tissues. Efficient abatacept therapy restores levels of these immune cells. Inclusion of additional patients in this ongoing study and analysis of immune cells levels at M3 and M6 should precise the impact of abatacept on DCs/T cells and eventually define predictive factors.

Impact of Abatacept on Synovitis and Structural Damage in Methotrexate (MTX)—Inadequate Responders with Active Rheumatoid Arthritis (RA): A Randomized, Controlled Magnetic Resonance Imaging (MRI) Exploratory Study. Philip G. Conaghan[9], Patrick Durez[8], Rieke Alten[6], Gerd Burmester[4], Paul P. Tak[1], Lars Klareskog[5], Corine Gaillez[2], Manuela Le Bars[2], Xianhuang Zhou[3] and Charles Peterfy[7]. [1]Academic Medical Center/University of Amsterdam, Amsterdam, The Netherlands, [2]Bristol-Myers Squibb, Rueil-Malmaison, France, [3]Bristol-Myers Squibb, Princeton, NJ, [4]Charité-Universitatsmedizin, Berlin, Germany, [5]Karolinska University Hospital, Stockholm, Sweden, [6]Schlosspark-Klinik, University Medicine Berlin, Germany, [7]Spire Science LCC, San Francisco, CA, [8]Université Catholique de Louvain, Brussels, Belgium, [9]University of Leeds, Leeds, UK

Background: X-ray can detect erosions in established RA, but is less sensitive for early changes[1]. MRI has the potential to study synovial inflammation and measure bone damage at an earlier stage and with greater sensitivity than X-ray.

Objective: Evaluate the impact of abatacept or placebo, + MTX, on MRI changes in wrist synovitis, osteitis and bone erosion in patients with RA and an inadequate response to MTX.

Methods: In this double-blind, randomized, Phase IIIb study of abatacept (~10 mg/kg) versus placebo, + MTX, patients had active RA despite MTX, defined as either DAS28 (CRP) >3.2, or ≥6 tender and swollen joints and CRP above the upper limit of normal. Patients had clinically detectable synovitis of ≥1 wrist, and had ≥1 X-ray erosion or were positive for anti-CCP or RF. Patients had 1.5T MRI (coronal fat-suppressed 3D gradient-echo ± IV gadolinium-contrast) of one wrist at baseline and Month 4. The primary endpoint was mean change at Month 4 in wrist synovitis score (OMERACT-RAMRIS method[2]). Wrist and hand osteitis and erosion scores were secondary endpoints. Exploratory efficacy analyses included DAS28 (CRP), LDAS (≤3.2) and remission (<2.6). Comparisons in wrist synovitis change between groups were based on non-parametric ANCOVA. Efficacy was reported for the intent-to-treat population. Safety was reported for patients who received ≥1 abatacept dose.

Results: Of 27 and 23 patients randomized to abatacept + MTX or placebo + MTX, 26 and 23 completed 4 months. Baseline characteristics were generally similar between groups: mean (SD) RA duration was 25.7 (18.0) and 28.2 (17.0) months, and DAS28 scores were 5.3 (1.1) and 5.3 (0.9) for abatacept and placebo, respectively. However, 55.6 and 48.1% of patients in the abatacept and 82.6 and 73.9% in the placebo group were RF and anti-CCP positive, respectively. Mean change from baseline to Month 4 in synovitis score was –0.44 for abatacept and 0.52 for placebo (p=0.103). For osteitis and erosion scores, mean changes were –1.94 and 0.45 for abatacept versus 1.54 and 0.95 for placebo (treatment difference [95% CI]: –0.50 [–1.77, 0.76] and –3.48 [–6.00, –0.96], respectively). The percentage of patients with newly involved joints at Month 4, by synovitis, osteitis and erosion scores was 8, 28 and 20% for abatacept versus 13, 30 and 30% for placebo. At Month 4, mean (95% CI) change from baseline in DAS28 was –1.68 (–2.15, –1.21) for abatacept and –0.55 (–0.95, –0.16) for placebo. Percentages (95% CI) of patients with LDAS and remission were 50.0 (30.8, 69.2) and 15.4% (1.5, 29.3) in the abatacept and 13.6 (0.0, 28.0) and 0.0% (0.0, 0.0) in the placebo group. Safety events were similar to previously reported abatacept trials.

Conclusions: The sensitivity of MRI is again demonstrated, in that even with small patient numbers and wrist-only assessments, abatacept + MTX treatment was associated with reductions in osteitis and erosion scores, and a trend toward reduced MRI synovitis scores versus placebo + MTX. The beneficial clinical outcomes were consistent with those in other large-scale abatacept clinical trials.

1818

Key Pharmacological Parameters Support Monthly Dosing for Golimumab. Mahboob U. Rahman[2], Ann Cai[1], Eilyn Lacy[1], Jonathan Kay[4], Ed C. Keystone[5], Eric L. Matteson[3], Chuanpu Hu[1], Honghui Zhou[1] and Dave Shealy[1]. [1]Centocor Research and Development, Inc., [2]Centocor Research and Development, Inc./ Univ. of Pennsylvania School of Medicine, Malvern, PA, [3]Mayo Clinic, Rochester, MN, [4]UMass Memorial Medical Center, Worcester, MA, [5]University of Toronto, Toronto, ON, Canada

Purpose: To compare the molecular characteristics and clinical pharmacology of SC golimumab (GLM) and adalimumab (ADA), two human anti-TNFα antibodies with similar half-lives but different dosing frequencies.

Methods: Affinity to soluble TNFα was measured by surface plasmon resonance. Evaluation of *in vitro* neutralization efficiency (NE) was accomplished using bioassays for TNFα-induced cytotoxicity on a human rhabdomyosarcoma cell line (KYM-1D4) and E-selectin expression by primary human umbilical vein endothelial cells. A PK/PD model was developed using serum GLM concentrations (conc) and ACR20/50/70 results from GO-FORWARD (Ph 3 trial) using the MTX + PBO, MTX + GLM 50 mg, and MTX+GLM 100 mg grps. Mixed-effect logistic regression was used with a latent variable approach, in conjunction with an inhibitory indirect effect model, to model ACR20/50/70 results simultaneously. The PK/PD model linked time profiles of GLM conc and ACR20/50/70. Results from a Ph 2 dose-ranging study evaluating efficacy of GLM 50 or 100 mg SC q2 or 4wk in pts with active RA despite MTX are presented. The GLM 50 and 100 mg q2 wk grps are combined into a (q2 wk) grp; GLM 50 and 100 mg q4 wk grps are combined into another (q4 wk) grp to assess the relative clinical efficacy of q2 and q4 wk dosing. Primary endpoint was ACR20 at wk 16. ACR20 is presented over time from wks 2–16.

Results: Affinity (mean; range) of GLM for TNFα (18pM; 9–27 pM) was significantly greater than ADA (127 pM; 99–154; p=0.018). Neutralization efficiency (NE) was compared as moles of antibody required to achieve 50% inhibition/mole of TNFα. NE for GLM in the cytotoxicity assay was 22.1 vs 124 for ADA (p<0.001); in the E-selectin assay, NE for GLM was 1.32 vs 4.32 for ADA (p=0.008). A 3 to 6 fold higher conc of ADA was necessary to neutralize the same level of TNFα as GLM *in vitro*. The EC_{50} value (*in vivo* potency) for GLM by the current exposure-response model, using GO-FORWARD data, was estimated to be 454 ± 296 ng/mL, which was smaller than the reported EC_{50} for ADA by PK/PD analysis (810 ± 370 ng/mL) (Nestorov et al. 2004). Although analyzed by different PK/PD methods, this appears consistent with the *in vitro* potency comparison. In the Ph 2 GLM dose ranging study, the proportions of pts who achieved ACR 20 at wk 16 (primary analysis) were 58.0% (p=0.045) and 64.7% (p=0.008) for GLM q4wk + MTX (n=69) and GLM q2wk + MTX (n=68) grps, respectively (vs 37.1% for the PBO + MTX grp [n=35]). Fig 1 shows q4 wk and q2 wk dosing had comparable efficacy.

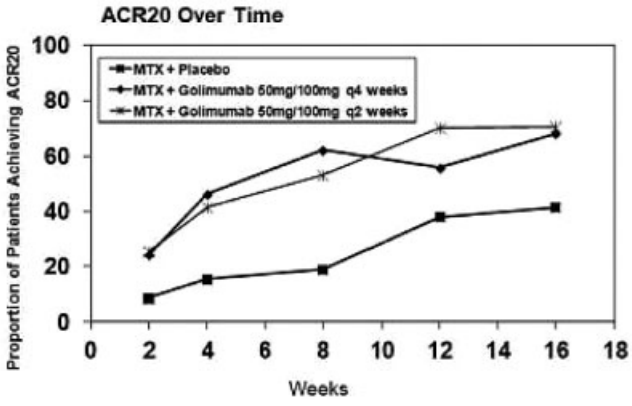

Figure 1.

Conclusions: Compared with ADA, GLM demonstrates greater affinity to TNFα and capacity to neutralize TNFα, in *in vitro* assays, and lower EC_{50} in PK/PD modeling. These data suggest that similar conc of GLM would maintain efficacy for longer duration than those of ADA and allow less frequent dosing, despite similar half-lives. A Ph2 dose ranging study also supports monthly dosing of GLM by demonstrating comparable clinical efficacy with q2 wk and q4 wk dosing.

1819

LITHE: Tocilizumab (TCZ) Inhibits Radiographic Progression and Improves Physical Function in Rheumatoid Arthritis (RA) Patients (pts) at 3 Years with Maintenance of Clinical Efficacy over Time. Joel M. Kremer[1], Daniel E. Furst[6], Ruben Burgos-Vargas[3], Jean Dudler[2], Christopher M. Mela[5], Emma Vernon[5] and Roy M. Fleischmann[4]. [1]Albany Medical College, Albany, NY, [2]Hôpital Orthopédique, Epalinges, Switzerland, [3]Hospital General de México and Universidad Nacional Autónoma de México, Mexico City, México, Mexico, [4]Metroplex Clinical Research Center, Dallas, TX, [5]Roche, Welwyn, United Kingdom, [6]UCLA Medical Center, Los Angeles, CA

Purpose: To report 3-yr data from the extension of a 3-arm, randomized, double-blind, placebo-controlled, phase 3 trial of TCZ in pts with moderate to severe RA who were MTX inadequate responders.

Methods: A total of 1190 pts were randomly assigned (1:1:1) to receive TCZ (4 mg/kg [TCZ4] or 8 mg/kg [TCZ8]) or placebo (control) every 4 wks plus MTX (10–25 mg/wk). After wk 52, pts switched to open-label treatment with TCZ8, an option chosen by the majority of pts (62%-68% across all 3 treatment groups). Radiographs of hands and feet were analyzed by Genant-modified Total Sharp Score (GmTSS) for any pt who had a baseline, wk 52, wk 104, and at least 1 post-wk 104 assessment. If a patient had a post-wk 104 but not a wk 152 value, linear extrapolation was used to impute up to wk 152. Signs and symptoms data and safety data are reported as pooled data (All TCZ) in all pts who received at least 1 dose of TCZ; data are presented from the first dose of TCZ to August 28, 2009 (mean duration, 2.43 yrs). LOCF was used for missing tender and swollen joint counts; no imputation was used for missing HAQ score, CRP, ESR, and VAS assessments.

Results: The radiographic population consisted of 704 pts, accounting for approximately 80% of the pts who ultimately would have a post-wk 104 assessments: 244, 241, and 219 pts had been initially assigned to TCZ8, TCZ4, and control, respectively. The majority of pts had received open-label TCZ8 for at least 2 of 3 yrs of the study; 9% of placebo and 19% of TCZ4 pts had remained on original blinded treatment at 1 yr. The mean change in GmTSS from baseline to yr 3 was 60% lower in pts who were randomly assigned to TCZ compared with those initially receiving control, demonstrating inhibition of joint damage by TCZ (Table). The majority of radiographic progression in pts randomly assigned to control was observed in the first yr before switching to TCZ. By yr 3, no radiographic progression was observed in a greater proportion of pts initially assigned to TCZ8 and TCZ4 than to control.

The All TCZ group included 1149 pts with 2790 pt-yrs (PY) of exposure. ACR response and DAS28 remission rates were high, demonstrating continued clinical benefit (Table). At wk 104, 34% (257/768) of pts had HAQ scores <0.5; the proportion of pts with HAQ scores <0.5 was maintained through wk 152.

Overall rates/100 PY of serious adverse events and serious infections were 11.0 and 3.2; overall rates/100 PY of deaths and deaths from infections were 0.39 and 0.14. Malignancies occurred at an overall rate of 0.7/100 PY, including solid cancers (0.6/100 PY) and nonmelanoma skin cancer (n = 1; 0.0/100 PY).

Table. Outcomes at Week 152

GmTSS	TCZ8 n=244	TCZ4 n=241	Control n=219
Mean (SD) change from baseline	0.72 (2.56)[a,b]	0.71 (2.14)[b,c]	1.78 (3.64)

Long-Term Efficacy of Tocilizumab (TCZ) in Patients (Pts) with Rheumatoid Arthritis (RA) Treated up to 3.7 Years. Majed Khraishi[3], Rieke Alten[8], Juan J. Gomez-Reino[2], Warren Rizzo[1], Joy Schechtman[6], Andre Kahan[4], Emma Vernon[5], Monet Taylor[5] and Josef Smolen[7]. [1]Advanced Arthritis Care, Scottsdale, AZ, [2]Hospital Clínico U. de Santiago, Santiago, Spain, [3]Memorial University of Newfoundland, St. John's, NL, Canada, [4]Paris Descartes University, Paris, France, [5]Roche, Welwyn, UK, [6]SunValley Arthritis Center, Peoria, AZ, [7]University Clinic for Internal Medicine, Vienna, Austria, [8]University of Berlin, Berlin, Germany

Background: Efficacy and safety of TCZ have been shown in RA pts in phase 3 trials for up to 2 y. Efficacy data from ongoing extension studies for up to 3.7 y (wk 192) are presented for pts treated with TCZ ± MTX/other DMARDs.

Methods: This analysis was in 2 populations from long-term extensions (GROWTH95, GROWTH96, open-label phase of LITHE) of phase 3 trials. One population comprised pts who were previous inadequate responders to DMARDs (DMARD-IR: OPTION, TOWARD, LITHE), and the other comprised pts who were never exposed to or who had never failed MTX (AMBITION). Pts received at least 1 dose of TCZ + DMARDs/MTX in the phase 3 or extension trials except pts in AMBITION, who received TCZ monotherapy. Pts from AMBITION with <50% reduction from baseline in tender and swollen joint counts (TJC, SJC) could receive DMARDs/MTX in the extension. Outcomes were assessed every 4 wks in the original studies and, in the extensions, every 8 (LITHE) or 12 (GROWTH95/96) wks from initial TCZ exposure to Aug 28, 2009; data were assigned to the nearest 12-wk point for pooling. Numbers of pts with assessments decreased over time because some pts had not yet reached later assessments or withdrew. Results include pts who had assessments at each visit; no imputation was performed for missing data. Data were included until <10% of the baseline pt number was reached.

Results: The analysis was in 2904 DMARD-IR pts and 618 pts who were never exposed to or had never failed MTX. By the cutoff date, 27.7% of DMARD-IR pts and 24.6% of never exposed/never failed MTX pts had withdrawn. In DMARD-IR pts, TCZ efficacy was shown by continuously increasing absolute numbers achieving ACR50, LDA (DAS28 ≤3.2), and DAS28 remission (DAS28 ≤2.6) through wk 96 and ACR70 through wk 120 (Table). In never exposed/never failed MTX pts, efficacy was shown by sustained absolute numbers achieving ACR50/70, LDA, and DAS28 remission to wk 96 (Table). While proportions who achieved ACR50/70, LDA, and DAS28 remission were maintained to wks 168 and 192, data must be interpreted with caution due to lower absolute numbers reaching these visits in the extensions (Table). By wk 144, 20% (396/1980) of assessed DMARD-IR pts and 27% (105/390) of assessed never exposed/never failed MTX pts had achieved the major clinical response of ACR70 maintained for 24 consecutive wks. At wk 120, 52.3% (1118/2139) and 38.4% (821/2139) of assessed DMARD-IR pts and 59.5% (278/467) and 38.3% (179/467) of assessed never exposed/never failed MTX pts, respectively, had ≤1 SJC and ≤1 TJC; 38.4% (772/2008) of DMARD-IR pts and 48.4% (216/446) of never exposed/never failed MTX pts had HAQ-DI scores ≤0.5.

DAS28 remission	**3** (20/616)	**37** (204/556)	**48** (243/502)	**52** (243/471)	**51** (236/461)	**55** (232/421)	**56** (184/329)	**57** (97/170)	**N/A**

Baseline (wk 0) was first active TCZ dose. For pts randomly assigned to TCZ in initial studies, this was at core study baseline. For pts assigned to placebo, first active dose of TCZ was at initiation of rescue or at first dose received in the open-label or exclusion studies. Data points with <10% of original sample size are not presented. n/n = pts with response/evaluable pts. For TJC and SJC. LOCF was used for any missing individual joint; total joint count used data available at that time point No imputation for missing HAQ-DI score. CRP, ESR, or VAS assessment. CRP was used to calculate ACR response If missing, ESR was used. LDA=DAS28≤3.2; DAS28 remission=DAS28<2.6.

Conclusions: Efficacy during long-term TCZ treatment was demonstrated by increasing numbers and/or proportions of pts achieving ACR50/70, LDA, and DAS28 remission until at least wk 96; for pts who reached wk 192, these benefits were maintained. These data support TCZ as an effective, long-term treatment for RA pts.

Mechanism of Inhibition of Joint Destruction by Rituximab in Rheumatoid Arthritis. Maria J. H. Boumans[2], Rogier M. Thurlings[3], Koen Vos[4], Danielle M. Gerlag[3] and Paul P. Tak[1]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Academic Medical Center/University of Amsterdam, Amsterdam, Noord-Holland, The Netherlands, [3]Academic Medical Center/University of Amsterdam, [4]Academic Medical Center/University of Amsterdam/Jan van Breemen Institute

Background: The RANK/RANKL/OPG system regulates osteoclast differentiation and activation. Osteoclasts are essential for the resorption of mineralised cartilage and subchondral bone in chronic arthritis. Treatment with rituximab may reduce the progression of joint destruction in rheumatoid arthritis (RA) patients, even in the absence of a clinical response. The underlying mechanisms are at present poorly understood.

Objective: To examine the effects of rituximab treatment on the RANK/RANKL/OPG system.

Methods: Twenty-eight rheumatoid factor positive and/or ACPA positive RA patients were treated with rituximab. Methylprednisolone pre-medication was omitted to study the specific effects of rituximab. Serum OPG was measured using multiplex analysis before and 16 weeks after treatment. Serum RANKL was measured by ELISA. OPG and RANK expression was measured in synovial biopsy samples of 20 patients before and 16 weeks after treatment using immunohistochemistry. Stained sections were evaluated by digital image analysis. Changes after treatment were assessed using the Wilcoxon's signed rank test.

Results: We found a significant decrease in serum levels of both OPG and RANKL 16 weeks after initiation of rituximab treatment (20 %, $P = 0.001$ and 40 %, $P = < 0.0001$ respectively) while the OPG/RANKL ratio increased ($P = 0.006$). In the synovial tissue, there was a significant decrease of 99 % in RANK-positive osteoclast precursors ($P = 0.018$), while OPG expression showed a non-significant decrease (25 %, $P = 0.069$).

Conclusion: The decrease in synovial osteoclast precursors associated with the increased OPG/RANKL ratio in the serum may explain in part the protective effect of rituximab treatment against progression of joint destruction.

Monocyte Migration to the Synovium in Rheumatoid Arthritis Patients Treated with Adalimumab. Marieke Herenius[3], Rogier Thurlings[4], Carla Wijbrandts[4], Roelof Bennink[5], Serge Dohmen[6], Carlijn Voermans[6], Diana Wouters[2], Elena Izmailova[7], Daniëlle Gerlag[4], Berthe van Eck-Smit[5] and Paul P. Tak[1]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Department of Immunopathology, Sanquin Research, Amsterdam, Noord Holland, The Netherlands, [3]Division of Clinical Immunology and Rheumatology, Academic Medical Center/University of Amsterdam, Amsterdam, The Netherlands, [4]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands, [5]Division of Nuclear Medicine, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands, [6]Landsteiner Laboratory, Department of Experimental Immunohematology, Sanquin Research, Amsterdam, The Netherlands, [7]Millennium Pharmaceuticals, Inc, Department of Research and Development, Cambridge, MA

Background: The mechanism of action of treatment with tumor necrosis factor –α (TNF-α) blockers in rheumatoid arthritis (RA) is still not completely understood. Since the recognition of synovial tissue as the primary site of inflammation, studying the synovium has provided insight into the pathogenesis of the disease and the mechanism of action of different therapies. Anti-TNF antibody treatment has been shown to result in marked reduction of synovial inflammation in both RA and psoriatic arthritis early after initiation of therapy. This early reduction in synovial inflammation could not be explained by apoptosis induction at the site of inflammation. This leaves either reduced cell influx or enhanced cell efflux to explain this process. The aim of this study was to test if adalimumab treatment could affect the influx of monocytes into the synovium.

Methods: We used a novel technique to analyze the migration of labelled autologous monocytes using scintigraphy. CD14+ monocytes were isolated from patients with RA, using a positive selection procedure with magnetic-activated cell sorting, and labeled with 99mTc-HMPAO. Scintigraphic scans were made 1 hour, 2 hours and 3 hours after re-infusion. This procedure was performed at three time points with a two weeks interval. Adalimumab treatment was started after the second set of scans.

Results: Re-infusion lead to a stable number of monocytes in the joint of interest after 1, 2 and 3 hours on all days. Already 14 days after the start of treatment with adalimumab a significant decrease in DAS28 was shown. There was no significant change in monocyte influx 1, 2 and 3 hours after re-infusion from day -14 to day 1, which was before the start of adalimumab treatment ($p=0.33$, $p = 0.67$, $p=0.21$, respectively). Of interest, the influx of monocytes did not decrease after re-infusion of monocytes comparing day 14 to baseline, indicating that adalimumab treatment did not affect the influx of monocytes early after initiation of treatment.

Conclusions: The results of this mechanistic study indicate that CD14+ monocyte influx into the synovium is not altered two weeks after the start of adalimumab treatment. As previous studies showed a rapid decrease in macrophage infiltration after anti-TNF- antibody therapy, which could not be explained by increased cell death, this points to an important role for enhanced efflux of inflammatory cells from the synovium. These data are in line with the recent observation that monocytes migrate towards the inflamed RA synovium at a slow macrophage-replacement rate and with the recently shown increase in lymphatic vessels in the synovium after TNF-α blockade.

1823

Multiple Regression Analysis on the Clinical Parameters Associating with Clinical, Structural and Functional Remission at 52 Weeks in RA Patients Treated with Anti-IL-6 Receptor Antibody, Tocilizumab – REACTION-2 Study. Tsutomu Takeuchi[2], Yoshiya Tanaka[5], Kouichi Amano[1], Eri Sato[4], Masao Nawata[5], Hayato Nagasawa[1], Daisuke Hoshi[4], Kazuyoshi Saito[5], Syunsuke Fukuyo[5], Kentarou Hanami[5], Takahiko Kurasawa[1], Hideto Kameda[3] and Hisashi Yamanaka[4]. [1]Division of Rheumatology and Clinical Immunology, Department of Internal Medicine, Saitama Medical Center, Saitama Medical University, Saitama, Japan, [2]Division of Rheumatology, School of Medicine, Keio University, Tokyo, Japan, [3]Division of Rheumatology, School of Medicine, Keio University, Tokyo, Japan, [4]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [5]The First Department of Internal Medicine, School of Medicine, University of Occupational & Environmental Health, Kitakyushu, Japan

Purpose: In order to identify the baseline clinical parameters associating with remission in RA patients treated with anti-IL-6 receptor monoclonal, tocilizumab (TCZ), we attempt to analyze clinical, laboratory and radiographic date set of REACTION-2 study by multiple logistic regression analysis.

Patients and Methods: In REACTION-2 study, a total of 255 RA patients were treated with TCZ 8 mg/kg every four weeks in three major rheumatic centers as daily clinical practice. In the assessment of disease activity, DAS28-ESR score <2.6 was defined as clinical remission, and non-responder imputation was used for missing data. For joint damage, modified TSS ≤0.5 was defined as structural remission, and for functional disability, HAQ score ≤0.5 was defined as functional remission. The associations with each type of remission were analyzed by multiple logistic regression analysis. The last-observation-carried-forward method was used in each of the analyses.

Results: Baseline characteristics of 255 patients showed that the mean age was 59.1 ± 13.3 years, the mean duration of RA was 12.4 ± 11.1 years, Methotrexate was used by 55.6% of patients, with the mean dose 5.31 ± 4.8 mg/week, and the mean steroid dose was 3.9 mg/day. Although a large proportion of patients, 62.8%, had been previously treated with biologics, the mean DAS28-ESR was 5.72.

Logistic regression analysis of baseline clinical parameters and clinical remission at 52 weeks demonstrated that clinical remission was significantly associated with younger age, lower DAS28-ESR, lower HAQ score, higher MTX dose and lower steroid dose at baseline. Multiple regression analysis of these associations confirmed that all the above factors independently influenced the achievement of clinical remission.

Similarly, multiple regression analysis revealed that HAQ score at baseline independently influenced the achievement of structural remission, while logistic regression analysis identified two significant parameters such as HAQ score and steroid dose at baseline.

Finally, multiple regression analysis demonstrated that only HAQ score at baseline independently influenced the achievement of functional remission, while logistic regression analysis showed six significant parameters including age, duration of RA, DAS28-ESR, HAQ score, mTSS score and MTX dose at baseline.

Conclusions: In this analysis, we identified the baseline clinical parameters influencing the various types of remission at 52 weeks by treatment with TCZ in clinical practice. It appears that baseline HAQ score before TCZ treatment is an important factor that influences clinical, structural and functional remission.

1824

Outcome of Interstitial Lung Disease (ILD) after Administration of Biologics in Patients with Pre-Existing ILD in RA. Shinji Motojima[1], Tamao Nakashita[1], Akira Inoue[1], Kei-ichi Inoue[1] and Natsuki Fujio[2]. [1]Department of Rheumatology and Allergy, Kameda Medical Center, Kamogawa, Chiba, Japan, [2]Department of Rheumatology and Allergy, Kameda Medical Center, Japan

Purpose: Development or exacerbation of interstitial lung disease (ILD) is a problem when biologics are administrated in patients with RA, and not a few fatal cases have been reported in Japan. According to the post-marketing surveillance report of TNF blockers, the development/exacerbation rate of ILD was 0.5 %. In our department, however, the rate was 4 % probably because we have many RA cases with ILD. Although the majority of the development/exacerbation is seen in patients with pre-existing ILD, there are no reports showing how frequently ILD exacerbates and what the outcome of ILD is in patients with pre-existing ILD. This study was carried out focusing on this viewpoint.

Method: Subjects were 34 patients with RA, with the mean age of 65. As a part of workup before administration of biologics, chest CT scan was done. After administration of biologics, chest X-ray film (CXR) was taken at least every 3 months. When newly developed shadows were found on CXR or when patients complained of respiratory symptoms for more than 2 weeks, chest CT scan was done again. The severity of ILD was graded into 4, grades 0 to grade 3, according to the extent of ILD on chest CT. The biologics administrated were infliximab (IFX) for 8, etanercept (ETN) for 24 and adalimumab (ADA) for 2, respectively. The duration of observation was from 1 to 46 months with the median of 9 months.

Results: The ILD of 18, 10 and 6 patients were graded into grade 1, 2 and 3, respectively. The ILD exacerbated in 11 subjects (32.3 %); the duration from the introduction of biologics to the exacerbation was from 1 to 27 months with the median of 9 months. The biologics used at the exacerbation of ILD were IFX in 5, ETN in 5 and ADA in 1, respectively. IFX induced the exacerbation of ILD more frequently than other biologics ($p < 0.05$). There were no differences between the subjects with ILD exacerbation and those without it in age, gender, RF titer, the ILD grade, KL-6 concentration, the dose of prednisolone and MTX, and DAS28-ESR. The biologics were withdrawn in 8 of 11 subjects with ILD exacerbation, and 2 subjects with ILD grade 2 and 3 died due to respiratory failure.

Conclusions: The exacerbation rate was very high in patients with pre-existing ILD when biologics were administrated. Unfortunately we could not extract the factors that predict the ILD exacerbation.

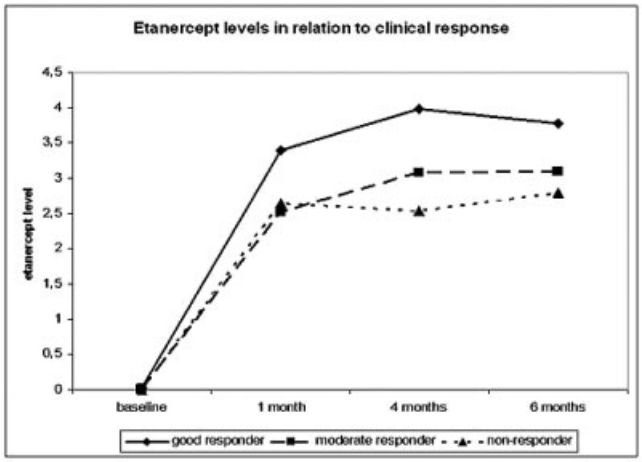
1825

Patients Not Responding to Etanercept Obtain Lower Trough Etanercept Concentrations Compared to Responding Patients. Anna Jamnitski[1], Michael T. Nurmohamed[1], Margreet M. Hart[2], Ben A. Dijkmans[3], Lucien Aarden[2] and Gerrit Jan Wolbink[1]. [1]Jan van Breemen Institute, [2]Sanquin Research, [3]VU Medical Center

Purpose: A substantial proportion of the patients with rheumatoid arthritis (RA) failed to respond on treatment with etanercept. Previous research has shown that etanercept appeared to be less immunogenic compared to adalimumab and infliximab. The goal of this study is to investigate the relationship between etanercept levels and clinical response in a large cohort of RA patients.

Methods: Between 2004 and 2008, 292 consecutive patients with active RA (DAS28 > 3.2) and a new etanercept prescription were included in an observational cohort at the Jan van Breemen Institute, Amsterdam. Clinical response variables and etanercept levels were collected at baseline and after 1, 4 and 6 months of etanercept treatment. Trough serum etanercept levels were measured by ELISA (Sanquin research, The Netherlands). Last observation carried forward (LOCF) data was used for patients who discontinued the treatment with etanercept before 28 weeks. Differences between EULAR responders and non responders were evaluated by using an independent t-test, confounding analyses were performed using multiple regression analysis.

Results: After 6 months of etanercept treatment 103 patients were good, 115 were moderate and 74 were non responders according to EULAR response criteria. Etanercept levels were undetectable at baseline (<0.001 mg/l). Patients with good EULAR response had significantly higher trough etanercept concentrations than EULAR non responders, $p = 0.009$ at 1 month and $p<0.001$ at both 4 and 6 months. To know, 3.40 (2.22 – 4.62) at 1 month, 3.98 (2.72 – 5.35) at 4 months and 3.78 (2.53 – 5.17) at 6 months in EULAR responders compared to 2.64 (1.20 – 3.89) at 1 month, 2.54 (1.12 – 3.94) at 4 months, and 2.80 (1.27 – 3.93) at 6 months in EULAR non responders. No antibodies were detected against etanercept.



Conclusion: This study demonstrates for the first time that patients with good EULAR response obtain significantly higher levels of etanercept than patients not responding to etanercept treatment. Furthermore this study confirms that etanercept is less immunogenic than another TNF-inhibitors.

Disclosure: A. Jamnitski: None; **M. T. Nurmohamed:** None; **M. M. Hart:** None; **B. A. Dijkmans:** None; **L. Aarden:** None; **G. J. Wolbink:** Wyeth Pharmaceuticals, 2.

1826

Prevalence and Persistence of Low Infliximab Serum Trough Levels in RA Patients with Low Disease Activity in Daily Clinical Practice. Aatke van der Maas[3], Alfons A. Den Broeder[4], Gert-Jan Wolbink[1], Frank H. J. van den Hoogen[4], Piet L. C. M. van Riel[5] and Bart J. F. van den Bemt[2]. [1]Department of Immunopathology, Sanquin Research, Amsterdam, The Netherlands, [2]Department of Pharmacy, St. Maartenskliniek, Nijmegen, The Netherlands, [3]Department of Rheumatology, St. Maartenskliniek, Nijmegen, The Netherlands, [4]Department of Rheumatology, St. Maartenskliniek, Nijmegen, The Netherlands, [5]Department of Rheumatology, St. Radboud UMCN, Nijmegen, The Netherlands

Treatment of RA with infliximab requires optimal dosing to balance maximum effect and minimal dose related side effects and costs. DAS driven dose de-escalation can be used in patients with low disease activity, but costs time and can lead to flaring. Since infliximab serum trough levels and presence of HACA's (Human Anti-Chimeric Antibodies) demonstrated a correlation with clinical effect in cross-sectional studies, they could be used as predictors for successful de-escalation. There is however not much data on prevalence and persistence of serum trough levels and HACA's in RA patients with low disease activity. This prospective observational study aims to study prevalence and longitudinal course of serum trough levels and HACA's and their persistence within patients treated in daily clinical practice, focussing on patients with low disease activity.

Methods: All RA patients treated with infliximab at the Sint Maartenskliniek Nijmegen for at least 6 months were included and followed in a 1.5 year period. At every visit DAS28, serum trough levels and HACA's were measured. Cross sectional analysis of the prevalence of low serum trough levels (<1.0 μg/ml) and/or HACA's was done in all patients and in a subgroup with stable low DAS28 ≤ 3.2 for at least 3 consecutive visits. Persistence at 2 consecutive visits in patients with stable DAS28 and infliximab dosing was analysed by means of a Spearman correlation coefficient and Wilcoxon test for serum trough levels, and with kappa analysis for HACA's presence.

Results: 147 RA patients were included, 65 and 40 patients had a DAS28 $<$ 3.2 and 2.6 respectively. In 35% of the patients with a DAS28$\leq$2.6 and in 31% with a DAS28$\leq$3.2 non-measurable/low serum trough levels were found. 30% was associated with presence of HACA's (see table 1). The longitudinally analysis showed that, in patients with stable low DAS28, 38% had low to non measurable serum trough levels, with nearly 50% showing HACA's. There was no statistical difference between trough levels at 2 consecutive visits in patients with stable DAS28 and dosing ($p=0.38$). The correlation between serum trough levels between two consecutive visits was very high ($r=0.97$, $p=0.00001$), as was the agreement for the presence of HACA's between visits (kappa 1.0).

Table 1. Number of patients with low and high infliximab serum trough levels and HACA's in patients with low and high DAS28.

DAS28	Infliximab serum trough levels		HACA's		Total
	Low* (%, [95% CI])	High* (%, [95% CI])	Yes (%, [95% CI])	No (%, [95% CI])	
≤3.2	20 (31%, [19–42])	45 (69%, [58–81]))	7 (11%, [3–19])	58 (89%, [81–97])	65
≤2.6	14	26	5	35	
2.6–3.2	6	19	2	23	
>3.2	39 (48%, [37–59])	43 (52%, [41–63])	25 (30%, [59–80])	57 (70%, [20–41])	82
Total	59	88	32	115	147

*Low serum trough levels are defined as <1.0 μg/ml, high as >1.0 μg/ml

Discussion: Among patients with sustained low disease activity low to non measurable serum trough levels are prevalent both in cross sectional and longitudinal analyses. In patients with stable treatment and DAS28 there is a high persistence between two consecutive measurements of trough levels and HACA's. Therefore, infliximab serum trough levels and HACA are promising candidates to be tested for their predictive value for successful dose de-escalation.

Regulatory T Cells from Patients with Rheumatoid Arthritis Are Not Affected by Adalimumab and Etanercept. Thierry Lequerré[3], Céline Blache[2], Stéphanie Beuteux[2], Arnaud Roucheux[1], Ingrid Dedreux[1], Serge Jacquot[1], Xavier Le Loët[4], Olivier Boyer[1] and Olivier Vittecoq[4]. [1]Department of Immunology, Inserm905, Rouen University Hospital, University of Rouen, [2]Inserm905, University of Rouen, [3]Rheumatology Department, Inserm905, Rouen University Hospital, University of Rouen, Rouen, France, [4]Rheumatology Department, Inserm905, Rouen University Hospital, University of Rouen

Background: Despite the overall benefits of TNFα blocking agents [adalimumab (ADA), etanercept (ETA), infliximab (INF)], their immune effects on $CD4^+CD25^+$ regulatory T cells (Tregs) in rheumatoid arthritis (RA) patients have not been fully characterized and is still controversial. It was suggested that INF increased significantly the number of Tregs in RA patients responding to INF. To our knowledge, any study compared the TNFα blocking agent effects' differentiating antibodies and soluble receptor on the number of Tregs cells. The objective is to analyse the ETA and ADA treatment effects' on the Tregs population in RA patients.

Material and Methods: RA patients (n = 48) were treated with either ADA (n = 28) or ETA (n = 20) associated with stable dose of methotrexate or leflunomide. Demographic and clinical data were collected at baseline, after 6 and 12 weeks of treatment. The disease activity score 28 (DAS28) criteria for response to these drugs were applied to assess clinical efficacy after 12 weeks of treatment, that led us to compare the Tregs population in responders [including good responders (GR) and moderate responders (MR)] and no responders (NR). Human blood mononuclear cells were isolated from whole venous blood by Ficoll–Hypaque centrifugation and samples were used fresh to perform flow cytometry analysis. Tregs were defined by different gating strategies ($CD4^+CD25^{hi}$, $CD4^+FoxP3^+$, $CD4^+CD25^+CD127^{lo}$). For all the statistical analyses, values less than 0.05 were considered significant.

Results: The overall mean ($\pm$ SD) disease duration was 9.54 $\pm$ 9.8 years and the DAS28 score indicated that all these patients had highly active RA (5.46 $\pm$ 0.9) at baseline. Prior to treatment, all variables were similar for ADA and ETA subsets. The majority of RA patients (57.1% in ADA group and 65% in ETA group) received corticosteroids. After 12 weeks of treatment, the percentages of GR, MR and NR were respectively 46.5, 35.7 and 17.8% in ADA group and 30, 20 and 50% in the ETA group. The percentage of Tregs was 5.5 $\pm$ 0.04% for ADA group and 4.95 $\pm$ 0.02% for ETA group before treatment. Stratifying our RA patients based on corticosteroids status did not reveal any differences in Tregs frequencies before treatment. Overall, and also when stratifying RA patients according to the drug, the TNFα blocking agent had no effect on the percentage and on the absolute number of $CD4^+CD25^+$ cells in these patients after 6 weeks or 12 weeks of treatment. Moreover, the percentage of Tregs did not change at 6 and 12 weeks in RA patients responding to ADA or ETA as compared to RA patients nonresponding. Furthermore, the $CD4^+CD25^+CD45RA^+$, $CD4^+CD25^+CD45RO^+$ and $CD4^+CD25^+CD62L^+$ cells populations were unaffected by TNFα blocking agents whatever the response to these drugs.

Conclusion: This is the first study analyzing the impact of ADA and ETA on the Tregs compartment of a substantial number of RA patients. None of these two molecules modified the phenotype and the percentage or the absolute number of blood Tregs after 6 and 12 weeks of treatment whatever the phenotype used to assay these Tregs. However, we can not exclude that ADA and ETA may have more subtle effects such as on the functionnal capacity of tregs to regulate cytokines production.

1828

Relationship between Rituximab Serum Levels and Progression of Structural Damage in Rheumatoid Arthritis Patients. Maria J. H. Boumans[2], Y. K. O. Teng[6], Rogier M. Thurlings[3], Koen Vos[4], Steven O. Stapel[7], Gertjan Wolbink[5], Janneke Tekstra[8] and Paul P. Tak[1]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Academic Medical Center/University of Amsterdam, Amsterdam, Noord-Holland, The Netherlands, [3]Academic Medical Center/University of Amsterdam, [4]Academic Medical Center/University of Amsterdam/Jan van Breemen Institute, [5]Jan van Breemen Institute, Sanquin Research, Amsterdam, [6]Leiden University Medical Center, [7]Sanquin Research, Amsterdam, [8]University Medical Centre, Utrecht

Background: Treatment with rituximab reduces disease activity in patients with rheumatoid arthritis (RA). The current dosing schedule of rituximab has been shown to induce and maintain a clinical response, and is also protective against progression of joint destruction. Studies on the relationship between serum levels of rituximab and its effects on structural damage may provide insights that may facilitate further optimisation of dosing regimens.

Objective: To determine whether low rituximab serum levels are associated with progression of structural damage in RA patients.

Method: Sixty-three RA patients were treated with two infusions of 1000 mg rituximab (days 1 and 15) in three different centres. The change in total Sharp score (TSS) after 1 year was used as radiographic endpoint and patients were divided into progressors (increase in TSS $\geq$ 5) versus non-progressors. Rituximab serum levels were measured by sandwich ELISA after 4 and 12 weeks (LUMC and UMCU) or 4 and 16 weeks (AMC). Differences were analyzed using the Mann-Whitney test.

Results: There was no (trend towards a) difference in rituximab levels between progressors versus non-progressors 4 weeks and 12/16 weeks after treatment in the different cohorts (week 4: LUMC: $P = 0.8$, UMCU: $P = 0.38$ and AMC: $P = 0.5$; week 12: LUMC: $P = 0.47$, UMCU: $P = 0.14$; week 16: AMC: $P = 0.46$)). There was also no difference in rituximab levels between progressors and non-progressors when the data of the cohorts were pooled (week 4: $P = 0.58$ (all 3 cohorts); week 12: $P = 0.64$ (LUMC and UMCU)) (Table 1).

Table 1. Rituximab serum levels 4, 12 and 16 weeks after initiation of treatment.

Week 4			
	Progressors	**Non-progressors**	**P-value**
LUMC	125 (57–149) n=12	81 (118–153) n=12	0.8
UMCU	188 (81–194) n=3	152 (64–179) n=6	0.38
AMC	112 (45–172) n=4	128 (103–160) n=19	0.5
3 cohorts pooled	126 (63–187) n=19	128 (99–161) n=37	0.58
Week 12			
	Progressors	**Non-progressors**	**P-value**
LUMC	4.4 (3.2–11.4) n=13	10.8 (2.9–21.6) n=12	0.47
UMCU	13.2 (2.5–28.2) n=6	2.6 (0.06–8.2) n=7	0.14
2 cohorts pooled	5.9 (3.2–19.4) n=15	6.6 (0.5–16.6) n=19	0.64
Week 16			
	Progressors	**Non-progressors**	**P-value**
AMC	1.8 (0.3–22.7) n=4	3.5 (1.3–7.8) n=19	0.46

Values represent the median and the interquartile range.

Conclusion: The rituximab serum levels between 4 and 16 weeks after initiation of treatment were similar between progressors and non-progressors. The results do not support the use of higher dosages of rituximab to inhibit progression of joint destruction.

1829

Response, Remission, and Flare during Early Treatment of Rheumatoid Arthritis with Infliximab. Ronald F. Van Vollenhoven[2], Dimitrios Boumpas[10], Rene Westhovens[9], Marek Brzosko[7], Karin E. Svensson[8], Olav Bjorneboe[3], Cees Meeuwisse[5], Shankar Srinivasan[4], Nathan Vastesaeger[6] and Philippe Gaudin[1]. [1]CHU Hôpital Sud, Echirolles Cedex, France, [2]Karolinska University Hospital, Stockholm, Sweden, [3]Martina Hansens Hospital, Gjettum, Norway, [4]Merck and Company, Inc, Kenilworth, NJ, [5]MSD, Oss, The Netherlands, [6]MSD, Brussels, Belgium, [7]Pomeranian Medical University, Szczecin, Poland, [8]Skövde Hospital, Skövde, Sweden, [9]University Hosp KU Leuven, Leuven, Belgium, [10]University Hospital of Heraklion, Heraklion Crete, Greece

Background: For RA patients who are treated with infliximab (IFX), increases in dose and/or frequency can maximize benefit. Our objective was to investigate response patterns during first 14 weeks of treatment with IFX to identify patients who may be candidates for dose optimization

Methods: This was a phase-IV, multicenter, observational study conducted in Europe. Enrollees were IFX- naïve adults with RA for whom treatment with IFX 3 mg/kg had been chosen per label. The relationship between patient characteristics and baseline DAS28 was explored using descriptive statistics. In the efficacy-evaluable population, subjects were retrospectively classified into 3 groups: disease duration $<$ 3 yr/anti-TNF naïve (group 1); disease duration $\geq$ 3 yr/anti-TNF naïve (group 2); failed/did not tolerate prior anti-TNF (group 3). EULAR criteria for response and remission and inverse EULAR criteria for flare were used to describe change in disease activity during induction (infusions weeks 0, 2 and 6) and the first 8-week infusion interval (week 14).

Results: 728 patients were enrolled—78.4% female, mean age 54.1 years (SD 13.1), mean disease duration 9 years (SD 9.0). Weak correlations with baseline DAS28 were found for age ($r = 0.1402$, $P < 0.005$) and weight ($r = 0.1152$, $P < 0.005$), but not for gender and disease duration. Of 662 patients evaluable for efficacy, 76 (11.5%) were in group 1, 447 (67.5%) were in group 2, and 123 (18.6%) were in group 3, with 2.4% unclassified. The mean baseline DAS28 was 5.2 (SD 1.2) and core DAS28 components were similar among groups, with the exception of mean CRP, which was higher in group 1 than in 2 and 3 (33.6, 21.4, and 22.0 mg/L, respectively).

EULAR response (moderate/good) was achieved in 74% of all patients by week 6, and by week 14 this proportion had increased to 81.8% in group 1, remained stable in group 2, and decreased to 67.3% in group 3 (differences not significant). Remission was achieved in 25% of patients in group 1, 25% in group 2, and 15.7% in group 3 at week 6; by week 14, 23% of all patients were in remission with no significant differences between groups. Of the 463 patients who had EULAR response at week 6, 75 (16.2%) had disease flare at week 14 (13.5% group 1, 15.1% group 2, 20.5% group 3). Of core DAS28 components, CRP showed an increase from 9.0 mg/L at week 2 to 18.3 mg/L at week 14, whereas others remained stable or continued to improve. Interestingly, the proportional contribution of global health VAS to the total DAS28 score increased from 35.7% at baseline to 43.4% at week 14 ($P < 0.01$). The most common adverse event (AE) was infections (13.2%). Serious AEs were reported by 5.5% of patients, and 6.8% discontinued IFX because of AEs.

Conclusion: Most patients treated with IFX achieve moderate/good EULAR response early in treatment. Response rates at 16 weeks are highest in patients naïve to anti-TNF agents. Early disease flare is uncommon and may be more frequent in prior anti-TNF users. Close monitoring with DAS28 during IFX treatment may help identify candidates for dose optimization.

Rituximab (RTX) Is More Effective in Active Sero-Positive RA Than Sero-Negative RA. Abdul Khan[3], Taher Mahmud[4], Tony Hammond[1], Mike Batley[2] and Alison Leak[5]. [1]Maidstone General Hospital Hermitage Lane Maidstone Kent, Maidstone, Kent, United Kingdom, [2]Maidstone General Hospital Maidstone Kent, Maidstone, Kent, United Kingdom, [3]Maidstone General Hospital, Maidstone, Kent, Maidstone, Kent, United Kingdom, [4]Pembury Hospital, Pembury, Kent, United Kingdom, [5]Queen Elizabeth Queen Mother Hospital, Margate, Kent, United Kingdom

Introduction: The efficacy of Rituximab (RTX) was established in an open label study of 161 patients with sero-positive RA (Edwards J *et al* 2004). Evidence is now accumulating from clinical trials that patients with sero-positive RA respond better to RTX than those with sero-negative disease (Isaacs J *et al* EULAR 2009, Tak P *et al* EULAR 2009). NICE guidance in the UK states that RTX is indicated for severe active RA (usually DAS28 > 5.1) when patient has had inadequate response to DMARDs, and also failed anti-TNF therapy. NICE defines an adequate response to RTX as improvement in DAS28 by 1.2 or more. We have retrospectively analysed the response to one course of RTX in all 139 RA patients treated within Kent & Medway Rheumatology Network, comparing sero-positive and sero-negative patients.

Methods: All 10 rheumatologists in the K&M Network treating RA patients with RTX agreed to submit data for audit purposes to define local practice. This abstract is based on a review of the hospital notes of all 139 patients known to have had at least 6 months follow-up after their first course of RTX (dosage 1000mg on day 1 and 15) for active RA. Data was analysed for age, sex, disease duration, prior DMARD and anti-TNF treatment, positivity of Rheumatoid factor and anti-CCP antibodies, and response to RTX (with current DMARDs). Categorical variables were compared using Fisher's exact test; normally distributed continuous measures were compared using unpaired t-test and variables not normally distributed were compared using Mann-Whitney test.

Results: There were 85 patients with sero-positive RA (RF+CCP+ 28, RF+CCP- 36, RF+CCP not done 7, CCP+RF- 14), and 54 patients with sero-negative RA (all RF negative, 50 CCP negative, 4 CCP not done). There were no differences between groups for age, sex, disease duration or number of prior anti-TNF drugs, nor current DMARD treatment with RTX, but sero-negative RA had more DMARDs prior to RTX 5.8 (SD1.4), compared to sero-positive RA 5.2 (SD1.5) $p = 0.03$.

Prior to treatment with RTX seropositive RA had a significant higher DAS28 score, mean 6.1, compared to 5.8 for sero-negatives ($p= 0.02$). However, post RTX sero-positive RA had significant lower DAS (mean 3.9) than sero-negatives (5.1), and reduction in DAS was significant greater in sero-positive RA (mean 2.2), compared to mean 0.6 in sero-negatives (both $p<0.001$)

81% of sero-positive RA had a good EULAR response, compared to only 22% for sero-negative RA ($p<0.001$). 67% of sero-positive RA reached low DAS (<3.2) and 15% remission (DAS<2.6), compared to 4% sero-negative RA ($p <0.001$), and none remission ($p =0.002$).

RTX Response

	Category	Seronegative Number (%)	Seropositive Number (%)	P-value
DAS28 pre treatment	<5.1	11 (20%)	9 (11%)	0.13
	5.1–6.5	35 (65%)	54 (64%)	
	>6.5	8 (15%)	22 (26%)	
Below 5.1 post treatment	Yes	22 (41%)	73 (86%)	<0.001
	No	32 (59%)	12 (14%)	
Low disease state post treatment	Yes	2 (4%)	57 (67%)	<0.001
	No	52 (96%)	28 (33%)	
Remission post treatment	Yes	0 (0%)	13 (15%)	0.002
	No	54 (100%)	72 (85%)	
EULAR response	No response	32 (59%)	8 (9%)	<0.001
	Moderate response	10 (19%)	8 (9%)	
	Good response	12 (22%)	69 (81%)	
EULAR outcome	None	38 (70%)	9 (11%)	<0.001
	Moderate	14 (26%)	49 (58%)	
	Good	54 (4%)	85 (32%)	

Conclusions: In this UK cohort, sero-positive RA patients respond more effectively to RTX than sero-negative RA, even when well matched for disease activity, disease duration and prior treatment.

Safety and Efficacy of IL-1 Trap in Resistant Adult Onset Still's Disease: 24 Month Follow-Up of Open Label Treatment and Biomarkers of Response. Cailin Henderson, Mildred Wilson, Tuyet-Hang Pham, Gregory Dolan, Adriana Gobbo, Christopher Snyder, Elizabeth Joyal and Raphaela Goldbach-Mansky. NIAMS/NIH

Purpose: To investigate IL-1 pathogenesis in adult onset Still's disease (AOSD) by studying the efficacy and safety of treatment with IL-1 Trap. Outcomes were clinical disease activity indicators, inflammatory markers, safety, and serum cytokine levels.

Methods: Prospective, open-label dose escalation treatment study with IL-1 Trap over 24 months in patients with treatment refractory AOSD. Patients were treated with 100mg weekly subcutaneous doses and escalated to 320 mg weekly in the event of an incomplete response.

Results: 5 patients (3 female, 2 male) with active disease were enrolled. Mean age on entry was 30 years and mean disease duration was 74.2 months (range 14–204 months). All patients had failed DMARDs including methotrexate (5/5), TNF-inhibiting drugs (4/5), thalidomide (1/5), azathioprine (1/5), rituximab (1/5), cyclophosphamide (1/5), and anakinra (3/5). Disease flares occurred in all patients necessitating dose escalation to 320 mg / week. Improvements were observed in mean abnormal WBC, hemoglobin, and platelet counts. Inflammatory markers including ferritin, SAA, ESR, and CRP decreased. Three patients met ACR 20% response criteria and two of these three met ACR 50% response criteria. The two non-responders required intermittent rescue therapy with systemic steroids for ongoing disease activity. At 24 months, the three responders had lower patient global scores, daily prednisone doses, ferritin, SAA, CRP, and ESR levels. Patients had significantly higher TNFα, IL-6, and IL-18 at baseline compared healthy controls. The reduction in IL-6 and TNFα but not IL-18 at 24 weeks tended to be higher in the responders. Patients responding to IL-1 Trap had higher levels of IL-18 at baseline than non-responders (34412 vs. 3943). Adverse events included macrophage activation syndrome in one patient and mycobacterial infections in two patients; one with bursitis and one with a skin infection.

	Responders (n=3)				Non-Responders (n=2)				Total (n=5)			
Outcome (SD)	Month 0	Month 6	Month 12	Month 24	Month 0	Month 6	Month 12	Month 24	Month 0	Month 6	Month 12	Month 24

CRP mg/dl	5.5 (1.6)	2.8 (1.3)	1.5 (1.1)	2.2 (2.3)	13.1 (4.6)	3.0 (3.2)	1.5 (1.0)	5.7 (1.9)	8.5 (4.9)	2.9 (1.9)	1.5 (0.9)	3.6 (2.7)
ESR mm/hr	40.3 (19.7)	25.7 (12.4)	27.7 (26.3)	26.3 (18.2)	99.0 (12.7)	40.0 (15.6)	31.5 (6.4)	61.5 (33.2)	63.8 (35.6)	31.4 (14.1)	29.2 (19.0)	40.4 (28.5)

Conclusions: Open label treatment of refractory AOSD patients with IL-1 Trap resulted in meaningful clinical improvements in 3/5 patients. 2/3 patients achieved a response after one year of treatment and dose adjustments suggesting that longer term treatment may be necessary to optimally control disease. Patients showed increased levels of IL-6, IL-18, and TNFα compared to controls and higher levels of serum IL-18 may predict a successful response. This proof of concept study detected differential responses to treatment with IL-1 Trap in patients with refractory Still's disease and suggests biomarkers that may be useful in predicting response to treatment.

Safety, Efficacy, and Sustained Improvements in Household Productivity and Daily Activities with Certolizumab Pegol (CZP) Monotherapy over 2 Years in Patients with Active Rheumatoid Arthritis (RA). Roy M. Fleischmann[4], Ernest Choy[3], Ronald van Vollenhoven[2], Niti Goel[6], Oana Purcaru[5], Kristel Luijtens[5] and Vibeke Strand[1]. [1]Division of Immunology and Rheumatology, Stanford University School of Medicine, Palo Alto, CA, [2]Karolinska Institute, Stockholm, Sweden, [3]Kings College Hospital, London, United Kingdom, [4]MCRC, University of Texas, Dallas, TX, [5]UCB, Brussels, Belgium, [6]UCB, Smyrna, GA

Background: CZP was effective and well tolerated as monotherapy vs placebo (P) when given as 400 mg every 4 wks (Q4W) for 24 wks in the FAST4WARD double-blind (DB) Phase III study in patients (pts) with active RA previously failing on DMARDs.[1] We present 2-yr data on safety (primary), efficacy (secondary), and effects on household work and daily activities from an open-label extension (OLE).

Methods: Pts who completed FAST4WARD or withdrew on/after Wk 12 were eligible for CZP 400 mg Q4W in the OLE. The majority of pts (75%)

enrolled were from the USA. Adverse event (AE) and serious AE (SAE) cases per 100 pt-yrs were analyzed according to original DB randomization and through Wk 112 for all those receiving ≥1 CZP dose during the DB phase or OLE. Efficacy, including ACR response rates (NRI) and components (LOCF), was assessed over 112 wks from FAST4WARD baseline (BL) in CZP completers entering the OLE and for the ITT (NRI/LOCF). Household productivity and impact on family/social/leisure activities were assessed from BL (Q4W for 6 months, then Q12W) using the Work Productivity Survey (WPS-RA).[2] FAST4WARD: NCT00548834; FAST4WARD OLE: NCT00160693.

Results: Of 220 randomized pts (111 CZP, 109 P), 104 completed and 116 withdrew (35 CZP, 81 P); 32 were excluded for methotrexate use. Of 188 pts included in this safety analysis, 170 received CZP in the DB phase or OLE. Total mean CZP exposure at Wk 112 was 17.2 months (Table). No evidence of an increased incidence of AEs following longer-term CZP exposure and no new safety signals were observed. The majority of AEs were mild or moderate in intensity (Table). Infections (Table) and cardiac disorders were the most frequently reported SAEs. AEs led to withdrawal in 26 CZP-treated pts. 3 pts died during the OLE: 1 each from acute MI, cardiac arrest, and metastatic lung cancer. No cases of tuberculosis were reported. In 69 CZP completers entering the OLE, ACR20 and 50 response rates (70.3% and 34.4%, respectively, at Wk 112), and individual ACR subcomponent improvements, were sustained throughout. ITT analysis yielded similar ACR20 and 50 response rates (56.3% and 25.2%). The CZP completers also had on average fewer 1) household days lost, 2) days with reduced household productivity, and 3) missed days of family/social/leisure activities per month at Wk 100 compared with BL (1.0 vs 10.1; 1.1 vs 12.1 and 0.3 vs 5.0, respectively). Improvements seen as early as Wk 4 were sustained to Wk 100.

Table. Treatment-emergent AEs (safety population)

	DB phase		DB+OLE
	P (n=92)	CZP (n=96)	CZP (n=170)
Total mean exposure (months)	3.9	5.2	17.2
AEs (cases/100 pt-yrs)			
Any AE	297.1	387.5	206.9
Mild AE	156.7	218.0	114.9
Moderate AE	163.0	165.4	95.4
Severe AE	28.0	17.0	16.1
SAEs	10.1	19.6	14.5
Serious infection	0	4.8	4.1

Conclusion: There was no evidence of increased incidence of AEs with longer-term exposure to CZP 400 mg monotherapy Q4W in the OLE. This treatment regimen conferred sustained improvements in RA signs, symptoms and productivity in the home, and was associated with increased participation in family/social/leisure activities over 2 yrs.

Statins Inhibit the Anti-Rheumatic Effects of Rituximab in Rheumatoid Arthritis—Results from the Dutch Rheumatoid Arthritis Monitoring (DREAM) Registry.

Elke Arts[4], Tim L. Jansen[2], Alfons Den Broeder[6], Harald E. Vonkeman[3], Ellen Dutmer[1], Mart A. F. J. Van de Laar[3], Piet L. C. M. Van Riel[5] and Jaap Fransen[5]. [1]Gelderse Vallei Hospital Ede, [2]Medical Centre Leeuwarden, [3]Medisch Spectrum Twente & University of Twente, [4]Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, [5]Radboud University Nijmegen Medical Centre, [6]Sint Maartenskliniek

Objective: Rituximab (RTX) is used in the treatment of lymphomas and Rheumatoid Arthritis (RA). In lymphoma studies, it has been suggested that statins may inhibit the efficacy of RTX by impairing its binding to CD20. However, evidence is ambiguous. This study aims to investigate whether in RA, the combination of statins and RTX, compared with RTX alone, reduces its effect on disease activity at 6 months.

Methods: All (N=187) RA patients who started on RTX in the DREAM registry were included in this prospective cohort study, 23 patients were exposed to the combination of statins and RTX. The primary outcome was disease activity (DAS28) at 6 months, analyzed using ANCOVA. Power was calculated in advance and exceeded 0.80, α=0.05. The secondary outcome was drug survival of the first RTX course, analyzed using Cox-proportional hazards regression.

Results: Patients exposed to statins were older and more frequently male. Disease duration, ESR, DAS28, rheumatoid factor, previous DMARDS, use of glucocorticoids, and concomitant MTX use did not differ ($p>0.05$) at baseline. At 6 months DAS28 scores differed significantly ($p=0.023$) between patients exposed (mean 4.8, SD 1.5) and unexposed (mean 4.3, SD 1.1) to statins. RTX survival was significantly shorter in the exposed group, HR (95%CI) of 2.3 (1.4–3.9). Baseline DAS28 and rheumatoid factor were included as covariates in all models.

Conclusion: In RA, concomitant use of statins significantly reduces the effect of RTX on disease activity. This lends support to the hypothesis that statins can reduce the clinical effects of RTX, possibly through cholesterol depletion.

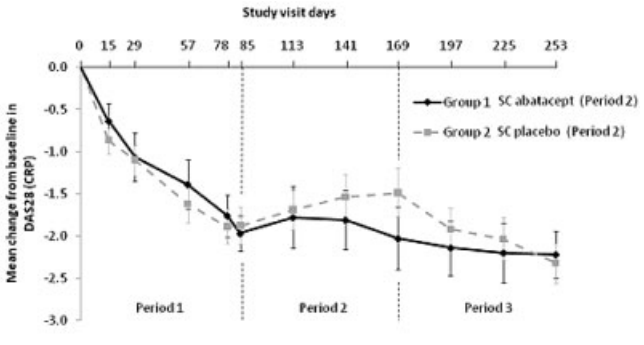
Subcutaneous (SC) Abatacept Is Well-Tolerated, Demonstrates Clinical Efficacy and Is Associated with Low Immunogenicity Following Withdrawal and Re-Introduction: Phase III Evaluation in Rheumatoid Arthritis (RA) Patients Responding to Abatacept. Jeffrey L. Kaine[6], Geoffrey S. Gladstein[5], Ingrid Strusberg[4], Manuel Robles[2], Ramesh Pappu[1], Ingrid Delaet[1], Miranda Pans[1] and Charles L. Ludivico[3]. [1]Bristol-Myers Squibb Co, Princeton, NJ, [2]Centro Médico Toluca, Metepec, Mexico, [3]East Penn Rheumatology Associates, East Stroudsburg, Philadelphia, PA, [4]Instituto Reumatológico, Strusberg, Cordoba, Argentina, [5]New England Research Associates, Trumbull, CT, [6]Sarasota Arthritis Center, Sarasota, FL

Background: In clinical practice, patients (pts) may temporarily interrupt their RA biologic therapy leading to reduced drug concentrations and immunogenicity, which can impact safety and efficacy, particularly during re-administration. We examine the impact of withdrawal and re-introduction of SC abatacept on safety, immunogenicity and efficacy in pts with RA receiving background methotrexate (MTX).

Methods: Pts with mild-to-moderate RA (receiving MTX for ≥3 mths) were enrolled in this randomized, double-blind, Phase III withdrawal trial. During a 12-wk, open-label (OL) period (I) pts received weekly SC abatacept 125 mg. On Day 1, pts also received an intravenous (IV) loading dose (~10 mg/kg according to weight range). Period I responders (DAS28 [CRP] reduction from baseline of ≥0.6) were randomized (1:2) in Period II to either continue SC abatacept (Group 1) or to receive placebo (PBO; Group 2) for 12 wks. All Period II-treated pts could enter the 12-wk, OL Period III; Group 1 pts continued SC abatacept, while Group 2 pts re-initiated SC abatacept with or without an IV loading dose (Groups 2a and 2b, respectively). Pts who received ≥1 dose of abatacept were monitored for safety, and events are presented by Period. Immunogenicity (pts with ELISA-detected anti-abatacept antibodies) and disease activity (DAS28) data are presented for pts who entered Period II (as-observed).

Results: Of 167 pts who entered Period I, 10 (6%) discontinued, 37 (22%) were non-responders, and 120 (72%) entered Period II (Group 1 n=40; Group 2 n=80); 40 from Group 1 and 79 from Group 2 entered Period III, of whom 40 and 77 completed Period III. At baseline (Period II population), mean age was 49.0 (SD: ± 13.2) yrs, disease duration was 6.6 (± 6.5) yrs, DAS28 was 4.8 (± 0.8). Serious adverse events (SAEs) were infrequent during Periods I–III (<2.5% of pts across groups), with no change in trend over time. Local injection-site reactions were reported in two pts in Period I. One serious infection (cellulitis, considered unrelated) was reported in Period I. No autoimmune disorders or malignancies were reported. Immunogenicity was low throughout, with a non-significant numerical increase upon drug withdrawal in Group 2; 0/38 and 7/73 pts in Groups 1 and 2, respectively, were seropositive at the end of Period II (p=0.119). At the end of Period III, seropositivity was observed in 1/38 and 2/73 of pts in Groups 1 and 2; immunogenicity was comparable between Groups 2a and 2b. At the end of Period III, reductions from baseline in DAS28 were comparable for both groups (Figure).



Visit day	15	29	57	78	85	113	141	169	197	225	253
Group 1, n	38	40	40	33	40	39	38	38	40	39	39
Group 2, n	75	80	79	76	78	80	76	75	79	77	74

Conclusions: Three-month interruption and subsequent re-introduction of SC abatacept is well-tolerated and does not negatively impact efficacy and safety. Furthermore, immunogenicity was consistent with the IV experience, and was not significantly affected by this stop-start schedule, an important consideration for the clinical use of SC abatacept.

1835

Subcutaneous Golimumab Sustains Effects of Intravenous Golimumab in Patients with Active Rheumatoid Arthritis: Results of the GO-LIVE Long Term Extension. Joel M. Kremer[4], Peter Taylor[3], Alan Mendelsohn[2], Daniel G. Baker[1], Lilianne Kim[2] and Christopher T. Ritchlin[5]. [1]Centocor Research and Development, Inc., Malvern, PA, [2]Centocor Research and Development, Inc., [3]Imperial College of London, [4]The Center for Rheumatology, Albany, NY, [5]University of Rochester Medical Center, Rochester, NY

Objectives: To evaluate the efficacy and safety of SC golimumab (GLM) in RA pts who previously received IV GLM q12 wks with and without MTX.

Methods: Adult RA pts(n=643), with persistent disease activity while receiving MTX≥15mg/wk for at least 3mos, were randomized to IV placebo + MTX (n=129) or GLM 2- or 4mg/kg, both with and without MTX, q12wks (n=514) up to Wk96 [median 68.4 wks]. Pts who received IV GLM completing the Wk48 database lock were eligible to participate in the long term extension (LTE) and receive open label GLM 50mg SC q4wks for an additional 24wks (E-0 to E-24) and 16wks of safety follow-up (E-24 to E-40) with and without MTX. At Wk E-14, changes in concomitant RA medication (including MTX) were permitted at the investigators discretion.

Results: Of the 505 pts who entered the LTE, 186 pts who did not change dosing strategy during the IV phase (GLM IV 2mg/kg IV + MTX [n=82]; GLM IV 4mg/kg + MTX [n=104]) participated in the LTE at Wk E-0; baseline demographics and disease characteristics were comparable between both groups. Through Wk E-0, ACR20, ACR50, and DAS28-CRP (good or moderate) response was achieved by 67.5%, 61.9%, 43.4% and 39.2%, 87.7% 82.1% in the IV GLM 2mg/kg and 4 mg/kg groups, respectively. Overall efficacy (ACR20, ACR50) and improvements in ACR components were sustained or improved in a majority of pts through Wk E-24 regardless of GLM IV dose(Table). Compared with the IV phase, DAS 28 response and CRP measures improved with SC GLM. The rates of GLM SC discontinuations from Wk E-0 through Wk E-24 were 2.4% and 4.8% in pts previously treated with IV GLM 2- and 4mg/kg, respectively, most commonly for adverse events(AEs). A total of 77.5% and 83.0% of patients in the GLM IV 2- and 4 mg/kg groups, respectively, experienced ≥1 AEs through Wk E-0. Rates of infusion reactions remained lower in GLM-treated pts compared with placebo-treated pts. During the LTE (Wk E-0 through Wk E-40), 69.5% of SC GLM-treated pts experienced ≥1 AE; 13.7% and 14.0% of pts previously treated with GLM IV 2- and 4 mg/kg, respectively, experienced ≥1 serious AE. Injection site reactions were rare [0.6% (19/3443)].

Conclusion: In pts switched to SC GLM 50mg through the LTE, overall efficacy was sustained or improved regardless of whether pts previously received IV GLM 2-or 4mg/kg. Both IV and SC GLM were well tolerated with acceptable safety profiles.

Wk 24 GLM Treatment Assignment	GLM IV 2mg/kg +MTX	GLM IV 4mg/kg + MTX
ACR20 at Wks E-0 relative to BL	56/82 (68.5%)	65/104 (62.5%)
Wk E-14/Wk E-24	40/56(87.5%) / 46/56(85.7%)	60/65(92.3%) / 59/65(90.8%)

1836

Sustained and Clinically Meaningful Improvements in Both Day- and Night-Time Aspects of HRQoL Are Observed with Abatacept Treatment in Patients with Rheumatoid Arthritis (RA) and Previous Inadequate Response to MTX: 5-Year Data from the AIM Trial. Joel Kremer[2], Anthony S. Russell[3], Rene Westhovens[5], Julie Teng[1], Lisa Rosenblatt[1] and Paul Emery[4]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]Center for Rheumatology, Albany Medical College, Albany, NY, [3]University of Alberta Hospital, Edmonton, AB, Canada, [4]University of Leeds, Leeds, United Kingdom, [5]UZ Gasthuisberg, Leuven, Belgium

Background: RA significantly impairs patients' quality of life and limits their ability to participate in daily activities. Long-term, sustainable improvements in HRQoL are important treatment goals for this chronic disease, and capturing this information is key to improving patient care. Here we report 5-year data from the AIM trial, examining the long-term impact of abatacept across multiple day- and night-time aspects of HRQoL in patients with established RA.

Methods: In the double-blind (DB), placebo-controlled AIM trial, patients were randomized to abatacept (~10 mg/kg) or placebo, plus methotrexate (MTX), for 1 year; patients who completed the 1-year period were eligible to enter an open-label (OL) long-term extension (LTE), during which all patients received abatacept (~10 mg/kg) plus MTX. Sleep quality (Medical Outcomes Study Sleep-Problem Index [SPI] scored 0–100) and fatigue (visual analog scale [0–100 mm]) were assessed up to Year 5 (1 year DB + 4 years OL), and activity (Activity Limitations Score, 0–30 days) up to Year 4 (1 year DB + 3 years OL). Minimal clinically important (MCI) changes in sleep, fatigue and activity were estimated at –6 units, –10 units and –4 days respectively.[1,2] Data are summarized over time by original randomization group using point estimates for patients who received ≥1 dose of abatacept in the LTE (as-observed data).

Results: 433 and 219 patients were randomized and treated with abatacept or placebo in the 1-year DB period; 378 and 161, respectively, entered and were treated in the LTE, of which 390 (72.4%) have completed 5 years. At baseline, the mean age of patients entering the LTE was 50.8 years, mean duration of RA was 8.5 years, and mean tender and swollen joint counts were 31.6 and 21.9, respectively; mean baseline values for sleep, fatigue and activity were similar between groups (Table). Initial improvements in HRQoL over 1-year DB treatment were greater for abatacept versus placebo (Table). Over 4–5 years' treatment, patients initially treated with abatacept sustained clinically important improvements, i.e. above the MCI threshold, in all HRQoL domains. Over time, patients who switched to abatacept plus MTX after 1 year of MTX plus placebo showed similar HRQoL improvements as those seen in patients continuously treated with abatacept.

Table. Mean changes from baseline over time in sleep problems, fatigue and activity limitations

	Year										
	BL	0.5	1	1.5	2	2.5	3	3.5	4	4.5	5
Sleep problem index (0–100): MCI is −6 units											
Abatacept	42.2*	−10.9	−10.8	−11.4	−10.9	−12.2	−11.9	−12.2	−11.7	−11.2	−10.6
Placebo	43.6*	−9.3	−8.0	−10.9	−11.3	−12.0	−11.3	−10.1	−10.4	−11.6	−9.1
Fatigue, VAS (0–100 mm): MCI is −10 units											
Abatacept	63.5*	−26.9	−28.0	−29.4	−31.2	−29.7	−32.8	−30.3	−32.2	−30.9	−30.3
Placebo	65.3*	−23.6	−22.6	−31.1	−30.0	−30.6	−31.3	−31.2	−32.6	−32.3	−32.0
Activity limitation, number of days of limitation (0–30): MCI is −4 days											
Abatacept	13.7*	−8.7	−9.0	−9.2	−9.6	−9.4	−10.1	−10.0	−9.7	-	-
Placebo	13.4*	−5.6	−6.4	−9	−8.2	−9.2	−8.7	−8.3	−10.3	-	-

*Baseline value equals mean for subjects entering long-term extension with data available at baseline and Day 29; Data represent mean change from baseline; higher scores for all variables represent more severe impairment; BL=baseline; VAS=visual analog scale.

Conclusions: In patients with RA and an inadequate response to MTX, abatacept provides sustained, long-term, MCI improvements across both day- and night-time measures of HRQoL, and reduces the limitation of patients' usual daily activities caused by their disease. These improvements represent tangible benefits to patients.

1837

Sustained and Clinically Meaningful Improvements in Physical Function and Fatigue and Reductions in Activity Limitation Are Observed in MTX-Naïve Patients with Early Rheumatoid Arthritis (RA) Treated with Abatacept over 2 Years of the AGREE Trial. Rene Westhovens[5], Jurgen Wollenhaupt[4], Boulos Haraoui[2], Jean-Claude Becker[1], Allison Covucci[1], Lisa Rosenblatt[1] and Joan Bathon[3]. [1]Bristol-Myers Squibb, NJ, [2]Institut de Rumatologie de Montreal, Montreal, QC, Canada, [3]John Hopkins University School of Medicine, Baltimore, MD, [4]Klinikum Eilbek, Hamburg, Germany, [5]UZ Gasthuisburg, Leuven, Belgium

Background: The ability to participate in normal work and/or social daily activities is central to a patient's (pts) Health-Related Quality of Life (HRQoL) and sense of well being. RA-associated fatigue and functional disability can significantly limit activities and have a profound impact on psychological and social health. Here for the first time in MTX-naïve pts with early RA and poor prognostic factors, we assess physical function and HRQoL from the pt perspective, over 2 yrs of abatacept treatment.

Methods: During the 1-yr double-blind period of the AGREE trial[1], RA pts with poor prognostic factors were randomized 1:1 to ABA (~10 mg/kg) + MTX or placebo + MTX (MTX alone). All pts continuing in the 1-yr open-label (OL) period received ABA + MTX. Normalization of physical function (Health Assessment Questionnaire-Disability index [HAQ-DI] ≤0.5), fatigue (100 mm visual analog scale [VAS]) and activity limitation (number of days/month a pt could not perform usual activities due to RA) were evaluated. Mean change from baseline (BL) is presented for pts who entered the OL period and had data available at the visit of interest (as observed), with consideration of established minimal clinically important differences (MCID).

Results: Pts had high BL disease activity (mean Disease Activity Score 28 [C-reactive protein]: 6.3; HAQ-DI: 1.7) and short disease duration (6.1–6.9 mths). Mean BL values for HRQoL outcomes were comparable between groups (fatigue: 64.3–65.8 mm; activity limitation: 15.4–16.0 days/month). The proportions of pts achieving normalized physical function increased from BL to Yr 2 in both treatment arms (Figure). Reductions in fatigue were maintained over 2 yrs in the ABA + MTX group (–36.1 at Yr 1; –40.2 at Yr 2) and exceeded the MCID of 10[2]; further reductions were noted at Yr 2 relative to Yr 1 for pts who switched to ABA + MTX from MTX alone (–28.0 at Yr 1; –37.0 at Yr 2). By Yrs 1 and 2, pts randomized to ABA + MTX gained 11.4 and 12.1 days/month of activity vs BL, respectively, surpassing the MCID of 4 days[2], with just 4.6 and 3.6 days/month of activity limitation reported. Improvements were also noted in the original MTX alone group at Yrs 1 and 2, with gains of 8.3 and 11.5 days/month vs BL, with 7.1 and 4.1 actual days/month of activity limitation reported.

Error bars represent 95% confidence intervals.

Conclusions: Treatment with ABA + MTX resulted in normalization of physical function and reductions in fatigue that were maintained over 2 yrs, and reduced RA-related limitation of daily activities. Pts originally treated with MTX alone demonstrated improvements in these patient-reported

outcomes in Yr 2 after addition of abatacept at Yr 1. These data support the early use of abatacept to provide meaningful improvements in QoL and daily functioning in MTX-naïve pts with early RA and poor prognostic factors.

TNF-alpha Antagonist Therapy Leads to an Expansion of IL-17 Expressing CD4+ T Cells Both In Vitro and In Vivo. Hayley G. Evans[2], Nicola J. Gullick[3], Bruce W. Kirkham[1] and Leonie S. Taams[3]. [1]Guy's & St Thomas' NHS Foundation Trust, [2]Kings College London, London, United Kingdom, [3]Kings College London

Purpose: TNF-alpha is a highly pro-inflammatory cytokine, which contributes to inflammation and joint damage progression in patients with Rheumatoid Arthritis (RA). Use of TNF-alpha antagonists has had considerable success in the clinic, by reducing disease activity and inhibiting joint damage progression. We have previously demonstrated that TNF-alpha can induce IL-17 expression and secretion from CD4+ T cells when produced in combination with IL-1-beta by in vitro activated monocytes. IL-17 has also been shown to induce tissue inflammation and bone destruction in RA. In the present study we investigated how the presence of IL-17-producing CD4+ T cells is affected by TNF-alpha antagonist therapy.

Methods: PBMC and CD4+ T cells from healthy controls (n=13) or patients with RA (n=34) were stimulated ex vivo with PMA/ionomycin and analysed via intracellular flow cytometry and ELISA for their production of IL-17 and IFN-gamma. PBMC (0.5×10^6 in a 48 well plate) and CD4+ T cell/monocyte (0.5×10^6:0.5×10^6, in a 24 well plate) co-cultures were also cultured in the absence or presence of Infliximab, Etanercept or Adalimumab followed by stimulation and analysis via flow cytometry and ELISA.

Results: The percentage of IL-17+ CD4+ T cells is significantly enriched in the blood of RA patients when compared to healthy controls (0.6±0.6% vs. 1.4±1.2%, p=0.003. When separated by treatment regimes, we observed a further enrichment of IL-17+ CD4+ T cells in patients treated with TNF-alpha antagonists compared to those on DMARD therapy (1.1±0.8% vs. 2.3±1.7%, p=0.02). This enrichment could not be explained by the method of stimulation, naïve/memory cell ratio, the age, sex, and disease duration or disease activity of the patients. Instead this may be a direct drug effect since in vitro experiments demonstrated that the presence of TNF-alpha antagonists can stimulate the expression of IL-17 by CD4+ T cells (63±41%, n=6). Finally, preliminary data indicate a rise in the percentage CD4+IL-17+ expressing T cells in the blood when measured ex vivo pre and post anti-TNF-alpha therapy.

Conclusions: Treatment of RA patients with TNF-alpha antagonists leads to an increase of Th17 cells in the peripheral blood. In vitro experiments suggest this may not simply be the result of re-distribution of joint Th17 cells. We propose that the presence of this primed pool of pro-inflammatory T cells may contribute to relapse of disease when anti-TNF-alpha therapy is ceased.

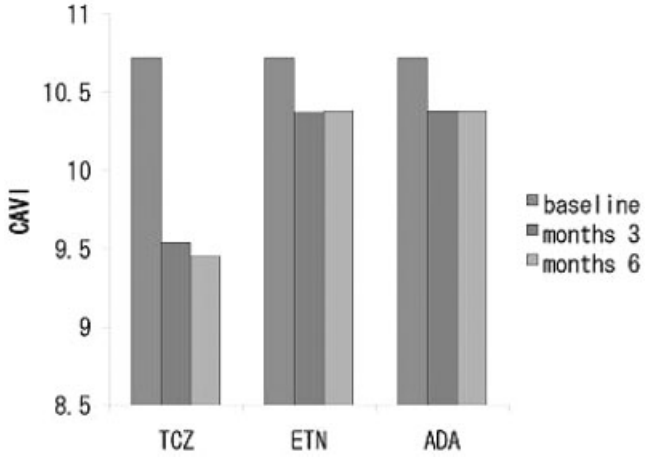
Tocilizumab Monotherapy Improves Arterial Stiffness Compared with Other Biologics Monotherapy in Rheumatoid Arthritis. Kensuke Kume[1], Kanzo Amano[1], Susumu Yamada[1] and Hiroyuki Ohta[2]. [1]Hiroshima Clinic, Hiroshima, Japan, [2]IGL School, Hiroshima, Japan

Background: Methotrexate (MTX) plus TNF inhibitor is very effective in rheumatoid arthritis (RA). But sometimes we choice biologics monotherapy, when it is difficult to use MTX. By the way, patients with RA have an increased cardiovascular (CV) risk. We should have strategies for prevent CV primary in RA patients. And some biologics reduce arterial stiffness and may improve CV morbidity in RA patients.

Objective: to examine the effect of tocilizumab (TCZ) alone, etanercept (ETN) alone, and Adalimumab (ADA) alone, compared respectively on arterial stiffness in RA patients in an open label randomized study design.

Methods: RA patients were eligible if they had active disease and no prior treatment with MTX or a TNF inhibitor. All patients have no previous history of CV. 32 RA patients with moderate to severe active disease(DAS 28>3.2) were randomly assigned to receive TCZ alone (n=11), ETN alone (n=11), or ADA alone (n=10). Arterial stiffness was assessed with augmentation index corrected for a heart rate of 75 beats per minute (AIx@75) and cardio-ankle vascular index (CAVI) at baseline, 3 months, and 6 months follow-up. Clinical data was collected at regular visits. CAVI measures arterial stiffness independent of blood pressure and it is superior to brachial ankle pulse wave velocity as an index of arterial stiffness.

Results: Each groups of characteristics (DAS 28, CRP, diastolic blood pressure, age, gender, disease duration, class) at baseline are no significantly different. Treatment with TCZ (36.3 ± 11, 33.8 ± 3and 33.9± 3%; P = 0.032), ETN (36.4 ± 8, 33.8 ± 5 and 33.5 ± 6%; P = 0.038), ADA (37.1 ± 8, 33.0 ± 5 and 34.1 ± 7%; P = 0.047) attenuated the Aix@75 significantly from baseline to 3 months and 6 months follow-up. Treatment with TCZ (10.82 ± 1.58, 9.62 ± 0.94 and 9.55 ± 1.42%; P = 0.028), ETN (10.92 ± 1.38, 10.29 ± 0.53 and 10.28 ± 1.31%; P = 0.035), ADA (10.74 ± 1.78, 10.38 ± 0.75 and 10.35 ± 0.98%; P = 0.025) attenuated the CAVI significantly from baseline to 3 months and 6 months follow-up. And the CAVI of the TCZ group has most significantly decreased in comparison with the CAVI of ETN or IFX group in 3 and 6 months follow-up.



Conclusions: Monotherapy of TCZ, ETN, and ADA reduces arterial stiffness in RA patients. TCZ monotherapy improves arterial stiffness more significantly compared with other biologics monotherapy in RA patients.

Tocilizumab Treatment in Patients with Rheumatoid Arthritis and an Inadequate Response to DMARDs and/or TNF Inhibitors: ACT-SURE Preliminary Results. Vivian P. Bykerk[7], Jose Álvaro-Gracia[3], Jose Andres Roman Ivorra[4], Michael T. Nurmohamed[6], Karel Pavelka[5], Corrado Bernasconi[8], Andrea Stancati[8], Jean Sibilia[2] and Andrew Östör and the ACT-SURE Study Group[1]. [1]Addenbrookes Hospital, Cambridge, United Kingdom, [2]Hautepierre Service de Rhumatologie, Strasbourg, France, [3]Hospital Universitario de La Princesa, IIS Princesa, Madrid, Spain, [4]Hospital Universitario Dr. Peset, Valencia, Spain, [5]Institute of Rheumatology, Prague, Czech Republic, [6]Jan van Breemen Institute, Amsterdam, The Netherlands, [7]Mount Sinai Hospital, Toronto, ON, Canada, [8]Roche, Basel, Switzerland

Background: Safety and efficacy of TCZ have been demonstrated in 7 phase 3 controlled studies in pts with RA and DMARD-IR or TNFi-IR but not in pts who switched to TCZ without TNFi washout. The ACT-SURE study evaluated TCZ safety and efficacy in pts who were DMARD-IR or TNFi-IR, treated in tertiary academic and non academic centers as well as in private practice setting.

Methods: ACT-SURE was a phase 3b, open-label, single-arm, 6-mo study of DMARD-IR/TNFi-IR pts with active RA treated with TCZ 8 mg/kg Q4W alone or in combination with DMARDs. Safety endpoints included adverse events (AEs) and serious AEs (SAEs). Efficacy endpoints included ACR and DAS28 responses. Analyses were stratified by prestudy TNFi use: TNFi-naive (DMARD-IR) pts, previous TNFi users (>2 mos since TNFi use) or recent TNFi users (≤2 mos since TNFi use). Subanalysis of pts who received TCZ monotherapy was also performed.

Results: Of 1681 evaluable pts, 58% were DMARD-IR, 18% were previous TNFi users and 24% were recent TNFi users. Mean age of pts was 54 years; 81% were women. Mean RA duration was 8.2 years in DMARD-IR pts and 11.2/11.7 years in previous/recent TNFi users. Baseline DAS28 was similar among groups (5.9–6.2). Overall, 12.8% pts withdrew, 4.8% for safety-related reasons; infections were the primary safety-related cause of withdrawal (1.1% of pts or 1.8/100 patient-years [PY]). Rates/100 PY AEs/SAEs and serious infections were slightly lower in TNFi-naive pts than in those with previous TNFi exposure (Table). ALT shifts from normal at baseline to >3′ ULN occurred in <3% of pts (Table). Onset of efficacy was rapid and increased over time: among the groups, DAS28 remission was achieved by 24%–38% of pts at wk 8 and 49%–62% of pts at wk 24. Clinical response tended to be higher in DMARD-IR pts, with little difference between recent and previous TNFi users (Table). At wk 24, mean DAS28 values were 2.34, 2.83 and 2.76 in DMARD-IR pts, previous TNFi users and recent TNFi users. Improvement in physical function was similar across groups: 74.1%, 71.1% and 70.2% of DMARD-IR pts, previous TNFi users and recent TNFi users achieved ≥0.22 point change from baseline in HAQ-DI. In the subgroup of pts who received TCZ monotherapy, 66.9%, 43.5% and 23.8% achieved ACR20/50/70 response at wk 24; 49.8% achieved DAS28 remission.

Conclusions: ACT-SURE was performed in a setting closer to clinical practice than is typical of phase 3 studies and confirmed the safety profile of TCZ shown in previous phase 3 trials. TCZ is effective when used in DMARD-IR pts as the first-line biologic and in TNFi-IR pts. TCZ was effective as monotherapy or with DMARDs. Efficacy was characterized by rapid onset of action and increasing response over time. These results did not show a difference in TCZ safety for pts who were previous or recent TNFi users, which supports treating pts with TCZ immediately after stopping TNFi use.

Table. Safety and Efficacy Outcomes at Wk 24

	AE Rate/ 100PY	SAE Rate/ 100PY	Serious Infections Rate/100PY	Infusion Reactions % (n)[a]	ALT Shift From Baseline to >3×ULN % (n)

Background: Real-life studies concerning the impact of tumour necrosis factor inhibitor (TNF-I) treatment on radiographic progression in rheumatoid arthritis (RA) patients are few.

Objectives: To compare radiographic progression (delta total Sharp (dTSS); erosion (dES); and joint space narrowing (dJSN) scores) during treatment with disease-modifying antirheumatic drugs (DMARDs) and during subsequent treatment with TNF-I in RA patients in clinical practice.

Methods: Conventional radiographs (CR) of hands and wrists were obtained ~2 years before start of TNF-I (time-point A), at the start of TNF-I (B) and ~2 years after start of TNF-I (C). Clinical data from the DANBIO registry and the patientfiles was collected for the patients with CRs. The CRs were scored blinded to chronology according to the van der Heijde modified Sharp score. Annual radiographic progression rates during DMARD (delta A-B) and TNF-I (delta B-C) treatments were calculated.

Results: 522 RA patients (76% women, 80% rheumatoid factor positive, 65% anti-CCP positive, 27% current smokers, age 54 (21–86) years (median (range)); disease duration 5 (0–67) years) had complete A-B-C series. At time-point A, 28-joint disease activity score (DAS28) was 4.4 (1.4) (mean (SD)) and patients received the following treatments: methotrexate (MTX) (45%), sulphasalazine (22%), hydroxychlorochine (12%), leflunomide (5%), other DMARDs (6%) or no DMARDs (10%). At time-point B, DAS28 was 5.0 (1.1) and treatment with infliximab (61%), etanercept (15%), or adalimumab (24%), was started (combination with MTX (78%), combination with other DMARDs (10%), monotherapy (12%)). At time-point C, 60% were on the initial TNF-I, 29% had switched to another TNF-I and 11% withdrawn from TNF-I. Mean DAS28 was 3.1(1.2). The duration of Period A-B was median 735(interquartile range 484–1002) days and of period B-C 562 (405–766) days. Radiographic data are shown in Table 1. The progression rate (deltaTSS) during TNF-I treatment was reduced by 61% compared to DMARD.

Table. Radiographic progression during treatment with DMARDs and subsequent treatment with TNF-I in RA patients in clinical practice.

	A DMARD	B TNF-I start	C 2 yr follow-up	Delta A-B/yr	Delta B-C/yr	P value
TSS mean(SD)	21.0 (29.8)	25.7 (32.0)	27.0 (32.8)	2.1 (3.8)	0.67 (2.3)	<0.0001 (1)
TSS median (IQR)	7 (1–31)	13 (2–40)	14 (3–42)	0.73 (0–2.9)	0 (0–0.89)	<0.0001 (2)
ES mean(SD)	13.1 (19.9)	15.5 (21.3)	16.2 (21.7)	1.04 (2.0)	0.36 (1.4)	<0.0001 (1)
ES median (IQR)	4 (0–18)	6 (1–23)	7 (1–24)	0.2 (0–1.4)	0 (0–0)	<0.0001 (2)
JSN mean(SD)	7.8 (11.5)	10.2 (12.7)	10.8 (13.2)	1 (2.6)	0.31 (1.2)	<0.0001 (1)
JSN median (IQR)	2 (0–12)	5 (0–16)	6 (0–17)	0 (0–1.4)	0 (0–0)	<0.0001 (2)
Progressing patients (%)				59	31	<0.0001 (3)

(1) Paired T-test (2) Paired Wilcoxon-test (3) Chi-square test A, 2 years before TNF-I treatment start; B, TNF-I treatment start; C, 2 years after TNF-I treatment start; TSS, total van der Heijde Sharp score; ES, erosion score; JSN, joint space narrowing; SD, standard deviation; IQR, inter quartile range; Delta A-B/yr, annual progression rate time A to B; Delta B-C/yr, annual progression rate time B to C.

Conclusion: Real-life data from a large nationwide observational cohort showed that use of TNF inhibitors in RA patients treated for ~2 years in

routine care significantly reduces the rate of joint damage progression when compared to the previous ~2 years on conventional treatment.

Accumulation of Traditional Risk Factors for Coronary Heart Disease in Patients with Systemic Lupus Erythematosus. Rosa W. Telles[2], Cristina C. D. Lanna[2], Fabricia F. Simil[1], Luana G. Machado[1], Fabiana L. Sousa[1], Luciana A. Rodrigues[2] and Antonio L. Ribeiro[3]. [1]Hospital das Clinicas, [2]School of Medicine, [3]School of Medicine-Universidade Federal de Minas Gerias-Brazil

Objective: to examine the accumulation of traditional risk factors for Coronary Heart Disease (CHD) in patients with SLE.

Patients and Methods: 157 patients included in a prospective study of atherosclerosis in lupus patients were followed during 39(37–42) months. Traditional risk factors for CHD were collected at entry (T_0), trough out the follow up (considered positive when the risk factors were identified in two different occasions for a period ≥1 year) and at the last study visit (T_1). The hypothesis of risk factors accumulation was investigated comparing the prevalence of those factors between T_0 and T_1 using either McNemar or Wilcoxon tests. The annual mean incidence of the risk factors was determined.

Results: median (IR) age at entry and age at lupus diagnosis of the 157 patients were 38(29–46) years and 27.3(21.5–34.7) years, respectively (96.2%: female gender; 75.8%: non-white). Median (IR) duration of lupus was 7.7(4.3–11.4) years. The prevalence of the following traditional risk factors increased during study interval (T_0 *x* T_1): positive family history for coronary heart disease (12.7% *x* 15.9%; p=0.025), postmenopausal status (38.2% *x* 45.2%; p=0.001), hypertension (46.5% *x* 55.4%; p=0.003), obesity (19.7% *x* 29.3%; p=0.006) and abdominal obesity (42% *x* 60.5%; p<0.001). The number of current smokers did not differ (14% *x* 12.1%; p=0.250). Although the prevalence of LDL≥130mg/dl (16,6% *x* 22,9%; p=0,036) and the total cholesterol≥200mg/dl (19,7% *x* 28,7%; p=0,024) increased, the prevalence of HDL<40mg/dl did not change (26,8% *x* 20,4%; p=0,268). The number of traditional risk factors (age and sex, hypertension, diabetes mellitus, dyslipidemia, hypertiglyceridemia, family history for CHD and smoking habit) per patient also increased during the study interval [1(0–2) *x* 2(1–3); p=0.015]. The annual mean incidence of the traditional risk factors were: hypertension 4%, diabetes mellitus 0.8%, dyslipidemia 10%, triglycerides≥150mg/dl 5.1%, obesity (BMI>30kg/m^2) 5.1% and abdominal obesity (abdominal circumference >102cm in men and >88cm in women) 11.5%.

Conclusion: the prevalence of traditional risk factors for CHD increased in a short-period in young patients with SLE. Some of these risk factors have already been associated with clinical and subclinical atherosclerosis in lupus. Lupus patients should be monitored for cardiovascular risk factors in a regular basis and appropriate treatment instituted.

Analysis of the Level of Agreement between Different Measures of Disease Flare in an Exploratory Study of Abatacept in Systemic Lupus Erythematosus (SLE). Caroline Gordon[3], Jean-Claude Becker[1], Sheila Kelly[1], Yun Peng[2], Michael Kinaszczuk[1] and Joan T. Merrill[4]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]Bristol-Myers Squibb, Pennington, NJ, [3]University of Birmingham, Birmingham, United Kingdom, [4]University of Oklahoma, Oklahoma City, OK

Background: This Phase II exploratory trial of abatacept used BILAG A/B flare (adjudicated per protocol) as the primary endpoint[1]. *Post-hoc* analyses examined other BILAG and physician- defined flare measures.

Methods: This was a double-blind, Phase II study in which SLE patients with active polyarthritis, serositis and/or discoid lesions were randomized to abatacept (~10 mg/kg) or placebo (PLC) for 1 year. Prednisone (30 mg/day or equivalent) was given for 1 month, then tapered by protocol. The primary endpoint was new adjudicated BILAG A/B flare (classic BILAG index)[2] over 1 year after the start of steroid taper. *Post-hoc* assessments included BILAG A only flare (adjudicated), or physician-defined flare in response to the question 'Since the last visit, does the patient exhibit symptoms of an acute SLE flare?' (yes/no). Treatment modifications were recorded on visits when physician-defined flares occurred. Analyses are based on data for all randomized and treated patients.

Results: 118 abatacept and 57 PLC patients were assessed. Proportions of patients with ≥1 BILAG A/B flare, BILAG A only flare or physician-assessed flare, respectively, were 79.7, 40.7 and 63.6% for abatacept versus 82.5, 54.4 and 82.5% for PLC. In the abatacept group, physician's assessment agreed with BILAG A/B flare in 71/165 (43%) cases: when the flare definition was restricted to BILAG A only, agreement occurred in 23/33 (70%) cases (Table). Most BILAG-defined flares that physicians did not rate as flares were B events (84/94 in abatacept-treated patients). 45.8% of physician-assessed flares occurred when no BILAG A/B flare was recorded. In instances where physicians recorded flare, BILAG A/B flare coincided with treatment modification the majority of the time (49/71 [69.0%]). Results in the PLC group were similar to abatacept.

Cross-tabulation of the presence/absence of flare according to BILAG and physician-defined measures

		Abatacept (n=118)			Placebo (n=57)		
		Total n	Yes n (%)	No n (%)	Total N	Yes n (%)	No n (%)
		Adjudicated BILAG A or B flare					
Physician assessment of flare	Yes	131	71 (54.2)	60 (45.8)	82	47 (57.3)	35 (42.7)
	No	1178	94* (8.0)	1084 (92.0)	533	32 (6.0)	501 (94.0)
		Adjudicated BILAG A flare					
Physician assessment of flare	Yes	131	23 (17.6)	108 (82.4)	82	17 (20.7)	65 (79.3)
	No	1178	10 (0.8)	1168 (99.2)	534	1 (0.2)	533 (99.8)

*10 were A flares; the remaining 84 were B flares

Conclusions: These data demonstrate some discordance between BILAG adjudication- and physician-determined flares. This may be due to: a) BILAG flare rules being based on an item worsening after improving at 2 prior visits (to avoid recording non-significant fluctuations in disease severity), whereas physicians may have recorded worsening irrespective of prior visits; b) physicians recording flare when items were the same over 4 prior weeks (not just when new, or worse after improving); c) the classic BILAG index may fail to capture some flare features detected by physicians. Some BILAG A/B flares occurred when no physician-defined flares were recorded; BILAG flares were more likely to be confirmed by the physician when restricted to BILAG A, suggesting increased ability of BILAG A to define events that physicians considered significant. These data provide valuable insight into issues encountered when assessing flare in clinical trials of SLE, and may help inform future trial design.

1844

Anti-NR2A Antibody as a Predictor for Neuropsychiatric Systemic Lupus Erythematosus. Masanori Hanaoka[3], Takahisa Gono[3], Yasushi Kawaguchi[1], Hirotaka Kaneko[2], Katsuji Nishimura[2], Yasuhiro Katsumata[2], Yuko Okamoto[2], Sayumi Baba[2], Sayuri Kataoka[2] and Hisashi Yamanaka[4]. [1]Tokyo Women's Medical Univ, Tokyo, Japan, [2]Tokyo Women's Medical Univ, [3]Tokyo Women's Medical University, [4]Tokyo Womens Med Univ, Shinjuku-ku, Tokyo, Japan

Purpose: N-methyl-D-aspartate receptors (NMDAR) are ligand-gated ion channels with crucial roles in synaptic transmission and plasticity of central

nervous system (CNS). Additionally, NMDAR are located on non-neuronal tissues, such as bone, skin, pancreas and megakaryocyte. Anti-NMDAR subunit 2A/2B (NR2A/2B) antibody has been reported to react against the peptide DWEYSVWLSN in systemic lupus erythematosus (SLE). Although DWEYS was reported as residues 283–287 in NR2A/2B, the actual sequence of residues 283–287 is DWDYS in NR2A and DEWDY in NR2B. This will make DWDYS-peptide more specific than DWEYS-peptide in NR2A, even though most reports that have measured anti-NR2 antibody by enzyme-linked immunosorbent assay (ELISA) have used DWEYS-peptide. The aim of the present study is to establish a method to detect serum anti-NR2A antibody by ELISA and to evaluate the relationship between anti-NR2A antibody and various tissue damages in SLE.

Methods: Measurement of anti-NR2A antibody in sera was performed by ELISA using either DWEYS- or DWDYS-peptide as autoantigen. Clinical characteristics were compared between anti-NR2A antibody-positive 27 patients (P group) and -negative 80 patients (N group) in SLE, using DWDYS-peptide.

Results: The optical density (OD) value using DWDYS-peptide correlated significantly ($r = 0.94$, $P < 0.0001$) with the one using DWEYS-peptide in SLE patients. The median OD value was significantly higher ($P < 0.0001$) in DWDYS-peptide than DWEYS-peptide. The median OD value [interquartile range] using DWDYS-peptide were 0.449 [0.327–0.622] and 0.197 [0.14–0.29] in 107 SLE patients and 74 non-SLE patients, respectively. There was a strikingly significant difference between two subsets ($P < 0.0001$). Additionally, SLE Disease Activity Index (SLEDAI) was significantly higher ($P = 0.023$) in P group. The frequency of serositis, nephritis and neuropsychiatric SLE (NP SLE) was significantly higher ($P = 0.039$, 0.015 and 0.0002, respectively) in P group. The frequency of diffuse CNS form and focal CNS form was significantly higher ($P = 0.036$ and 0.01, and odds ration 3.5 and 5.3, respectively) in P group. The leukocyte count and hemoglobin was significantly decreasing ($P = 0.021$ and 0.0008, respectively) in P group. Although no correlation were found between anti-NR2A antibody and the titer of anti-DNA antibody, significant correlations were found between anti-NR2A antibody and leukocyte count ($r = -0.31$, $P = 0.001$) and hemoglobin ($r = -0.42$, $P < 0.0001$). NP SLE was a most significant independent variable ($P = 0.0008$), associated with anti-NR2A antibody-positivity, estimated by multiple liner regression analysis. The leukocyte count and hemoglobin were also significant variables ($P = 0.0095$ and 0.013, respectively) associated with anti-NR2A antibody-positivity.

Conclusion: Serum anti-NR2A antibody can be a predictor for NP SLE and may damage also non-nervous tissues. The usage of peptide including DWDYS is more preferable for detecting anti-NR2A antibody in ELISA.

1845

Assessing the ANA Test as a Screening Tool: Utility or Futility? Aryeh M. Abeles and Micha Abeles. University of Connecticut Health Center

Introduction: Current ANA testing may be overly sensitive, resulting in frequent false positives as well as unnecessary follow-up testing and misdiagnosis. Several studies have focused on ANA prevalence and predictive value, but the purpose of this investigation was to evaluate the clinical utility of a positive ANA test in a real-world setting, by reviewing the outcomes of patients referred to a tertiary rheumatology clinic for evaluation of a positive ANA test. No prior study has directly addressed this question.

Method: We reviewed records for all consultation patients presenting to the authors at the UCHC rheumatology clinic between July 2007 and July 2009. Patients were included in the evaluation if they had been referred for a positive ANA. Patients presenting with an already-diagnosed ANA-associated rheumatic disease (AARD) were excluded. All ANA tests and all referrals had been ordered by non-rheumatologists. A complete review of systems and physical examination was performed on each patient. 91 out of 101 patients with ANA titers ≥1:320 had the following labs drawn: antibody (Ab) panel (Anti-dsDNA, SSA/SSB, Sm, RNP), C3, C4, CH50, CBC, and ESR. Of 67 patients with ANA ≥1:640, 64 had lab evaluations performed as above. Referring physician reasons for ordering ANA testing were also collated.

Results: Of 1,306 initial consultation visits to our clinic, 232 were referrals for a positive ANA, with titers ranging from 1:40 to greater than 1:5120. Initial ANA testing had been performed at several different laboratories (the majority at UCHC). 98% of all initial ANA tests had been run using immunofluoresence assay with Hep-2 cells.

9.1% of patients evaluated (21/232) had an AARD (5 SLE, 12 Sjogren's syndrome, 3 scleroderma, 1 MCTD). The remainder of patients had no AARD, of whom twenty-one (9.1%) had isolated autoimmune thyroid Ab present. No patient with an ANA ≤1:80, and only 1 patient with ANA≤1:160, had a rheumatic disease. There was no correlation between the highest ANA titers with a specific rheumatic illness. The most common reason for ordering ANA testing was widespread pain and tenderness (54/232, 23.2%) but also included, among others, chronic lower back pain, episodic chronic rhinitis, palpitations, thinning hair, unilateral heel pain, and lateral buttock pain. The positive predictive value of an ANA test in our cohort of patients was 2.2% for lupus and 9.1% for any AARD.

Conclusion: In this retrospective study, over 90% of patients referred to a tertiary rheumatology clinic for positive ANA testing had no evidence of an AARD. The poor predictive value of a positive ANA test may in part be attributable to poor patient selection with concomitant low pretest probabilities. The extremely low positive predictive value of ANA tests at titers below or equal to 1:160 suggests that the cutoff of a "positive" ANA may need to be re-evaluated by testing laboratories. Even at high titers, however, many patients referred for a positive ANA had no discernible AARD, corroborating previously noted lack of predictive value of ANA testing.

Atherosclerosis in SLE; a Cross Sectional Study of 223 Patients with 223 Individually Matched Population Controls. Johanna T. Gustafsson[2], Kerstin Urstad Jensen[1], Marie Herlitz-Lindberg[1], Sonia Möller[4], Susanne Petterson[3], Iva Gunnarsson[2] and Elisabet Svenungsson[2]. [1]Department of Clinical Physiology, Södersjukhuset, Karolinska Institute, Stockholm, Sweden, [2]Department of Medicine Solna, Karolinska Institute. Rheumatology Unit, Karolinska University Hospital, Stockholm, Sweden, [3]Department of Neurobiology, Care Sciences and Society (NVS), Division of Nursing, Karolinska Institutet, Rheumatology Unit, Karolinska University Hospital, Stockholm, Sweden, [4]Rheumatology Unit, Karolinska University Hospital, Stockholm, Sweden

Objective: Accelerated atherosclerosis is believed to contribute to premature cardiovascular disease (CVD) in patients with Systemic Lupus Erythematosus (SLE). We investigated the prevalence of subclinical atherosclerosis in SLE patients and controls.

Patients and Methods: 223 SLE patients/ 223 population controls, individually matched for age, sex and region of living were included after overnight fasting. All were investigated clinically including CVD risk factors and inflammatory biomarkers. The same investigator performed B-mode ultrasonography of carotid arteries. Intima media thickness (IMT) and plaques occurrence (local intima-medial thickening >1mm) were tabulated

Results: Mean age was 48,5 ± 14,3 years in patients and 48,7 ±14,2 in controls. Manifest CVD (ischemic heart, cerebro- and peripheral vascular disease) was more common in SLE patients (13 % vs. 3 %, $p < 0.0001$). Patients were more likely to smoke, have antihypertensive and lipid lowering treatment, lower high density lipoprotein, and higher triglycerides (TG). They had lower low density lipoprotein levels ($p<0.05$ for all).

Patients had thicker mean IMT than controls ($p=0.02$), but there was no difference in plaque occurrence, 21% and 17% respectively.

After age adjustment:

Manifest CVD was associated with plaques in the SLE group, but not with IMT.

In SLE, IMT was positively associated with systolic blood pressure (sBP, <0.0001), TGs ($p=0.008$) and hemoglobin levels($p=0.04$) and negatively with discoid skin lesions ($p=0.03$) and leukopenia($p=0.03$). Plaques were positively associated with TGs ($p=0.01$) and systolic blood pressure ($p=0.02$) and negatively with discoid skin lesions ($p=0.04$).

In controls, IMT was associated with high CRP levels ($p=0.02$) and sBP (<0.0001). Smoking ($p=0.03$) and TG levels ($p=0.03$) were associated with plaques.

Multivariable adjusted models:

In patients age and sBP remained associated with IMT ($p<0.001$ for both) and plaques ($p<0.001$ and $p=0.01$ respectively). In controls age ($p<0.001$) and sBP ($p=0.001$) remained associated with IMT and age ($p<0.001$) and smoking ($p=0.03$) with plaques.

Conclusions: This is to our knowledge the largest study of subclinical atherosclerosis in SLE patients. Patients had thicker IMT, but we could not confirm the increased prevalence of carotid plaques previously reported. Selection of controls, definition of plaques and possibly ethnicity are possible underlying explanations. Plaques and IMT were mainly associated with

traditional CVD risk factors in both patients and controls. The relative contribution of subclinical atherosclerosis for hard outcomes i.e. events in SLE needs to be investigated and should be in focus of future studies.

1847

Autoantibodies Predate the Onset of Systemic Lupus Erythematosus. Solbritt Rantapää-Dahlqvist[2], Catharina Eriksson[1], Heidi Kokkonen[1], Martin Johansson[1], Göran Hallmans[1] and Göran Wadell[1]. [1]Umeå, Sweden, [2]Rheumatology, Umeå, Sweden

Objective: To identify the presence of autoantibodies in a Northern European population antedating disease onset of SLE using blood samples donated to the Medical Biobank of Northern Sweden before onset of symptoms and relate the predating antibodies with first symptoms of disease.

Methods: The register of patients fulfilling the ACR criteria for SLE and the given date for the onset of symptoms was co-analysed with the register of the Medical Biobank and the Maternity cohort of northern Sweden. Thirty-eight patients (35 females and 3 males) were identified as donating blood samples prior to disease onset. A nested case-control study, designed 1:4, was performed with 152 age and sex matched controls being identified. Antibodies (abs) against SSA (60 and 52 kDa), SSB, Sm, RNP, Scl-70, Jo-1, dsDNA, Centromere B and histones were analysed using a multiplex detection kit, ANA-II Plus Test System (Athena Multi-Lyte®) on a Bio-Plex Array Reader (Luminex200, LabmapTM). Autoantibody tests for ANA were performed by indirect immunofluorescence on HEp2-cells at a sample dilution of 1:100.

Results: In 22/35 (63 %) of the patients with SLE autoantibodies against nuclear antigens were detected in the blood 5.6 (±4.7; mean±SD) years before the onset of symptoms and 8.7 (±5.6) years before diagnosis. The sensitivity was highest for ANA at 45.7% with a specificity of 95%, followed by anti-dsDNA and anti-SSA abs both with a sensitivity of 20.0% at a specificity of 98.7% and 97.4%, respectively. The odds ratio (OR) for anti-DNA predicting disease was 18.13 (CI 95%: 3.58–91.84), and for ANA 11.5 (CI 95%: 4.54–28.87). The sensitivity for the other autoantibodies varied between 14.3% and 2.9% with specificity ranging between 97.4% and 100%. The autoantibody appearing first, i.e., 6.6±2.5 (mean±SD) years prior to the onset of symptoms is anti-SSA antibodies whilst those closest to disease onset are anti-Centromere B antibodies at 0.2 years, anti-Sm at 0.7 years, and anti-Scl70 at 1.4±0.6 years. The number of individuals with antibodies present increased the closer to onset of symptoms. The mean number of antibodies present in pre-diseased individuals was 1.4 and after disease onset 3.1 ($p < 0.001$). The time predating disease was shorter, and the number of antibodies greater, in those individuals with serositis as a presenting symptom in comparison to those with arthritis and skin manifestations.

Conclusion: Autoantibodies against nuclear antigens can be detected in the blood of patients with SLE several years before the onset of symptoms and diagnosis. The most sensitive autoantibodies were ANA, SSA and dsDNA, with the highest predictive OR for anti-dsDNA abs. The autoantibody appearing first was anti-SSA abs.

Belimumab, a BLyS-Specific Inhibitor, Improved Fatigue and SF-36 Physical and Mental Component Summary Scores in Patients with SLE: BLISS-76 and -52 Studies. V. Strand[8], R. A. Levy[3], R. Cervera[2], M. A. Petri[6], H. Rudge[1], L. Pineda[5], W. Freimuth[5], Z. J. Zhong[4], A. E. Clarke[7] and for the BLISS-76 and −52 Study Group. [1]GlaxoSmithKline, Uxbridge, Uxbridge, UK, [2]Hospital Clinic, Barcelona, Spain, [3]Hospital Universitário Pedro Ernesto, Rio de Janeiro, Brazil, [4]Human Genome Sciences, Inc, Rockville, MD, [5]Human Genome Sciences, Inc, Rockville, Rockville, MD, [6]Johns Hopkins University School of Medicine, Timonium, MD, [7]McGill University Health Centre, Montreal, QC, Canada, [8]Stanford University, Palo Alto, Portola Valley, CA

Purpose: To evaluate the effects of belimumab on fatigue and other health-related quality-of-life (HRQOL) measures in patients with seropositive (ANA ≥1:80 and/or anti-dsDNA ≥30 IU/mL) SLE.

Methods: BLISS-76 (NCT00410384) and BLISS-52 (NCT00424476) were phase 3, multicenter, randomized, double-blind, placebo-controlled studies of 819 and 865 seropositive SLE patients, respectively. Patients with screening SELENA-SLEDAI scores ≥6 were randomly assigned to receive belimumab 1 or 10 mg/kg plus standard of care (SOC) SLE therapy, or placebo plus SOC, with dosing on d 0, 14, and 28, and then q28d for 72 or 48 wk. The primary endpoint in both studies was patient response (SLE Responder Index) at wk 52. HRQOL assessments included SF-36 and FACIT-Fatigue questionnaires at multiple time points throughout the study, including baseline and wk 52. Data for the 2 studies are presented separately and pooled.

Results: In BLISS-76, mean improvements (MIs; absolute change from baseline) in SF-36 physical and mental component summary (PCS and MCS, respectively) and FACIT-Fatigue scores were significantly greater with belimumab 1 mg/kg vs placebo at wk 52 (Table 1). In BLISS-52, MIs from baseline in SF-36 PCS and FACIT-Fatigue scores were significantly greater with belimumab 1 and 10 mg/kg vs placebo at wk 52 (Table 1). Based on pooled data, MIs from baseline were significantly greater with belimumab 1 and 10 mg/kg for SF-36 PCS, and with 1 mg/kg for MCS vs placebo at wk 52 (Table 2). Both belimumab treatment groups demonstrated greater MIs in FACIT-Fatigue score vs placebo at wk 8, 12, and 52 (Figure 1).

Causes and Predictors of Death in 181 Brazilian Patients with Systemic Lupus. Rosa W. Telles[2], Cristina C. D. Lanna[2], Rodrigo C. P. Reis[4], Fabiana L. Sousa[1], Luciana A. Rodrigues[2] and Antonio L. Ribeiro[3]. [1]Hospital das Clinicas, [2]School of Medicine, [3]School of Medicine-Universidade Federal de Minas Gerais-Brazil, [4]Statistics Department

Objective: To determine the causes and predictors of death in SLE patients.

Patients and Methods: 181 outpatients were enrolled from May 2005 to February 2006 (T_0) in a prospective study. These patients were followed up to either the last visit at outpatient clinic, death or end of study visit (from October 2008 to July 2009). Causes of death were defined on the basis of death certificates, medical records and information collected from doctors and relatives. Variables predicting mortality were assessed by Kaplan-Meier and Cox regression methods. The final multivariate model was selected according to clinical and biological plausibility and was corrected for optimism.

Results: Two patients were lost to follow up. Median (IR) age at diagnosis and age at the T_0 of the 179 patients were 26.7(21.8–34.6) and 38(29–46) years, respectively. Median (IR) disease duration was 8.2(4.3–12.4) years. After a median (IR) follow up of 3.3(3.1–3.5) years, 13(73%) patients died due to end-organ failure (5), infection (5), disease activity (1) and atherosclerosis (1). The cause of the mesenteric ischemia of one patient could not be determinate. These 13 patients died a median (IR) of 9.6(7.6–19.3) years after being diagnosed as having SLE. Predictors of mortality observed at T_0 were: nephritis, chronic renal disease (creatinina clearance$<$60ml/min/1,73m^2), antiphospholipid syndrome, higher modified SLEDAI-2k and higher damage index score, cyclophosphamide intravenous use, higher daily dose of prednisone and higher systolic blood pressure, univariate analysis ($p<0.05$). Independent predictors of mortality in Cox regression model were a higher damage index score (HR: 1.401; CI95%: 1.076–1.824), cyclophosphamide use (HR: 3.800; CI95%: 1.313–12.766), and antiphospholipid syndrome (HR: 3.818; CI95%: 1.073–13.587)

Conclusion: This study presents a high frequency of late mortality in lupus patients due to SLE itself and infection. This result is not in agreement with the proposed bimodal pattern of lupus mortality and with the high frequency of atherosclerosis as a cause of death in developed countries. The most important predictors of death were related to lupus itself.

Cigarette Smoking and Cutaneous Damage in Patients with Systemic Lupus Erythematosus. Josiane Bourré-Tessier[5], Christine A. Peschken[13], Lawrence Joseph[5], Patrick Belisle[5], Ann E. Clarke[7], Sasha R. Bernatsky[3], Marie Hudson[6], Carol A. Hitchon[14], Shikha Mittoo[13], Janet E. Pope[8], Paul R. Fortin[11], C. Douglas Smith[10], Hector Arbillaga[2], Dafna D. Gladman[12], Murray B. Urowitz[9], Michel Zummer[1], CANIOS 1000 Canadian Faces of Lupus Investigators[15] and Christian A. Pineau[4]. [1]Ch Maisonneuve-Rosemont, Montreal, QC, Canada, [2]Chinook Regional Hospital, [3]McGill UHC/RVH, Montreal, QC, Canada, [4]McGill Univ Health Center, Montreal, QC, Canada, [5]McGill University, [6]McGill University and Jewish General Hospital, [7]Montreal General Hospital, Montreal, QC, Canada, [8]St Joseph Health Care London, London, ON, Canada, [9]The Toronto Western Hospital, Toronto, ON, Canada, [10]TOH Riverside Campus, Ottawa, ON, Canada, [11]Toronto Western Hospital, Toronto, ON, Canada, [12]Toronto Western Hospital, Toronto, ON, Canada, [13]Univ of Manitoba, Winnipeg, MB, Canada, [14]University of Manitoba, Winnipeg, MB, Canada, [15]Various Sites

Background: In patients with systemic lupus erythematosus (SLE), cutaneous damage is common and can produce considerable morbidity. Moreover, since smoking may decrease the effectiveness of antimalarial agents, tobacco use may be associated with increased skin manifestations in SLE patients. We examined the association between cigarette smoking and cutaneous involvement in a multicenter Canadian SLE cohort.

Methods: Adults with SLE were enrolled in a multicenter cohort. Various cutaneous elements, as recorded at last visit by the SLICC/ACR Damage Index (SDI; alopecia, extensive scarring and skin ulceration) and the ACR criteria (discoid rash, malar rash and photosensitivity) were used as primary outcomes. Cross-sectional analysis with multivariate logistic regression models were used to estimate the association between cigarette smoking (defined as smoking regularly 3 or more months in the lifetime) and cutaneous involvement. Other potentially associated factors included age, sex, lupus duration, medication including antimalarials, and laboratory data.

Results: In our cohort of 1724 adults, most (83.3%) were female, mean age (SD) was 40.7 years (17.9), mean disease duration was 12.4 years (10.1) and 36.1% had smoked regularly in their lifetime. Cutaneous involvement included malar rash (59.9%), photosensitivity (50.7%), alopecia (11.0%), extensive scarring (3.5%), discoid rash (3.4%) and skin ulceration (0.2%). In multivariate analysis, smoking was associated with discoid rash (OR 1.96; 95%CI 1.41–2.71) and photosensitivity (1.52; 1.17–2.00). We did not find an association between smoking and alopecia, extensive scarring, skin ulceration or malar rash. An association between antimalarials and skin manifestations was expected since antimalarials are regularly used to treat cutaneous involvement in SLE. Indeed, the use of hydroxychloroquine was associated with discoid rash (2.23; 1.10–4.53) and malar rash (2.0; 1.02–3.93) in multivariate analysis.

Conclusion: Cigarette smoking is associated with discoid rash and photosensitivity in this large cohort of SLE patients. Our results emphasize the need to counsel patients on smoking cessation.

Clinical and Serologic Characteristics of Filipino Multiplex Systemic Lupus Erythematosus (SLE). Helmar F. Soldevilla and Sandra V. Navarra. University of Santo Tomas, Philippines

Purpose: To describe the clinical and serologic characteristics of multiplex systemic lupus erythematosus (SLE) in a Filipino Lupus Database, and compare these with patients with simplex or sporadic SLE from the same database.

Methods: An active search for multiplex SLE patients i.e. belonging to families with at least 2 first degree relatives diagnosed with SLE, was done among patients included in the Lupus Database of the University of Santo Tomas (UST) in Manila, Philippines. Simplex SLE patients i.e. ascertained by review of medical records and verified by phone interview to have no first to third degree family history of SLE or other autoimmune disease, were chosen from the same database to match disease duration. The demographic and cumulative clinical characteristics based on American College of Rheumatology (ACR) criteria and other SLE-related manifestations were compared between the 2 groups, with statistical significance at a p value <0.05.

Results: There were 166 patients (138 females) with an average age at diagnosis of 28.61$\pm$13.07 SD years (range 1–73), belonging to 75 multiplex families. The relationships included 21 parent-child and 54 siblings including three sets of twins. The average age at diagnosis of the simplex SLE patients (N=309, 257 females) was 36.53 $\pm$ 15.04 SD years (range 4–85). The mean disease duration was 98.28 $\pm$ 65.21 months SD (range 1–300) and 96.46 $\pm$ 47 months SD among the multiplex and simplex patients respectively, p=0.77. Among the clinical manifestations, serositis (multiplex=36, 22.08% vs. simplex= 36, 11.65%, p=0.0027), neurologic manifestations (multiplex =25, 15.33% vs. simplex = 26, 8.41%, p=0.0283) and cutaneous vasculitis (multiplex = 27, 17.0% vs simplex= 23, 8.04%, p= 0.0042) were more common in multiplex patients. The other clinical manifestations and serology including antinuclear antibody (ANA) and anti-dsDNA were comparable between both groups.

Conclusions: SLE patients from multiplex families were younger with relatively higher number of males than in those with sporadic SLE. Serositis, neurologic manifestations and cutaneous vasculitis were more frequently recorded in multiplex patients. These findings suggest a role for genetics in the clinical expression of SLE, with potentially more serious organ involvement among patients from multiplex families.

CNS Lupus: The Prevalence and Antibodies Depend on the Definition. Results from the 1000 Faces of Lupus Cohort. Alan Borowoy[3], Christine A. Peschken[2] and Janet E. Pope[1]. [1]St Joseph Health Care London, London, ON, Canada, [2]Univ of Manitoba, Winnipeg, MB, Canada, [3]University of Western Ontario, London, ON, Canada

Background: Neuropsychiatric involvement in SLE (NPSLE) is common and encompasses a broad spectrum of neurologic and psychiatric syndromes with significant impact on morbidity and mortality and prevalence varies depending on the definition used (from 12–80%). We determined the prevalence of NPSLE and associated factors in 1000 Faces of Lupus, a large multi-centre Canadian cohort.

Methods: Adults were enrolled who satisfied the ACR classification for SLE and had completed SLEDAI, SLAM and SLICC damage indices. NPSLE was defined as: (i) NPSLE by ACR classification criteria (seizure or psychosis), (ii) ACR, SLEDAI (seizure, psychosis, organic brain syndrome, cranial nerve disorder, headache and CVA), SLAM (CVA, seizure, cortical dysfunction and headache) and SLICC (cognitive impairment, psychosis, seizures, CVA, cranial or peripheral neuropathy or transverse myelitis) with and without (iii) NPSLE syndromes considered minor and nonspecific, and (iv) ACR criteria and SLEDAI NP indices. Factors associated with NPSLE were explored using univariate and multivariate regression including antibodies, # of ACR criteria, disease duration, disease activity, ethnicity, education and income.

Results: Cohort size was 1417, mean disease 12±10 years, mean age 41±16 years, 86% females. Subgroup size was dependent on the specific definition of NPSLE. The prevalence of NPSLE was: (i) 6.4%, (ii) 38.6%, (iii) 28.7% and (iv) 10.2%. In univariate analysis, Aboriginals had increased NPSLE (>twice as common) versus Caucasians, Asians and Blacks {p=0.04 in Group (i)}. Anti-SSA/Ro was increased in groups (i) and (iv) and antiphospholipid (aPL) was increased in (i), (ii) and (iii). In group (iv) absence of anti-Sm was significant. NPSLE was not increased in those with positive anti-DNA, anti-SSB/La, anti-RNP, LAC (lupus anticoagulant) or aCL(anti-cardiolipin antibody). Total number of ACR criteria, SLAM, age at diagnosis, disease duration and gender were not associated with NPSLE. If thromboembolic events were excluded, aPL was no longer associated. Education level was not associated with NPSLE (p=0.32) and income was only significant in group (i) (p=0.03). The results are shown below for Group (i).

Characteristics Group (i)	NPSLE (n=80)	Non-NPSLE (n=1173)	p-value
Age at diagnosis	29.9 +/− 12.3	32.0 +/− 14.0	0.19
Disease duration	13.2 +/− 10.4	12.7 +/− 10.2	0.67
Gender *n*	69:10	1021:110	0.88
(% F:M)	90.8 : 9.2 %	90.3 : 9.7 %	
Ethnicity (%)			0.04
Aboriginal	9 (12.5)	56 (5.3)	
Asian	14 (19.4)	162 (15.3)	
Black	5 (6.9)	106 (10.0)	
White	44 (61.1)	732 (69.3)	
Total ACR criteria	5.9 +/− 1.5	6.1 +/− 1.7	0.31
SLAM-2 Score	5.8 +/− 4.1	5.8 +/− 4.0	1.0
Antibody positive (%)			
anti-dsDNA	26 (61.9)	448 (48.8)	0.12
Anti-Smith	18 (24.0)	305 (28.6)	0.43
Anti-RNP	18 (25.4)	291 (26.7)	0.89
Anti-Ro	36 (51.4)	369 (34.1)	0.004
Anti-La	14 (20.0)	136 (12.6)	0.19
LAC	3 (4.0)	26 (2.4)	0.43
aCL	10 (13.3)	76 (7.1)	0.66
aPL	27 (36.0)	191 (18.0)	<0.001

Conclusions: The prevalence and factors associated with NPSLE varied depending on the definition used and was highest in the Aboriginal group, and may be higher if positive anti-Ro or aPL. SLAM, SLICC and SLEDAI include mild subjective disease manifestations, which contributed to a 10% higher prevalence of NPSLE compared to a strict definition. NPSLE may be less frequent in this database than other publications as it may be decreasing, or due to selection bias of those who enter an observational cohort.

Cognitive Disfunction in Young Patients within the Early-Years If the Disease. An Inception-Cohort Study. Ali Duarte-Garcia[2], Sandra Juárez-Arellano, Juanita Romero-Diaz, Hilda Fragoso-Loyo and Jorge Sánchez-Guerrero[1]. [1]Insituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, México, [2]Instituto Nacional de Nutricion Salvador Zubiran

Cognitive dysfunction is considered a late manifestation in SLE patients. It is still undefined the factors associated with its presentation as well as the time of onset during lupus evolution. We aimed to identify time of onset, and lupus-related factors associated with cognitive dysfunction in an inception cohort of SLE patients.

Methods: We included 76 patients (96% females) with SLE of recent-onset at enrollment. At entry, a standardized medical evaluation was done assessing lupus characteristics, medications, cardiovascular risk-factors, and laboratory tests. Patients were seen every 3–6 months, and assessed for disease activity and medications. Information was updated yearly and a blood sample drawn.

At 6.2 (0.6–9.8) years of follow-up, all the 76 patients were evaluated for cognitive dysfunction using the following tests: Trail Making test, Digit Span, California Verbal Learning test, Rey-Osterrieth complex figure test, the Stroop Color-Word test, WAIS III letter-number sequencing, Animal naming test, Controlled Oral Word association, WAIS-R/III digit symbol substitution test, Grooved pegboard test, and WAIS-R/III similarities. Tests were grouped in 7 cognitive domains: memory, attention/executive function, visuo-spatial, motor, psycho-motor speed, language, and problem solving. Cognitive dysfunction was present when results were at least -2 SD in 2 or more cognitive domains.

Results: At enrollment, mean (SD) age of lupus patients was 25.2 (9.1) years, lupus duration 5.4 (3.8) months, and SLEDAI-2K score 6.9 (5.8). At screening, mean age of patients was 30 (19–51) years. Eleven patients (14%) were diagnosed with cognitive dysfunction, females (91%). Cognitive dysfunction was observed as early as age 21–30 years, after 3 years of evolution.

Comparing patients with and without cognitive dysfunction, the single difference was observed in education 9 (5–16) vs. 12 (8–17) years, P=0.05. No difference was observed in body mass index, hypertension, diabetes mellitus, lipid profile (total cholesterol, c-LDL, c-HDL, triglycerides, Lp(a), Apo-B), glucose, homocystein, and hsCRP. Also, the Framingham risk scores were similar in both groups.

Comparing patients with and without cognitive dysfunction, SLE characteristics did not differ between groups: age at diagnosis 23 (17–43) vs. 24 (14–46) yrs, disease duration 7.1 (3.2–9.4) vs. (6.–.–.8) yrs, P=0.45, disease activity–SLEDAI-2K AUC 18.7 (9.3–26.3) vs. 14.2 (0–35.5), P=0.10, adjusted mean SLEDAI-2K 5.67 vs. 3.98, P=0.32, and SLICC/DI score 0 (0–3) vs. 0 (0–4), respectively. The prevalence of anti ds-DNA, Sm, RNP, SSA, SSB, anti-cardiolipin and anti-b2-glycoprotein-I antibodies did not differ. The cumulative dose of prednisone was 19.8 and 16.5 grams, respectively (P=0.58). No difference was observed with the use and cumulative dose of immunosuppressants, as well as the use of antimalarials and low-dose aspirin

Conclusions: In this inception cohort of young lupus patients, cognitive dysfunction was observed from age 21–30 years, and after 3 years of lupus. The single association observed was with a lower education level, but no lupus-related variables were identified.

Cognitive Dysfunction in Patients with SLE: A Prospective Study. Andres Piatti[2], Tara Adhikari[2] and Michael Luggen[1]. [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]University of Cincinnati College of Medicine

Background: Cognitive dysfunction (CD) has been reported to occur frequently in SLE. It is unclear, however, it this CD is transient, persistent, or progressive. Published reports have estimated persistence or progression in anywhere from 17% to 93% of patients. These widely divergent results may be due in part to the definition of CD and the control population employed. Chronic rheumatic diseases cause pain, fatigue, and depression which may affect cognitive function. All studies of progression to date have employed normal healthy individuals as controls. Definitions of CD relative to this population will identify some pts whose major problems are depression, pain, or fatigue, which may improve, and some who have structural CNS disease,

which may not. Previous work from our group utilizing an age, sex, and race matched RA control population and a community based cohort of SLE pts suggested that the frequency of CD was low (17.2%), but that most patients had persistent deficits. This work extends those observations.

Methods: Patients with SLE by ACR Criteria from several sources were examined at baseline and again after ≥ 6 months. Cognitive function was assessed by the ANAM (Automated Neuropyschologic Assessment Metrics), a validated, computerized, cognitive testing battery, utilizing as the primary outcome measure the total throughput score (TTS=total number of correct responses/time). Disease activity, damage, and treatment variables were ascertained at baseline and at 6 mos. Abnormality was defined as having scores 1.5 SD below the mean of a comparable RA control population. Results were compared using paired t-tests or Wilcoxon sign rank test and by Fisher's exact test.

Results: Thirty-eight (38) patients have been examined to date on at least 2 occasions. Four (10.6%) had CD at baseline. CD persisted in all pts at 6 mos. None, however, showed progression and no additional subjects developed CD. Pts with CD were significantly older than those without (58.3 ± 8.9 vs 44.1 ± 9.0, $p < 0.05$). Other differences were found but none were statistically significant, perhaps due to small numbers with CD. TTS improved significantly in those without CD (increase of 9.4% (95% CI: 0.1%, 19.0%) but decreased in those with CD by 4.0% (95% CI: −13.9%, 5.8%).

Conclusions: Using RA controls, 10.6% of SLE pts had CD and all remained unchanged over a 6 month interval. Age was a significant correlate of CD. Pts without CD improved scores over 6 mos perhaps demonstrating a learning effect. Those with CD had no such improvement. This may represent another measure of CD.

Cognitive Dysfunction in Systemic Lupus Erythematosus: Development of a Screening Tool. Tara Adhikari[2], Andres Piatti[2] and Michael Luggen[1]. [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]University of Cincinnati College of Medicine

Background: Cognitive Dysfunction (CD) is said to occur frequently is SLE and to be associated with increased unemployment rates and decreased quality of life. Yet, it is oftentimes undiagnosed because of difficulties in doing so. There are only two validated tools for detecting the CD in SLE patients. Traditional neuropsychologic testing (NPT), which consist of a variable battery of tests, administered and interpreted by a clinical psychologist, requiring 4 to 6 hours to complete, and costing oftentimes over $1000. And, the Automated Neuropsychologic Assessment Metrics (ANAM), a computerized battery of tests which assess some of the same cognitive domains as NPT, requires approximately 45 minutes, and costs approximately $400 for a software license. While more efficient and less costly, the ANAM is neither readily available nor practical for clinic administration or for screening larger populations. What is needed for both situations is a brief, sensitive, and reliable screening questionnaire.

Methods: The Montreal Cognitive Assessment Questionnaire (MoCA) has been developed and tested to identify mild cognitive impairment in the elderly. It is a brief (<10 mins), performance-based questionnaire that has been utilized in a number of other diseases with fair sensitivity (85–90%) and variable specificity (53–87%). The MoCA has never been utilized to screen for CD in patients with lupus.

Patients with SLE fulfilling American College of Rheumatology criteria were recruited and evaluated. Demographic, clinical, and treatment information was obtained. In addition, depression was assessed using the Beck Depression Inventory (BDI) and fatigue, pain, and overall well being scored on a 10 cm visual analogue scale. All subjects were administered the ANAM as the gold standard and the MoCA.

The total throughput score (TTS) is a standard measure of cognitive performance of the ANAM. It is the average of the total number of correct responses/time required for those responses. Abnormal was defined as any score 2 SD or more below the mean established for a comparable rheumatoid arthritis population. The scores of the MoCA were compared to the TTS and the classification of normal or abnormal by the ANAM compared to that of the MoCA using various cutoffs.

Descriptive statistics of the study population were computed. Using various cutpoints for the MoCA, the sensitivity, specificity, accuracy, predictive values, and likelihood ratios were also computed.

Results: Fourty-four (44) patients have been recruited to date. Eleven (25%) were identified by the ANAM as being impaired in comparison to 13 (29.5%) by the MoCA. The scores of the two tests were significantly correlated ($r = 0.57$, $p < .001$). Using the standard cut-off of 26, the sensitivity of MoCA was 83%, specificity 73%, accuracy 75%, with a positive predictive value of 50% and negative predictive value of 92% compared to ANAM. Other cut points were less efficient.

Conclusion: The MoCA appears to be a useful screening tool for the detection of CD in SLE using the standard cutoff of 26. However, improved performance might be obtained by weighting individual questions differently or by developing additional items with enhanced discrimination.

Determinants of Treatment Adherence in Patients with Systemic Lupus Erythematosus (SLE). Shazia A. Beg[1], Sofia de Achaval[2], Michael A. Kallen[2], Vanessa L. Cox[2], Marsha N. Richardson[2], John D. Reveille[3] and Maria E. Suarez-Almazor[4]. [1]Baylor College of Medicine, Houston, TX, [2]The University of Texas M. D. Anderson Cancer Center, Houston, TX, [3]Univ Texas Health Sci Ctr, Houston, TX, [4]University of Texas, MD Anderson Cancer Center, Houston, TX

Objective: Patients' health-related beliefs may ultimately influence their health-related behaviors, including their adherence to medications. The Health Belief Model (HBM) has been widely used to explain individual health behaviors under different chronic disease conditions. This study examines the relationships between HBM domains and medication adherence in SLE patients.

Methods: We examined a cohort of 110 ethnically diverse SLE patients from publicly funded hospitals in Houston, Texas. At baseline, 12 and 24 months patients completed a HBM questionnaire and two adherence questionnaires—the Compliance Questionnaire Rheumatology (CQR), with scores ranging from 0 to 100 and higher scores indicating better adherence; and the Adult AIDS Clinical Trials Group-Adherence (AACTG-Adh) with scores ranging from 0 to 3 and higher scores indicating worse adherence. HBM domains of study interest included perceived severity of disease, perceived benefits and risks of treatment, self efficacy and barriers to treatment. Statistical analyses included Pearson correlational analysis and multi-variable stepwise linear regression modeling.

Results: Of 110 SLE patients, 90% were female; mean age was 37 years; 55% were African-Americans and 38% Hispanic. Mean CQR score was 69.6 (sd=11.6), while mean AACTG-Adh score was 0.7 (sd=0.5). Both adherence measures showed similar correlational results; however, AACTG-Adh results are presented here, as these were consistently of higher magnitude. At baseline, HBM domains that were statistically significantly associated with better adherence included: (i) elements of self-efficacy i.e. function (r=0.20), optimism (r=0.22), pain (r=0.34), and symptoms (r=0.41); and (ii) perceived effectiveness (r=0.28). Domains significantly associated with worse adherence included: (i) perceived disease severity (r=0.39) and perceived threat (r=0.36); (ii) barriers i.e. access (r=0.21), transportation (r=0.39), financial (r=0.36), and clinic logistics (r=0.37); (iii) forgetting (r=0.58); (iv) perceived toxicity (r=0.44); and (v) lack of benefit (r=0.45). In the multi-variable regression analysis using AACTG-Adh as the dependent variable, the following beliefs were independent predictors in the final stepwise model: self-efficacy about symptom control which was associated with increased adherence; financial barriers, forgetting, perceived toxicity and perceived disease severity which were all associated with decreased adherence. Throughout the study's time period, most HBM constructs and treatment adherence itself remained at generally constant levels, highlighting the stability of beliefs and behaviors in the absence of targeted interventions.

Conclusions: Several HBM dimensions are closely associated with adherence in SLE patients. While some barriers may be difficult to modify, educational interventions outlining medication benefits and risks, introducing strategies to remember taking medications and enhancing self efficacy could potentially increase treatment adherence in this patient population.

1857

Discordance between Self-Report and Physician-Assessed Disease Activity in Patients with Systemic Lupus Erythematosus (SLE): Implications for Clinical Trial Design and Clinical Care. Anca D. Askanase[3], Isabel Castrejón[4], Jill P. Buyon[5], Yusuf Yazici[1] and Theodore Pincus[2]. [1]Hospital for Joint Diseases, Hastings on Hudson, NY, [2]New York University Hospital for Joint Disease, Hastings-on-Hudson, NY, [3]NYU Hospital for Joint Diseases, New York, NY, [4]NYU Hospital for Joint Diseases, [5]NYU School of Medicine, New York, NY

Purpose: To analyze agreement levels between patient (PT) and physician (MD) assessments in 50 patients with SLE seen in usual care, including ***a)*** global PT and MD estimates of status; ***b)*** patient self-report scores on the SLAQ (Systemic Lupus Activity Questionnaire) and MDHAQ (Multidimensional Health Assessment Questionnaire) for physical function (FN), pain (PN), patient global estimate (PTGL), fatigue (FT), RAPID3 (FN, PN, and PTGL), and review of systems checklist (SX); ***c)*** physician-scored indices SLEDAI-2K (SLE Disease Activity Index), BILAG (British Isles Lupus Assessment Group index), SLAM (SLE Activity Measure) and ECLAM (European Consensus Lupus Activity Measurement).

Methods: A cross-sectional study was performed in 50 consecutive SLE patients of one rheumatologist. Patients completed the SLAQ and MDHAQ, including PTGL. The rheumatologist scored a physician global estimate (MDGL) (scored 0–3 in 0.1 increments) without knowledge of PTGL, and completed the SLEDAI 2K, BILAG, SLAM, and ECLAM. Agreement levels of various measures were analyzed using Spearman rank order correlations.

Results: The study included 45 women and 5 men, mean age 38.7 years, mean disease duration 7.3 years, 36% Caucasian, 18% Black, 26% Hispanic, 18% Asian. The mean MDGL (1.10±0.62), PTGL (3.11 ±2.81) and SLE indices (SLEDAI 5.02±3.75; BILAG 4.60±4.31; SLAM 3.86±2.92; ECLAM 1.97±1.37) indicated mild/moderate lupus activity. The correlation between MDGL and PTGL of rho=0.14 was not statistically significant. Correlations between MDGL and SLE indices were significant, rho=0.60–0.72 ($p<0.001$). Correlations between PTGL and patient measures also were significant, rho=0.58–0.87 ($p<0.001$). However, PTGL was correlated at lower levels with SLE indices – significantly with BILAG and SLAM (0.35–0.40; $p<0.01$), and not significantly with SLEDAI or ECLAM. MDGL was not correlated significantly with any patient measure or index.

		PTGL	MDGL
Patient Measures	SLAQ		
	• Total score	0.60*	−0.08
	• # positives	0.58*	−0.06
	• VAS activity	0.69*	0.34
	MDHAQ		
	• FN	0.68*	0.08
	• PN	0.87*	0.08
	• FT	0.79*	−0.02
	• PTGL	-	0.14
	• # SX	0.66*	0.03
Physician Measures	MDGL	0.14	-
	SLEDAI	0.16	0.72*
	BILAG	0.35†	0.70*
	SLAM	0.40*	0.64*
	ECLAM	0.26	0.60*

*$p<0.0001$; †$p<0.01$

Conclusion: MDGL and PTGL are not correlated significantly, an observation made previously. MDGL was correlated significantly with all physician-derived indices, and PTGL was correlated significantly with all patient-derived measures and indices. By contrast, MDGL was correlated at much lower, non-significant levels with patient-derived measures and indices, and PTGL was correlated at lower levels with physician-derived indices. Further analysis of these discordances may clarify the clinical relevance of various measures in clinical trials, and may lead to improved care and compliance in patients with SLE.

1858

Ethnicity Affects the Frequency of CNS Manifestations of SLE. Maryna Shayuk[2], Hong Fang[2] and Michelle A. Petri[1]. [1]Timonium, MD, [2]Johns Hopkins University

Purpose: The new SLICC classification criteria have added mononeuritis multiplex, myelitis, peripheral or cranial neuropathy and acute confusional state to the previous CNS manifestations (psychosis and seizure) of the neurologic criterion for SLE. We investigated the frequency of these neurologic manifestations, as well as depression, lupus headache and stroke in a prospective SLE cohort.

Method: 1889 SLE patients (88.5% female, 56.5% Caucasians, 36.9% African-Americans) were included. Neurologic manifestations were recorded at cohort entry and updated at every visit.

Result:

Table 1. Neurologic manifestations, by ethnicity

	Caucasian	Af-Am	P-value*	Odds Ratio**	95% CI (Odds Ratio)
Seizure	105/1135 (9.25%)	80/744 (10.75%)	0.2853	0.8461	0.6226–1.1499
Psychosis	34/11 (3.00%)	36/743 (4.85%)	0.0389	0.6070	0.3763–0.9792
OBS	54/1135 (4.76%)	39/743 (5.25%)	0.6313	0.9017	0.5909–1.3761
Meningitis	21/1135 (1.85%)	17/743 (2.29%)	0.5100	0.8050	0.4219–1.5363
Stroke	40/1135 (3.52%)	42/742 (5.66%)	0.0268	0.6088	0.3908–0.9484
Depression	455/1134 (40.12%)	239/741 (32.25%)	0.0006	1.4075	1.1587–1.7097

Optic Neuritis	16/1117 (1.43%)	7/732 (0.96%)	0.3663	1.5051	0.6162–3.6766
Cranial Neuropathy	25/1117 (2.24%)	11/730 (1.51%)	0.2664	1.4964	0.7318–3.0601
Peripheral Neuropathy	86/1117 (7.70%)	48/730 (6.58%)	0.3626	1.1852	0.8218–1.7092
Transverse Myelitis	9/1113 (0.81%)	9/729 (1.23%)	0.3635	0.6522	0.2577–1.6508

*based on chi-square test for the binary outcomes
**the ratio of the odds of the event occurring in Caucasian to the odds of it occurring in Af-Am

Conclusion: Caucasians have significantly more depression, but African-Americans have significantly more psychosis, stroke, and mononeuritis multiplex. Depression is the most common neurologic manifestations in both ethnicities. The addition of acute confusional state, mononeuritis multiplex, optic neuritis, other cranial neuropathies, peripheral neuropathy and myelitis allow an additional 21% of SLE patients to meet the neurologic classification criterion who did NOT have seizures or psychosis.

Five Year Follow-Up Study of Bone Mineral Density in Patients with Systemic Lupus Erythematosus: The Influence of Corticosteroid Treatment. Anna M. Schilder, Jonathan Jacobs, Lindy-Anne Korswagen, Ben A. C. Dijkmans, Willem F. Lems, Alexandre E. Voskuyl and Irene E. M. Bultink. VU University Medical Center, Amsterdam, The Netherlands

Introduction and Objective: The influence of corticosteroids on bone mineral density (BMD) in systemic lupus erythematosus (SLE) is still under debate. Various studies have reported an association between corticosteroid use and low BMD in SLE but other studies did not demonstrate a significant relationship. This discrepancy might be explained partially by the cross-sectional design of the far majority of studies. Only a few longitudinal studies on BMD change and the associated factors in patients with SLE have been performed. However, in these studies, the numbers of patients were small and the duration of follow-up was relatively short (three years).

The aim of this study was to assess change in BMD during long-term follow-up in patients with SLE and to identify factors associated with BMD loss. In particular the effect of corticosteroid treatment on BMD change was studied.

Methods: We prospectively studied 82 patients with SLE. Demographic and clinical data were collected and BMD measurements of the lumbar spine and total hip were performed by dual energy x-ray absorptiometry at baseline and at follow-up. Osteoporosis was defined as a T score less than -2.5 SD and osteopenia as a T score less than −1.0 SD in at least 1 region of measurement. Statistical analysis was performed using independent sample t-test for comparison of means, univariate and multiple regression analysis.

Results: At baseline, osteopenia was present in 49% of the patients and osteoporosis in 9% (93% female, mean age 38.8 years, mean disease duration 6.3 years). During the observation period, 67.1% of the patients were treated with corticosteroids. The mean cumulative dose of prednisone used between baseline and follow-up was 13.4 ± 8.5 grams. The mean daily dose of prednisone was 6.6 ± 3.9 mg in the corticosteroid users.

After a mean follow-up of 5.7 years, no significant change in BMD of the total hip or the lumbar spine was observed at group level. However, higher cumulative corticosteroid dose during the observation period was significantly

associated with BMD loss in the lumbar spine, but not at the hip (p = 0.851). A mean daily dose of more than 7.5 mg prednisone was associated with significant BMD loss at the lumbar spine as compared to patients receiving less than 7.5 mg per day (P = 0.003).

Conclusion: In this long-term follow-up study, no significant change in BMD of the lumbar spine or the total hip is observed in patients with SLE. However, higher mean daily and cumulative corticosteroid dose is associated with BMD loss in the lumbar spine. The high prevalence of reduced BMD and the negative influence of corticosteroid use on bone density in the lumbar spine underline the importance of permanent attention for monitoring and treatment of low BMD in SLE, especially in patients using higher doses of corticosteroids.

High Prevalence of Fetal Loss and Pregnancy Complications in African-American Lupus Patients: A Retrospective Case-Control Study. Kirk C. Eddleman[2] and Vikas Majithia[1]. [1]University of Mississippi Medical Center, Jackson, MS, [2]University of Mississippi Medical Center

Introduction: Pregnancy in Systemic Lupus Erythematosus (SLE) patients is associated with a high rate of fetal loss and pregnancy complications which are about 2–4 times higher than non-SLE patients. The rates are felt to be even higher in African-American (AA) patients, but an exact prevalence and risk is not yet characterized. We undertook this study to assess the risk of fetal loss and complications in SLE patients at University of Mississippi Medical Center, caring for predominantly (gt]90%) AA patients.

Methods: A retrospective chart review of pregnancies in 83 women with SLE and 99 age-matched controls was performed for time-period between 2004 and 2006. Patients were identified by cross referencing billing codes 710.0 (Lupus) and 648.1 or 648.3 (Pregnancy). Data included: demographics, SLE related information, medications, compliance with follow-up visits (>60%), fetal outcomes and complications. Odds ratio were calculated and statistical significance was determined using Fischer's Exact test.

Results: Mean age of two groups were 22 years and both groups had 95 % AA patients. Results are summarized below.

Table 1. Fetal loss in SLE versus non-SLE patients

	SLE group	Control group	Odds ratio	P-value
Overall Fetal Loss	16.9% (n=83)	3% (n=99)	6.49	0.001
Overall Fetal loss in hydroxycholoroquine users	6% (n=30)	3% (n=99)	2.28	NS
Overall Fetal loss in compliant patients*	3% (n=67)	1% (n=54)	1.6	NS

(*compliance=> 60% follow-up visits).

Table 2. Maternal Complications in pregnancy for SLE versus non-SLE patients

	SLE group	Control group	Odds ratio	P-value
Pre-term Labor	50.7%	31.2%	2.26	0.01
Baseline Hypertension	33.7%	9%	5.09	<0.0001
Pre-Eclampsia	31.3%	18.2%	2.05	0.04
HELLP Syndrome*	6%	2%	3.10	NS
Hyperglycemia	2%	3%	NS	NS

(HELLP=Hypertension, Elevated Liver enzymes and Low platelets)

Discussion: We found SLE significantly increased the risk of fetal loss in 2nd and 3rd trimesters (OR 6.49). The risk was similarly increased in this study for miscarriage (fetal loss<20 weeks) and stillbirth (fetal loss>20 weeks). In contrast, patients who were being treated with hydroxychloroquine (OR 2.28) or were compliant (OR 1.6) only had a minor increase in the risk as compared to control group. SLE patients had increased likelihood of having baseline hypertension, pre-eclampsia and pre-term labor. There was no increase in likelihood of association with hyperglycemia, C-sections, HELLP syndrome, anti-phospholipid antibodies or lupus activity markers in our comparison.

Our data suggest the likelihood of the fetal loss (6 vs 4 times), any complication (80% vs 50%), pre-eclampsia(33% vs 20%) or pre-term labor (50% vs 33%) may be higher than previously reported. The AA ethnicity may be a contributing factor here but a small sample size limits further characterization of the specific factors contributing to the increased risk.

Conclusion: There is a marked increase in risk of fetal loss and adverse pregnancy complications in African-American SLE patients many of which are higher than previously reported. Plaquenil and compliance with physician care seem to help decrease the likelihood of these adverse outcomes.

Hyperuricemia Is a Predictor of Subclinical CVD in SLE Patients but Not Controls. Joseph L. Enama[2], Robert Gilkeson[1] and Lisabeth Scalzi[2]. [1]Case Western Reserve University, [2]Penn State Univ Hershey, Hershey, PA

Purpose: Both systemic lupus erythematosus (SLE) and hyperuricemia are non-traditional risk factors for atherosclerotic cardiovascular disease (CVD). We compared the associations of serum uric acid levels (UA) and subclinical CVD, while adjusting for traditional CVD risk factors, between patients with SLE and controls.

Methods: 222 patients (140 with SLE, 82 controls), all without clinical CVD, were recruited from rheumatology clinics at two academic medical centers. Demographic information and fasting blood samples were collected from each patient. Coronary artery calcium scores (CAC) were calculated in each patient. Subclinical CVD (lCAC) was defined by [log (CAC +1)]. Associations of uric acid with traditional predictors of CVD were examined in univariate analyses. Traditional and non-traditional CVD risk factors—including dyslipidemia, body mass index (BMI), hypertension (HTN), high sensitivity C-reactive protein, smoking history, diabetes (DM), race, age, and UA—were examined as independent predictors of subclinical CVD. Variables were analyzed using either Chi-square or Student's t-test, dependent on whether they were ordinal versus continuous measures respectively. Final linear regression models were calculated for SLE and controls, including all significant covariates ($p < 0.1$) for the analyses.

Results: Mean serum UA levels did not significantly differ between SLE and control patients. (6.0 mg/dL versus 6.4 mg/dL, p = 0.9). UA was significantly associated with advanced age (p = 0.01), hypertension ($p < 0.01$), and BMI ($p < 0.01$) in SLE patients. Significant covariates for lCAC in the control group included dyslipidemia (p = 0.05), HTN (p = 0.01), DM (p = 0.037), age ($p < 0.01$), and UA ($p < 0.01$). Significant covariates for lCAC in SLE patients included smoking history (p = 0.01), age ($p < 0.01$), and UA ($p < 0.01$). The linear regression model in controls demonstrated that only age was a significant predictor for lCAC (p = 0.01). UA was found to be a significant predictor for lCAC in SLE patients, when controlling for age and smoking (p = 0.03). SLE patients with UA in the upper tertile (uric acid ≥ 4.7 mg/dL) had a significantly higher lCAC (p = 0.04).

Conclusions: In patients with SLE, the presence of hyperuricemia in patients may predict CVD, independent of other traditional CVD risk factors. Larger studies are needed to determine if uric acid-lowering interventions may lower the risk of CVD in SLE.

Identifying Modifiable Risk Factors for Depression in Systemic Lupus Erythematosus. David Karol[2], Lisa G. Criscione-Schreiber[2] and Megan E. B. Clowse[1]. [1]Duke Univ Med, Durham, NC, [2]Duke University, Durham, NC

Background: Depression is common (40%) in individuals with systemic lupus erythematosus (SLE), and may be exacerbated by disease activity and chronic pain. We aimed to measure the rate of depression in our SLE cohort, and to identify modifiable factors associated with depression.

Methods: Upon enrollment in our university-based SLE registry, each patient completed a questionnaire that included the Beck Depression Inventory II (BDI-II), pain scores, and demographic information. Disease activity was measured by the treating rheumatologist using the physician's global assessment (PGA) and SLE disease activity index (SLEDAI). Current medications were recorded. For statistical analysis, patients were divided into two groups: depressed (BDI-II≥18) and not depressed (BDI-II<18). Student's t-test was used to compare the means of continuous variables and z-test was used for dichotomous variables.

Results: The BDI-II was completed by 105 patients, 40 (38.1%) of whom were depressed (BDI≥18). Depression was associated with several measures of disease activity, prednisone and antidepressant use. It was not associated with demographic characteristics, including race, income, type of insurance, or age. (Table) Half of the patients with depression had clinically evident

arthritis as indicated on the SLEDAI (2 or more joints with current inflammation), but only 17% of those without depression had arthritis (p=0.0003). On the other hand, SLE rash, which can be disfiguring and lead to social isolation, was not associated with depression. The other individual measures of SLE activity in the SLEDAI, including hypocomplementemia and anti-dsDNA antibody, were not associated with depression. Prednisone dose and antidepressant use were associated with depression. Only 40% of patients with depression, however, were currently taking a selective serotonin-reuptake inhibitor (SSRI). In a multivariate analysis that included the measures that were independently associated with depression (including PGA, SLEDAI arthritis, current pain, prednisone dose, and antidepressant use), only the level of current pain remained significantly correlated with moderate to severe depression.

Conclusions: We found that depression was statistically significantly associated with pain, arthritis, lupus activity, prednisone dose and antidepressant use. In multivariate analysis, pain appeared to be the most important predictor of depression. It is unclear whether pain promotes depression or vice versa. However, pain may be a modifiable risk factor for depression in SLE patients, and treatment will likely be most successful when addressing both components.

Table. Demographics and independent variables in SLE patients with and without depression.

	Not Depressed (N=65)	Depressed (N=40)	P value
	Demographics:		
Female no. (%)	60 (92%)	37 (93%)	0.97
Race			
Caucasian	31 (48%)	25 (63%)	0.16
African-American	29 (45%)	13 (33%)	
Age	38 ± 12	40 ± 12	0.61
	Measures of Lupus Activity		
PGA‡	0.6 ± 0.7	0.9 ± 0.7	0.012
SLEDAI¶	3.4 ± 3.7	4.9 ± 4.6	0.06
SLEDAI arthritis	11 (17%)	20 (50%)	0.0003
SLEDAI rash	14 (22%)	8 (20%)	0.85
Current pain (0–10)	3.0 ± 3.0	6.0 ± 2.5	0.00001
	Medications

In Systemic Lupus Erythematosus (SLE) Patients, Patient Reported Outcomes and Physician Assessment of Disease Activity Are Poorly Correlated: Implications for Outcome Measures in SLE. Magaly Villafradez Diaz[1], Ashwini Shadakshari, Andy McCracken, Christopher Swearingen, Daniel Ricciardi and Yusuf Yazici[2]. [1]Long Island College Hospital, [2]NYU Hospital for Joint Diseases

Purpose: To evaluate the correlation of patient vs physician reported outcome measures in a routine care SLE cohort.

Methods: The first recorded physician global observations in patients with the primary diagnosis of systemic lupus were identified; corresponding demographic, patient reported functional outcomes and current usage of prednisone, hydroxychloroquine and non-steroidal anti-inflammatory medications and immunosupressive medication use were abstracted. Current medication usage was operational defined as medications taken prior to and including the visit date; patient discontinuations prior to the selected visit and medication initiations at the selected visit were defined as non-current usage. Summary statistics for demographic, outcome measures and median visit of physician global observation were estimated by current medication usage. Lin's concordance correlation was estimated for each patient reported functional outcome compared to the physician global. Spearman's correlation coefficient were calculated for patient and physician measures.

Results: 180 patients were included in this analysis (mean age 42, disease duration 0.7 years, 93% female, education 14 years). On average patients had active disease, with (mean (SD)) pain 5.0 (3.0), function 2.5 (1.9), fatigue 6.1 (3.0) patient global assessment of disease activity 4.9 (2.6) and physician global assessment of disease activity 2.4 (1.7), (all measures' range 0–10). Mean RAPID3 score (range 0–30) was 12.8 (6.1). Spearman and concordance correlations are given in Table 1. There was only moderate correlation seen with physician assessment of disease activity with all patient reported outcomes and the RAPID3 composite index.

Table 1. Spearman and Concordance Correlations (95% Confidence Intervals) between Physician Global and Patient Reported Outcomes in SLE

MD Global Association	Spearman	Concordance
Function	0.356 (0.189, 0.504)	0.334 (0.177, 0.492)
Pain	0.365 (0.207, 0.504)	0.160 (0.076, 0.245)
Global	0.391 (0.235, 0.527)	0.179 (0.091, 0.268)
RAPID3	0.431 (0.259, 0.576)	0.264 (0.141, 0.387)
Fatigue	0.279 (0.110, 0.432)	0.108 (0.033, 0.182)

Conclusions: In this cohort of SLE patients seen in routine care, there was moderate correlation between what the patients reported about their disease activity and physicians perceptions of their disease activity. Measures that primarily depend on physician assessment o disease activity may be poor correlates of SLE activity and may not be ideal measures to be sued in clinical trials of SLE.

1864

Incidence and Predictors of Hospitalization in Systemic Lupus Erythematosus (SLE): Results from a Large Contemporary Multi-Ethnic Cohort. June Lee[3], Janet E. Pope[1], Christine A. Peschken[2] and The 1000 Faces of Lupus. [1]St Joseph Health Care London, London, ON, Canada, [2]Univ of Manitoba, Winnipeg, MB, Canada, [3]University of Western Ontario, London, ON, Canada

Background: Annual rates of hospitalization for lupus are as high as 30 to 40%. The aim of this study was to determine the rate of, causes for, and determinants of hospitalization in a large contemporary SLE cohort.

Methods: Data from the 1000 Canadian Faces of Lupus (a prospective multi-centre cohort study) were used. Data on hospitalization, lupus flares, demographics, medication history, disease activity and damage, and co-morbidities are collected annually. Univariate and regression analyses were performed.

Results: Data on hospitalization (yes or no) were available on 724 participants; 68 reported hospitalizations related to SLE (hospitalization rate of 9.4% overall and an annual hospital rate of 7.2%). The most common causes of SLE-related hospitalization were hematologic (18.1%), serositis (16.9%), musculoskeletal (13.3%), and renal (12.0%). Some were hospitalized for more than one reason. The occurrence of hospitalization was significantly associated with: Aboriginal compared to Caucasian, Asian and Blacks (p=0.003), having a lower household income (p=0.01), being work disabled (p=0.001), having greater disease activity as indicated by the SLAM-2 (p=0.004), having a greater number of ACR criteria (p=0.006), positive anti-Sm (anti-Smith) antibody (p=0.018) and use of azathioprine (p=0.039). There was no significant relationship between hospitalization and gender, age, number of co-morbidities (as indicated by the Charlson Co-morbidity Score), or number of medications used.

Table. Demographic Characteristics of the 2 Groups

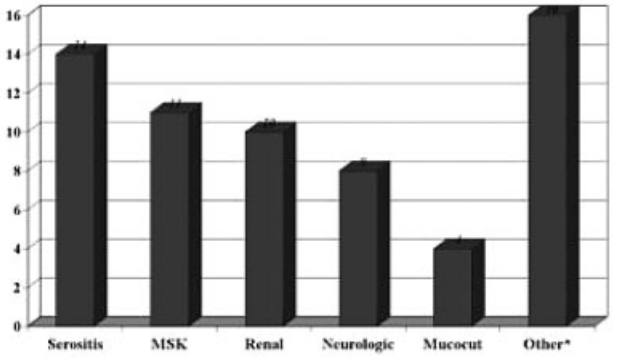
	No. (%) of Patients	
	Non-Hospitalized	Hospitalized
Total	656 (90.6)	68 (9.4)
Gender, Ratio F:M	8.8:1	8.5:1
Age, mean (SD), years	40.5 (17.4)	39.8 (16.9)
Ethnicity†		
Caucasian	417 (92.7)	33 (7.3)
Black	56 (93.3)	4 (6.7)
Asian	118 (95.9)	5 (4.1)
Aboriginal*	44 (81.5)	10 (18.5)
Work Disabled**	102 (15.5)	25 (36.6)
High School Education	55 (81.0)	468 (71.3)
Income Level††		
<$15,000***	63 (85.1)	11 (14.8)
$15,000–$29,999	72 (94.7)	4 (5.3)
$30,000–$49,999	123 (95.3)	6 (4.7)
≥$50,000	247 (96.1)	10 (3.9)

†Excluded 37 participants whose ethnicity not available or belonged to ethnic group other than the 4 of interest.
*Significant relationship between being of Aboriginal race and hospitalization (p=0.004).
**p=0.001.

Table. Disease Activity and Co-Morbidities

	Mean (SD)	
	Non-Hospitalized	Hospitalized
ACR Criteria*	5.2 (1.4)	5.9 (1.7)
SLAM Score**	5.4 (3.9)	6.9 (4.7)
SLEDAI-2K Score	4.4 (4.3)	4.8 (5.0)
SLICC Score	1.3 (1.8)	1.3 (1.7)
Charlson Co-Morbidity Score	1.4 (0.9)	1.7 (1.2)

*p=0.006
**p=0.004



*Other reasons for hospitalization reported were gastrointestinal, infection, pulmonary hypertension, adrenal insufficiency, hepatitis, and thromboembolic events. Some patients had more than one reason for hospitalization

Figure 1. Reasons for hospitalization by number of patients.

Conclusions: The rate of hospitalization of patients with SLE was lower than expected; however this may indicate that the care of lupus is improving, that the cohort is biased towards healthy patients, or that flares are more likely to be handled as an outpatient. Also some renal lupus may be followed solely by a nephrologist. Some hospitalizations may have been under ascertained and we did not record hospitalizations for non-lupus reasons such as pregnancy. The causes of hospitalization were varied and different than what other studies have shown. Several predictors of hospitalization are related to ethnicity, socioeconomic factors and disease activity, which is consistent with results of other studies.

Measuring Therapeutic Adherence in Systemic Lupus Erythematosus (SLE) Using the Medication Event Monitoring System (MEMS®). Maria F. Marengo, Christian A. Waimann, Sofia de Achaval, Vanessa L. Cox, Araceli Garcia Gonzalez, Marsha N. Richardson and Maria E. Suarez-Almazor. The University of Texas M. D. Anderson Cancer Center, Houston, TX

Background: Treatment adherence is crucial in chronic diseases such as SLE. Multiple methods for measuring adherence have been proposed. Electronic monitoring is considered one of the most accurate measures of adherence. The objective of our study was to quantify adherence to medical therapy in patients with SLE with electronic monitoring.

Methods: This study was part of a 2– year prospective cohort of 110 patients with SLE from 2 publicly-funded county hospitals, in which 74 patients agreed to have their SLE drug therapy electronically monitored, with MEMS® caps (AARDEX). These are medication bottle caps with a microchip which records the time and date of bottle openings. Adherence to daily medications was determined as the percentage of days with correct number of doses taken. Adherence to weekly methotrexate (MTX) was determined as the percentage of doses taken within intervals of 7 ± 1.75 days. We also estimated percentage of prescribed doses taken (not considering dosing interval). MEMS® data was downloaded with each refill. Patient outcomes were assessed at baseline, 3, 6, 12, 18 and 24 months including Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), Systemic Lupus International Collaborating Clinics Damage Index (SLICC), SF-12 and flares. We also collected baseline Medical Outcome Study social support (MOS), Center for Epidemiologic Studies Depression Scale 10 items (CDES-10) and sociodemographic variables. 85% of the patients completed 2 years follow-up; for the remainder we used the last observation for analysis. Statistical analysis was performed with SAS

Summary of Results: 89% were female, 49% African-American, and 46% Hispanic; mean age was 36y (±11), disease duration 6y (±5), SLEDAI 3.2 (±3.2) and SLICC 0.8 (±1.2); 97% received prednisone, 92% hydroxychloroquine, 30% mycophenolate mofetil, 13% MTX, 8% azathioprine (not all medications were monitored with MEMS) (table). Adherence for doses taken on schedule (day/wk) was 64% for prednisone and 46% to 62% for the other drugs. Only 15 (20%) of the patients had an average adherence ≥ 80%. Depression was associated with worse adherence ($r=-0.24$, $p<0.04$), and increasing SF-12 mental scores (MCS) with better adherence ($r=0.31$, $p=0.02$). Mean SLEDAI decreased significantly overtime ($p<0.002$); % doses taken had a small but significant correlation with decrease in SLEDAI for all drugs ($r=-0.25$, $p<0.04$) and for prednisone alone ($r=-0.31$, $p<0.02$); % doses on schedule showed similar trends but did not reach statistical significance. No differences were observed for SLICC.

Drugs	N	Total days monitored	Mean dose	% prescribed doses taken on schedule	% prescribed doses taken
Prednisone	65	511 (±260)	12 mg/day	64.3 (±24)	75.9 (±24.6)
Hydroxychloroquine	51	556 (230)	248 mg/day	56.2 (±26.2)	72.0 (±26.1)
Methotrexate	7	350 (267)	134 mg/week	62.0 (±28.7)	94.6 (±30.9)
Micophenolate Mofetil	3	459 (178)	1087 mg/day	46.3 (±20)	67.1 (±22.6)
Average all drugs	74	–	–	58.6 (±24.9)	73.3 (±25.2)

Conclusion: Adherence to drug therapy measured by electronic monitoring appears to be low in patients with SLE, and related to depression and overall mental health. Only 1 out of 5 patients was at least 80% adherent. Low adherence appeared to have a detrimental effect on health outcomes.

Mycophenolate Mofetil (MMF): Physician Prescribing Practices. Seema Malani[1] and Ellen M. Ginzler[2]. [1]SUNY Downstate Medical Center, Brooklyn, NY, [2]SUNY-Downstate Medical Center, Brooklyn, NY

Aim: To determine physician prescribing practices for mycophenolate mofetil (MMF, CellCept®) in North America

Purpose: MMF is commercially available and used off-label for the treatment of SLE but consensus guidelines for its use in lupus and other autoimmune diseases are lacking. We were interested in learning the prescribing practices for MMF among rheumatologists and nephrologists, and their experience with efficacy and toxicity.

Method: Approximately 700 adult and pediatric rheumatologists and nephrologists interested in SLE from the U.S. and Canada were invited via e-mail to complete an electronic survey, including 20 questions regarding their practice setting, ethnic composition of patients treated, dose and duration of MMF use, ethnic differences in response to MMF, and MMF use for extra-renal lupus and other autoimmune diseases.

Results: 141 physicians responded to the survey. The majority were rheumatologists (95.5%) with 3.5% nephrologists; 55% practice in an academic institution. The majority (60%) treat 10–50 SLE patients/month. African-American/Afro-Caribbeans and Caucasians were the predominant population.

57% of respondents prescribe steroids with MMF as first line therapy for active lupus nephritis, predominantly for class III and IV nephritis; 36% favor steroids plus IV cyclophosphamide (IVC). 38% of respondents continue to prescribe MMF for treatment of severe active nephritis with worsening renal function. 85% of academic vs. 71% of private physicians prescribe MMF for both induction and maintenance in lupus nephritis ($p=0.04$). For patients who relapse on maintenance MMF, a similar number of respondents prescribe IVC for reinduction followed by maintenance MMF vs. azathioprine maintenance. Most respondents (75%) attempt a target MMF dose of 3 grams/day. 52% prefer to continue MMF indefinitely while 41% taper and discontinue the dose after achieving remission.

53% of respondents found no racial difference in response to MMF, while 23% did not have a heterogeneous racial population. Few commented on a need for a higher MMF dose in African-American patients.

MMF use for extra-renal lupus manifestations was reported for pulmonary disease (65%), hematologic (57%), cutaneous (48%), neuropsychiatric (44%), and arthritis (41%). MMF use in other autoimmune disease included systemic vasculitis (56%), inflammatory myopathies (50%), interstitial lung disease (44%), systemic sclerosis (33%).

Most respondents change from MMF to other maintenance drugs only for side effects or insurance coverage issues. GI side effects were the most common adverse events reported (84%), followed by infection (30%), and hematologic events (27%).

Conclusion: Despite a lack of guidelines for MMF use, it is the first choice therapy both in remission induction and maintenance of lupus nephritis. Most physicians continue MMF for a long duration. There also appears to be considerable use of MMF for treatment of extra-renal manifestations of SLE.

Novel Cardiovascular Risk Prediction Models in Patients with Systemic Lupus Erythematosus. Vivian K. Kawai[2], Annette M. Oeser[4], Joseph Solus[3], Young H. Rho[3], Paolo Raggi[1], Aihua Bian[3], Tebeb Gebretsadik[3], Ayumi Shintani[3] and C. Michael Stein[2]. [1]Emory University, [2]Vanderbilt University, Nashville, TN, [3]Vanderbilt University, [4]VUMC 23rd Ave South Pierce, Nashville, TN

Background: Women with systemic lupus erythematosus (SLE) have accelerated atherosclerosis and increased coronary heart disease (CHD), but the Framingham risk score (FRS) underestimates risk. Several new approaches have improved prediction of CHD risk in the general population. These include the Reynolds risk score (RRS), that is of particular interest because it includes a measure of inflammation (C-reactive protein), and novel risk scores that substitute "coronary age" in place of chronological age. We examined the hypothesis that these new CHD risk prediction models would better identify increased risk of CHD in women with SLE, particularly in those with subclinical coronary atherosclerosis.

Methods: We studied 121 women with SLE and 65 age-matched female-controls without a previous cardiovascular event. Demographic and clinical data were recorded and FRS and RRS calculated. Coronary artery calcium (CAC) was measured by computed tomography using the Agatston score, and coronary age was derived as described by McClelland. Coronary age-modified risk scores (camFRS, camRRS) were calculated in which chronological age in the existing FRS and RRS calculations was replaced with coronary age. Risk scores were compared in patients with SLE and controls, and in SLE patients with and without CAC, using Wilcoxon rank sum tests. We examined the association between risk scores and CAC using proportional odds logistic regression models. Paired analyses were performed using Wilcoxon signed-rank test or McNemar's test, as appropriate. All analyses used a 5% two-sided significance level.

Results: Coronary artery calcium was present in 21 patients with SLE (17%) and 4 controls (6%) (P=0.033). However, despite more frequent and severe atherosclerosis in SLE, the FRS, camFRS, RRS and camRRS did not differ significantly among women with SLE and controls ($p>0.05$). In women with SLE with CAC the FRS (OR=1.42, 95%CI (1.06–1.90), P=0.017) and RRS (OR=1.29, 95% CI (1.11–1.51), P=0.001) were higher than in those without CAC, however few patients (≤5%) with CAC had 10-year risk scores ≥10% - the threshold used to determine moderate CHD risk. Coronary age-modified risk scores were significantly lower than their respective conventional risk scores in lupus patients without CAC, and higher in those with CAC (both P values <0.001). Coronary age-modified risk scores assigned more patients with CAC to a risk category of ≥10% (camFRS 48%, cam RRS 29%) than conventional scores (FRS 0%, RRS 5%) (P =0.004 and P=0.073, respectively).

Conclusions: The RRS, a novel 10-year risk prediction model that includes C-reactive protein in the risk calculation, was of limited use in women with SLE. Incorporation of coronary age, calculated from CAC scores, into risk prediction models increases the number of patients with CAC with a predicted CHD risk above the 10% 10-year threshold. The ability of models that include coronary age to predict risk of cardiovascular events will be of interest.

Optimal Frequency of Visits for SLE Patients To Capture Disease Activity over Time. Dominique Ibañez[3], Dafna D. Gladman[2] and Murray B. Urowitz[1]. [1]The Toronto Western Hospital, Toronto, ON, Canada, [2]Toronto Western Hospital, Toronto, ON, Canada, [3]University of Toronto Lupus Clinic, Toronto Western Hospital, Toronto, ON, Canada

Objective: Disease activity in SLE patients, measured by SLEDAI-2K, is evaluated at each clinic visit and covers a period of 30 days prior to the assessment. Having consecutive monthly clinic visits would capture the entire disease activity for that period of time. Adjusted Mean SLEDAI (AMS) calculates the areas under the curve of SLEDAI-2K over time. AMS evaluated using monthly visits would be the gold standard for disease activity over time. The usual clinical practice is to see patients every 3–6 months. The aim of this study is to compare the AMS obtained over a one year period when visits are done monthly and compare it to AMS obtained using quarterly, semi-annual or annual visits.

Methods: Patients followed monthly for 12 consecutive visits are included. AMS is evaluated using all of the SLEDAI-2K (AMS_{GOLD} using all 12 visits), only quarterly visits (AMS_3, using visits 3 months apart), semi-annual visits (AMS_6, using 1st, middle and last visits only) and annual visits (AMS_{12} using only the 1st and last visits). Comparisons between AMS_3, ASM_6 and AMS_{12} with AMS_{GOLD} are made using descriptive statistics.

Results: 78 patients were seen monthly for a year. 72 (92%) were women with mean (std) age at SLE diagnosis of 30.1 (11.4) years and mean age and disease duration at study start of 46.2 (12.0) years and 15.5 (9.7) years respectively. The SLEDAI-2K values seen have a mean (std) of 2.05 (2.07) and range in values from 0 to 15, with 7% of all visits having a SLEDAI-2K ≥ 5. The mean (std) AMS_{GOLD} for the entire year is 2.05 (1.66), for AMS_3 = 1.99 (1.65), for AMS_6 = 2.12 (1.87) and for AMS_{12} = 2.08 (1.83). Mean (std) of the absolute differences with AMS_{GOLD} are: for AMS_3 = 0.29 (0.33), for AMS_6 = 0.45 (0.59) and for AMS_{12} = 0.61 (0.58). Differences which were < 0.5 were considered minimal while those ≥ 1 were deemed important. Comparing AMS_{GOLD} to AMS_3, 82% of the differences were minimal and 3% were important. When comparing to AMS_6, 68% were minimal and 10% were important while when comparing to AMS_{12}, 50% were minimal and 21% were important.

Conclusion: Usual clinical visits occurring quarterly offer a good estimation of disease activity over a one year period and are preferred over semi-annual and annual visits.

Disclosure: D. Ibañez: None; **D. D. Gladman:** None; **M. B. Urowitz:** None.

1869

Optimal Frequency of Visits To Capture Disease Activity over Time in SLE Patients with Varying Levels of Disease Activity. Dominique Ibanez[2], Murray B. Urowitz[3] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto Lupus Clinic, Toronto Western Hospital, [3]University of Toronto Lupus Clinic, Toronto Western Hospital, Toronto, ON, Canada

Objective: Disease activity in SLE patients, measured by SLEDAI-2K, is evaluated at each clinic visit. Adjusted Mean SLEDAI (AMS) calculates the area under the curve of SLEDAI-2K over time. A previous study in patients with mild disease activity showed that quarterly visits offer a good estimation of disease activity. The aim of this study was to extend the study by using patients with varying levels of disease activity and to compare the AMS obtained over a 3-year period in patients with regular quarterly visits to AMS obtained using semi-annual, annual visits or visits every 18 months.

Methods: Patients followed every 3 months over a 36 month period are included. AMS is evaluated using all of the visits (AMS_3), using only the semi-annual visits (AMS_6), the annual visits (AMS_{12}), and the visits 18 months apart (AMS_{18}). Based on AMS_3, patients' disease activity is classified as Minimal (AMS_3 <3), Mild (AMS_3 ≥3 and <7) or Moderate (AMS_3 ≥7). Comparisons between AMS_6, AMS_{12} and AMS_{18} with AMS_3 are made using descriptive statistics. An important error is measured as the increase in AMS_3 associated with each additional flare.

Results: 202 patients were seen quarterly for a 3-years period. 178 (88%) were women with mean (std) age at SLE diagnosis of 30.1 (12.8) years and disease duration at study start of 9.7 (8.1) years. 82 patients are Minimal, 80 are Mild and 40 are Moderate. The mean (std) AMS_3 for the entire period is 5.0 (3.0), for AMS_6 = 5.1 (3.0), for AMS_{12} = 5.0 (3.1) and for AMS_{18} = 5.2 (3.4). In the 3 years interval, 179 (89%) of the patients experienced at least 1 flare. The presence of each flare is associated with an increase in AMS_3 of magnitude 1.0. Therefore, absolute differences which were < 0.5 were considered minor, those between 0.5 and 1 acceptable, those ≥1 were deemed important and those ≥3 were considered serious.

Percent of Errors Based on Visit Frequency and Level of Disease Activity

	Level of Disease Activity			
	Minimal (n=82)	Mild (n=80)	Moderate (n=40)	All Patients (n=202)
Using Semi-annual Visits				
Minor	56%	51%	45%	52%
Acceptable	35%	31%	17%	30%
Important	9%	18%	38%	18%
Serious	0%	1%	3%	1%
Using Annual visits				
Minor	45%	34%	30%	37%
Acceptable	23%	16%	7%	18%
Important	32%	50%	63%	45%
Serious	2%	7.5%	18%	7.5%
Using Visits 18 months apart				
Minor	35%	26%	15%	28%
Acceptable	26%	16%	5%	17%
Important	39%	58%	80%	55%
Serious	6%	15%	28%	14%

Conclusion: Quarterly visits are preferred over visits further apart. In patients with lower disease activity, semi-annual visits are a good estimation of disease activity over time while in patients with more active disease, shorter times between visits are necessary.

Performance of Anti-Nucleosome, Anti-C1q and Anti-dsDNA Antibodies for the Diagnosis of Concurrent Disease Activity of Systemic Lupus Erythematosus. Chi Chiu Mok, Ling Yin Ho, Hoi Wah Leung and Lap Gate Wong. Tuen Mun Hospital

Objectives: To evaluate the specificity and sensitivity of anti-nucleosome, anti-C1q and anti-dsDNA antibodies in the diagnosis of disease activity in systemic lupus erythematosus (SLE)

Methods: Consecutive patients with SLE were recruited for serological testing of anti-dsDNA (Euro-diagnostica, Arnhem, Netherlands), IgG-anti-nucleosome and IgG-anti-C1q (Euroimmun, Lubeck, Germany) antibodies by ELISA and complement levels by immunonephelometry (Siemens, Germany). Concurrent renal and extra-renal disease activity was assessed by SLEDAI-2K and physician global assessment (PGA). Correlation among levels of these antibodies, complements and disease activity scores was made by spearman's rank correlation test. The specificity and sensitivity of these antibodies in diagnosing concurrent renal and extra-renal activity was calculated.

Results: 245 SLE patients were studied (95% women). The mean age was 40.6±12.2 years at the time of blood tests; and the duration of SLE was 8.7±7.1 years. The prevalence of positive anti-dsDNA (≥50IU/ml), anti-nucleosome (≥20RU/ml) and anti-C1q antibodies (≥20RU/ml) was 55%, 44% and 21%, respectively. All the 3 antibodies correlated significantly with complement levels (C3 and C4), SLEDAI (with deduction of scores due to elevation of anti-dsDNA and depression of complements) and PGA scores ($P<0.001$ in all). Positive anti-dsDNA and anti-C1q, but not anti-nucleosome antibodies correlated significantly with the presence of active renal disease as scored by the SLEDAI. The sensitivity of anti-dsDNA, anti-nucleosome and anti-C1q antibodies for the presence of active renal disease was 75%, 47% and 53%, respectively. The specificity was highest for anti-C1q for active lupus renal disease (84%), followed by anti-nucleosome (57%) and anti-dsDNA antibodies (49%). The specificity of combined anti-dsDNA and anti-C1q for active renal disease was 88%. The negative predictive value of a negative anti-dsDNA and anti-C1q for active renal disease was 91%. For the prediction of concurrent extra-renal SLE activity, the specificity was also highest with anti-C1q (83%), followed by anti-nucleosome (60%) and anti-dsDNA (48%) antibodies.

Conclusions: Anti-nucleosome does not perform better than anti-dsDNA for the presence of concurrent SLE activity. Anti-C1q antibodies, however, is more specific than anti-dsDNA for both renal and extra-renal lupus activity. The absence of both anti-dsDNA and anti-C1q has a high negative predictive value for concurrent active renal disease.

Predictive Value of High Levels of Antinuclear Antibodies in People without Other Feature of Autoinmunity. A Prospective Study. Ignacio Villa-Blanco[4], Marcos Lopez-Hoyos[1], Ana Ruibal[2] and Jaime Calvo-Alen[3]. [1]Hospital "Marques de Valdecilla", [2]Hospital "Txagorritxu", [3]Hospital Sierrallana, Torrelavega, Spain, [4]Hospital Sierrallana, Spain

Background: Low levels of antinuclear antibodies (ANA) are not an uncommon finding in otherwise healthy people but the presence of high levels of ANA is a far less common situation. On the other hand, different studies have shown that diseases as systemic lupus erythematosus (LES) may be heralded by the presence of these autoantibodies several years before. Therefore, it is possible to hypothesize that people with high ANA titers may portend and special risk for the development of autoimmune diseases but prospective data to this regard are lacking.

Objective: To analyze the outcome of healthy people with high levels of ANA.

Methods: All patient of our centre with a positive ANA test with a titter ≥1/1280 obtained between January of 1996 and December of 2006 were identify regardless the reason to order such test. A medical record review was performed in all cases and only those cases where any type of inflammatory or autoimmune disease had been excluded at the moment when the ANA test was performed and with a minimum time of follow up (from the date when the positive ANA test was obtained up the time of study onset) of 36 months were selected. In all cases, the development of any autoimmune disease during the follow up was established by chart review and then the rest of patient were contacted for further clinical and laboratory evaluation at he outpatient clinic.

Results: Overall, 133 patient were identified with a positive ANA test with a titter ≥1/1280. Out of them, 68 had been diagnosed of having different types of inflammatory or autoimmune disease (11 Rheumatoid arthritis, 11 Sjögren syndrome (SS), 8 autoimmune hepatitis, 5 LES, 4 undifferentiated connective tissue disease, 4 CREST syndrome, 3 primary biliary cirrhosis (PBC), 3 Dermatomyositis, 3 Inflammatory Bowel disease, 2 Morfea, 2 pernicious anaemia, 1 polymyalgia rheumatica, 1 Sweet, 1 antiphospholipid syndrome, 1 VIH, 1 VHC, 2 Hashimoto thyroiditis, 1 myelodisplastic syndrome, 1 mixed connective tissue disease, 1 sarcoidosis, 1 BONO, 1 ankylosing spondylitis. In 65 patients [78% women; mean age (range) 60.7 years (20–92)] this type of diseases were excluded. During the follow up [mean time (range) 86 months (36–120)], 8 patients (12%) developed systemic diseases: 2 LES with renal involvement after 96 and 48 months from the initial ANA test, 2 SS (45 and 59 months after the initial ANA test), 2 PBC (36 and 38 months after the initial ANA test), 1 autoimmune hepatitis (95 months after the initial ANA test) and 1 incomplete CREST syndrome (46 months after the initial ANA test). No other findings suggestive of autoimmune diseases were identify in the rest of 57 patients but in 39 % of them, ANA titters remained high (≥1/1280).

Conclusions: According to our data, during the follow up, a significant percentage (12%) of asymptomatic patients with high titters of ANA develop an autoimmune disease. Patients with persistent positive ANA test have a special risk for the development of autoimmune disease and may need longer periods of follow up.

Hilário[10], Flavio Sztajnbok[9], Rozana Gasparello de Almeida[9], Feng Qi Wu[2], Xiaolan L. Huang[2], Fernanda Falcini[13], Donato Rigante[11], Rolando Cimaz[12], Jordi Antón Lopez[8], Consuelo Modesto[7], Rubén J. Cuttica[5], Lisette W. A. van Suijlekom-Smit[3], Marieke H. Otten[3], Maria J. Baratelli[14], Margaret G. E. Peterson[6], Afton L. Hassett[15] and Thomas J. A. Lehman[4]. [1]Botucatu Medical School-São Paulo State University, Brazil, [2]Capital Institute of Pediatrics, China, [3]Erasmus MC, Sophia Childrens Hospital, The Netherlands, [4]Hosp for Special Surgery, New York, NY, [5]Hospital de Pediatría Pedro de Elizalde, Argentina, [6]Hospital for Special Surgery, [7]Hospital Infantil Valle de Hebron, Spain, [8]Hospital Sant Joan de Déu, Spain, [9]Universidade do Estado do Rio de Janeiro, Brazil, [10]Universidade Federal de São Paulo, Brazil, [11]Università Cattolica Sacro Cuore, Italy, [12]University of Firenze, Firenze, Italy, [13]University of Florence, Florence, Italy, [14]University of Medicine and Dentistry of NJ-Robert Wood Johnson Medical School, New Brunswick, NJ, [15]University of Michigan Medical School, Ann Arbor, MI

Background: Simple Measure of Impact of Lupus Erythematosus in Youngsters© (SMILEY©) is a brief 24-item health-related quality of life (HRQOL) assessment tool for pediatric systemic lupus erythematosus (SLE). Responses are in the form of a 5-faces scale for easy comprehension. Higher percentage scores indicate better HRQOL. SMILEY is valid in US-English and has been translated and adapted to 21 languages. Currently, we are conducting cross-cultural validation of SMILEY. We are also preliminarily exploring differences in HRQOL using SMILEY across different countries and examining factors influencing these differences.

Objective: We conducted preliminary analysis of SMILEY scores from various countries in South America, Europe and Asia.

Methods: Children ≤18 years with SLE and parents completed the appropriate SMILEY translation, and gold standard quality of life and physical function scales. Physicians completed the Systemic Lupus International Collaborating Clinics/ACR Damage Index (SDI). Across the countries, we compared age, SMILEY and PedsQL generic total scores, Child Health Assessment Questionnaire (CHAQ) disability index, and SDI. Contingent upon the data distribution of the above variables, we used one-way ANOVA or the Kruskal-Wallis (KW) test. Because of the limited sample size for each country, we have combined data by similar geographic regions (continents).

Results: 125 children (106 girls) and parents participated from South America (Brazil= 45, Argentina=11), Europe (Italy=16, Spain=15, Netherlands=10), and Asia (China=28). Table 1 shows the means/medians of child and parent reports of SMILEY and PedsQL generic total scores; parent CHAQ disability index; age; and SDI. Children from Asia had the highest SMILEY and PedsQL scores (indicating higher HRQOL), and lowest age. Significant differences between continents were found for age, parent PedsQL and child SMILEY scores. Parents' PedsQL and SMILEY scores were lower compared to child scores and this difference was most pronounced for children from South America.

Table 1. HRQOL, SDI, SLE-duration and age across the continents

	South America	Europe	Asia	p value
SMILEY total*				
Mean ± SD (range, n)				
Child	68 ± 15 (33–97, 52)	70 ± 16 (26–93, 41)	77 ± 13 (58–96, 28)	0.03 (ANOVA)
Parent	64 ± 16 (36–100, 54)	69 ± 16 (35–94, 38)	72 ± 16 (39–100, 28)	0.1 (ANOVA)
PedsQL total*				
Mean ± SD (range, n)				
Child	74 ± 15 (38–98, 42)	74 ± 21 (24–100, 30)	81 ± 11 (57–99, 27)	0.14 (ANOVA)
Parent	66 ± 22 (15–100, 40)	73 ± 19 (32–96, 28)	79 ± 19 (35–100, 28)	0.03 (ANOVA)
CHAQ score				
Median (range, n)				
Parent	0 (0–2.375, 42)	0 (0–1.25, 25)	Not completed	0.3 (KW)
SDI				
Median (range, n)	0 (0–4, 45)	0 (0–4, 40)	0 (0–3, 11)	0.7 (KW)
Duration (months)				
Median (range, n)	27 (1–116, 54)	31 (1–150, 40)	23 (1–188, 25)	0.2 (ANOVA)
Age (years)				
Mean ± SD (range, n)	14 ± 3 (6–18, 52)	15 ± 2 (7–18, 40)	12 ± 3 (5–16, 27)	0.005 (ANOVA)

*Higher percentage scores indicate better HRQOL

Conclusion: On preliminary analysis, differences in HRQOL and age were found across continents. Children from Asia (China) were the youngest and had the highest HRQOL. Age and cultural differences can influence HRQOL. Parents seemed to perceive a lower HRQOL for children with SLE; either reflecting a greater perception of their child's vulnerability, their own anxiety, or HRQOL. We are expanding our sample and exploring these differences further.

1873

Prevalence and Risk Factors of Glucocorticoid-Induced Diabetes Mellitus in Patients with Systemic Lupus Erythematosus. You Jung Ha[1], Kwang-Hoon Lee[2], Se-jin Jung[1], Yoon Kang[1], Min-Chan Park[3], Sang-Won Lee[1], Soo Kon Lee[1] and Yong-Beom Park[1]. [1]Division of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Division of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of, [3]Gangnam Severance Hospital, Seoul, Korea, Republic of

Background and Purpose: Glucocorticoid is a main strategy for the treatment of systemic lupus erythematosus (SLE). Although it is well known that glucocorticoid may cause diabetes mellitus (DM), there have been only few studies about glucocorticoid-induced DM in patients with SLE. This study was performed to investigate the prevalence and risk factors of glucocorticoid-induced DM in patients with SLE.

Methods: Patients with SLE who had received high-dose glucocorticoid therapy (prednisolone ≥1mg/kg/day) were recruited in Yonsei University Medical Center, Seoul, Korea from January 1999 through June 2009. Patients diagnosed with DM before glucocorticoid therapy were excluded. Risk factors for the development of glucocorticoid-induced DM were identified by univariate and multivariate analysis.

Results: A total of 127 patients with SLE were studied (9 males and 118 females). The mean age of the patients was 34.9 ± 12.7 years. Sixteen (12.6%) of the 127 patients developed glucocorticoid-induced DM after high-dose glucocorticoid therapy. Median duration from high-dose glucocorticoid treatment to the development of DM was 34 days. Univariate analysis showed that old age, family history of DM, hypertension, higher body mass index, and concurrent use of mycophenolate mofetil would increase the risk for glucocorticoid-induced DM. In multivariate analysis, age (OR 1.08, 95% CI 1.03–1.14), family history of DM (OR 9.60, 95% CI 2.22–41.47) and concurrent use of mycophenolate mofetil (OR 4.50, 95% CI 1.29–15.68) were determined as independent risk factors for glucocorticoid-induced DM.

Conclusion: DM was developed among 12.6% of patients with SLE after high-dose glucocorticoid treatment. Old age, family history of DM, and concurrent use of mycophenolate mofetil were the factors responsible for increased risk of developing glucocorticoid-induced DM.

1874

Prolonged Serologically Active Clinically Quiescent (SACQ) Systemic Lupus Erythematosus (SLE): Novel Predictors of Flare? Amanda Steiman[1], Murray B. Urowitz[2], Joan E. Wither[4], Dominique Ibañez[1], Timothy Li[3] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, Toronto, ON, Canada, [2]Toronto Western Hospital, Toronto, ON, Canada, [3]Toronto Western Hospital, [4]University Health Network, Toronto, ON, Canada

Purpose: Anti-double stranded DNA antibodies (anti-dsDNA) and complement levels are routinely used to predict flare in SLE patients. Some SLE patients, however, are clinically quiescent despite persistent serologic activity, as evidenced by elevated anti-dsDNA and/or hypocomplementemia. Past studies reveal that nearly 60% of such SACQ patients flare, but do so only after average 182 weeks. In these patients changes in total serum anti-dsDNA and/or C3/C4 levels measured at routine clinic visits were not predictive of flare. Some studies suggest that anti-chromatin (-nucleosome) antibodies are more sensitive than anti-dsDNA to detect active SLE, and that the time to first flare after a SACQ period was significantly correlated with their presence. This study investigates whether levels of anti-dsDNA and anti-chromatin isotypes, measured during a prolonged SACQ period, differed in SACQ patients who remained SACQ versus those who flared.

Methods: Archived serum samples of patients with a prolonged SACQ period, stored at −80 °C, were retrieved and divided by disease activity (during a SACQ period vs during flare). Serum levels of IgM, IgA, IgG, IgG1, IgG2, IgG3, and IgG4 anti-dsDNA and anti-chromatin antibodies were measured by ELISA. H1-stripped chromatin was prepared from the human cell line, MOLT4. ELISA plates were coated overnight with dsDNA (40 ug/ml) and chromatin (8 ug/ml) diluted in PBS at 4°C. Serum was diluted 1/100 for measurement of IgM, IgA, and IgG, or 1/50 for IgG1–4. SACQ was defined as at least a two year sustained period with SLEDAI of 2 or 4 from serologic activity only, during which patients could be taking antimalarials, but not steroids or immunosuppressives. Flare was defined as any increase in clinical disease activity. P-values were reported using Wilcoxon rank sum tests.

Results: Thirty-eight serum samples which corresponded to a prolonged SACQ period (from 23 patients) were analyzed. Fifteen of the 38 (39%) samples corresponded to patients whose SACQ period ended in flare. Anti-chromatin total IgG levels were significantly lower in SACQ patients who flared than in those who remained SACQ (0.361 ± 0.277 vs 0.835 ± 0.700, p=0.007; normal < 0.147), however there was no significant difference between these groups when IgG was broken down by subtype. Anti-chromatin IgM and IgA values were comparable between groups. Anti-dsDNA IgA (but not IgM or IgG) was significantly lower in SACQ patients who flared compared to those who remained SACQ (0.028 ± 0.025 vs 0.081 ± 0.095, p=0.018). When only the most recent sample from each SACQ patient was analyzed (9/23 (39%) of whom flared), there was no difference between anti-chromatin or anti-dsDNA isotype levels between patients who flared and those who remained SACQ.

Conclusions: In this small pilot study neither anti-chromatin nor anti-dsDNA antibody levels were predictive of flare in SACQ patients. Alternate serum biomarkers must be sought.

Racial Disparities in Treatment Preferences among Lupus Patients. Ernest R. Vina, Christopher M. Masi, Stephanie L. Green and Tammy O. Utset. University of Chicago Medical Center, Chicago, IL

Background: Worse health outcomes among African-American compared to white SLE patients are well documented. While racial differences in patient treatment decisions have been identified in other diseases, this phenomenon has not been explored in SLE. The objectives of this study are: (1) to determine whether there are differences between African American and white SLE patients' willingness to a) receive an immunosuppressive medication (cyclophosphamide, CTX) when clinically indicated and b) participate in clinical trials involving novel, experimental medications; and (2) to determine whether demographic, psychosocial and clinical characteristics explain racial differences in either measure of medical management.

Methods: Data from 25 African-American and 25 white lupus patients were evaluated. Structured telephone interviews were conducted to determine treatment preferences, as well as characteristics and beliefs that may affect these preferences. Chart reviews were conducted to evaluate clinical characteristics (disease duration, SLEDAI, SLICC Damage Index, Charlson Comorbidity). Serial hierarchical multivariate logistic regression analyses using forward selection of variables with $p<0.20$ were conducted.

Results: Compared to white SLE patients, African American SLE patients were less willing to receive CTX (96% vs. 56%, $p=0.001$). They also had lower incomes ($p<0.005$), were less likely to have private insurance ($p=0.001$), and were more likely to believe that prayer can affect health outcomes ($p=0.016$). Lupus patients willing to receive CTX were more likely to be older ($p=0.027$), to have higher incomes ($p=0.004$), to have private insurance ($p=0.034$), to be more educated ($p=0.047$) and to perceive CTX to be effective ($p=0.001$). Multivariate logistic regression analysis showed that age (OR=1.13, $p=0.042$), educational level (OR=8.90, $p=0.025$) and perception of effectiveness of treatment (OR=1.67, $p=0.025$) were significant predictors of willingness to receive CTX. After adjustment for these variables, willingness to receive CTX was higher among whites compared to African Americans (OR=11.74) but this effect did not reach significance ($p=0.056$).

In contrast, no significant racial differences were observed in willingness to participate in a clinical trial (84% among whites vs. 68% among African-Americans, $p=0.185$). Willingness to participate in a clinical trial was positively associated with being married ($p=0.015$), having private insurance ($p=0.05$) and having a physician with a participatory decision-making (PDM) style ($p=0.001$). A logistic regression model showed that the CES-D score (OR=0.91, $p=.017$) and physician PDM style (OR=1.08, $p=0.003$) were significant predictors of willingness to participate in a clinical trial.

Conclusions: We found a trend toward decreased likelihood of accepting CTX among African American compared to white lupus patients after adjusting for multiple covariates. In contrast, African American and white SLE patients did not differ in willingness to participate in a clinical trial. We continue to collect data and will determine whether these results persist with larger cohorts of African-American and white SLE patients.

Risk Factors Associated with the Presence of Pneumonia in Patients with Lupus Erythematosus (SLE): A Nested Case-Control Study. Iñigo Rúa-Figueroa[1], Francisco J. Nóvoa[2], Celia Erausquin[2], Miguel Garcia-Bello[2], Felipe Rodríguez de Castro[2], Juan C. Quevedo[2], Isabel García-Laorden[2], Carlos Rodriguez-Gallego[2], Felix Francisco[2] and Carlos Rodriguez-Lozano[2]. [1]Hospital Dr Negrin, Las Palmas GC, Spain, [2]Hospital Dr Negrin

Purpose: To determine the incidence of pneumonia and the associated risks factors in a monocentric SLE cohort.

Methods: We included SLE patients (1997 criteria) with pneumonia and 196 age and sex-matched SLE controls. Clinical data, comorbidity and risk factors for pneumonia were retrospectively collected. Katz severity index (SI) and weighted SLICC/ACR damage index (wDI) were recorded. The standardized incidence ratio (SIR) of pneumonia was estimated. MBL, FCγR IIA, MASP-2, C2, IL6–174, SPD y SPA1 y 2 single nucleotide polymorphisms (SNP) were studied based on previous evidence of association with pulmonary infection. Differences were analysed using Pearson's χ^2 or Fisher's exact test as appropriate, and Student's t-test or Wilcoxon for qualitative variables.

Results: Mean age at diagnosis: 31 years (p25-p75: 24–40); mean disease duration: 12 years (6–18); 92% were women; mean follow up: 6.7 (2.2–11.5). Leukopenia 48%; SLE criteria: 6 (5–7); SI 3 (2–5); wDI: 2 (0–5); exitus 14 (6%). 36 patients presented one or more pneumonia (29 defined, 7 probable); 9 patients suffered from pneumonia before SLE onset. 58% had received steroids, 16% at high doses, and 44% immunosuppressors at any time. Only 13% of patients were taking immunosuppressors at the moment of pneumonia. The SIR for pneumonia was 7.2. Excluding pneumonia cases after SLE onset, we also found an increased ratio (1.3). An association with a SNP of SPA2 1A1/1A0 gene, a protein crucial in pulmonary innate immunity, was found but the significance disappeared after Bonferroni correction. Excluding patients with immunosuppressors at the time of pneumonia, associations were found with SI (OR 1.2; 95% CI 1–1.4; $p=0.016$), wDI: $p=0.044$, number of SLE criteria ($p=0.04$), number of hospital admissions: (OR 17; 95%CI 2.4–130; $p<0.01$), and a strong trend for exitus (OR 3.2; 95% IC: 9–11.1; $p=0.07$) in univariate analysis. We found also association with high doses steroids treatment any time (OR 2; 95% CI 0.9–4.6; $p= 0.087$), immunosuppressors (OR 2.2; 95% IC: 1–4.9; $p=0.049$), cutaneous ulcers (OR 6.7; 95% IC: 2.1–21; $p<0.01$) and vasculitis (OR 3; 95% IC: 1.3–7.2; $p =0.008$). Furthermore, a trend was found for other infections ($p=0.130$) and admissions for non-pulmonary infections ($p=0.087$). In the multivariate analysis, adjusting for immunosuppressor treatment, the single statistically significant risk factor was SI ($p=0.023$).

Conclusions: The incidence of pneumonia in patients with SLE is higher than in the general population and this probably also happens before the onset of SLE. Most patients were not receiving immunosupressive therapy at the moment of the pneumonia. Pneumonia is more frequent in severe SLE, independently of immunosupressive therapy.As suggested by current literature, infections - pneumonia in our study -, could be a severity marker in SLE.

A large multicentre multinational inception cohort was established to study risk factors for atherosclerosis (AS) in SLE. We have previously shown that a significant number of atherosclerotic disease risk factors are present within the first year of SLE. This study examines the presence of SLE and atherosclerotic risk factors at inception in a multicenter, international cohort of SLE patients according to ethnic groups and by geographic distribution.

Methods: 30 centres from 11 countries assembled an inception cohort of SLE patients according to a standardized protocol between 2000 and 2010 to study risk factors for atherosclerosis. Simple statistics are provided. Comparisons between ethnic groups and geographic distributions were made using chi square tests and analysis of variance.

Results: Of the inception cohort of 1593 SLE patients 89% were female and age at diagnosis was 35±13 yrs. Patient characteristics were as follows:

Table 1. Distribution by Geographical Area of Residence

	Asia	Canada	Europe	Mexico	USA	P value
N	168 (10.6)	352 (22.1)	425 (26.7)	202 (12.7)	446 (28.0)	
Sex F	89%	89%	91%	90%	88%	0.85
Age at diagnosis	29 ± 10	38 ± 15	37 ± 14	28 ± 9	36 ± 13	<0.0001

SDI	0.25 ± 0.70	0.31 ± 0.70	0.16 ± 0.59	0.25 ± 0.56	0.41 ± 0.86	0.009
SF36 PCS	43 ± 8	39 ± 11	39 ± 11	42 ± 10	39 ± 11	<0.0001
MCS	44 ± 11	45 ± 12	44 ± 12	45 ± 12	45 ± 12	0.93
Hypertensive	32%	33%	32%	41%	34%	0.20
Cholesterolemia	35%	41%	31%	36%	37%	0.09
Current Smoker	7%	18%	17%	9%	17%	0.0004
Metabolic Syndrome	8%	12%	11%	25%	15%	<0.0001
Family History of CAD	8%	27%	23%	15%	31%	0.03
Steroids	95%	60%	63%	93%	61%	<0.0001
Antimalarial	73%	73%	64%	48%	68%	<0.0001
Immunosuppressive	50%	35%	35%	65%	33%	<0.0001

Table 2. Distribution by Ethnic Group

	Asian	Black	Caucasian	Hispanic	Other	P value
N	257 (16.2)	247 (15.2)	772 (48.5)	250 (15.7)	65 (4.1)	
Sex F	90%	90%	88%	90%	95%	0.27
Age at diagnosis	30 ± 11	34 ± 11	38 ± 15	29 ± 10	35 ± 14	<0.0001
SLEDAI-2K	7.1 ± 6.1	4.7 ± 5.0	4.5 ± 5.0	6.8 ± 5.9	5.7 ± 4.8	<0.0001
SDI	0.28 ± 0.73	0.37 ± 0.88	0.23 ± 0.60	0.29 ± 0.70	0.26 ± 0.81	0.44
SF36 PCS	42 ± 9	37 ± 11	38 ± 11	40 ± 10	37 ± 11	<0.0001
MCS	45 ± 11	45 ± 12	45 ± 12	44 ± 12	44 ± 11	0.97
Hypertensive	31%	48%	30%	38%	25%	<0.0001
Cholesterolemia	37%	43%	33%	34%	41%	0.06
Current Smoker	7%	13%	20%	9%	27%	<0.0001
Metabolic Syndrome	7%	14%	13%	22%	15%	0.0001
Family History of CAD	18%	32%	24%	23%	46%	0.07
Steroids	89%	79%	53%	88%	67%	<0.0001
Antimalarial	71%	61%	70%	52%	61%	<0.0001
Immunosuppressive	47%	43%	30%	60%	42%	<0.0001

SLEDAI-2K was higher in Asians and Hispanics and also in the geographical areas in which they are a majority. SDI on the other hand is not associated with ethnicity but is higher in the United States. Metabolic syndrome is higher in Mexicans and in Hispanics in general. Hypertension does not show a geographic distribution but is associated with Black ethnicity.

Conclusion: There are differences in the features of SLE and atherosclerotic risk factors at inception when studied by geographic and ethnicity origins. Whether there will be differences in the development of CAD events among these ethnic groups remains to be elucidated.

Systemic Lupus Erythematosus Disease Activity Index (SLEDAI-2K) Responder Index (SRI)-50: A Valid Index for Measuring Improvement in Disease Activity. Zahi Touma[2], Dafna D. Gladman[1], Dominique Ibañez[2] and Murray B. Urowitz[2]. [1]Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto Lupus Clinic, Toronto Western Hospital, Toronto, ON, Canada

Background: We have previously described the development of SRI-50, an index that can describe partial improvement in disease activity between visits in lupus patients.

Objective: To determine whether SRI-50 would capture patients who have improved by ≥50% as determined by physician global assessment (PGA), construct validity of SRI-50 for assessing improvement in disease activity in SLE.

Methods: All patients attending the Lupus Clinic from September 2009 to December 2009 were enrolled in a prospective longitudinal study. Of the 298 patients enrolled 141 had a follow-up visit and were studied further. SLEDAI-2K and SRI-50 scores were determined initially and on a follow-up visit at 1–3 months. During the first visit a PGA was determined on a visual analog scale (VAS) line of 100 mm, with anchors of 0 "no disease activity" and 10 for very active disease". During the follow-up visit a PGA was determined on a 7-point Likert VAS; 7 much, 6 moderately, and 5 slightly improved, 4 unchanged, 3 slightly, 2 moderately, and 1 much worse. We defined a 50% improvement as PGA≥6. An external clinician evaluated patients' records and grouped them on follow-up visit into: improved, same and worse using standardized predefined definitions. The external construct was the Likert VAS. We hypothesized that patients who had ≥50% improvement (PGA≥6) would be captured by SRI-50 and the change in their SRI-50 scores would meet the definition of improvement by SLEDAI (decrease ≥4).

Results: The Characteristic of 141 patients are represented in table 1.

Sex (F/M)		89.4%/10.6%
Race	Caucasian	57.4%
	Black	16.3%
	Asian	9.9%
	Other	16.3%
Age at diagnosis		29.1 ± 11.4 years
Age at 1st visit in study		29.1 ± 11.4 years
Disease duration at 1st visit in study		15.3 ± 11.2 years
Time between baseline and follow-up visits		3.2 ± 1.4 months
SLEDAI-2K at 1st visit in study		4.79 ± 4.67

Patients were assessed as: worse 14, same 65 and improved 62. SRI-50 scores did not decrease below their presenting SLEDAI-2K score in patients who remained stable or worsened. In patients who improved, the SRI-50 score decreased by a mean of −2.40±3.11 while SLEDAI scores did not decrease (Table 2).

Table 2. Statistical results in patients who changed their disease activity

	Worse (n=14)	Same (n=65)	Improved (n=62)
SLEDAI 0	4.43 ± 3.32	3.15 ± 4.16	6.58 ± 4.84
SLEDAI 1	7.29 ± 4.55	2.97 ± 4.03	4.94 ± 4.47
SRI-50	7.21 ± 4.61	2.76 ± 3.86	4.18 ± 4.06
Δ SLEDAI	2.86 ± 3.76	−0.18 ± 2.64	1.65 ± 2.91
Δ SRI-50	2.79 ± 3.79	−0.39 ± 2.74	−2.40 ± 3.11

Δ SLEDAI=SLEDAI 0 - SLEDAI 1
Δ SRI-50=SLEDAI 0 - SRI-50

SRI-50 scores decreased more in patients with PGA≥6 compared to PGA 4–5 with a decrease of ≥4 (r=0.52; p=0.0001). The decrease in SRI-50 scores compared to the decrease in SLEDAI scores were statistically and clinically more significant in patients with PGA≥6 (p <0.0001) compared to those with PGA 4–5 (p=0.003) (Table 3).

Table 3. Change in SLEDAI and SRI-50 scores in patients who improved in association with the external construct

	Δ SLEDAI	Δ SRI-50
PGA 4 (n=15)	−0.33 ± 1.99	−0.47 ± 2.07
PGA 5 (n=20)	−0.95 ± 2.68	−1.50 ± 2.72
PGA 6 (n=20)	−2.40 ± 2.60	−3.80 ± 2.95
PGA 7 (n=7)	−4.29 ± 4.07	−5.14 ± 3.18
r	0.42	0.52
p	0.0009	0.0001
	Improvement (n=62)	
PGA 4–5	−0.69 ± 2.40	−1.06 ± 2.48
PGA ≥ 6	−2.89 ± 3.09	−4.15 ± 3.01
t-test	0.003	<0.0001

Conclusions: These results show that the SRI-50 has construct validity. SRI-50 is able to demonstrate incomplete improvement which would not have been discerned using SLEDAI-2K.

1879

The Relative Importance of Current Versus Past Use of Medication in Excess Rates of Adverse Cardiovascular Events among Patients with SLE. Michelle A. Petri[1] and Laurence S. Magder[2]. [1]Timonium, MD, [2]Department of Epidemiology and Preventive Medicine, University of Maryland School of Medicine, Baltimore, MD

Background: Previous studies have suggested that some of the excess risk of adverse cardiovascular events (CVE) in patients with SLE may be due to treatments such as prednisone. Other studies have suggested that treatment with hydroxychloroquine results in reduced risk. In this study, we investigated whether past or current drug exposures have greater association with CVE.

Methods: We examined CVE rates in a large clinical cohort, in subgroups defined by medication history. CVE was defined as myocardial infarction (MI), stroke, coronary procedure, incident angina, or claudication. The analysis was based a data set which had one record per patient-month of participation in the cohort. Each record contained data regarding the clinical history up until that time, the most recently measured levels of disease activity, medications taken at that time, and whether a CVE occurred during that month. This file was analyzed using pooled logistic regression.

Results: 134 CVE events were observed from among 1874 patients who were followed for 9485 person-years during periods between 1987 to 2010. Events included 65 strokes, 27 MI, 29 cases of angina or coronary procedures, and 13 cases of claudication. The table shows rates of CVE in subgroups defined by current and past medication use.

Table. Rates of CVE in Subgroups defined by Current and Past Medication Use

Subgroup	Number of CVE	Rate of CVE per 1000 person-years	Rate Ratios based on a model that adjusts for age (95% CI)	P-value
Prednisone exposure				
None	22	13.3	1.0 (Ref. Group)	
Past (not current)	23	7.9	0.6 (0.4, 1.2)	.14
Currently taking (any dose)	88	18.2	1.6 (1.0, 2.5)	.057
Currently taking >=20 mg/day	25	35.4	4.0 (2.2, 7.1)	<.0001
Plaquenil Use				
None	46	17.9	1.0 (Ref. Group)	
Past (not current)	20	20.3	1.1 (0.7, 1.9)	.65
Currently used but for <6 consec. mo.	14	16.9	1.0 (0.6, 1.9)	.95
Current use, >6 consec. mo	54	10.6	0.5 (0.4, 0.8)	.0019
NSAID Use				
None	51	12.6	1.0 (Ref. Group)	
Past (not current)	42	15.0	1.0 (0.7, 1.6)	.86
Current	41	15.6	1.1 (0.7, 1.6)	.78
Immunosuppresant Use				
None	56	12.1	1.0 (Ref. Group)	
Past (not current)	3	10.1	0.8 (0.2, 2.5)	.67
Current	75	16.5	1.5 (1.0, 2.5)	.31

In multivariable models, cumulative (past) corticosteroid exposure was not associated with CVE after controlling for current use. Similarly, cumulative exposure to hydroxychloroquine was not protective after controlling for current use. Also, in multivariable models, the association between current corticosteroid use and CVE persisted after controlling for the most recent measure of disease activity.

Conclusion: Current (but not past) use of high-dose corticosteroids was associated with high rates of CVE. Current (but not past) use of hydroxychloroquine for 6 or more months was associated with lower rates of CVE. This study strongly supports long-term use of hydroxychloroquine in SLE.

1880

Validation of CLASI Scale with Lupus Disease Activity, Damage, Body Image and Quality of Life. Meenakshi Jolly[1], Rachel A. Mikolaitis[3], Thomas F. Cash[2] and Joel A. Block[2]. [1]Rush University Medical Center, Chicago, IL, [2]Rush University Medical Center, Chicago, IL, [3]Rush University Medical Center

Purpose: Cutaneous Lupus Erythematosus Disease Area &Severity Index (CLASI) has been developed to assess cutaneous activity & damage in Systemic Lupus Erythematosus (SLE). Its validation against SLE disease activity & damage is not known. Also, its association with body image (BI) and quality of Life (QOL) is not known. Herein, we present the results of correlation between CLASI items, CLASI total activity &CLASI total damage with (a) Physician global assessment (PGA), total SLE disease activity & itemized disease activity, (b) Total SLE disease damage (SDI), itemized SLE damage, (c) BI, and (d) QOL.

Methods: CLASI, BILS (body Image in Lupus Screen), BIQLI (body Image Quality of Life Index) and LupusPRO were administered to 14 consenting SLE patients. SLE disease activity & damage were evaluated using SELENA-SLEDAI and SLICC-SDI. Descriptive statistics & correlation analysis were obtained. A p value of ≤ 0.05 on two tailed test was considered significant.

Results: Mean $\pm$ SD age was 45.1 $\pm$ 12.7 yrs. Ninety three percent of participants were women; 71.4% African American, 14.3% Caucasian and 14.3% Hispanic. Mean $\pm$ SD (Median) PGA & SLEDAI score were 1.1 $\pm$0.7 (1.0) &3.7$\pm$4.6 (2). Mean $\pm$ SD (Median) SDI was 1.8$\pm$1.5 (2). Mean $\pm$ SD (Median) CLASI activity and damage scores were 8.3$\pm$4.2 (7) & 8.6$\pm$5.8 (8.5).

Total CLASI activity score correlated with PGA (r 0.62, p=0.03), SLEDAI- proteinuria (r 0.59, p=0.03). CLASI activity item "Ear Scale" correlated with total SLEDAI (r 0.62, p=0.02). CLASI activity items correlated with SLEDAI "rash" included "chest erythema" (r 0.63, p=0.02), & "arms erythema" (r 0.56, p=0.04). Mucous membrane lesions on CLASI correlated with SLEDAI-mucous membrane lesions (r 0.53, p=0.05). Recent hair loss on CLASI correlated with SLEDAI recent hair loss (r 0.60, p=0.02).

Total CLASI damage score correlated with SDI-extensive skin scarring/panniculum (r 0.60, p=0.05). CLASI "nose dys-pigmentation" correlated with SDI "skin ulceration" (p 0.77,p=0.01). "Arms dys-pigmentation" (r 0.61, p =0.05), "arms scarring" (r 0.63, p=0.04), "hands dys-pigmentation" (r 0.69,p=0.02), "hands scarring" (r 0.73, p=0.01) & 'feet dys-pigmentation" (r 0.62, p=0.04) were associated with SDI "skin extensive scarring/panniculum". CLASI 'scalp scarring" correlated with SDI skin scarring/alopecia (r 0.99, p=0.001).

CLASI "face scale" (r −0.56, p=0.04) and "hand scale" (r −0.46, p =0.09) were associated with BILS. CLASI "nose scale" (r −0.56, p=0.04) & "V area neck erythema" (r −0.52, p=0.06) correlated with BIQLI. Overall QOL was inversely associated with "ear Scale" (r −0.50, p=0.07) & "chest erythema" (r −0.51, p=0.06). Poor coping was associated with "nose scale" (r −0.60, p=0.02), "V area of neck erythema" (r −0.58, p=0.03), "posterior neck-shoulders erythema" (r −0.52, p=0.06). Satisfaction with treatment &"Hands scale" (r −0.59, p=0.03) were related.

Conclusions: This is the first study on performance of CLASI against SLE disease activity & damage. CLASI activity and damage scores do correlate with muco-cutaneous manifestations of SLE activity & damage. Data suggest poor QOL (coping and body image) among SLE Patients with cutaneous manifestations of the disease.

Validity of the ACR Criteria and SLICC Proposed Criteria for the Diagnosis and Classification of Systemic Lupus Erythematosus. Felipe Rodriguez-García[2], Karina Santana- de Anda[2], Ali Duarte-García[1], Virginia Pascual-Ramos[2], Gabriela Hernández-Medina[2], Tatiana Rodríguez-Reyna[2] and Jorge Sanchez-Guerrero[3]. [1]Instituto Nacional ce Ciencias Medicas y Nutricion Salvador Zubiran, [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, [3]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico

Objective: To validate the 2007 ACR and the SLICC proposed criteria for the diagnosis and classification of SLE.

Methods: We included 55 patients (Group A) who were hospitalized in our Institute for the diagnosis of systemic manifestations of recent-onset

(<6months). All the patients were evaluated by 2 physicians with specialty in Internal Medicine and who are in-training in Rheumatology. A complete physical examination was done, and pertinent studies were requested according to the medical condition. In all of them, all the tests necessary to evaluate the ACR and SLICC SLE criteria were done. The final diagnosis was established according to the treating physicians after 6 months of the clinical evaluation in order to have the final reports of all studies performed (laboratories, X-ray, pathology, etc) and looking after the stability of the diagnosis. We also included 51 consecutive patients (Group B), participating in a cohort of patients with SLE of recent-onset (<12 months) according to the 1982/2007ACR criteria. In this group we looked for the fulfillment of the proposed SLICC criteria within 6 months of enrollment into the cohort. Finally, 33 patients participating in cohorts of early inflammatory arthritis and Sjögren's syndrome (Group C) were also included.

The validity of the ACR and SLICC criteria for SLE diagnosis was evaluated among the patients in Group A. and the validity for classification among all the patients in the 3 groups.

Results: Patients in group A had a mean (SD) age of 37.3 (17.7) years, and 40 (73%) were females. The main reasons for hospitalization were: chronic fever 16, nephritic/nephrotic syndrome 9, severe weight loss 8, polyarthritis 4, cytopenias 3, lymphadenopathy 2, others 13. Patients in group B had a mean age of 29.9 (8.8) years, and 43 (84%) were females. Patients in group C had a mean age of 40.4 (14.6) years, and 30 (86%) were females.

In group A, 21 (38%) patients were newly diagnosed as SLE, and the observed agreement between both sets of criteria was 87.3, kappa 74.5. Also, among all the patients in the three groups, the observed agreement for SLE classification was 92.2, kappa 84.3.

No significant differences were observed between both sets of criteria in terms of sensitivity (SN), specificity (SP), positive (PPV) and negative predictive value (NPV) for the diagnosis and the classification of SLE (table). Overall, the efficacy of both sets of criteria was inferior for diagnosis than classification.

	SN (95% C.I.)	SP (95% C.I.)	PPV (95% C.I.)	PPV (95% C.I.)
SLE diagnosis				
Group A (n=55)				
ACR Criteria	85.7 (76–95)	82.4 (72–92)	74.5 (63–86)	90.6 (83–98)
SLICC Criteria	90.5 (82.7–98.3)	76.5 (70.8–82.2)	70.0 (58.0–82.0)	93.0 (88.0–99.7)
SLE classification				
Groups A, B, C (n=141)				
ACR Criteria	94.4 (89.2–99.7)	88.4 (80.9–96.0)	89.5 (82.6–96.3)	93.9 (88.0–99.7)
SLICC Criteria	95.8 (91.2–100)	85.5 (77.2–93.8)	87.3 (80.0–94.7)	95.2 (89.8–100)

Conclusion: The efficacy of the current ACR and the proposed SLICC criteria for the diagnosis and classification of SLE patients is similar; however, their utility for diagnosis is inferior to classification.

1882

Work Disability, Lost Productivity and Associated Risk Factors in Patients Diagnosed with Systemic Lupus Erythematosus (SLE). Tammy O. Utset[5], Barbara M. Segal[6], Laura Trupin[4], Sarika Ogale[1], Ellen Herberich[2] and Kenneth C. Kalunian[3]. [1]Genentech, [2]Harris Interactive, [3]UCSD School of Medicine, La Jolla, CA, [4]University of California, San Francisco, [5]University of Chicago, Chicago, IL, [6]University of Minnesota, Minneapolis, MN

Purpose: To compare self-reported workplace and household productivity, physical function, and symptoms in SLE patients and healthy controls.

Methods: US-based adult ambulatory SLE patients without co-morbid rheumatoid arthritis (RA) completed a questionnaire. Patients gave a similar survey to two age and gender matched friends. Patient and control surveys included The Health and Work Performance Questionnaire (HPQ), Short Form 12 (SF-12), FACIT-Fatigue, Thinking Scale and the Center for Epidemiologic Studies (CESD) Depression Scale. Rheumatologists completed a survey which included the Mexican SLEDAI and a global rating of disease severity over the previous 12 months. Logistic regression was used to study the association between these measures and being unemployed due to health among SLE patients.

Results: 200 patients, and 221 controls have submitted surveys to date. In SLE patients, disease activity as measured by the Mex-SLEDAI had a mean score of 3.5 (median 1.0). Approximately 40% of lupus patients had no activity by the Mex-SLEDAI.

Mean scores for controls were close to the US population on all SF-12 domains (50 points) and on the FACIT-Fatigue (40 points), indicating that the controls in our study had symptom levels representative of the US population.

Patients reported higher levels of pain, fatigue and depression, and lower levels of physical, cognitive and social function, compared with controls (See table).

	MEAN SCORES		
	Patients	Controls	*p*-value
SF-12 [Health Related Quality of Life] ***(Patient n=200; Control n=221)***			
(Range of expected scores 0–100; higher scores indicate better functioning)			
Physical Functioning	34.8	50.3	$p<.01$
Role Limitations - Physical	34.8	49.6	$p<.01$
Role Limitations - Emotional	36.5	47.7	$p<.01$
Vitality	39.0	52.4	$p<.01$
Mental Health	42.2	50.6	$p<.01$
Social Functioning	36.0	49.4	$p<.01$
Pain	35.7	50.9	$p<.01$
General Health	34.7	50.4	$p<.01$
FACIT-F [Fatigue] ***(Patient n=198; Control n=221)***	22.41	41.14	$p<.01$
(Range of expected scores 0–52, higher scores indicate lower fatigue)			
HPQ [Absenteeism & Presenteeism] (Patient n=68; Control n=138)			
Absolute Absenteeism	8.24 hours	−4.26 hours	$p=.14$
(Higher scores indicate a higher amount of absenteeism]			
Absolute Presenteeism	75.07%	85.70%	$p<.01$
(Higher scores indicate a lower amount of lost performance, 100% indicates ideal performance)			
CESD [Depression] ***(Patient n=199; Control n=220)***	13.70	5.87	$p<.01$
(A score of 10 or greater is considered depressed)			
THINK [Cognitive Functioning] ***(Patient n=200; Control n=220)***	39.72	16.34	$p<.01$
(Range of expected scores 0–100, higher scores indicate worse functioning)			
Pain ***(Patient n=198; Control n=212)***	5.2	2.1	$p<.01$
(Range of expected scores 0–10, higher scores indicate worse pain)			

SLE patients were more likely to not be employed nor looking for work, compared to controls (31% vs 4%) and/or on extended sick leave or disability (34% vs. 5%). Among those not employed, 86% of patients report that they were not employed at least in part due to health, in comparison to 16% of controls.

Average absenteeism (time missed from paid work), suggests that patients worked 8 hours less and controls worked 4 hours more than expected by their employer over a 7 day period. Presenteeism (the level of performance while at work), was 75% for SLE patients and 85% for controls, where 100% indicates ideal performance. On average, patients were unable to do housework for 8 days and controls 1.9 days of the last 28 days due to problems with physical or mental health.

In multivariate logistic regression, pain severity (OR= 1.21; $p=0.009$) and depression (OR=1.07; $p=0.024$) were significantly associated with the odds of being unemployed due to health among SLE patients, but fatigue, SLE duration, global severity score and MEX-SLEDAI were not associated with this outcome.

Conclusions: SLE patients report significantly higher burden from symptoms such as pain, fatigue and depression relative to healthy controls. Despite

low disease activity on the Mex-SLEDAI, work and household productivity is lower in SLE patients compared with healthy controls. Higher levels of pain severity and depression increase the likelihood of health-related unemployment in SLE patients.

1883

Activation of Innate Immunity and Sjögren's Syndrome Development. Seshagiri Rao Nandula[1], Yogesh M. Scindia[2], Harini Bagavant[1] and Umesh S. Deshmukh[2]. [1]University of Virginia, Charlottesville, VA, [2]University of Virginia

Objectives: Previously our laboratory has demonstrated that activation of innate immunity through toll-like receptor 3 (TLR3) agonist poly IC causes an acute loss of salivary gland function. This study was undertaken to investigate the effects of innate immunity activation through TLR dependent and TLR independent pathways on development of Sjögren's Syndrome (SS) in experimental mouse model systems.

Methods: To determine the role of TLR mediated innate immunity activation in SS, female NZB/W F1 mice were injected with TLR3 agonist, poly IC. To investigate TLR independent pathways, female NZM2758 mice were injected with alum, which activates innate immunity through the inflammasome pathway. Submandibular glands (SMG) were analyzed for sialadenitis and lymphocytic infiltrates were characterized by flow cytometry and immunohistochemistry. Gene expression levels of inflammatory cytokines and chemokines were determined by real time PCR. Mice were monitored for salivary gland hypofunction by checking pilocarpine induced saliva flow.

Results: Within 2 weeks of poly IC treatment, the SMG showed evidence for lymphocytic infiltration. The dominant cell types infiltrating the SMG at early stages were NK cells and dendritic cells, which correlated with the chemokine pattern induced by poly IC. At later time points, T-B cell aggregates were seen within the SMG with significantly higher levels of IL-12A, IL-21 and IL-21R gene expression. Characterization of CD4+ T cells within the infiltrates showed presence of ICOS+CXCR5+ cells indicative of the T follicular helper cell phenotype. SMG from poly IC treated mice showed IgM and IgG deposition. Although the severity of sialadenitis increased with time, it did not correlate with loss of function. In the inflammasome mediated innate immunity activation model, mice showed evidence for loss of glandular function by 8–10 weeks after alum treatment. At this time point no lymphocytic foci were seen in the SMG. By 4–5 months, SMG from alum treated mice showed evidence for sialadenitis. Interestingly, this did not translate in to further worsening of glandular function.

Conclusions: Our data clearly demonstrates that activation of innate immunity accelerates the development of SS. Although the characteristics of disease development vary depending upon the innate stimulus, the models reinforce a lack of correlation between extent of of sialadenitis and severity of glandular dysfunction, as observed in SS patients. The ability of alum to induce SS in genetically susceptible mouse strains suggests that exposure to aluminum compounds can be a novel risk factor for SS.

This work is supported by grants from Sjögren's Syndrome Foundation USA and NIDCR.

Anticentromere Antibodies (ACA)-Positive Systemic Sclerosis (SSc) Patients with Sjögren's Syndrome: A Distintict Subset at High Risk of Lymphoma. Chiara Baldini, Sara Grossi, Alessandra Della Rossa, Nicoletta Luciano, Marica Doveri, Antonio Gaetano Tavoni and Stefano Bombardieri. Rheumatology Unit, Department of Internal Medicine, University of Pisa, Italy

Background: Sjögren's syndrome (SS) has been considerably associated with anticentromere positive (ACA)-limited cutaneous subtype Systemic Sclerosis (SSc). Nonetheless, only a few studies have analysed the pattern of clinical expression and disease evolution in ACA-SSc-SS patients.

Objectives: to compare the disease phenotype and clinical evolution of ACA-SSc-sSS patients with (a) patients with ACA-SSc and no SS (ACA-SSc) and (b) patients with primary SS (pSS), in order to verify whether the concomitant association between SS and SSc influence the patients' clinical presentation and outcome.

Patients and Methods: Seventy-eight ACA-SSc-sSS patients (78 F: 0 M; mean age = 62 ± 12, yrs; mean follow-up = 5.4±6, yrs), 127 ACA-SSc patients without SS (119 F: 8 M; mean age = 60 ± 13, yrs; mean follow-up = 4.9±6, yrs), and 374 patients with primary SS (pSS) (363F: 11M; mean age 58± 14, years; mean follow-up = 7.3±6.6 years) who had attended our Unit between 1989 and 2009 were included in the study. Diagnosis of SSc was based on the ARA criteria, while diagnosis of pSS and sSS on AECG criteria. Categorical data were compared using the chi-square test and continuous variables by the Student t-test.

Results: (a)When compared to ACA-SSc, ACA-SSc-sSS patients presented a higher frequency of arthralgias ($p<0.0001$), peripheral nervous involvement ($p=0.006$), and altered laboratory findings ($p<0.0001$) (i.e leukopenia, hypocomplementemia, hypergammaglobulinemia, anti-Ro/SSA, anti-La/SSB, Rheumatoid Factor), in addition to the expected increase of symptoms suggestive for glandular involvement. They also presented a lower frequency of pulmonary hypertension ($p= 0.02$) and sclerodactyly ($p<0.0001$) with 26/78 ACA-SSc-sSS patients versus 11/127 ACA-SSc patients being classified as "sine scleroderma" ($p<0.0001$). Noteworthy, ACA-SSc-sSS also presented a higher frequency of MALT lymphomas ($p=0.0009$) which occurred after a mean disease duration of 19±11 yrs, and was not correlated to skin sclerosis. (b) When compared to pSS patients, ACA-SSc-sSS patients presented a higher frequency of signs and symptoms belonging to the spectrum of SSc ($p<0.0001$), i.e Raynaud's phenomenon, dysphagia, teleangectasias, heart involvement and pulmonary hypertension, but also an increased prevalence of salivary glands enlargement ($p<0.0001$). Altered laboratory findings were also more frequent in pSS patients while no differences were observed for lymphoproliferative disorders ($p=0.09$)

Conclusions: Patients with ACA-SSc-sSS presented features from both diseases: we observed that the presence of SS in ACA-SSc dramatically increased the risk of lymphoma. A careful work up is thus mandatory in the follow-up of ACA-SSc-sSS patients.

[1]Department of Clinical Dentistry-Periodontics, University of Bergen, Bergen, Norway, [2]Department of Clinical Medicine, University of Bergen, Center of Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway, [3]Department of Medical Sciences, Molecular Medicine, Uppsala University, Uppsala, Sweden, [4]Department of Medical Sciences, Section of Rheumatology, Uppsala University, Uppsala, Sweden, [5]Department of Medicine, Section of Rheumatology, University of Bergen, Bergen, Norway, [6]Karolinska Institutet, Stockholm, Sweden, [7]Malmö University Hospital, Malmö, Sweden, [8]Section of Rheumatology, Uppsala University, Uppsala, Sweden, [9]Stavanger University Hospital, Stavanger, Norway, [10]Stavanger University Hospital, Stavanger, Norway [11]The Gade Institute, University of Bergen, Bergen, Norway, [12]University Hospital Linköping, Sweden, Linköping, Sweden, [13]University Hospital, Linköping, Linköping, Sweden

Primary Sjögren′s syndrome (pSS) is an autoimmune chronic inflammatory disease characterized by lymphoid infiltrations of exocrine glands and increased levels of autoantibodies against the ribonucleoproteins Ro/SSA and La/SSB. Microarray studies have demonstrated increased gene expression of lymphotoxin beta (*LTB*) in pSS salivary glands. The aim of the present study was to investigate whether single nucleotide polymorphisms (SNPs) in the lymphotoxin alpha (*LTA), LTB* and tumor necrosis factor (*TNF)* gene clusters are associated with pSS.

A total of 527 pSS patients and 532 controls participated in the study. All

of them were of Caucasian origin from Sweden and Norway. Eleven SNP markers were genotyped and analysed for their association with pSS using single marker logistic regression and for genotypic association with a chi square test. Eight markers showed significant association with pSS. The SNP rs909253 in intron 1 of *LTA* showed the strongest association with pSS in both the Norwegian cohort (P = 1.3E-03) and the Swedish cohort (P = 2.6E-05). Importantly, the strength of the association increased (P = 1.3E-07) when the two cohorts were analysed together, showing an odds ratio (OR) of 1.59 [95% CI: 1.34 – 1.89]. When only pSS patients positive for anti-Ro/SSA -La/SSB (n = 381) were compared with the controls, the association with SNP rs909253 was even stronger (P = 4.2E-10, OR 1.82 95% CI: 1.51–2.20). Some SNPs within this locus were also associated with extraglandular manifestations such as high plasma levels of IgG, hypothyroidism, arthritis and leucopenia in pSS patients. In conclusion, a strong association was found between several SNPs in the *LTA* gene locus and pSS, some of which lead to amino acid changes. Our data together with previously published reports suggest a direct role for lymphotoxin alpha in the development of pSS. The importance of this finding for the inflammatory processes in pSS needs further investigation.

1886

B-Cell Profiling Using Multi-Color Flow Cytometry as Biomarker of Disease Progression in Primary Sjogren's Syndrome (pSS). Mustimbo Roberts[2], Craig Maguire[3], Alex Rosenberg[3], Andreea Coca[2], Jennifer H. Anolik[1] and Iñaki Sanz[2]. [1]University of Rochester, Rochester, NY, [2]University of Rochester Medical Center, Rochester, NY, [3]University of Rochester Medical Center

Purpose: Current classification criteria for pSS are limited in their ability to conclusively diagnose patients with sub-clinical manifestations of disease. To remedy these limitations, we have initiated exploratory studies to identify candidate biomarkers for pSS. Multi-color flow cytometry was used cross-sectionally to identify a B-cell phenotypic signature of pSS and to determine if altered B-cell homeostasis in pSS is a predictive indicator of disease onset and/or progression. These signatures are currently being evaluated for their predictive value in an ongoing longitudinal analysis of patients with sicca symptoms, of no obvious clinical reason, that do not meet American European Consensus Group (AECG) criteria.

Methods: B cells from pSS (n=20), sicca (n=14) and healthy (HC) patients (n=20) were analyzed by multicolor flow cytometry to identify differential memory and transitional B-cell subsets. Clinical parameters were used to examine the relationship of phenotypic abnormalities to disease status using Spearman Correlation. Complex, multidimensional immunological data were analyzed using reduction techniques including Principal Component Analysis (PCA).

Results: We report decreased frequencies of switched (SM) ($p<=0.0001$) and unswitched (UM) ($p<=0.0001$) memory cells, and increased frequencies of IgD-CD27- switched B cells ($p=0.03$) and naïve B cells ($p<=0.0001$) in pSS compared to HC. Additionally, pSS patients exhibit increased frequencies of T1 and T2 transitional B cells compared to HC ($p=0.005$). The increased frequency of T1 and T2 cells correlated significantly with serum levels of BAFF, the main survival factor for transitional cells, which were significantly increased in pSS ($p=0.05$). Similar to pSS, sicca patients also feature decreased frequencies of SM ($p=0.02$) and UM ($p=0.01$) and increased frequencies of naïve B cells ($p=0.02$). Longitudinally, sicca patients with normal UM frequencies at baseline experience a dramatic permanent decline in frequency at 1 year and 2 years of follow-up that precedes a relative expansion in the CD27- memory and naive populations. Of note the decrease of UM cells correlated significantly with increased serum IgG, ESR, and years with sicca symptoms. Of great interest, UM decline preceded in some patients the presence of anti-Ro/La antibodies and decreased salivary function.

Discussion: We have defined a B cell signature of pSS that allows for clustering/differentiation of Sicca patients that share a similar signature that clearly separates them from healthy controls and sicca patients that do not progress to pSS. Clinical parameters—elevated IgG, ESR and reduced C4 also cluster based on pSS B-cell signatures. The reduction of UM frequencies seem to be the first immunologic and permanent sign that Sicca patients may develop pSS. PCA of the complex multidimensional flow cytometric data identify the decrease in UM and increase in CD27- memory cells as the driving parameters of the B-cell signature in pSS. Further longitudinal examination of the pSS B-cell signature in Sicca patients will confirm the predictive value of peripheral blood multicolor flow cytometry as a diagnostic tool in pSS.

1887

Best Scintigraphic Measures of Parotid Gland Dysfunction in Sjogren's Syndrome. Anthony Keyes[4], Julius Birnbaum[2], John Petronis[1] and Alan N. Baer3. [1]Johns Holins University School of Medicine, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD, [4]Johns Hopkins University School of Medicine

Purpose: Parotid gland scintigraphy is utilized to document the oral component of Sjogren's syndrome (SS); however the best parameters of dysfunction have not been defined. We sought to determine which parameters of parotid gland scintigraphy best differentiate patients with SS from those with suspected, but unconfirmed, SS.

Methods: In a 12-month period, 61 patients with suspected or confirmed SS underwent parotid gland scintigraphy in order to document or quantify parotid gland dysfunction. Following evaluation in our clinic, 23 had a confirmed diagnosis of SS according to the American-European Consensus Classification Criteria (AECC), independent of scintigraphy, and 32 had symptoms and/or signs of dry eyes and dry mouth but did not meet classification criteria ("sicca controls"). Five patients could not be classified further and were not included in subsequent analyses. Following an intravenous injection of pertechnetate, dynamic imaging was performed over 60 minutes. Hard lemon candy was provided after an elapse of 45 minutes to stimulate parotid gland excretion. Quantitative parameters of parotid gland parenchymal function included the net uptake ratio (NUR, ratio of maximum count and the count at 60 seconds) and the maximum count time (MCT, time at which the maximum count was reached). The parameter of parotid gland excretion function was the discharge fraction [DF, (pre-stimulus maximum count-post-stimulus minimum count/pre-stimulus maximum count)].

Results: The 56 patients, 50 women and 6 men, had a mean age of 53 ± 14 yrs (SD). Measurements of NUR, MCT, and DF in the right and left parotid (P) glands showed strong correlations in all patients. NUR in the parotid gland had a negative correlation with the duration of dry mouth symptoms in the SS patients (left gland: $r^2=.27$, $p=0.02$; right gland: $r^2=.1$, $p=0.19$) but not in the sicca control patients. There was no correlation between these symptoms and MCT or DF in either group. The mean NUR and DF values for the right and left glands were each significantly lower in the SS patients compared with those of the sicca controls ($p<0.05$, Mann-Whitney test). The SS patient group could be differentiated from the sicca control group, using specific parotid gland scintigraphic parameters, as shown in the Table.

Parameter	Cutoff value	Sensitivity (%)	Specificity (%)	+LR	−LR
Net uptake ratio (%)	≤2	57	88	4.75	0.49
	≤2.5	83	50	1.66	0.34
	≤3	96	31	1.39	0.13
Maximum count time (min)	≤40	43	62	1.13	0.92
	≤42	57	50	1.14	0.86
Discharge fraction (%)	≤40	36	97	12	0.66
	≤50	50	87	3.85	0.57
	≤55	59	77	2.57	0.53
	≤60	73	71	2.52	0.38
Combination	NUR ≤2.5, DF ≤60	68	84	4.25	0.38

+LR= positive likelihood ratio; −LR=negative likelihood ratio

The best individual parameter was a DF of ≤60%, which identified SS patients with 73% sensitivity and 71% specificity. A DF of ≤60%, when combined with a NUR of ≤ 2.5 % identified SS patients with 68% sensitivity and 84% specificity.

Conclusions: Measures of radiotracer uptake and discharge, indicative of parenchymal and excretion function, are each lower in SS patients. A combination of these two parameters achieves the best balance of

sensitivity and specificity in differentiating SS patients from suspected SS patients with sicca symptoms and/or signs who do not meet AECC diagnostic criteria.

Clinical and Immunological Profile of Patients with Primary Sjogren Syndrome Who Developed B-Cell Lymphoma. Analysis of 1010 Spanish Patients (The GEMESS Cohort). Manuel Ramos-Casals[3], Roser Solans[11], Jose Rosas[6], Maria Teresa Camps[2], Antonio Gil[9], Javier Del-Pino[10], Carmen Hidalgo[12], Jaime Calvo[4], Maria Luisa Mico[8], Roberto Perez-Alvarez[7], Rafael Belenguer[1] and Lucio Pallares[5]. [1]Hospital 9 d'Octubre, València, Spain, [2]Hospital Carlos Haya, Malaga, Spain, [3]Hospital Clinic, Barcelona, Spain, [4]Hospital de Sierrallana, Torrelavega, Spain, [5]Hospital de Son Dureta, Palma de Mallorca, Spain, [6]Hospital de Vilajoyosa, Alicante, Spain, [7]Hospital do Meixoeiro, Vigo, Spain, [8]Hospital La Fe, Valencia, Spain, [9]Hospital La Paz, Madrid, Spain, [10]Hospital Universitario de Salamanca, Salamanca, Spain, [11]Hospital Vall d'Hebron, Barcelona, Spain, [12]Hospital Virgen de las Nieves, Granada, Spain

Objective: To analyse the epidemiological, clinical and analytical features related to the development of B-cell lymphoma in a large cohort of Spanish patients with primary Sjogren syndrome (SS).

PATIENTS. The GEMESS Study Group was formed in 2005 with the aim of collecting a large series of Spanish patients with primary SS, and included twelve Spanish reference centers with substantial experience in the management of SS patients. By March 2007, the database included 1010 consecutive patients, recruited since 1994.

Results: The cohort consisted of 1010 patients, including 937 (93%) women and 73 (7%) men (female:male ratio, 13:1), with a mean age at diagnosis of 53.0 + 0.48 years (range, 14–88) and of 58.7 + 0.46 years (range, 16–94) at inclusion in the Registry. Twenty-six (2.57%) patients developed B-cell lymphoma. There were 22 (85%) women and 4 (15%) men, with a mean age of 59 years at diagnosis of lymphoma and a length of SS evolution of 6 years from SS diagnosis to lymphoma diagnosis. Patients with B-cell lymphoma had a higher prevalence of vasculitis (23% vs 9%, $p=0.024$), lung involvement (31% vs 11%, $p=0.005$), anemia (38% vs 17%, $p=0.015$), leukopenia (38% vs 15%, $p=0.004$), thrombocytopenia (42% vs 12%, $p<0.001$) and low C3/C4 levels (42% vs 13%, $p=0.001$) in comparison with patients without lymphoma. Multivariate analysis adjusted by age, gender and length of SS evolution identified lung involvement ($p=0.022$), thrombocytopenia ($p<0.001$) and low C3/C4 levels ($p=0.004$) as significant independent variables related to B-cell lymphoma.

Conclusion: We identified a specific clinical and immunological profile (vasculitic and pulmonary involvement, cytopenias and hypocomplementemia) in patients with primary SS who developed B-cell lymphoma. The adjusted multivariate model confirmed the close association with low C3/C4 levels reported in previous series and identified as new factors associated with B-cell lymphoma lung involvement and thrombocytopenia in patients with primary SS.

Clonal Analysis of Ig-Expressing Cells in Salivary Glands of Primary Sjögren's Syndrome Patients after Anti-CD20 Treatment. Nishath Hamza[3], Hendrika Bootsma[4], Rodney P. E. Pollard[2], Jiska M. Meijer[2], Fred K. L. Spijkervet[2], Arjan Vissink[2], Hans G. M. Burgerhof[5], Frans G. M. Kroese[1], Cees G. M. Kallenberg[4] and Nicolaas A. Bos[1]. [1]Dept. of Cell Biology, Immunology Section, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands, [2]Dept. of Oral and Maxillofacial Surgery, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands, [3]Dept. of Rheumatology and Clinical Immunology & Dept. of Cell Biology, Immunology Section, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands, [4]Dept. of Rheumatology and Clinical Immunology, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands, [5]University Medical Center Groningen, University of Groningen, Groningen, The Netherlands

Background: B cell depletion by anti-CD20 treatment with Rituximab (RTX) has been shown to be clinically effective in patients with primary Sjögren's syndrome (pSS) suggesting a role for B cells in the pathogenesis. The effect of RTX on the B cell repertoire in salivary glands is largely unknown. This study investigated clonal relationships of IgA & IgG expressing cells that are present within salivary glands of patients before and after treatment with RTX.

Methods: Parotid salivary gland biopsies were taken from 7 immunesuppressed naive pSS patients before treatment and at 12 weeks after treatment [5 RTX and 2 placebo (PL)] and at 36 weeks after treatment (for 5 RTX patients only). All RTX patients improved clinically after treatment. Variable immunoglobulin heavy-chain gene (IGHV) cloning and sequence analysis were carried out on RNA extracted from each parotid biopsy, using a primer specific for IGHV-3 genes in combination with constant region primers for IgA and IgG isotypes.

Results: In total 747 unique Ig sequences were analyzed. Clonally related sequences were identified in biopsies of 4/5 RTX patients before and 12 weeks after RTX when there is complete depletion of B cells in the peripheral blood. Even at 36 weeks after RTX when B cells reappeared in the blood, sequences clonally related to the sequences before RTX were found. In one RTX patient a single clone set was found at all time points. Clonally related sets of sequences expressing IgA and/or IgG isotypes at different timepoints were observed. The same pattern was also seen in different biopsies of each patient in the PL-treated patient group.

Strikingly, in 3/5 RTX patients, significantly more non-unique (redundant) sequences were seen at 36 weeks after RTX compared to baseline (Fisher's exact test, $p \leq 0.01$).

The occurrence of Vh3–23 and Vh3–30 genes were found to be quite high at all timepoints in both PL and RTX patients.

Conclusions: In this study we show the presence of clonally related Ig sequences from parotid gland biopsies of pSS patients before and after RTX. These data indicate the persistence of some B cell clones despite RTX treatment. Furthermore, the diversity of the IgA and IgG repertoire becomes progressively more restricted with time after RTX, suggesting selective advantage for certain B cell clones. The high frequency of Vh3–23 and Vh3–30 genes seen in all pSS patients studied here, has also been previously noted in other autoimmune disorders. This study indicates that the selective persistence of particular B cell clones may contribute to the disease relapse and manifestations of the disease after RTX.

1890

Correlation of Serum BAFF and Markers of B-Cell Activation with Systemic Involvement Assessed by the EULAR Sjögren's Syndrome Disease Activity Index: Results from the ASSESS Prospective Cohort. Jacques-Eric Gottenberg[16], Raphaele Seror[2], Joelle Benessiano[3], Karine Inamo[2], Philippe Dieude[3], Jean-Jacques Dubost[5], Anne-Laure Fauchais[11], Eric Hachulla[10], Claire Larroche[1], Veronique Le Guern[6], Jacques Morel[12], Aleth Perdriger[14], Xavier Puéchal[9], Stéphanie Rist[13], Alain Saraux[4], Damien Sene[7], Jean Sibilia[16], Olivier Vittecoq[15], Charles Zarnitsky[8], Philippe Ravaud[3] and Xavier Mariette[2]. [1]Avicenne Hospital, [2]Bicetre Hospital, [3]Bichat Hospital, [4]Brest Hospital, [5]Clermont-Ferrand Hospital, [6]Cochin Hospital, [7]La Pitié Hospital, [8]Le Havre Hospital, [9]Le Mans Hospital, [10]Lille Hospital, [11]Limoges Hospital, [12]Montpellier Hospital, [13]Orleans Hospital, [14]Rennes Hospital, [15]Rouen Hospital, [16]Strasbourg Hospital

Objectives: In primary Sjögren's syndrome (pSS), systemic disease activity might result from the stimulation of autoreactive B lymphocytes. Thus, markers of B-cell activation could be useful in the clinical assessment of the disease. However, due to the lack of consensual disease activity score and of prospective cohorts, the only available studies are retrospective and evaluated disease activity only by the presence/absence of extraglandular involvement. A multinational consensual disease activity score was recently established, the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI). We therefore investigated the correlation between markers of B-cell activation and the ESSDAI at enrollment in a multicenter prospective cohort of patients with pSS.

Methods: 15 centers of Rheumatology and Internal Medicine have included patients with pSS according to AECG criteria in the "Assessment of Systemic Signs and Evolution of Sjögren's Syndrome" (ASSESS) 5-year prospective cohort since May 2006. At enrollment, clinical data, ESSDAI disease activity and serum are collected and centralized. Serum IgG, A, M,

beta2-microglobulin and kappa and lambda free light chains (FLCs) of immunoglobulins were assessed at enrollment using nephelometry and B-cell activating factor of the TNF family (BAFF) was assessed using ELISA.

Results: In the 349 analyzed patients (women: 93.7%), mean age and disease duration were 60.5 ± 12.6 years and 9 ± 5.9 years (1st quartile: 5 years), respectively. Anti-SSA antibody was detected in 60.2% of patients, anti-SSB in 35.2% of patients. 189 patients (54.9%) had records of systemic involvement at enrollment, including 19 patients (5.4%) with previous lymphoma. Median BAFF and beta2microglobulin at enrollment were higher in patients with a history of lymphoma (1187.7 vs 893.3 pg/ml, P= 0.002 and 2.6 vs 2.1 mg/l, P= 0.01, respectively).

At inclusion, 31.8% of patients had features of systemic involvement. Median ESSDAI at enrollment, analyzed in 324 patients, was 4 (25^{th} –75^{th}: 1–9).

At inclusion, patients with anti-SSA/SSB had a significantly higher ESSDAI (4[2–9] vs 2[0–6.6] in patients without anti-SSA/SSB, P=0.04). The ESSDAI score at enrollment was significantly correlated with total IgG (r=0.11, P= 0.05), kappa FLCs (r=0.22, P<0.0001), beta2-microglobulin (r=0.2, P=0.0003) and BAFF (r=0.14, P=0.015). Patients with an ESSDAI score greater than 4 had significantly more frequently increased levels of BAFF (>908.8 pg/ml, 75^{th} value in the cohort, 31.5% of increased levels vs 18.3% in patients with an ESSDAI≤4, P=0.009), kappa FLC (>19.4 mg/l, 32.7% vs 15.7%, P= 0.0005), and beta2-microglobulin (>2.34 mg/l, 46.8% vs 25.5%, P= 0.0001)

Conclusion: In pSS, disease activity assessed by the ESSDAI is correlated with serum levels of BAFF, a pivotal B-cell activating cytokine, and markers of B-cell activation (anti-SSA/SSB, kappa FLCs, and beta2-microgobulin). Prospective follow-up in the ASSESS cohort will allow to determine whether these markers predict new systemic complications of the disease, including lymphomas.

1891

Detection of HTLV-1 p19 Protein in Labial Salivary Glands from Patients with Sjögren's Syndrome: A Distinct Clinical Subgroup? Sung-Ji Lee[1], Seong-Rye Seo[1], Tae-Jong Kim[1], Yong-Wook Park[1] and Shin-Seok Lee[2]. [1]Chonnam National University Medical School, [2]Chonnam Natl Univ Med School, Gwangju, Korea, Republic of

Purpose: Etiologically, human T-cell lymphotropic virus type 1 (HTLV-1) is associated with two major diseases: adult T-cell leukemia and HTLV-1-associated myelopathy-tropical spastic paraparesis. Of interest, recent studies have suggested that HTLV-1 is involved in the pathogenesis of Sjögren's syndrome (SS). However, the clinical and serological differences in SS patients with and without this infection are not well characterized. Therefore, we examined whether SS patients could be distinguished based on the expression of HTLV-1 p19 protein and, if so, whether the subgroups differ in their clinical features and serological parameters.

Methods: The polymerase chain reaction was used to amplify viral DNA from peripheral blood mononuclear cells (PBMCs) in 54 patients with SS, using primers from the HTLV-1 p19 region and minor salivary gland (MSG) biopsy specimens from 33 SS patients who were examined for the presence of HTLV-1 p19 genes immunohistochemically. The sociodemographic, glandular, and extraglandular manifestations, and laboratory findings including autoantibodies, complements, and immunoglobulin levels, were analyzed.

Results: The HTLV-1 p19 gene was not detected in PBMC samples from 54 patients, while HTLV-1 p19 protein was expressed immunohistochemically in MSG specimens in 10 out of 33 SS patients (30.3%). On separating the SS patients into two groups based on HTLV-1 p19-positive immunohistochemistry, the p19-positive patients had lower anti-Ro/SS-A titers, rheumatoid factor, and C3 levels, and higher lymphocyte counts than the p19-negative patients (p=0.049, p=0.014, p=0.018, and p<0.001, respectively). The prevalence of glandular and extraglandular manifestations, including dryness of the eyes and mouth, enlargement of the parotid gland, photosensitivity, swollen hands, Raynaud's phenomenon, arthralgia, lymphadenopathy, renal disease, psychosis, interstitial lung disease, peripheral neuropathy, and autoimmune thyroid disease, did not differ between the p19-positive and p19-negative patients.

Conclusions: Our findings suggest that the presence of HTLV-1 p19 in the salivary gland is involved in the pathogenesis of a subpopulation of SS, and HTLV-1-associated SS could have different immunological patterns compared to idiopathic SS, raising the possibility that HTLV-1 p19 is a marker of a pathogenetically distinct form of SS.

1892

Effect of Rituximab Treatment on BAFF Levels in Patients with Primary Sjögren's Syndrome: A Placebo-Controlled Clinical Trial. Rodney Pollard[2], Wayel Abdulahad[2], Jiska Meijer[2], Frans Kroese[2], Fred Spijkervet[2], Cees Kallenberg[1], Arjan Vissink[2] and Hendrika Bootsma[2]. [1]Univer Med Center Groningen, Groningen, The Netherlands, [2]Univer Med Center Groningen

Objective: To assess the effect of rituximab (anti-CD20) treatment on B-cell activating factor (BAFF) levels in patients with primary Sjögren's syndrome (pSS).

Background: pSS is a systemic autoimmune disease characterized by mononuclear infiltrates of B-and T-cells in exocrine glands eventually leading to destruction of these glands. B-cell activating factor (BAFF), a member of the tumor necrosis factor (TNF)-ligand family, is essential for the control of B-cell maturation and survival.

Methods: In a randomised double-blinded placebo-controlled trial patients were treated on days 1 and 15 with either rituximab (n= 20) or placebo (n= 10). To minimise side effects (infusion reactions, serum sickness), all patients were pre-medicated with methylprednisolone and oral prednisone. Fresh blood samples were collected at various time points (before, 5, 12, 36 and 48 weeks following treatment). In addition, age- and sex-matched blood samples were collected from healthy controls (n=10). BAFF levels were assessed by Enzyme-Linked Immunosorbent Assay (R&D Systems). In addition, percentages and numbers of B-cell subsets were examined by four-color cytometry.

Results: Depletion of B-cells was observed in the rituximab treated group after infusion, while B-cell levels remained unchanged after placebo treatment. B-cells reappeared in the rituximab treated group within 24 to 48 weeks after treatment. Repopulation of the B-cell compartment started with reappearance of transitional B-cells, followed by naïve B-cells, and a relative late recovery of memory B-cells. At baseline, BAFF levels were significantly increased in all pSS-patients in comparison to healthy controls.

Placebo-treated patients showed a slight (0.5 fold, p<0.05), but significant, increase in BAFF levels only at week 5, likely due to methylprednisolone administration.

Strikingly, long-term elevated levels of BAFF (3.0–4.0 fold, p<0.05) were observed during 36 weeks following rituximab-treatment. By week 48, BAFF levels had reached baseline values in rituximab treated group.

Conclusion: These preliminary data show a sharp increase in BAFF levels after rituximab therapy. These levels appear to correlate negatively with the presence of B-cells in the peripheral blood. BAFF could be involved in the pathogenesis of SS, possibly by triggering the activation of self-antigen-driven autoimmune B-cells. Since BAFF levels are much higher after rituximab treatment, this may also have implications for manifestations of the disease, related to therapy. This observation might be important for treatment strategies with biologicals like anti-BAFF and /or B-cell depletion. Extended data are in progress and can be presented at the ACR meeting.

1893

Efficacy of Rituximab in Primary Sjogren's Syndrome with Peripheral Nervous System Involvement: Results from the French AIR Registry. Arsene Mekinian[6], Eric Hachulla[9], Claire Larroche[2], Jean Leone[11], Bruno Gomberg[7], Mohamed Hamidou[8], Alain G. Cantagrel[5], Christian Marcelli[4], Stephanie Rist[10], Maxime A. Breban[1], Olivier Fain[6], Jacques E. Gottenberg[12] and Xavier Mariette[3]. [1]Courbevoie, France, [2]Avicenne Hospital, [3]Bicetre Hospital/Paris Univ, Le Kremlin Bicetre, France, [4]Caen Hospital, [5]Hopital Purpan, Toulouse, France, [6]Jean Verdier Hospital, [7]La Rochelle Hospital, [8]Nantes Hospital, [9]National Scleroderma Centre, Lille Cedex, France, [10]Orleans Hospital, [11]Reims Hospital, [12]Strasbourg Hospitals, Strasbourg, France

Purpose: To evaluate the efficacy of Rituximab in primary Sjogren'syndrome with peripheral nervous system involvement.

Methods: Prospective data from patients with primary Sjogren's syndrome and peripheral nervous involvement included in the French AutoImmunity and Rituximab (AIR) registry, were analyzed. Peripheral nervous involvement was defined by clinical signs of peripheral neuropathy confirmed by nerve conduction study. Vasculitis was defined by the presence positive neuromuscular biopsy and/or of purpura. Neurological response to Rituximab was defined by the clinician in charge of the patient.

Results: Seventeen patients (median age 63 years [31–82], 14 female sexes) with Sjogren's syndrome and peripheral nervous involvement received treatment by Rituximab. The median duration of Sjogren's syndrome was 10 years [2–26]. Median baseline ESSDAI index was 18 [10–44], joint and cutaneous involvement were present in 7 cases each. Neurological features were sensory neuropathy (n=3), axonal sensory-motor neuropathy (n=12) and multiple mononeuropathy (n=2). Twelve patients have been treated by another immunosuppressor before Rituximab and 10 patients were on corticoids. Other immunosuppressive treatment was associated to Rituximab in 5 cases (methotrexate in 2 cases, mycophénolate mofetil, azathioprine and plasma exchange in 1 case each).

Cryoglobulinemia was present in 9/17 cases (53%) and in these 9 patients neuropathy was considered to be related to the cryoglobulinemia (axonal sensory-motor neuropathy in 7 cases and multiple mononeuropathy in 2 case). Patients with cryoglobulinemia were significantly younger (56 vs 76 years; p=0.02), had more important ESSDAI (24 vs 14; p=0.003), and more profound hypocomplementia (p=0.0001). Vasculitis (defined by biopsy (n=2) or purpura (n=5)) was present in 7/17 patients (41%), and 6/7 (86%) had cryoglobulinemic vasculitis.

Neurological improvement was noted in 11 patients (65%) at 3 months and persisted in 9 cases (53%) at 6 months. Median ESSDAI index was 11 [7–21] at 3 month with joint and skin improvement in 9/12 cases each. Rituximab was effective at 3 month in 9/10 cases (90%) with vasculitis and/or cryoglobulinemia, and in 2/7 cases (29%) in the absence of cryoglobulinemia and vasculitis (p=0.03). Among responders to Rituximab, 4 (36%) experienced a relapse, and 3 of them responded after retreatment with Rituximab.

Conclusion: Rituximab could be effective in peripheral nervous system involvement of patients with primary Sjogren'syndrome, in particular when related to cryoglobulinemia or vasculitis.

1894

Efficacy of Rituximab in Primary Sjogren's Syndrome with Central Nervous System Involvement: Results from the French AIR Registry. Arsene Mekinian[4], Claire Larroche[1], Eric Hachulla[7], Bruno Gomberg[6], Claire Blanchard-Delaunay[8], Alain G. Cantagrel[3], Olivier Fain[5], Jean Sibilia[9], Jacques E. Gottenberg[10] and Xavier Mariette[2]. [1]Avicenne Hospital, [2]Bicetre Hospital/Paris Univ, Le Kremlin Bicetre, France, [3]Hopital Purpan, Toulouse, France, [4]Jean Verdier Hospital, [5]Jean Verdier Hospital, [6]La Rochelle Hospital, [7]National Scleroderma Centre, Lille Cedex, France, [8]Niort Hospital, [9]Strasbourg Hospital, [10]Strasbourg Hospitals, Strasbourg, France

Purpose: To evaluate the efficacy of Rituximab in primary Sjogren's syndrome with central nervous system (CNS) involvement.

Methods: Prospective data from patients with primary Sjogren's syndrome and CNS involvement included in the French AutoImmunity and Rituximab (AIR) registry were analyzed. CNS involvement was defined by the presence of central nervous impairment associated with diffuse white matter T2-weigted hypersignal in the exclusion of other aetiologies. Neurological response was defined as complete disappearance of neurological impairment, or improvement of subjective and/or clinical signs. Expanding Disability Status Scale (EDSS) was used as previously defined.

Results: Eleven patients (median age 57 years [42–81], 10 female sexes) with Sjogren's syndrome and central nervous involvement received treatment by Rituximab. The median duration of Sjogren's syndrome was 8 years [3–23]. Median baseline ESSDAI index was 17 [5–25]. Articular involvement was present in 4 cases, cutaneous in 2 cases, biological and haematological involvements in 6 and 4 cases respectively. Neurological features were progressive multiple sclerosis-like manifestations in 8 patients, anxiety and depression disorder in 1 patient and cognitive dysfunction in 2 cases. Median EDSS score before Rituximab was 4 [2–6]. Magnetic resonance imaging showed white matter abnormalities in all cases.

Rituximab was indicated for neurological involvement in all cases. Other immunosuppressive treatment was associated with Rituximab in 4 cases (cyclophosphamide in 3 cases and mycophenolate mofetil in 1 case). The median number of post-rituximab visits was 3 [1–5]. No neurological modification was noted in the 7 patients with multiple sclerosis-like symptoms and 2 patients with cognitive dysfunction at 3, 6 and 9 months visits. EDSS score was 3.5 [2–6], 3.3 [2–6.5] and 4.5 [2–6.5] at 3, 6 and 9 months respectively. One patient with depression disclosed subjective improvement. One patient with myelitis which has been treated before Rituximab by cyclophosphamide had improvement of his walk perimeter (160 meters versus 116). Median ESSDAI index was 15 [5–19] at 3 month with articular and cutaneous improvement in all cases.

Conclusion: Rituximab is not effective in CNS progressive multiple sclerosis-like manifestations of patients with primary Sjogren'syndrome.

1895

Epitope Mapping of the Autoantigen Aquaporin-4 Reveals Linear Epitopes Located in the Intracellular Region of the Molecule. Eleni I. Kabylafka[1], John G. Routsias[1], Haralampos Alexopoulos[1] and Athanasios G. Tzioufas[2]. [1]Department of Pathophysiology, Medical School of Athens, Athens, Greece, [2]Medical School-Univ of Athens, Athens, Greece

Background: Autoantibodies to aquaporin-4 (AQP4), a water channel localized in astrocytic foot processes at the blood-brain barrier, have been shown to correlate with Neuromyelitis Optica (Devic's syndrome), a rare syndrome. The main symptoms of the syndrome are optic neuritis and myelitis. The latter can be found in the context of a systemic autoimmune disease, such as Systemic Lupus Erythematosus (SLE), and primary Sjögren's syndrome (pSS). Despite the fact that anti-AQP4 antibodies have an established role in the pathogenesis of Neuromyelitis Optica, their fine specificity and regulation of their production has not been clarified. The aim of the present study was to identify the B cell linear epitopes of the AQP4 protein, investigate putative similarities with other molecules and evaluate the sensitivity and specificity in detecting anti-AQP4 autoantibodies.

Methods: Sera from 21 patients with Devic's syndrome, all positive for anti-AQP4 antibodies using indirect immunofluorescence in mouse brain tissue, were used. Sera from 23 SLE and 23 pSS patients, without neurologic involvement were utilized as disease controls. 26 healthy individuals were also used. 11 overlapping peptides, spanning the entire intracellular and extracellular domains of the AQP4 molecule, were synthesized (Bio-synthesis Inc, U.S.A.), and all sera were screened by ELISA for the presence of antibodies against the peptides. The cut-off values for each peptide assay were determined using the mean OD plus 2 SD of sera from 26 healthy controls. Specificity was evaluated by homologous inhibition assays.

Results: Reactivity against 3 different peptides spanning the sequences aa1–22 [MSDRPTARRWGKCGPLCTRENI], aa88–113 [FGHISGGHINPAVTVAMVCTRKISIA] and aa252–275 [FCPDVEFKRRFKEAFSKAAQQTKG] was demonstrated in 33%, 24% and 24% of sera from Devic's patients, respectively, while 38% of patients' sera were reactive against at least one of the 3 peptides. All epitopes were localized in the intracellular domains of AQP4. A 73% sequence similarity was observed between the [aa252–275] peptide (amino acids 257–271), and the aa219–233 domain of the Tax-1 HTLV-1 protein, which appears to play a pathogenetic role for spastic paraparesis. None of healthy controls showed any reactivity. Homologous inhibition assays produced high inhibition rates (84.3%, 71.1% and 84% for peptides aa1–22, aa88–113 and aa252–275, respectively). SLE patients tested positive for antibodies against peptides aa1–22, aa88–113 and aa252–275 in 8.6%, 0% and 8.6%, respectively, while pSS patients recognized the above peptides in 8.6%, 4.3% and 8.6%.

Conclusions: This is the first epitope mapping of the autoantigen AQP4. Most of antibodies to AQP4 are directed against conformational epitopes but a significant proportion targets certain linear epitopes, located in the intracellular domains of the molecule. Future studies in our laboratory are aiming to determine the pathogenic relevance of these epitopes.

Background: We previously developed a score to assess disease activity in patients with systemic complications of primary Sjögren's syndrome (SS): the ESSDAI.

Objectives: We now aim to develop a second score a disease-specifi patient-reported outcomes, complementary to ESSDAI, to assess patients' symptoms: the EULAR Sjögren's Syndrome Patient reported Index (ESSPRI).

Methods: Based on studies developing the Sicca Symptoms Inventory (SSI) and the Profile of Fatigue and Discomfort (PROFAD), dryness, limb pain, mental and physical fatigue were selected as the main relevant symptoms for primary SS patients. It was suspected that, compared to these long questionnaires, a single 0–10 numerical scale for each of these 4 domains would be sufficient to assess these symptoms. These 4 scales were gathered to form the ESSPRI. Patients were included in 12 different countries by 21 SS experts participating in this international collaborative project promoted by EULAR. All patients completed the ESSPRI, SSI and PROFAD questionnaires and a 0–10 patient global assessment (PGA). Correlations between domains, dryness features and PGA were obtained. Multiple regression modelling, using PGA as the dependent variable, was used to select domains and estimate their weights, and construct the ESSPRI.

Results: 230 primary SS patients (mean age = 55.9 ± 13.9 yrs, 219 [95.6%] females, mean disease duration = 8.3 ± 5.6 yrs, 184 [80.0%] anti-SSA and/or SSB positive) were included. In univariate analysis, PGA had good correlation with dryness, pain, mental and physical fatigue (rho: 0.50 to 0.58, all $p<0.0001$), but was less correlated with each separate dryness feature (rho: 0.38 to 0.48) except ocular dryness (rho=0.54). In multivariate analysis, dryness, pain and physical fatigue, but not mental fatigue, were significantly associated with PGA; weights derived from the regression coefficients were identical for these 3 domains ($R^2=0.49$). Thus, we redefined ESSPRI as the mean of the 3 scales (dryness, limb pain and physical fatigue). Correlation with PGA (rho) was, 0.70, 0.66 and 0.56 for ESSPRI, PROFAD and SSI, respectively. Last ESSPRI correlated with PROFAD (rho=0.73) and with SSI (rho=0.66).

Conclusion: ESSPRI is a patient index designed to measure patients' symptoms in primary SS. This very simple index has good construct validity when PGA is considered as the gold standard and good correlations with more complicated validated indexes: SSI and PROFAD. ESSPRI and ESSDAI are currently being evaluated for sensitivity to change and validated in order to be used as an outcome measure in clinical trials.

1897

Evolution of Autoimmune Minor Salivary Gland (MSG) Lesions in Sjögren's Syndrome (SS). Efstathia K. Kapsogeorgou[3], Maria I. Christodoulou[4], Demosthenes B. Panagiotakos[2], Spyros Paikos[1] and Haralampos M. Moutsopoulos[4]. [1]Dental Department, "Laikon" General Hospital of Athens, Athens, Greece, [2]Dietetics and Nutrition Dept, Harokopio University of Athens, [3]Pathophysiology Dept, School of Medicine, National University of Athens, Athens, Attica, Greece, [4]Pathophysiology Dept, School of Medicine, National University of Athens, Athens, Greece

Purpose: The MSG lesions of SS patients extend from mild to severe. The prevalence of certain types of infiltrating mononuclear cells (MNC), including total T cells and their subpopulations, B cells, macrophages (MΦ) and interdigitating dendritic cells (iDC) varies according to lesion severity. MSG lesions are generally thought to develop stepwise, starting from mild infiltrates that progress through time. However, studies of sequential biopsies evaluating this progress are missing. The aim of this study was to evaluate repetitive MSG samples of SS patients and define the evolution of the grade and composition of lesions through time.

Methods: 28 SS patients, which agreed to perform second MSG biopsy, were studied. In 24 patients, the first biopsy had been performed at diagnosis. The median interval (range) between the two sequential biopsies was 55 (30–110) months. The evolution of the grade of MSG lesions was evaluated by the number of lymphocytic foci/4 mm^2 of tissue (biopsy focus score), Tarpley score and the number of total infiltrating MNC/mm^2-tissue. The percentage of total T, $CD4^+$ T, $CD8^+$ T, Treg and B cells, MΦ, iDC, follicular DC (fDC) and natural killer (NK) cells to total infiltrating MNC was analyzed immunohistochemically in the entire tissue. General linear model for repeated measures adjusted for biopsy time interval and non-parametric Wilcoxon test for paired observations were used.

Results: The biopsy focus score was found to change in 4 patients [1^{st} - 2^{nd} biopsy focus score (%-change): 8.2–11.4 (39), 1.8–3.1 (71), 4.0–11.6 (190) and 6.9–2.0 (−71)]; in two of them was followed by a change in Tarpley score (from 3+ to 4+ and 3+ to 2+, respectively). The number of infiltrating MNC/mm^2-tissue was found to increase in 7 patients (% increase: 37, 38, 48, 70, 89, 185 and 204) and reduce in 2 patients (% decrease: 62 and 68). This progression was not found to associate with biopsy time interval, incidence of the various inflammatory cell types, other histological, demographic and clinical features or therapy. Statistical analysis of all SS samples revealed that the biopsy focus score and MNC number/mm^2-tissue did not change significantly between the two sequential biopsies. From the cell populations studied, only the $CD4^+$ T cell incidence changed through time. The percentage of $CD4^+$ T/MNC cells was found significantly decreased in the second biopsy (mean±SD in the 1^{st} *vs* 2^{nd} biopsy: 30.8±7.9 *vs* 26.9±10.2, p:0.038); however, without affecting the $CD4^+/CD8^+$ T cell ratio (2.2±1.03 *vs* 1.4±0.9, p:0.29). Other histological parameters, such as fibrosis, fat infiltration or germinal center formation did not differ between the two sequential biopsies. The biopsy time interval was not found to affect the evolution of the lesion grade or composition. Finally, the histological parameters tested were not found to correlate with any demographic, clinical and therapeutic features of patients.

Conclusions: In the majority of SS patients, the grade and composition of MSG lesions at diagnosis remained mainly unchanged through follow-up. These findings suggest that the MSG autoimmune infiltrates do not significantly progress and accordingly, the progression of SS lesions is a rather slow process.

Extra-Glandular Manifestations of Primary Sjögren's Syndrome in the SICCA International Sjögren's Syndrome Registry. Arundathi S. Malladi[12], Kenneth E. Sack[8], Stephen Shiboski[10], Caroline Shiboski[10], Alan N. Baer[2], Pekka Helin[7], Bruce Kirkham[4], Hisanori Umehara[3], Frederick B. Vivino[6], Cristina F. Vollenweider[1], Yan Zhao[5], John Greenspan[10], Troy Daniels[9] and Lindsey A. Criswell[11]. [1]German Hospital, Buenos Aires, Argentina, [2]Johns Hopkins University, Baltimore, MD, [3]Kanazawa Medical University, Ishikawa, Japan, [4]King's College London, UK, [5]Peking Union Medical College Hospital, Beijing, China, [6]Penn Presbyt Med Ctr, Philadelphia, PA, [7]Rigshospitalet, Copenhagen, Denmark, [8]UCSF, Tiburon, CA, [9]UCSF, San Francisco, CA, [10]UCSF, [11]UCSF-Box 0500, San Francisco, CA, [12]University of California at San Francisco (UCSF), San Francisco, CA

Purpose: To study the prevalence of extra-glandular manifestations (EGM) in patients with primary Sjögren's Syndrome (pSS) among participants enrolled in the Sjögren's International Collaborative Clinical Alliance (SICCA) cohort.

Methods: We studied 1618 participants (ppts) enrolled in the SICCA cohort. Inclusion required one of the following: symptoms of dry eyes or dry mouth; prior suspicion/diagnosis of SS; positive serum SSA, SSB, RF or ANA; increase in dental caries; parotid gland enlargement; or a possible diagnosis of secondary SS. We excluded ppts with RA, SLE or scleroderma (n=87) from this analysis. Ppts underwent thorough rheumatologic, ocular and oral examinations. Medical questionnaires were completed and ppts were asked about the presence of thyroid, liver, kidney disease or lymphoma. We then confirmed details of these diagnoses from treating physicians, specifically inquiring about the 8 diseases listed below. The frequency of EGM between the cases and each control group were compared using the chi square statistic.

Results: For the 1529 ppts in this analysis, average age at enrollment was 54 years; 92% were female; 47% were Caucasian, 34% Asian/Pacific islander and 11% Hispanic; 84% had complaints of dry eye symptoms and 90% had complaints of dry mouth symptoms. 635 ppts met the 2002 American-European (AmEu) Consensus Group criteria for pSS. Two "control" groups were defined. Group 1 (N=744) consisted of all ppts who did not meet AmEu criteria. Group 2 (N=264), a subset of Group 1, included ppts who had negative labial salivary gland biopsy (FOCUS score <1), negative anti-SSA/SSB *and* negative ocular staining score (OSS<3). Results are summarized in the table.

Characteristic	pSS Number (%)	Control Group 1 Number (%)	Control Group 2 Number (%)	P1	P2
Number	635	744	264	–	–
RF positive	399 (63)	106 (14)	31 (12)	<0.001	<0.001
ANA ≥ 320	426 (67)	130 (18)	29 (11)	<0.001	<0.001
IgG > 2013	200 (32)	19 (3)	1 (0.4)	<0.001	<0.001
IgA > 463	63 (10)	18 (2)	4 (2)	<0.001	<0.001

PBC	13	4	0	0.011	0.019
Autoimmune hepatitis	5	4	0	0.57	0.15
RTA	3	1	0	0.25	0.26
Glomerulonephritis	2	5	2	0.35	0.36
Lymphoma	2	2	0	0.87	0.36
Neuro Motor Sx	273 (43)	429 (58)	161 (61)	<0.001	<0.001
Neuro Sensory Sx	337 (53)	484 (65)	187 (71)	<0.001	<0.001
Joint stiffness >1hr	171 (27)	288 (39)	115 (44)	<0.001	<0.001
Joint pain/swelling	314 (50)	481 (65)	178 (68)	<0.001	<0.001
Joint Synovitis on exam	53 (8)	63 (9)	20 (8)	0.93	0.7
Raynaud's	105 (17)	94 (13)	26 (10)	0.041	0.01
Lymphadenopathy	44 (7)	38 (5)	13 (5)	0.15	0.26

P1 compares pSS with Group 1 controls
P2 compares pSS with Group 2 controls
Wbc: white blood cell, Hct: hematocrit, PBC: primary biliary cirrhosis, RTA: renal tubular acidosis. Sx: Symptoms

The frequency of positive RF, ANA titer ≥320, hypergammaglobulinemia (IgG and IgA) and low C4 are significantly higher in the patient group vs. control groups. Hematologic abnormalities (leukopenia, anemia and thrombocytopenia) are also more prevalent in the pSS cases. There was no significant difference in the frequency of the 8 diseases studied, with the exception of PBC. Joint and neurological symptoms were common in all three groups but significantly higher in the control groups.

Conclusions: Our results confirm that primary SS is associated with serum auto-antibodies, hypergammagobulinemia, low C4 levels, and hematologic abnormalities. Furthermore, the prevalence of EGM such as thyroid, liver and kidney disease may be lower than reported in previous, smaller studies. While neurological symptoms may be common in pSS patients, our results suggest that the prevalence of these symptoms may be similarly high in control populations, thereby stressing the importance of controls when evaluating these symptoms in pSS. A limitation of our study is the difficulty in fully characterizing EGM due to the large size and international nature of the SICCA cohort.

1899

Germinal Center (GC) Formation in Salivary Gland Biopsies at Diagnosis of Primary Sjögren's Syndrome (pSS) Is a New and Strong Predictor of Non-Hodgkin's Lymphoma (NHL) during Follow-Up. Elke Theander[4], Lilian Vasaitis[3], Eva Baecklund[5], Gunnel Nordmark[5], Gunnar Warfvinge[4], Rolf Liedholm[4], Karl Brokstad[1], Roland Jonsson[1] and Malin V. Jonsson[2]. [1]University of Bergen, Bergen, Norway, [2]University of Bergen, Bergen, Norway, [3]University of Lund, Uppsala, Sweden, [4]University of Lund, Malmö, Sweden, [5]University of Uppsala, Uppsala, Sweden

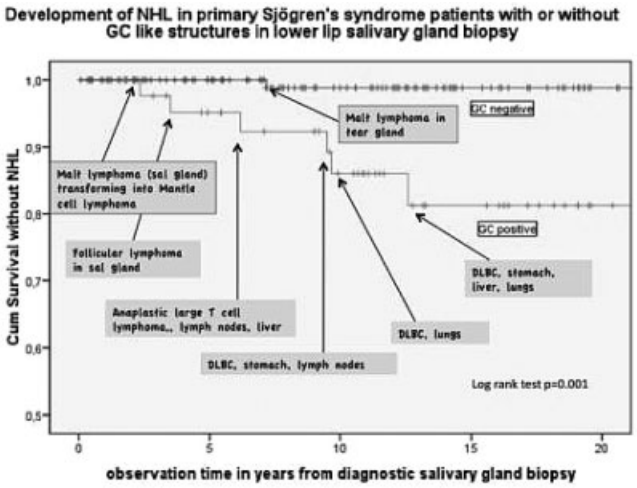
Background: Due to increased risk of NHL in pSS the identification of better markers for lymphoma development is crucial.

Objective: Does GC formation in salivary gland biopsies from the time point of pSS diagnosis predict NHL? Does GC formation correlate with other markers of NHL?

Methods: 174 pSS minor salivary gland biopsies from the Swedish SS centers in Malmoe and Uppsala underwent blind and independent reevaluation by light-microscopy at the Broegelmann Research Laboratory, Bergen, Norway for the presence of GC-like structures.These were determined by a densely packed dark zone and a light zone in biopsies with classical focal infiltration within otherwise normal salivary glands. The presence of NHL was determined by linkage of the local SS registries to the Swedish cancer registry. Observation time was defined as time from the salivary gland biopsy until lymphoma diagnosis, death or end of follow-up. The median (IQ range) time between diagnosing pSS and biopsy was 1 week (0–16). The total observation time was 1859 patient years at risk (range:1 month - 26 yrs).Time between salivary gland biopsy and NHL diagnosis was in median 8 years (range: 2 yrs and 4 months – 12 yrs and 7 months).

Statistics: Risk of developing NHL in patients with or without GC formation was compared by Cox regression analysis and Kaplan Meier statistics/log rank test. Associations between GC formation and other risk variables were determined by χ^2statistics.

Results: In total 136 biopsies showed focal sialadenitis (focus score ≥1) at reevaluation. In 43 (32%) of the biopsies with focal sialadenits GC like structures were detected. Seven patients had developed NHL. Six of the 7 NHL patients (86%) had GC like structures at the time of diagnosing pSS. Patients with GC-like structures had 15 times increased risk of developing NHL compared to those without. Hazard Ratio (HR) 15.4, 95%CI: 1.85–128, p=0.01. Log-rank test: p=0.001. Positive predictive value 16%, negative predictive value 99%.



GC positivity correlated with autoantibodies to SSA/SSB, lymphadenopathy, systemic disease activity (ESSDAI domains), high-risk type of SS (all $p<0.05$).

Conclusion: The presence of GC-like structures in the diagnostic salivary gland biopsies in pSS is highly predictive of lymphoma development with a HR of >15. This marker is an important new prognostic factor in the care of pSS patients. It may be included in guidelines for selection of pSS patients for biological B-cell directed treatment.

1900

IL-7 Receptor Effector T Cells Are Increased in the Inflamed Salivary Glands of pSS Patients and Correlate with Inflammatory Markers. A. Bikker, A. A. Kruize, M. J. G. Wenting, J. W. J. Bijlsma, F. P. J. G. Lafeber and J. A. G. van Roon. Rheumatology & Clinical Immunology, University Medical Center Utrecht, The Netherlands

Background: In patients with primary Sjögren's syndrome (pSS) local T cell-driven inflammation can contribute to destruction of exocrine glands associated with clinical symptoms of dryness. Recently we documented increased IL-7 in labial salivary glands (LSG) of pSS patients that was capable to induce Th1 and Th17 activity and proinflammatory cytokine secretion. IL-7 mediates its effects by signaling through the high affinity IL7R (IL-7Rα subunit in conjunction with the γc chain). We and others have shown that IL-7R+ CD4 T cells that strongly proliferate upon TCR activation, while IL-7R- CD4 T cells remain anergic and can be regulatory of nature. At the level of the salivary gland this could lead to a heightened and ongoing inflammatory response, especially in the presence of increased local IL-7 expression.

Objective: To identify IL-7R expression in the labial salivary gland of and to examine the phenotypical characteristics of IL-7R+ CD4 T cells between pSS and non-Sjögren's syndrome sicca (nSS) patients. Additionally, to study the capacity of soluble human IL-7R in preventing immune activation.

Methods: The presence of infiltrating immune cells and IL-7R+ cells in inflamed salivary glands of pSS patients (n=14) and non-inflamed LSG of nSS patients (n=7) was studied by immunohistochemistry and FACS analysis upon tissue digestion.

Results: In the LSG of pSS patients significantly increased numbers of IL-7R+ cells were found as compared to nSS (pSS vs nSS; 244.3 $\pm$40.7 vs 12.3 $\pm$4.6 cells/mm^2). IL7R+ T cells were found throughout the tissue but mainly in the CD3-rich lymphocytic areas. In the salivary glands of nSS patients only a few resident CD3+ T cells were detected. IL7R+ T cells strongly correlated with local disease parameters (lymphocytic focus score [LFS]; $p\leq0.001$,$r=0.744$ and % IgA+ cells $p\leq0.005$,$r=-0.658$) as well as with immune cells present in the LSG (CD3 $p\leq0.001$, $r=0.890$; CD20 $p\leq0.005$, $r=0.717$; CD1a $p\leq0.005$, $r=0.660$; CD208 $p\leq0.001$, $r=0.763$).

FACS analysis of isolated cells from patients' LSG confirmed a strongly increased percentage of both CD3 and IL-7R+ CD3 T cells in pSS as compared to nSS (both $p<0.01$). Furthermore, abundant IL-7R expression was detected on high proportions of CD4 and CD8 (on average 66% $\pm$ 5% and 56% $\pm$ 4% respectively). Other CD45+ leucocytes and CD45-tissue cells did not or hardly express the IL-7R. IL-7R+ CD3, CD4, and CD8 T cells as percentage of the total LSG cells showed a significant correlation with the LFS ($p\leq0.05$, $r=0.533$; $p\leq0.01$, $r=0.593$; $p\leq0.01$, $r=0.631$ respectively).

Blockade of IL-7R-mediated signaling by soluble human IL-7R furthermore inhibited lymphocyte proliferation that was induced by ligands for Toll-like receptors 7, 8 and 9 (all $p<0.05$).

Conclusions: The abundant presence of IL-7R+ T cells in the inflamed salivary glands of pSS patients, which correlates to inflammation, suggests that increased IL-7 expression could significantly contribute to glandular inflammation by activation of IL-7R+ effector T cells. Blockade of the IL-7R might be a novel therapeutic strategy for pSS.

1901

Immunization with Ro60 Peptide Leads to Sjögren's Like Syndrome in Mice with Appropriate Genetic Background. Biji T. Kurien[1], Sima Asfa[3], Anil D'souza[3], Yaser Dorri[3], Skyler P. Dillon[3], Sherry Hubbel[3], Ali W. Khalili[2], Olga Yeliosof, Yun Jong Lee, Shannon Maier[3] and R. Hal Scofield[3]. [1]Oklahoma Medical Research Foundation, [2]University of Oklahoma, [3]University of Oklahoma Health Sciences Center

Purpose: Our previous studies showed that BALB/c mice are amenable as an animal model for Sjögren's syndrome (SS) with (a) diminished salivary flow (b) intramolecular epitope spreading to Ro 60 autoantigen and (c) salivary gland lymphocytic infiltration upon immunization with Ro 274 peptide derived from Ro 60 autoantigen. We hypothesized that there would be a strain dependent susceptibility for SS induction.

Methods: Fourteen mice each from BALB/c, DBA-2, SJL/J, C57Bl/6 and PL/J strains were used. Seven mice from each strain were immunized (day one) with 50 μg of a linear peptide (273–289 amino acid sequence from Ro 60) or saline emulsified in Freund's Complete Adjuvant (FCA). Subsequent boosts were in Freund's Incomplete Adjuvant. The first, second and third boosts were given on day 7, 27 and 60 respectively. Ro 60 multiple antigenic peptide ELISA, Ro 60 ELISA and immunoblots were performed. Epitope spreading, salivary flow (upon induction with pilocarpine and isoproterenol) and histochemical lymphocytic infiltration were determined. Upon sacrifice, salivary glands were excised and a portion was saved for histopathological studies.

Results: Immunization with Ro-274 linear peptide resulted in anti-Ro-274 antibodies as early as the first bleed in BALB/c, DBA-2 and PL/J strain of mice. A milder anti-Ro 274 response was elicited in the B6 strain of mice by the sixth bleed while the SJL/J mice displayed a very poor response throughout the study. In the Ro-274 peptide immunized group 5/5 BALB/c, 1/5 DBA, 3/4 PL/J mice bound Ro 60 antigen by immunoblot. SJL/J and C57Bl/6 mice did not bind. Except for one DBA control mice that bound Ro 60 antigen on immunoblot the remaining control mice did not make antibodies to this antigen. Ro-peptide immunized BALB/c and DBA mice had lymphocytic infiltration of the salivary glands greater than controls However, salivary flow was significantly decreased only in the BALB/c mice compared to controls.

Conclusions: Only BALB/c mice displayed the complete SS-like condition, with diminished salivary flow, anti-Ro 60 antibodies and salivary gland lymphocytic infiltration upon immunization with Ro 274 peptide. DBA mice had significant salivary infiltrates and anti-Ro 60 antibodies but no salivary dysfunction. PL/J mice made antibodies and had epitope spreading but did not have salivary pathology or dysfunction. C57Bl6 bound the peptide but had no further progression in the model while SJL/J never produced antibodies to the immunogen, These data suggest a stepwise, or quantum, genetic control of the response that leads to a Sjögren's-like illness after Ro-peptide immunization.

Impaired Gastric Emptying in Primary Sjögren's Syndrome. Oskar Hammar, Bodil Ohlsson, Per Wollmer and Thomas Mandl. Skåne University Hospital Malmö, Malmö, Sweden

Purpose: To investigate the prevalence of impaired gastric emptying (IGE) and its relation to autonomic dysfunction (AD), functional bowel syndrome as well as inflammatory and serological variables in patients with primary Sjögren's syndrome (pSS).

Materials: 28 patients with pSS (median age 62 (range 29–65) years, 26 females) according to the American-European Consensus Criteria, without diabetes or other disease affecting autonomic nervous function, were included in the study. The controls consisted of previously investigated healthy individuals, i.e. 50 controls for the octanoate breath test (median age 43 (range 25–59) years, 25 females), 56 controls for the deep-breathing and orthostatic heart rate tests (median age 40 (range 16–59) years, 22 females), 80 controls for the finger-skin blood flow test (median age 43 (range 19–81) years, 37 females), 238 controls for the orthostatic blood pressure test (median age 60 (range 16–96), 106 females) as well as 200 population based controls for the Autonomic Symptom Profile (ASP) questionnaire on autonomic nervous dysfunction symptoms (median age 45 (range 20–69) years, 100 females).

Methods: Gastric emptying was evaluated by the octanoate breath test, from which half time ($t_{½}$) and lag time (t_{lag}) were determined. The results were corrected according to age and gender and expressed as z-scores. AD was evaluated by 5 objective autonomic reflex tests (ART), i.e. the deep-breathing test (expiration/inspiration (E/I)-ratio), the orthostatic heart rate test (acceleration index (AI)), the finger-skin blood flow test (vasoconstrictory (VAC)-index), and the orthostatic blood pressure test (systolic and diastolic blood pressure (SBP & DBP)-ratios). The results were age-corrected and expressed as z-scores by comparison with three previously examined control groups. Patients also filled out the ASP and these results were corrected according to age, gender, height and weight and were mainly expressed as z-scores. Patients were also assessed regarding symptoms of functional bowel syndrome as well as by inflammatory and serological tests. For comparison between groups the Mann-Whitney-U test and Fisher's exact test were used and for correlations the Spearman rank correlation test.

Results: The $t_{½}$ and the t_{lag} were significantly prolonged in patients compared to controls (1.18 (−0.71, 2.06) vs. −0.06 (−0.72, 0.74); p=0.03 and 1.40 (−0.14, 3.11) vs. −0.03 (−0.57, 0.66); p=0.00 respectively). Thus 43% of pSS patients presented signs of IGE whilst 29% fulfilled criteria for gastroparesis. Significant correlations between t_{lag} and increased levels of IgG (p=0.03) and erythrocyte sedimentation rate (ESR) (p=0.02) were found. In addition, rheumatoid factor (RF) seropositives showed objective signs of IGE to a greater extent than RF seronegatives. No associations between IGE, ART variables, ASP variables or functional bowel syndrome were found.

Conclusions: Impaired gastric emptying was common in pSS. Associations with inflammatory and serological features of pSS could imply immunological mechanisms behind the IGE. Objective signs of IGE were not associated with objective or subjective signs of AD nor functional bowel syndrome.

1903

Increased Numbers of IL-7Rα-CD25+FoxP3+ T Cells in pSS Patients Do Not Prevent Th1 and Th17 Induction by IL-7. A. Bikker, F. M. Moret, A. A. Kruize, J. W. J. Bijlsma, F. P. J. G. Lafeber and J. A. G. van Roon. Rheumatology & Clinical Immunology, University Medical Center Utrecht, The Netherlands

Background: In patients with primary Sjögren's syndrome (pSS) local T cell-driven inflammation can contribute to destruction of exocrine glands associated with clinical symptoms of dryness. Recently we documented increased IL-7 expression in salivary glands of pSS patients that was capable to induce Th1 and Th17 activity and proinflammatory cytokine secretion by mononuclear cells from peripheral blood. Previously, a specific subset of T cells, expressing the receptor for IL-7 (IL-7R; IL-7Rα subunit in conjunction with the γc chain) has been classified as pro-inflammatory responder T cells. These T cells could potentially activate B cells and monocytes and also induce tissue damage. In contrast, T cells lacking the IL-7Rα and expressing CD25 and FoxP3 are said to be regulatory of nature. A shift in the balance between these two opposing subsets could lead to an increase in local inflammation and eventually cause tissue destruction, especially in the presence of increased IL-7 levels.

Objective: To examine the phenotypical characteristics of IL-7Rα+ and IL-7Rα- CD4 T cells and the possible imbalance between these immune cells in pSS patients versus healthy controls (HC) and the functional consequences this has for IL-7R-mediated T cell activation.

Methods: Expression of CD25, and FoxP3 on IL-7Rα (CD127) positive and negative CD4 T cells from 15 pSS patients and 15 HC was assessed using FACS analysis. The functional properties of IL-7Rα+ and IL-7Rα- CD4 T from pSS patients were tested in vitro upon α-CD3 T cell stimulation (n=9). Also, the capacity of IL-7 to activate total CD4 T cells from pSS patients as compared to HC was tested in coculture with monocytes (n=6).

Results: IL-7Rα- and IL-7Rα-CD25+ T cells (both p<0.01) were significantly increased in blood of pSS patients as compared to HC. This was in contrast to T cells defined by CD25 alone. IL-7Rα- and IL-7Rα-CD25+ T cells contained a high % of Foxp3 expressing T cells (70% and 94% resp.), but this did not differ between patients and HC. IL-7Rα+ CD4 T cells strongly proliferated upon activation in vitro TCR triggering (6812 ± 3067 cpm), whereas IL-7Rα-CD25+ T cells were anergic (107 ± 28 cpm). Despite increased numbers IL-7Rα-CD25+FoxP3+ T cells the proliferative capacity of total CD4 T cells to respond strongly to IL-7 was not prevented in pSS patients as compared to HC. Also, IL-7 induced strong expression of IFNg, IL-17 and to a lesser extent IL-4 (on average from 112 ± 52 pg/ml to 1886 ± 477 pg/ml, from 45 ± 17 pg/ml to 512 ± 129 pg/ml, from 103 ± 84 pg/ml to 473 ± 169 pg/ml respectively, all p<0.001) by CD4 T cells which was similar in pSS patients and HC.

Conclusion: This study reveals that IL-7R+ cells are highly proliferating cells that systemically respond strongly to IL-7, despite an increased number of FoxP3-expressing (CD25+)IL-7Rα- T cells. These data suggest that increased IL-7 expression could contribute to glandular inflammation by activation of IL-7Rα+ responder T cells.

Interferon Type I Signature in Monocytes in Primary Sjögren's Syndrome. Zana Brkic[1], Cornelia G. van Helden-Meeuwsen[1], Joop van der Merwe[1], Hemmo A. Drexhage[1] and Marjan A. Versnel[2]. [1]Dept Immunology, Rotterdam, The Netherlands, [2]Dept Immunology, Erasmus MC, Rotterdam, The Netherlands

Establishment of the diagnosis of primary Sjögren's syndrome (pSS) is difficult due to lack of specific diagnostic biomarkers and the heterogeneity of the disease. If, however, specific diagnostic biomarkers based on pathogenic pathways could be found, this heterogenic group of patients could be divided into different subgroups. This could eventually lead to new options for evidence-based individualized therapies. Using microarray analysis we described an Interferon (IFN) type I induced signature in monocytes of pSS patients (Wildenberg et al., 2008). B-cell activating factor of the tumour necrosis factor family (BAFF) is an IFN type I inducible factor recently found to be involved in the pathogenesis of pSS.

The aim of this study was to determine the prevalence of the IFN type I signature in a large group of pSS patients and relate it to complement levels, immunoglobulin levels, in vivo BAFF expression by monocytes, and the disease activity.

The expression of monocyte RNA profiles was determined by Real time Quantitative Polymerase Chain Reaction (RQ-PCR) in 50 pSS patients and 35 healthy controls. The disease activity of the pSS patients was determined by use of the Sjögren's Syndrome Disease Activity Index (SSDAI). Using Enzyme-Linked Immuno Sorbent Assay (ELISA), complement and immunoglobulin levels were determined.

We found a significant increased expression of the IFN type I inducible genes (IFN type I signature) in 40% of pSS patients compared to healthy controls. A significant positive correlation was found between the IFN type I signature and the expression of BAFF mRNA (r=0.771, p<0.001), IgG level (r=0.288, p=0.045) and disease activity (r=0.476, p=0.034). A significant negative correlation was found between C3 (r=0.450, p=0.016), C4 (r=0.415, p=0.031) and the IFN type I signature.

We conclude that determination of the IFN type I signature in pSS can be used to identify a subgroup of pSS with a high BAFF mRNA expression, high level of IgG, high disease activity and low complement level. This knowledge opens new doors for specific treatment of this subgroup by blocking the IFN type I activity.

Is Retreatment with Rituximab in Patients with Primary Sjögren's Syndrome Safe and Effective? Petra M. Meiners, Arjan Vissink, Jiska M. Meijer, Fred K. L. Spijkervet, Cees G. M. Kallenberg and Hendrika Bootsma. University Medical Center Groningen, Groningen, The Netherlands

Purpose: To assess the treatment outcome of retreatment with rituximab in patients with primary Sjögren's syndrome (pSS).

Methods: Thirty-seven patients with pSS, all fulfilling the revised European–US criteria, were subjected to repeated rituximab treatments (up to 4 courses, 65 courses in total). Retreatment was started on basis of return of complaints after previous treatment (objective: return of B cells, increase of IgM-rheumatoid factor level (IgM-Rf), decrease of salivary flow and subjective symptoms: e.g. sicca complains, fatigue, and/or extraglandular manifestations). Sixteen patients received 1 course, 16 patients received 2 courses, 3 patients received 3 courses and 2 patients received 4 courses of rituximab.

Safety of rituximab (re)treatment was assessed in all patients. Efficacy was assessed up to 24 weeks after each course. Stimulated whole saliva (SWS) was chosen as primary end-point. Secondary end-points were IgM-Rf and level of general fatigue (Multidimensional Fatigue Inventory; MFI).

Results: *Safety*

The first 8 patients were treated with 4 infusions of rituximab per course (375 mg/m2 per infusion; premedication 25mg prednisolone i.v.); 5 of these patients were retreated. Because of a high occurrence of serum sickness-like disorder in this initial cohort of pSS patients (in 3 out of 13 courses), the treatment schedule was changed; patients were treated with 2 infusions of rituximab per course (1000 mg per infusion; premedication 100 mg prednisolone i.v., 1000 mg oral paracetamol and 2 mg clemastine i.v.). Both courses were accompanied by a tapering dosage of oral prednisone 60-15 mg/day in 5 days afterwards. Serum sickness-like disorder occurred in 2 patients after the schedule had changed (in 2 out of 52 courses).

Efficacy

After initial treatment, a rapid decrease in peripheral B cells occurred in all patients. In rituximab treated pSS patients, SWS stayed at the same or a higher level during follow-up, whereas SWS declined in untreated patients. At 24 weeks after the first course of rituximab, there was still a decrease in IgM-Rf levels and a decrease in general fatigue compared to baseline. Next a gradual return of the various complaints to baseline was observed. Most, but not all, complaints had returned to baseline by the 9th month. Additional treatments with a second, third and fourth course led to results comparable to initial treatment.

Conclusion: Rituximab was shown to be effective for 6–9 months in pSS patients after the first course of rituximab. Additional courses of rituximab resulted in a comparable beneficial effects in pSS patients on functional parameters, serological parameters and fatigue. Higher doses of corticosteroids led to a reduction of the occurrence of serum sickness-like disorder. Based on these interim results, additional courses with rituximab seem to be a safe and effective treatment for pSS.

Molecular and Cellular Evolution of Functional Tertiary Lymphoid Structures in Salivary Glands of NOD Mice. Elisa Astorri[3], Michele Bombardieri[3], Elisa Corsiero[3], Francesca Barone[1], Gordon Proctor[2] and Costantino Pitzalis[3]. [1]Birmingham University, Birmingham, United Kingdom, [2]King's College, London, London, United Kingdom, [3]Queen Mary University London, London, United Kingdom

Background: Tertiary Lymphoid Structures (TLSs) formation is a common feature of chronic inflammatory diseases including Sjogren's syndrome (SS). We recently showed that these ectopic structures acquire functional properties typical of secondary lymphoid organs and are capable of supporting autoreactive B cell activation and autoantibody production as demonstrated by expression of activation-induced cytidine deaminase (AID) and Ig class switching. Dissecting TLSs dynamics in humans is technically and ethically challenging. Thus, we used the NOD mouse model, a spontaneous model of autoimmune sialoadenitis, to characterize the cellular and molecular basis of autoreactive B cell activation and evolution of functional Ectopic Lymphoid Structures (ELS) in the chronically inflamed NOD salivary glands.

Methods: Submandibolar (SUBM) glands from 110 female NOD mice from 4 to 35 weeks of age were collected. Paired snap-frozen, OCT-embedded samples were analysed by immunohistochemistry (IHC) for T and B lymphocytes (CD3/CD20) in order to evaluate immune cell infiltration and the degree of B/T cell segregation. ELS were detected by staining for FDC-M1 (follicular dendritic cell networks), GL7 (germinal centre B cells) and AID (marker for ELS functionality). Characterization of B cell subsets within the infiltrates was carried out by immunostaining and by FACS analysis with CD19, CD21, CD23, B220, IgD, IgM, CD1d and CXCR5 antibodies. Quantitative TaqMan real-time PCR was performed to investigate the mRNA expression of ELS related genes. The same analysis was performed in sex/age matched Balb/c mice as controls.

Results: NOD infiltrates in SUBM glands displayed progressive features of ELS from week 8, with 75% of mice developing B/T cell segregation, FDC networks and GL7+ ectopic germinal centers (GCs) from week 20. Formation of ectopic GCs was always associated with B/T segregation. Evolution of TLSs was closely associated with mRNA upregulation of genes regulating ectopic lymphoid tissue organization and function such as lymphoid chemokines CXCL13/CCL19 and their specific receptors CXCR5/CCR7, lymphotoxins and B cell survival factors BAFF and APRIL. In agreement with CXCL13/CXCR5 mRNA expression, B cells infiltrating NOD SUBM glands display strong CXCR5 expression and were mostly characterised by a follicular phenotype (B220+/IgD+/IgMlow/CD23+/CD21low) as demonstrated by both IHC and FACS analysis on isolated cells. Finally, functionality of ELS was demonstrated by expression of AID mRNA and protein within FDC networks, which paralleled the detection of circulating SS-related autoantibodies.

Conclusion: This work provided the first in depth characterization of the cellular and molecular mechanisms underlying the evolution of functional TLSs within SUBM infiltrates of NOD mice. These data strongly support the hypothesis that B cells can be activated within TLSs in the target organ and promote an in situ autoantibody response. Overall, these data support the critical importance of ELS formation in chronic autoimmune inflammation and identified NOD mice as a suitable model to test therapeutic strategies aimed at modulating B cell functionality.

1907

New Classification Criteria for Childhood Sjögren's Syndrome. Naoto Yokogawa[8], Scott M. Lieberman[1], Sharon M. Bout-Tabaku[3], Faizan Alawi[7], Juan P. Palazzo[6], Martha Guttenberg[2], David D. Sherry[5] and Frederick B. Vivino[4]. [1]Children's Hosp of Philadelphia, Philadelphia, PA, [2]Children's Hosp of Philadelphia, [3]Nationwide Children's Hospital, Columbus, OH, [4]Penn Presbyt Med Ctr, Philadelphia, PA, [5]The Children's Hospital of Philadelphia, Philadelphia, PA, [6]Thomas Jefferson Univ., [7]Univ. of Pennsylvania, [8]Univ. of Pennsylvania/Tokyo Metropolitan Tama Medical Center

Purpose: To develop new classification criteria for childhood Sjögren's syndrome (SS).

Background: Adult classification criteria for SS have not been validated in children and currently proposed pediatric criteria lack diagnostic sensitivity.

Methods: Retrospective review of medical records of 41 patients (pts) was performed at Children's Hospital of Philadelphia and the Penn Sjögren Center to identify cases of suspected pediatric SS. Diagnosis by physician global assessment required 1) symptom onset at age <20 yrs, 2) consensus agreement on diagnosis by pediatric and adult rheumatologists, 3) abnormal serologies and/or lip biopsy. Pts with overlapping autoimmune disease were not excluded. Clinical presentation, serologies, objective tests for sicca and histopathology were reviewed. All available salivary gland biopsies were blindly reviewed by oral pathologists to calculate a focus score (FS) and compared to biopsy findings from non-SS pts. Pts were also classified as childhood SS (score:3 or more) or non SS (score 2 or less) using a novel scoring system (maximum = 8) based on a modification of American-European Consensus Group (AECG) criteria (Vitali et al, 2002).

		Point
Sicca symptoms	Dey eye (I) AND dry mouth/parotid swelling (II)*[1]	2
	Dry eye (I) OR dry mouth/parolid swelling (II)	1
	No sicca symptoms	0
Objective findings	Abnormal eye exams (III) AND abnormal salvary flow (V)	2
	Abnormal eye exams (III) OR abnormal salivary flow (V)	1
	Normal eye exams and normal salivary flow	0
Laboratory findings	Positive SSA and/or SSB (VI)	2
	Positive ANA AND Negative SSA/SSB	1
	Negative ANA/SSA/SSB	0
Biopsy findings	Focus score≥ 1 OR characteristic findings of SS*[2]	2
	Presence of focus AND Focus Score<1	1
	Absence of focus	0

Childhood SS: total score≥3 points
*[1]Include parotid enlargement by radiological study
*[2]Parotid biopsy may be sufficient to diagnose SS.

Results: Following global assessment and long term follow-up of the pediatric cohort (41 pts), 35 pts had confirmed childhood SS, 3 pts had suspected but unconfirmed SS, and 3 pts were diagnosed as HIV, sarcoidosis, or IPEX syndrome. Using the novel scoring system, all 35 pts with definite childhood SS were classified as SS and all 3 pts with other final diagnosis were classified as non SS.

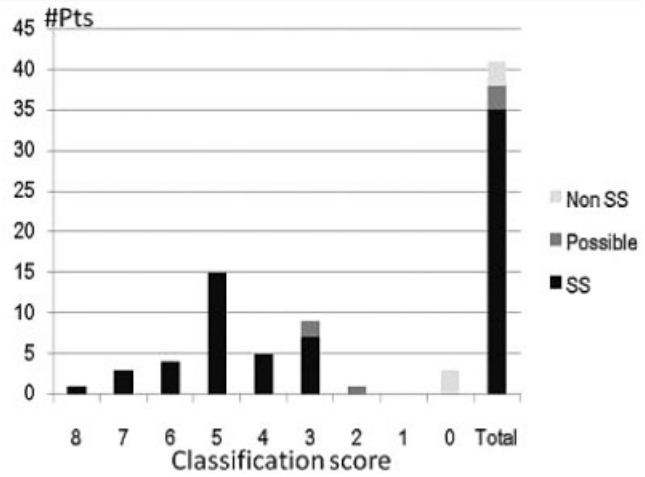

Figure 1.

An expert oral pathologist blindly calculated FS in 21 pts. Among 17 pts with definite childhood SS, FS and Classification Score were positively correlated ($R=0.67$ $p<0.005$) and 8 pts had FS less than 1.

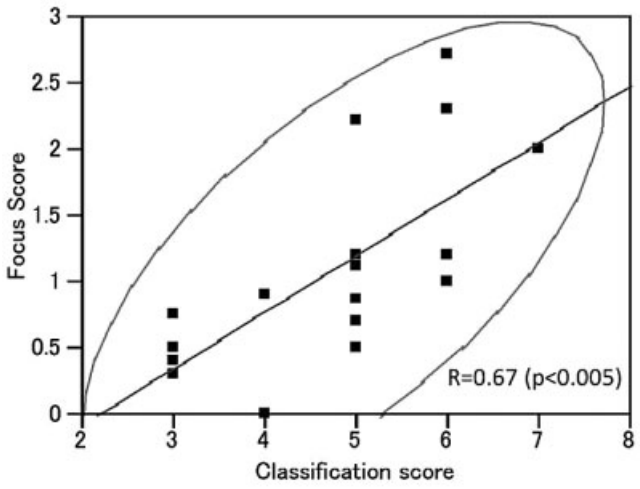

Figure 2.

Conclusions: Inclusion of the presence of ANAs and any focal lymphocytic sialadenitis (both more clinically significant in children than adults) in classification criteria for childhood SS can be used to maximize diagnostic sensitivity in order to facilitate earlier treatment and prevent long-term complications.

1908

New Insights in Sjögren Syndrome Associated Peripheral Neuropathies: The Small Fibre Neuropathy and Its Clinical, Immunological and Neurophysiological Features from a Moncentre Cohort of 24 Patients. Damien Sène[2], Jean-Pascal Lefaucheur[1], Julien Haroche[2], David Saadoun[2], Baptiste Hervier[2], Jean-Charles Piette[2], Zahir Amoura[2] and Patrice Cacoub[2]. [1]Henri-Mondor Hospital, [2]Pitié-Salpêtrière Hospital

Objective: Primary Sjögren syndrome (pSS) may account for 9 to 30% of causes of sensory small fibre neuropathies (SFN), clinically characterized by sensory painful symptoms mostly associated with normal clinical and electromyographic examinations. Nevertheless, the main features of SFN have never been evaluated in a large cohort of pSS-patients. The aim of this study was to analyze the clinical, immunological and neurophysiological features of pSS-associated SFN.

Patients and Methods: 24 consecutive pSS-patients (according to Americano-European group criteria consensus revised on 2002) presenting a definite SFN were included. The SFN was defined by the presence of sensory painful symptoms with a DN4 score ≥ 4 and the evidence of abnormal nerve small fibre neurophysiological tests, including laser evoked potentials (LEP), quantitative sensory test (QST) and sensory skin reflex (SSR). The 24 included patients were compared to 89 SS-patients without peripheral neuropathy.

Results: the 24 patients included 20 female (83%) and 4 men (17%) with a mean age of 64 ± 10 years. For 21 patients (87.5%), SFN led to pSS diagnosis. SFN involved both upper and lower limbs for 19 patients (79%) and lower limbs alone for 5 patients (21%). The neurophysiological tests abnormalities included altered LEP in 21 patients (87.5%), abnormal QST in 21 patients (87.5%) and abnormal SSR in 13 patients (54.2%).

Compared to the 89 pSS-patients who did not present with a peripheral neuropathy, patients with a pSS-associated SFN were older at the time of pSS diagnosis (63 ± 10.5 vs 48.5 ± 14 years; $P<10^{-4}$), and had more frequently a central nervous system involvement (25% vs 2%; $P<10^{-4}$). They were featured by a lower frequency of serum B cell activation markers, i.e, less often positive ANA (58% vs 90%; $P<10^{-3}$), anti-SSA (37.5% vs 73%; $P=0.001$), anti-SSB (12.5% vs 42%; $P=0.008$) and rheumatoid factor (37.5% vs 68%; $P=0.008$), and lower serum gammaglobulins levels (12.5 ± 5 vs 16 ± 7 mg/L; $P=0.0045$).

Conclusion: Our study reported for the first time the main features of SFN in pSS patients. Our results showed that patients with a pSS-associated SFN are characterized by an older age at SS diagnosis and a more frequent CNS involvement, and a distinctive immunological profile hallmarked by a lower frequency of serum B cell activation markers (ANA, anti-SSA, anti-SSB, rheumatoid factor, and gammaglobulins).

1909

Novel Lupus Susceptible Gene Polymorphisms in Patients with Sjögren's Syndrome in Japanese Population. Tetsuya Horita[1], Hisako Nakagawa[1], Takashi Kurita[1], Toshio Odani[1], Yuichiro Fujieda[1], Kotaro Otomo[2], Masaru Kato[1], Shinsuke Yasuda[1], Tatsuya Atsumi[1] and Takao Koike[1]. [1]Medicine II, Hokkaido University, Sapporo, Hokkaido, Japan, [2]Medicine II, Hokkaido University

Background: Genetic background of Sjögren's syndrome (SS) is still unknown. SS can occur alone (primary SS) or in conjunction with other autoimmune diseases such as systemic lupus erythematosus (SLE) or rheumatoid arthritis (secondary SS). Several novel lupus susceptible genes were reported in the recent candidate gene approaches and genome wide association studies in Caucasian population. In this study, we analyzed these lupus susceptible gene polymorphisms in patients with SS in Japanese population.

Patients and Methods: This study comprised 190 SS patients and ethnically matched 428 healthy controls. Patients with SLE were excluded. B lymphocyte specific tyrosine kinase (BLK) (rs13277113), B-cell scaffold protein with ankyrin repeats 1 (BANK1) (rs10516487 and rs3733197), signal transducer and activator of transcription 4 (STAT4) (rs7574865), interferon regulatory factor 5 (IRF5) (rs2004640), tumor necrosis factor ligand superfamily member 13 (TNFSF13) (rs11552708), tumor necrosis factor alpha induced protein 3 (TNFAIP3) (rs13192841, rs2230926 and rs6922466), tumor necrosis factor ligand superfamily member 4 (TNFSF4) (rs844644), rs10798269 in 1q25.1 region were evaluated using TaqMan Genotyping Assay. Allele frequencies in each polymorphism were compared using chi-square test and the related risk was approximated by the odds ratios. In addition, stratification analysis by anti-SS-A and anti-SS-B was performed. The genetic risk scores composed of the numbers of risk alleles in SS susceptible genes were also calculated and the scoring system was evaluated.

Results: The allele frequencies of lupus risk in SS were significantly higher in BLK (odds ratio (OR) $=1.61$, 95% confidence interval (CI):1.21–2.15), STAT4 (OR=1.83, 95%CI:1.43–2.36), IRF5 (OR=1.40, 95%CI:1.07–1.82) and rs10798269 in 1q25.1 region (OR=1.62, 95%CI:1.20–2.18), compared with those in healthy controls. No significant associations were found in BANK1, TNFSF13, TNFAIP3 and TNFSF4. In stratification analysis. STAT4 was associated with the presence of both anti-SS-A and anti-SS-B, whereas BLK and SNP (rs10798269) in 1q25.1 region were associated with anti-SS-A and IRF5 was associated with anti-SS-B. In genetic risk scoring system for SS, the presence of five or more risk alleles in 4 common susceptible genes (BLK, STAT4, IRF5 and 1q25.1) was strongly associated with SS (OR=2.79, 95%CI:1.89–4.14).

Conclusions: BLK, STAT4, IRF5 and 1q25.1 region were not only lupus susceptible genes but SS susceptible genes in Japanese population. SS share, in part, common genetic background with SLE.

Objectives: To determine whether common symptoms of dryness, fatigue and pain differed between patients with or without systemic complications in primary Sjögren's syndrome (SS).

Methods: Data concerning primary SS patients were analyzed from 2 different prospective studies: 1–230 patients included by 21 SS experts participating in an EULAR study for the development of the EULAR Sjögren's Syndrome Patient reported Index (ESSPRI), and 2–354 patients from the French prospective SS cohort (ASSESS). All patients completed the ESSPRI (0–10 numerical scales for pain, fatigue, and dryness features), Sicca Symptoms Inventory (SSI), Profile of Fatigue and Discomfort (PROFAD) questionnaires and a 0–10 patient global assessment (PGA). Severity of each symptom was compared between patients with and without systemic involvement.

Results: 140 (60.9%) of the 230 patients from the EULAR study (mean age = 55.9 ± 13.9 yrs, 219 [95.6%] females, mean disease duration = 8.3 ± 5.6 yrs, 80.0% anti-SSA and/or SSB positive), and 253 (71.5%) 354 patient from the ASSESS cohort (mean age = 57.5 ± 12.9 yrs, 332 [93.8%] females, mean disease duration = 6.6 ± 5.8 yrs, 60.7% anti-SSA and/or SSB positive) had past or present systemic involvement. Systemic involvements included articular (if arthritis), cutaneous, peripheral or central nervous system, pulmonary, muscular (if myositis) involvements or B-cell proliferative disorder.

Patients with past or present systemic complications had higher levels of symptoms severity for fatigue, and limb pain, but not for dryness.

	EULAR Study			ASSESS cohort		
	Systemic N=140	Non-systemic N=90		Systemic N=140	Non-systemic N=90	
Fatigue	6.4 ± 2.7	5.4 ± 3.0	p=0.01	6.2 ± 2.7	5.5 ± 2.6	p=0.04
Pain	5.6 ± 2.9	4.2 ± 3.0	p=0.0009	5.1 ± 2.9	3.9 ± 2.9	p=0.00009
Dryness	6.7 ± 2.3	6.4 ± 2.4	p=0.53	5.4 ± 2.3	5.0 ± 2.3	p=0.20
ESSPRI	6.2 ± 2.1	5.4 ± 2.2	p=0.004	5.6 ± 2.2	4.8 ± 1.9	p=0.03
PROFAD	4.2 ± 2.4	5.1 ± 2.4	p=0.007	4.9 ± 2.2	3.9 ± 1.9	p=0.0008
SSI	5.0 ± 2.2	5.3 ± 2.2	p=0.26	5.3 ± 2.3	4.9 ± 2.0	p=0.18

Similarly, PROFAD and ESSPRI scores were higher in patients with systemic features, but SSI scores were not.

Conclusion: In 2 independent cohorts of primary SS patients, we showed that patients with systemic complications have higher levels of fatigue, pain, but similar levels of dryness, compared to those without. Thus, alterations of common patient reported outcomes, present in most of the patients with pSS, are more intense in patients with systemic complications. This supports the interest of using ESSPRI in both groups of patients with and without systemic complications.

1911

Primary Sjögren's Syndrome-Associated Non Ataxic Sensory Neuropathies and Sensorimotor Neuropathies Are Characterized by Distinctive Immunological Profiles. Damien Sène[2], Moez Jallouli[2], Jean-Pascal Lefaucheur[1], David Saadoun[2], Thierry Maisonobe[2], Julien Haroche[2], Marie-Claude Diemert[2], Lucile Musset[2], Jean-Charles Piette[2], Zahir Amoura[2] and Patrice Cacoub[2]. [1]Henri-Mondor Hospital, [2]Pitie-Salpetriére Hospital

Objective: To characterize the relationship between primary Sjögren's Syndrome (pSS)-associated peripheral neuropathies (PN) and markers of B cell monoclonal proliferation and chronic activation.

Patients and Methods: 120 consecutive patients presenting with a definite pSS were included. Serum markers of chronic B-cell activation included auto-antibodies and hypergammaglobulinemia. Monoclonal B-cell proliferation markers included mixed cryoglobulin, monoclonal gammopathy, abnormal κ/λ free light chain (FLC) ratio or B-cell non Hodgkin lymphoma (B-NHL).

Results: A definite PN was present in 30 patients (25%) including 7 patients with a sensorimotor neuropathy (23%), 3 patients with an ataxic sensory neuropathy (10%) and 20 patients with a non-ataxic sensory neuropathy (67%). Patients with a sensorimotor neuropathy differed from those without PN by higher rates of monoclonal B-cell proliferation markers, i.e. mixed cryoglobulin (57% vs. 11%; P=0.008), monoclonal gammopathy (71% vs. 17%; P=0.004), higher FLC ratio (2.7±1.5 vs. 1.7±1.8; P=0.024) and B-NHL (57% vs. 3%; P<0.001). Patients with non-ataxic sensory neuropathy were featured by a higher age (57.5±10.7 vs. 48.7±14.3 years; P=0.007), a more frequent CNS involvement (15% vs. 2%; P=0.04) and a lower prevalence of chronic B-cell activation serum markers, i.e., ANA (60% vs. 90%; P=0.003), anti-SSA (Ro) (40% vs. 72%; P=0.009), anti-SSB (La) (15% vs. 41%; P=0.039), RF (37% vs. 67%; P=0.02), and hypergammaglobulinemia (35% vs. 64%; P=0.023). In multivariate analysis, a sensorimotor neuropathy was associated with the presence of B-NHL (OR=39.0; P<0.001), whereas a non-ataxic sensory neuropathy was associated with the presence of a CNS involvement (OR=17.0; P=0.025) and ANA (OR=0.07; P<0.001).

Conclusion: Up to 25% of pSS-patients presented with peripheral neuropathy, which was predominantly a sensory neuropathy. Distinctive immunological profiles were found according to the type of SS-associated neuropathy, as non-ataxic sensory neuropathy was hallmarked by a low prevalence of B-cell activation markers and sensorimotor neuropathy by a high prevalence of B-cell monoclonal proliferation markers

Prognosis of Non-Hodgkin Lymphomas in Primary Sjogren's Syndrome. Michael Voulgarelis, Panayiotis D. Ziakas, Aristea Papageorgiou, Athanasios G. Tzioufas and Haralampos M. Moutsopoulos. Dept of Pathophysiology, Medical School, University of Athens, Greece

Background: Sjogren's syndrome (SS) has been associated with the development of Non-Hodgkin's lymphomas (NHL).

Methods: Fifty-three consecutive lymphoma cases (51 female/2 male), with a median age of 54 years (range 28 to 90 years) were retrospectively analyzed. Overall survival (OS), event-free survival (EFS) and standardized mortality ratio (SMR) were calculated. An event was defined as relapse, treatment failure, progression, transformation, or death, whichever occured first following lymphoma diagnosis.

Results: Mucosa-associated lymphoid tissue (MALT) lymphomas constituted the majority (59%) of lymphoma subtypes, followed by nodal marginal zone lymphomas (NMZLs) (15%), diffuse large B-cell lymphomas (DLBCLs) (15%) and other histologies (11%).

After a long median follow-up of 40.8 months for the entire lymphoma cohort, 6 patients died. Median survival was not reached, and 3-year OS was 0.96 (95% CI 0.83 to 0.98). Median EFS was 85.3 months. The corresponding

age-sex adjusted SMR of lymphoma compared to the general population was 3.25, suggesting a shorter life expectancy.

In nine localized MALT lymphomas with low International prognostic index(IPI), treatment was withheld. Among these cases, only one transformed to DLCBL. Eight patients with limited stage MALT and extraglandular manifestations were treated with rituximab monotherapy. The remaining MALT cases were treated with combined modality protocols. Treatment resulted in high complete response rates (94%), upon completion of therapy. Overall, 3-year OS and EFS were 0.97 and 0.78 respectively for MALT cases.

Combined immunochemotherapy was the standard therapeutic intervention for DLCBLs, resulting in 100% OS and EFS at 3 years. NMZLs had a disappointing outcome (3-year OS 0.80 and EFS 0.53), warranting the urgent need for a new standard of treatment.

Conclusion: Our results explicitly describe the course and prognosis of SS-associated lymphomas and highlight the need for a risk-stratified treatment approach.

Risk of Non-Hodgkin's Lymphoma in Primary Sjögren's Syndrome. Svein J A. Johnsen[3], Johan G. Brun[1], Tom B. Johannesen[2], Lasse Gøransson[3], Karstein Haldorsen[1], Roland Jonsson[4] and Roald Omdal[3]. [1]Haukeland University Hospital, [2]Norwegian Cancer Registry, [3]Stavanger University Hospital, [4]University of Bergen

Background: It is well known that patients with primary Sjögrens syndrome (PSS) have an increased risk for developing non-Hodgkin lymphoma (NHL), although the exact risk reported has varied in different studies. Such discrepancies could be due to the use of different criteria applied for PSS diagnosis over time, and the inclusion of more or less biased patient samples. The aim of this study was to assess the risk of NHL and other hematological malignancies in a well-defined population in Western Norway applying the widely accepted American-European Consensus Group criteria for PSS (1).

Methods: All patients with PSS were identified in the two counties Hordaland and Rogaland (896 840 subjects—18.59% of the total population of Norway). A linked registry study between the PSS registry and the Cancer Registry of Norway was performed, and in addition all medical files were screened for ascertainment of diagnoses. The risk of NHL in PSS patients was compared with the risk in the general population based on the Cancer Registry data. Descriptive statistics with mean, SD and ranges were used to present patient demographic data.

Results: As of June 1st 2009, 432 Caucasian PSS-patients were alive, of which 406 (94%) were women and 26 men (6%). Mean age was 62 years, SD 13.2 [range 16–95]. Mean age at diagnosis was 53.8 years, SD 13.5 [range 15–89]. Mean duration of disease PSS was 8.65 years, SD 5.2 [range 1–35]. Total follow-up was 3,722 patient years. Five cases of NHL (1.16%) were identified, all marginal zone lymphomas. Three of these were MALT-lymphomas of the salivary glands, one MALT-lymphoma from the lingual tonsil and one extranodal marginal zone lymphoma located in the bone marrow. In addition, the latter patient presented a monoclonal B-cell population consistent with a κ-positive B-cell chronic lymphocytic, also classified as NHL. No high-grade lymphomas were detected.

Conclusion: PSS patients have an increased risk of developing NHL compared with the risk in the general population ($p<0.001$). The risk, however, seems lower than previously reported.

1914

The FMS-Like Tyrosine Kinase3-Ligand (FL) Is a Marker for Lymphoma in Primary Sjögren's Syndrome (SS). Jacques-Olivier Pers[1], Gabriel J. Tobon[1], Jacques E. Gottenberg[7], Raphaèle Seror[4], Valérie Devauchelle[2], Jacques Morel[5], Stéphanie Rist[6], Alain Saraux[3] and Pierre Youinou[1]. [1]Brest University, Brest, France, [2]Brest University, [3]CHU de la Cavale Blanche, Brest Cedex, France, [4]Le Kremlin Bicetre Hospital, [5]Montpellier University, [6]Orleans Hospital, [7]Strasbourg Hospitals, Strasbourg, France

Background: The exocrine glands of patients with primary SS become sites of intense immunological activity and thereby present with tissue damage. Salivary glands exhibit a lymphoproliferative sialadenitis, associates with lymphocyte infiltration and epithelial cell apoptosis. Compared with healthy individuals, patients with SS are at greater risk of developing non-Hodgkin's lymphoma. We recently published that FL, a cytokine implicated in B-cell ontogenesis and malignant proliferation, might unveil primary SS at risk of developing lymphoma (Tobón et al., Arthritis Rheum. 2010).

Methods: In order to confirm this observation, serum levels of FL were measured in 334 patients enrolled in the French cohort of primary SS patients. All fulfilled the European American criteria for SS. Association between FL positivity and: 1- criteria linked to a high risk of lymphoma such as purpura, low C4 levels, enlargement of the parotid glands, monoclonal Ig, cryoglobulinemia; 2- lymphoma development; 3- disease activity according to visual analogic score (VAS) for subjective signs and the EULAR SS Disease Activity Index (ESSDAI).

120 pg/mL of FL was considered as positive (FL+) i.e. 2 SD above the mean of 50 controls. Nevertheless, sensitivity and specificity were calculated at different cut-off values. To compare data FL+ and FL-, we used the chi-square or Fisher exact test for qualitative variables and the Mann-Whitney test for quantitative variables (Statistical Package for the Social Sciences).

Results: Main results are listed in the Table. FL+ patients were younger. The sex ratio, subjective symptoms of dryness and parotidomegaly were not statistically associated to FL. In contrast, purpura and lymphoma, as well as ESSDAI were significantly associated with elevated levels of FL. ROC analysis showed that 175 pg/mL was ideal cut-off to detect the association with lymphoma: sensitivity 44%, specificity 97.5%.

	FL+	FL−
Age (years)	56.59	62.58 ($P<0.0001$)
Sex M/F	5/94	17/240
Parotidomegaly	29/93	90/239
Purpura	16/9	21/235 ($P<0.01$)
History of lymphoma	13/94	5/240 ($P<0.0001$)
VAS sicca	5.12	5.45
VAS pain	4.71	4.82
VAS fatigue	5.94	6.01
ESSDAI	6.68	5.33 ($P<0.05$)

Conclusion: FL is elevated and correlated with history or presence of lymphoma in primary SS 334 patients. The role of FL in B cell proliferation may explain the clinical evolution to B cell lymphoma in some patients and targeting FL open new therapeutic options.

1915

The Role of Immunostaining Against the Panaxonal Protein PGP 9.5 in the Evaluation of Sjogren's Sensory Neuropathies, and the Increased Frequency of Male Sex and Seronegativity to Anti-La/SS-B Autoantibody with Peripheral Neuropathies. Julius Birnbaum, Alan N. Baer and Michael Polydefkis. Johns Hopkins University, Baltimore, MD

Purpose: The frequency of different subtypes of peripheral neuropathies (PNS) in larger number of Sjogren's patients has not been studied using diagnostic techniques which have been validated for other PNS syndromes. Specifically, the quantification of nerves immunostained against the PGP 9.5 panaxonal protein allows for the diagnosis of a "small-fiber" neuropathy affecting unmyelinated nerves. Therefore, we sought to understand the frequency of different subtypes of neuropathies in Sjogren's patients, and to characterize whether Sjogren's patients with neuropathies may have distinguishing demographic, clinical, and immunologic features.

Methods: We characterized the neuropathy occurring in 186 consecutively evaluated Sjogren's patients, by examination, electrodiagnostic studies, and by skin biopsy when there was suspicion for a small-fiber neuropathy. The diagnosis of small-fiber neuropathy was based on decreased intraepidermal innervation (IENF) of unmyelinated nerves immunostained against the PGP 9.5 panaxonal protein. Logistic regression analysis was performed to determine whether the presence of neuropathies (as the dependent variable), was independently associated with demographic, clinical, and autoantibody covariates.

Results: Forty-seven patients had peripheral neuropathies; of 41 patients with sensory neuropathies, 32 patients had neuropathies affecting the unmyelinated nerves, versus 9 patients with axonal sensory neuropathies and ganglionopathies assessed by electrodiagnostic studies. The association of demographic, clinical, and immunologic covariates with peripheral neuropathies was assessed by logistic regression. Male sex ($p=0.04$) and seronegativity to the anti-La/SS-B autoantibody ($p=0.04$) were respecitvely and independently associated with neuropathies.

Conclusions: The most common subtype of neuropathy in Sjogren's patients is a neuropathy targeting the unmyelinated nerves. The integrity of the smaller-fiber, unmyelinated nerves can be assessed by immunostaining against the PGP 9.5 protein 9.5, cannot be assessed by routine electrodiagnostic studies, and may account for the lower frequency of neuropathies reported in larger cohort studies of Sjogren's patients. The increased frequency of male sex and seronegativity of anti-La/SS-B autoantibodies seen in Sjogren's patients with PNS manifestations suggests discriminating hormonal and immunologic mechanisms.

1916

The Temporal Appearance of Symptoms and Signs in Primary Sjögren's Syndrome. Chiara Baldini, Nicoletta Luciano, Pasquale Pepe, Rosaria Talarico, Sara Grossi, Antonio Gaetano Tavoni and Stefano Bombardieri. Rheumatology Unit, Department of Internal Medicine, University of Pisa, Italy.

Aims of the Study: (1) to characterise the clinical presentation of primary Sjögren's syndrome (pSS) in a large cohort of patients and to determine whether epidemiological, clinical and analytical features modulate disease expression; (2) to determine possible changes in clinical and immunological patients'profiles over time.

Methods: We reviewed the case records of 515 pSS patients (17 M: 498 F, mean age 57.4 years, mean follow-up 6.5± 6.4 years) who had attended our Unit in the decades between 1989 and 2009. The diagnosis was made according to either the AECG criteria (390/515) or the European Preliminary Criteria for pSS (125/515). Patients' cumulative clinical and immunologic features were collected. The lag time between the onset of the disease and the onset of each pSS clinical and serological manifestation was recorded in order to group the disease features according to their mean periods of appearance. Logistic regression analysis was applied to explore clinical and serological associations.

Results: Demographic, clinical and immunologic features of the patients are summarised in Table 1.

Disease manifestations	Prevalence (%)	Lag time from the disease onset (yrs)	
Dry mouth/Dry eyes	94%/96%	0.3 ± 0.6/0.2 ± 0.6	At the onset
Arthralgia	63%	0.8 ± 2.7	
Fatigue	45%	0.3 ± 0.7	
Raynaud's phenomenon	26%	0.7 ± 2.7	
Dry vagina	19%	0.5 ± 1.8	
Skin involvement	16%	0.7 ± 1.4	
Difficulty in swallowing	14%	0.3 ± 0.7	
Hypocomplementemia	18%	0.3 ± 0.6	
Hypegammaglobulinemia	48%	0.2 ± 0.7	
Antinuclear antibodies	83%	0.2 ± 0.2	
Anti Ro/SSA/anti La/SSB	62%/28%	0.2 ± 0.4	
Salivary gland enlargement	32%	2.2 ± 4.7	Within the first 5 years
Hematological manifestations	25%	2.3 ± 5.4	
Kidney involvement	1%	1 ± 2	
Arthritis	11%	3 ± 4.2	
Lung	7%	5.8 ± 7.0	
Peripheral nervous system	6%	5.1 ± 6.7	
Central nervous system	0.3%	11 ± 1.4	Late disease manifestations
Lymphoma	3%	17.4 ± 10.8	

Glandular manifestations were generally present at the onset of the disease. Among pSS extraglandular manifestations, arthralgias, Raynaud's phenomenon (RP), skin involvement, fatigue and difficulty in swallowing were also mainly observed at the onset of the disease, and significantly correlated with the positivity for anti-Ro/SSA and hypocomplementemia. Parotid enlargement, cytopenias, kidney involvement, peripheral nervous system and lung involvement were more frequent within the first five years of the disease, especially in seropositive patients and in patients with a lower age at diagnosis. Finally, lymphoma was generally a late disease manifestation with the lymphoproliferative risk increasing over time with an exponential function ($p=0.002$). The multivariate analysis identified a disease duration longer than 9 years ($p=0.006$), salivary glands enlargement ($p=0.003$) and hypocomplementemia ($p=0.03$) as independent variables for lymphoma.

Conclusion: This study confirmed that pSS can be considered as a mild, benign chronic disorder, the most severe lymphoproliferative manifestations being usually late complications of the disease. Epidemiological, clinical and serological features have a significant impact on the clinical presentation of pSS influencing the prevalence of extraglandular involvement and the disease outcome.

1917

Vaccination of Patients with Primary Sjogren's Syndrome Induces IL-7 and Skewed B Cell Maturation with Increased Levels of Plasmablasts Resulting in Higher Titers of Vaccine-Specific IgG Antibodies. Susanna R. Brauner[2], Marika Kvarnstrom[2], Sabrina Goergen[2], Karl A. Brokstad[3], Christina Trollmo[2], Lars Klareskog[1], Roland Jonsson[3], Vivianne Malmstrom[2] and Marie Wahren-Herlenius[2]. [1]Karolinska University Hospital, Stockholm, Sweden, [2]Reumatology Unit, Karolinska Institutet, Stockholm, Sweden, [3]University of Bergen, Bergen, Norway

Background: Multiple immune disturbances underlying disease development and progression have been implicated in Sjogren's syndrome, including defects in the B cell compartment. In this study we used vaccination as a tool for in vivo intervention to understand defects in immune regulation by studying the primary immune response of individuals with primary Sjogren's syndrome, and specifically to characterize B cell development and responses.

Methods: Fourteen SSA/Ro positive women with primary Sjogren's syndrome and 18 gender and age matched healthy controls were vaccinated with A H1N1 influenza vaccine and boosted three weeks later. Blood samples were taken at vaccine administrations, as well as one and three weeks after, with a total of five sample points for each subject. At each sampling total Ig and vaccine specific immunity was analyzed by ELISPOT, ELISA and hemagglutination tests, lymphocyte phenotype was characterized by flow cytometry and routine laboratory tests were performed. Cytokine levels were analyzed in serum using a Luminex assay. Clinical parameters and potential adverse reactions of vaccination were monitored with a clinical questionnaire at each of the five visits.

Results: No significant differences in immunoglobulin levels or lymphocyte compartments were observed between patients and controls at the start of the study. After vaccination, all subjects developed protective immunity as determined by hemagglutination assay. However, already one week after the first vaccination the patients had developed significantly fewer class switched CD19+ B cells ($p<0.05$), and more immature B cells (CD19+IgD+IgM+) persisted in circulation ($p<0.05$). This skewed pattern of B cell maturation remained throughout the whole study. Surprisingly, plasmablasts (CD19lowCD138+) still increased, and were detected at a significantly higher level in patients after the second vaccination ($p<0.01$). In accordance, signficantly higher levels of several innate proinflammatory cytokines (IL-6, IL-10, IL-12p40 and TNF-alpha) as well as IL-7 ($p<0.05$), a B cell promoting cytokine, were induced in the patients. Further, the Sjögren's syndrome patients developed significantly higher titers of IgG vaccine specific antibodies ($p<0.02$). Despite this humoral immune activation in the patients, SSA/Ro52 titers remained unaffected throughout the study.

Several commonly reported adverse reactions to the vaccine were observed. Surprisingly controls reported significantly more fever and myalgia as side effects after vaccinations.

Conclusions: Patients with Sjogren's syndrome respond to vaccination and develop protective immunity. However, the induced titers of vaccine specific antibodies are significantly higher than in controls. Analysis of the immune reactions leading to antibody production revealed a skewed B cell maturation and proinflammatory cytokine response, which may reflect the mechanisms allowing high titers of autoantibodies to develop in autoimmune patients.

1918

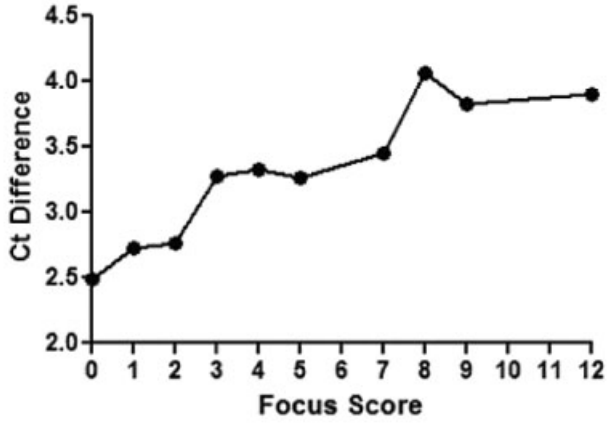
Validation of microRNAs as Biomarkers of Salivary Gland Inflammation in Sjögren's Syndrome. Seyed M. Emamian[1], Ilias Alevizos[1] and Gabor G. Illei[2]. [1]NIDCR, [2]NIDCR, NIH #10 1N114, Bethesda, MD

The diagnosis of Sjögren's syndrome (SS) is based on a number of diagnostic criteria, including the assessment of inflammation (quantified by the focus score) in a minor salivary gland (MSG) biopsy. MicroRNAs (miRNAs) are a group of RNAs, 18–24 nucleotides in length, involved in the regulation of cellular processes. miRNAs are promising as biomarkers as they are resistant to degradation and can be isolated from various sources including formalin-fixed, paraffin-embedded (FFPE) biopsies. In a preliminary study done on frozen MSG biopsies we have demonstrated that the relative expression of two miRNAs showed good association with various degrees of inflammation in a small cohort.

Purpose: To validate hsa-mir-574-3p and hsa-mir-768-3p as biomarkers of inflammation in a larger cohort of subjects.

Methods: the training cohort consisted of 49 subjects 33 with primary Sjögren's patients and 16 non-Sjogren's controls. In the validation cohort 49 subjects had pSS, 26 had sicca symptoms but no SS and 12 were healthy controls. miRNA was isolated from FFPE biopsies from MSGs. The relative expression of hsa-mir-574-3p and hsa-mir-768-3p was determined by calculating the difference of their respective threshold level (ΔCt) from the same quantitative TaqMan Real Time PCR reaction. A one unit difference in the Ct between the two microRNAs represents a two-fold difference of expression between the two microRNAs.

Results: Using a teaching cohort of 49 subjects, we first showed the ΔCt of hsa-mir-574-3p and hsa-mir-768-3p derived from FFPE samples can distinguish samples from Sjögren's from non-Sjögren's MSGs regardless of focus score (p 0.0001, one-way analysis of variance) as well as groups with various degree of inflammation. To validate the applicability of these miRNAs as biomarkers we determined the correlation between individual focus scores and the ΔCt in an independent set of 87 subjects.



A Pearson's correlation analysis showed a significant relationship between ΔCt of hsa-mir-574-3p and hsa-mir-768-3p and focus scores (r=0.85, r2=0.72, p= 0.0001).

Conclusion: The relative expression of hsa-mir-574-3p and hsa-mir-768-3p shows a strong correlation with focus scores in MSGs of Sjögren's patients validating these miRNAs are biomarkers of MSG inflammation and suggesting that they may be used to reduce the subjectivity involved in the diagnosis of SS.

ACR Poster Session C
Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment II
Wednesday, November 10, 2010, 9:00 AM–6:00 PM

1919

Abatacept (ABA) in the Treatment of Psoriatic Arthritis (PsA): 12-Month Results of a Phase II Study. Philip J. Mease[8], Mark C. Genovese[9], Geoffrey S. Gladstein[3], Alan J. Kivitz[2], Christopher T. Ritchlin[11], Paul P. Tak[1], Jurgen Wollenhaupt[7], Jean-Claude P. Becker[4], Sheila M. Kelly[6], Yun Peng[5] and Dafna D. Gladman[10]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Altoona Arthritis & Osteo Ctr, Duncansville, PA, [3]Arthritis Int Med Assoc LLC, Trumbull, CT, [4]Bristol-Myers Squibb, Princeton, NJ, [5]Bristol-Myers Squibb, Pennington, NJ, [6]Bristol-Myers Squibb, Doylestown, PA, [7]Schoen Klinik, Hamburg, Germany, [8]Seattle Rheumatology Associate, Seattle, WA, [9]Stanford University, Sunnyvale, CA, [10]Toronto Western Hospital, Toronto, ON, Canada, [11]University of Rochester Medical Center, Rochester, NY

Purpose: A phase II study evaluating ABA in PsA patients (pts) previously exposed to disease-modifying antirheumatic drugs (DMARDs) including anti-TNF agents demonstrated the efficacy of ABA against both arthritis and psoriasis after 6 months (mos) of double-blind (DB) treatment (Mease P, et al. *Ann Rheum Dis* 2010;69(Suppl3):98. Abstract SAT0288). Here, we assess the efficacy and safety of ABA after pts completed at least 6 mos of an open-label (OL) extension phase.

Methods: In the 6-mo DB study, 170 PsA pts previously exposed to DMARDs, including anti-TNF agents, were randomized (1:1:1:1) to receive placebo (PBO) or ABA 30/10 (2 initial doses of 30 mg/kg, followed by 10 mg/kg), 10 or 3 mg/kg on Days 1, 15, 29, and once every 28 days thereafter. Pts who completed this phase were eligible to continue in an OL study, and received ABA 10 mg/kg every 28 days for at least 6 mos. Endpoints included measures of joint disease (ACR20, DAS28), joint inflammation by magnetic resonance imaging (MRI), skin disease (target lesion [TL] score, Psoriasis Area and Severity Index [PASI]), physical function (Health Assessment Questionnaire-Disability Index [HAQ-DI]), and safety. Data were as-observed and analyzed on a modified intent-to-treat basis.

Results: A total of 147 pts from all 4 DB treatment groups entered the OL phase; baseline characteristics were similar among groups except for more pts being previously exposed to anti-TNF agents in the 30/10 mg/kg group (49%) than other groups (24–37%). Eighty-eight pts were still on treatment with 47 pts discontinuing due to lack of efficacy. Efficacy data are presented by original randomization group [Table 1]. At Day 169 of DB treatment, ABA improved ACR20 and DAS28, HAQ-DI, TL and PASI scores, and also resulted in less joint damage by MRI evaluation, as compared to PBO. Improvements in ACR and DAS28, reduction in joint damage by MRI and improvement in HAQ-DI continued through Day 365 in pts treated with ABA in the OL phase. Improvements in TL and PASI scores also continued through Day 365. Pts on PBO during the DB period achieved comparable improvements in joint and skin disease, joint inflammation and physical function after ABA treatment in the OL phase. Pts treated with ABA 10 mg/kg during the DB period appeared to have achieved the greatest overall improvements. The safety profile during the OL treatment was consistent with that during the DB period. Serious adverse events were numerically higher in the 10 mg/kg group (18%) vs other groups (8–12%); these were single events with no obvious pattern. One serious infection was reported in each group except for 2 cases in the 10 mg/kg group. There was 1 malignancy, a lentigo maligna, in the 3 mg/kg group. There were no autoimmune events or deaths.

Conclusions: The efficacy of ABA in pts with PsA, demonstrated during short-term DB treatment, was sustained throughout 6 mos of OL treatment. No new safety issue was detected.

Table 1. Efficacy of ABA in PsA pts at Days 169 (DB) and 365 (OL)

Response	ABA 30/10 mg/kg N=37	ABA 10 mg/kg N=34	ABA 3 mg/kg N=43	Placebo N=33
ACR20* at Day 169	49 (33, 65)	56 (39, 73)	35 (21, 49)	24 (10, 39)

Agreement between Total Joint Count and DAS 28 Joint Count in Psoriatic Arthritis. Jose Luis Fernandez-Sueiro[1], Eugenia Gonzalez Diaz de Rabago[1], J. Pinto-Tasende[1], Sonia Pertega-Diaz[1], J. C. Fernandez-Lopez[1], N. Oreiro-Villar[1], F. Galdo[1] and Francisco J. Blanco[2]. [1]Complejo Hospitalario Universitario La Coruña, La Coruña, Spain, [2]Complejo Hospitalario Universitario La Coruña, A Coruna, Spain

Background: Distal interphalangeal involvement is a characteristic feature of psoriatic arthritis (PsA), in this sense total joint count in PsA can be considered as 78 tender and 76 swollen joints. DAS 28 only evaluates 28 joints, therefore it is not clear whether counting only 28 joints is sufficient to evaluate peripheral joint involvement in PsA.

Objective: to evaluate the agreement between total joint count and DAS 28 joint count in PsA patients.

Patients and Methods: analysis at three consecutive time points (T0, T1 and T2) of a longitudinal observational cohort of PsA patients. In all patients total joint count (78 tender joint count (TJC) and 76 swollen joint count (SJC)) were performed. Analysis of the agreement between total joint count and DAS28 joint count was performed with the Bland-Altman methodology and the Kappa index.

Results: Mean TJC was: T0 total 3.9±6.7 vs DAS28: 2.5±5.0 (p<0,001), T1 2.3±4.5 vs 1.2±2.7 (p<0.001), T2 3.2±7.3 vs 1.8±4.5 (p=0.001). Mean SJC: T0 total 1.3±3.5 versus DAS28 0.9±2.7 (p=0.004), T1 0.6±0.5 vs 0.5±1.5 (p=0.002), T2 0.5±1.5 vs 0.1±0.4 (p=0.021). The mean difference between the number of tender joints (total joint count – DAS 28) was: T0 1.4±3.0, T1 1.3±2.9, T2 1.4±3.7, in swollen joints was T0 0.4±1.7, T1 0.3±1.1, T2 0.3±1.5.

Disagreement in one or more tender joints between the total count and the DAS 28 was found in T0 30.4%, T1 28.8%, T2 28.3% of the patients. In swollen joints, these figures were T0 11.1%, T1 14.4% and T2 13.0%. After categorizing TJC in ≤1 joint and >1 joint, Kappa index for the agreement between the total joint count and DAS28 was T0 0.764, T1 0.722, T2 0.836. For SJC, Kappa index was T0 0.811, T1 0.704, T2 0.378.

Using DAS28 joint count, at T0 51.9% (T1 60.5%, T2 65.5%) of the patients met minimal disease activity criteria. Of these, 7.5% (T1 12.0%, T2 5.1%) would not meet the criteria when using the total joint count (Kappa index=0.923).

Conclusions: At three different time-points, there are differences between total tender and swollen joint count and DAS 28 joint count, however the agreement between total joint count and DAS28 is high. On the other hand the agreement to classify patients with minimal disease activity is fairly good. These data suggest that DAS 28 joint count may be reliable for evaluating peripheral involvement in PsA.

1921

An Initial Diagnosis of Lumbar Disc Herniation Is Associated with a Late Refferral to the Rheumatologist and a Delay in the Diagnosis of Ankylosing Spondylitis. Servet Akar[1], Vedat Gerdan[1], Dilek Solmaz[1], Mehmet Sayarlioglu[4], Mehmet Akif Ozturk[2], Ahmet Mesut Onat[3], Bünyamin Kisacik[3], Mehmet Emin Tezcan[2], Merih Birlik[1], Fatos Onen[1] and Nurullah Akkoc[1]. [1]Rheumatology, Dokuz Eylul Univerisity Faculty of Medicine, Izmir, Turkey, [2]Rheumatology, Gazi University, Ankara, Turkey, [3]Rheumatology, Gaziantep University Faculty of Medcine, Gaziantep, Turkey, [4]Rheumatology, KahramanMaras Sutcu Imam University Faculty of Medicine, KahramanMaras, Turkey

Background: Among all the rheumatologic diseases, AS still remains to be the one with, the longest diagnostic delay mostly due to the slow development of radiographic sacroiliitis. In clinical practice, many patients with AS are diagnosed to have lumbar disk herniation (LDH), which in our opinion might be one of the the possible determinants of diagnostic delay in these patients. In this study we assessed the diagnostic delay in AS patients with an initial diagnosis of LDH compared with those without such diagnosis.

Patients and Methods: 393 patients (258 male [65,6%], mean age 39,3 ± 10,8 years) with AS according to the modified New York criteria from five rheumatology clinics in different cities were included in this analysis. A face to face interview was performed by using a structured questionnaire addressing all the possible factors that may lead to diagnostic delay, including the specialty of the first consulted physician, the initial diagnosis and history for LDH. Total *diagnostic delay was calculated* as the time elapsed from the initial visit to the physician due to back pain until the diagnosis of AS. Factors associated with the diagnostic delay were evaluated by Spearman's correlation and linear regression methods

Results: An initial diagnosis of LDH was reported by 33% of the 300 patients who could answer this question. The diagnostic delay in patients with an initial diagnosis of LDH vs those without such diagnosis was 9.1± 8,5 years and 6,2±7,4, years, respectively (p=0.002). Twenty six patients had undergone operation for LDH and the diagnostic delay in those patients was markedly higher than the patients without LDH surgery (13,3 ± 11,3 vs 6.2 ± years, P=0,023). Referral time to the rheumatologist was also significantly greater in patients with an initial diagnosis of LDH and in patients with a history of LDH surgery compared to the others.

Rheumatologists were seen as the initial physicians by only 4% of the patients whereas, 30% consulted physiatrist, 25% consulted orthopedists and 16% consulted orthopedists at their 1st medical visit due to back pain. The shortest delay in diagnosis was observed when rheumatologists were the first consulted physicians (2,9 ± 5,3 years).The delay period for the physiatrists was shorter (6,3 ± 7,6 years) than the orthopedists (9,6 ± 9,1 years) and neurosurgeons (8,8 ± 6,6 years). However, diagnostic delay was not found to be correlated with sex, family history, HLA-B 27 status and acute phae response. In the linear regression analysis age at spondyloarthritic symptom onset (p=0,013), age at back pain onset (p=0,01), and education level (p=0,003) were also found to be significant predictors of the diagnostic delay.

Conclusion: Our results suggest that prior diagnosis of LDH may lead to late referral of AS patients to rheumatologists resulting in a delay in diagnosis. A relatively high percentage of patients with LDH surgery is of concern, pointing out the necessity of continuous medical education of the specialists who are likely to see patients with AS, on the concept of spondyloarthritis.

Ankylosing Spondylitis Disease Activity Score (ASDAS): Defining Cut-Off Values for Disease Activity States and Improvement Scores. Pedro Machado[1], Robert Landewe[7], Elisabeth Lie[3], Tore K. Kvien[2], Juergen Braun[6], Daniel G. Baker[5] and Desiree M. Van Der Heijde[4]. [1]Coimbra University Hospital, Coimbra, Portugal; Leiden University Medical Center, Leiden, The Netherlands, [2]Diakonhjemmet Hospital, Oslo, Oslo, Norway, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Leiden University Medical Center, Meerssen, The Netherlands, [5]Research and Development, Centocor Inc, Malvern, PA, [6]Rheumazentrum Ruhrgebiet, Herne, Germany, [7]Univ Hosp Maastricht, Maastricht, The Netherlands

Purpose: ASDAS is a new composite index to assess disease activity in ankylosing spondylitis (AS). It has high construct and discriminatory validity. Criteria for disease activity states and improvement scores are important for clinical trials and clinical practice and have not been developed so far. Our aim was to determine clinically relevant cut-off values for disease activity states and improvement scores using the ASDAS.

Methods: The ASDAS is calculated using BASDAI questions 2, 3 and 6, patient global assessment (all 0–10cm VAS) and CRP (mg/L). We performed receiver operating characteristic (ROC)-curve analysis against several external criteria (ExCr) and used several approaches to determine the optimal cut-off (fixed 90% specificity, Youden index and closest point to (0,1)). The final choice was made on clinical and statistical grounds, after debate and voting by Assessment in SpondyloArthritis Society (ASAS) members. For the identification of proposed cut-offs we used baseline (BL) and 3-month (M) data of NOR-DMARD (N=295–477), a registry that includes AS patients starting a conventional DMARD or a TNF-blocker. Cross-validation was performed in ASSERT, a database of AS patients participating in a randomized placebo-controlled trial with infliximab.

Results: Four disease activity states were chosen by consensus: inactive disease, moderate-, high- and very high disease activity. The 3 cut-offs for separating them were: 1.3 (ExCr: ASAS partial remission, patient and physician global <1cm), 2.1 (ExCr: patient and physician global <3cm) and 3.5 (ExCr: patient and physician global >6cm). Selected cut-offs for improvement scores were: change ≥1.1 units for clinically important improvement (ExCr: patient reporting as being "better" or "much better" since start of treatment) and change ≥2.0 units for major improvement (ExCr: patient reporting as being "much better" since start of treatment). Results of the cross-validation in ASSERT strongly supported the cut-offs (tables 1 and 2).

Table 1. Disease activity states (%) in ASSERT: Infliximab vs Placebo (Chi^2, p-value)

Time-point	n	ASAS Partial Remission	ASDAS <1.3	1.3 ≤ ASADAS < 2.1	2.1 ≤ ASDAS ≤ 3.5	ASDAS >3.5
BL	166 vs 57	0 vs 0 (NA)	0 vs 0 (NA)	1.2 vs 1.8 (0.1, 0.756)	30.1 vs 26.3 (0.3, 0.586)	68.7 vs 71.9 (0.2, 0.645)
3M	163 vs 56	21.5 vs 1.8 (11.8, 0.001)	25.8 vs 1.8 (15.2, <0.001)	26.4 vs 3.6 (13.3, <0.001)	38.7 vs 39.3 (0.01, 0.933)	9.2 vs 55.4 (53.5, <0.001)
6M	163 vs 56	23.3 vs 1.8 (13.2, <0.001)	31.9 vs 0 (23.4, <0.001)	23.3 vs 12.5 (3.0, 0.084)	32.5 vs 33.9 (0.04, 0.846)	12.3 vs 53.6 (40.6, <0.001)

Table 2. Improvement criteria (%) in ASSERT: Infliximab vs Placebo

Improvement criteria	3 months (n=164 vs 56)	chi-square (p-value)	6 months (n=163 vs 56)	chi^2 (p-value)
Δ ASDAS≥ 1.1	71.3 *vs* 19.6	45.9 (<0.001)	69.3 *vs* 23.2	36.3 (<0.001)
Δ ASDAS≥2.0	43.9 *vs* 3.6	30.4 (<0.001)	50.9 *vs* 5.4	36.3 (<0.001)
Δ BASDAI≥2	60.4 *vs* 23.2	23.1 (<0.001)	62.6 *vs* 19.6	30.8 (<0.001)
BASDA150	50.6 *vs* 10.7	27.6 (<0.001)	51.5 *vs* 12.5	26.1 (<0.001)
ASAS20	64.0 *vs* 25.0	25.6 (<0.001)	63.2 *vs* 21.4	29.2 (<0.001)
ASAS40	50.6 *vs* 16.1	20.5 (<0.001)	47.2 *vs* 14.3	19.1 (<0.001)

Conclusions: Cut-off values for disease activity states and improvement scores using the ASDAS have been developed. They proved to have external validity and a very good performance compared to existing criteria.

1923

Ankylosing Spondylitis Patient Organisations—Are There Benefits of Membership? In-Ho Song[1], Cornelia Brenneis[1], Ludwig Hammel[2], Ernst Feldtkeller[2], Joachim Listing[3], Joachim Sieper[1] and Martin Rudwaleit[1]. [1]Charite Campus Benjamin-Franklin, Medical Clinic I, Rheumatology, Berlin, Germany, [2]German Ankylosing Spondylitis Society (DVMB), Schweinfurt, Germany, [3]German Rheumatism Research Center, Berlin, Germany

Background: Patient organisations for ankylosing spondylitis (AS) exist in many countries. The aims of these patient organisations are to inform and to educate patients in order to help them better deal and cope with the disease, to organize supervised physiotherapy groups, to support the exchange of experiences, and to represent the interests of patients in society and law (see www.spondylitis-international.org).

Objective: To evaluate differences between AS patients who are members of a patient organisation and AS patients who are not such members.

Methods: The German Ankylosing Spondylitis Society (DVMB) is a large patient organisation with more than 14,000 members in Germany. A cross-sectional survey based on a questionnaire was performed between December 2008 and April 2009. The questionnaire consisted of 82 questions regarding demographics, diagnosis, smoking, acquisition of information about the disease, disease activity, mobility, functional status, patient satisfaction, quality of life, treatment and disability to work and educational level. The questionnaire was distributed to AS patients by rheumatolgists in 51 hospitals and/ or private practices. In addition, the questionnaire was sent to 3400 randomly selected members of the German AS society. Data collection and analysis was done anonymously.

Results: In total, 1273 patients responded (1068 members of the patient organisation and 205 non-members). As DVMB members and non-members were not comparable regarding age (mean 54.9 vs. 46.6 years) and disease duration (mean 30.2 vs. 20.1 years) we performed a 2:1-matching of members to non-members regarding age, disease duration and also sex. In the matched population (n=549), members (n=366, mean age 47.0 years, mean disease duration 21.1 years, 63.9% male, HLA-B27 positive 89.0%) and non-members (n=183, mean age 46.3 years, mean disease duration 20.1 years, 63.9% male, HLA-B27 positive94.6%) differed in the following aspects: members more often felt that they were well informed (62.2% vs. 35.4%, p= < 0.001), more often used the information provided by the patient organisation (58.5% vs. 11.5%, p< 0.001), and more often had a positive family history for AS (34.4% vs. 23.3%, p= 0.004). There were nodifferences regarding disease activity (BASDAI 4.0 vs. 4.2, p= 0.172) or in the percentage of patients taking NSAIDs, DMARDs or anti-TNF-blocking agents.

Members as opposed to non-members had a better functional status (BASFI 3.4 vs. 3.9), p= 0.021), had less work days missed during the last year (15.1 days vs. 31.2 days, p= 0.003), were more often non-smokers (55.9% vs. 71.0%, p= 0.001). However, significantly more members had a higher educational status (e.g. percentage with university diploma 26.0% vs. 12.4%, p< 0.001).

Conclusion: There are numerous benefits associated with the membership in an ankylosing spondylitis patient organisation. AS patients who are members feel better informed about AS, have a better functional status and a healthier life style, and, overall, seem to cope better with the disease than non-members. Whether the educational status and the degree of physically challenging jobs influence the findings needs further examination.

1924

Anterior Chest Wall Pain in Spondyloarthritis Is a Frequent Manifestation, Appearing Early in the Disease Course, Which May Respond to NSAIDs. Muriel Elhai[1], Simon Paternotte[1], Fanny Roure[1], Eugénie Koumakis[1], Judith Payet[1], Vincent Burki[1], Isabelle Fabreguet[1], Magali Meyer[1], Maxime Dougados[2] and Laure Gossec[1]. [1]Cochin Hospital and Paris Descartes University, Paris, France, [2]Hospital Cochin, Paris, France

Background: Chest pain is a common but little studied feature of spondyloarthritis (SpA).

Objective: To assess the prevalence of anterior chest wall pain (ACWP) among a cohort of patients with SpA in a tertiary care center and to describe clinical characteristics of ACWP.

Method: *Study design*: retrolective single center observational study in

2010 (COSPA). *Patients*: definite SpA (Amor's criteria). Each patient underwent direct interview by a physician. *Data collection*: prevalence of ACWP, according to SpA subtype (axial versus peripheral, enthesitic or extra-articular) and if present, the date of appearance, the localization and nature of the pain, and effectiveness of the different treatments. *Analysis*: descriptive analysis.

Results: To date, 151 consecutive SpA patients were assessed: median age 43 (inter-quartile range 35–55) years, median disease duration 15 (8–25) years, 97 (64%) were men. In all, 56 patients (37%) suffered from SpA-associated ACWP. ACWP appeared before the diagnosis of SpA in 38% (17/45) cases; it was the first symptom of SpA in 5% (3/56) cases, and it appeared during the first 5 years of disease duration in 69% (31/45) cases. ACWP was localized in the sternoclavicular joint (26%), the manubrio-sternal joint (48%), the upper sternocostal joints (67%) and/or the lower sternocostal joints (55%). ACWP was usually acute, with painful flares (76%), with (N=16) or without (N=24) chronic pain. Coronary tests were performed for this pain in 2 cases. Respiratory movements and movements of the arm increased the pain in respectively 78% (40/51) and 55% (26/47) of cases; pain during the night was less frequent (40%, 21/53). Nonsteroidal anti-inflammatory drugs prescribed for this indication were effective in 53 % of cases (17/32), whereas anti-tumor necrosis factor agents were reported as effective in 73 % of cases (19/26).

Conclusion: This study is the largest clinical description of ACWP in SpA. ACWP is a frequent manifestation in SpA (37%); it occurs early in the disease which may be a challenge for diagnosis. ACWP in SpA is usually acute; it does not frequently lead to night pain. NSAIDs may be a useful first line treatment.

1925

Assessment of Efficacy and Safety of Pamidronate in Undifferentiated Spondyloarthropathy (uSpA): A Placebo Control Trial in a Tertiary Level Centre. Rathindra N. Sarkar[1], Sibaji Phaujdar[2], Sattik Siddhanta[2], Siwalik Banerjee[2], Dibeyendu De[2], Kuntal Bhattacharyya[2] and H. K. Pal[2]. [1]Calcutta Medical College, Kolkata, West Bengal, India, [2]Calcutta Medical College, Kolkata

Background: Undifferentiated spondyloarthropathy (uSpA) represents an incomplete form or early phase of Ankylosing spondylitis (AS) or another distinct type of spondyloarthropathy, whereas nonsteroidal anti-inflammatory drugs (NSAIDs) and disease modifying anti-rheumatic drugs (DMARDs) are still mainstay of treatment, tumour necrosis factor antagonists have shown good results in patients (pts) with severe symptoms or axial involvement but are very expensive and suppresses immunity. Pamidronate, an aminobisphosphonate, has shown anti-tumour necrosis factor properties. We evaluated efficacy and safety of Pamidronate in Indian uSpA pts refractory to NSAIDs therapy.

Methods: Fifty four pts fulfilling the modified Amor criteria for diagnosis of uSpA, having active disease even after 3 month's continuous therapy with two NSAIDs in maximal dose were selected. Active disease was defined as a Visuo-Analogue Scale (VAS) >50 (0–100mm scale) in 3 out of 4 following parameters: pts' global assessment, pain, Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI-morning stiffness). Patients receiving Sulfasalazine, 2–3g orally per day for peripheral arthritis were allowed to continue.

Patients were divided into Pamidronate group (N=40, received 60 mg monthly i.v. infusion in 500 ml Normal saline) and Placebo group (N=14, received Normal saline monthly i.v. infusion). Pts allowed continuing the analgesics. Efficacy assessment at the baseline and at 6-month was done using BASMI, BASFI, BASDAI, Bath Ankylosing Spondylitis Global Score (BAS-G), CRP and ESR. Proportion of pts achieving ASAS-20 and BASDAI-50 were also recorded at 6 months. Pts were observed for any AE. This study has clearance from Institutional Ethics Committee.

Results: Pts with USpA (n=54, M: F: 8:1), mean (SD) age was 46.54 (8.57) years, mean (SD) disease duration was 3.94 (1.14) years. Baseline characteristics and the disease activity in both treatment groups were similar. Changes in the parameters from baseline to 6 months in both groups are as described in Table 1. In Pamidronate group, there was significant reduction in all parameters compared to baseline while 32 pts (80 %) achieved ASAS-20 and 27 pts (67.5 %) achieved BASDAI-50 response, Pts in the placebo group showed increase in all the parameters. Very early feel good response was found in 23 pts (57.5 %) within 36 hours of first Pamidronate infusion. Mild fever, arthralgia, myalgia noted in 7 (17.5%) pts after first dose and in 3 cases (7.5 %) after second dose of Pamidronate.

Table 1. Clinical and laboratory parameters at baseline and 6 months

	Pamidronate (N=40)		Placebo (N=14)	
Parameter	**Baseline**	**6 months**	**Baseline**	**6 months**
BASDAI	7.68 ± 1.33	3.80 ± 1.74*	8.04 ± 1.22	8.31 ± 1.05
BASFI	7.53 ± 0.98	3.67 ± 1.79*	7.53 ± 0.84	7.97 ± 0.87
BAS-G	7.56 ± 0.941	3.14 ± 0.62*	7.57 ± 0.90	7.68 ± 1.22
BASMI	7.33 ± 1.12	3.05 ± 0.71*	7.36 ± 1.01	7.86 ± 0.86
CRP(mg/L)	9.40 ± 3.74	8.83 ± 2.76*	8.83 ± 2.77	9.76 ± 2.81
ESR(mm/h)	78.93 ± 22.05	30.00 ± 5.33*	81.64 ± 19.63	86.21 ± 11.05

All values mean ± SD; *p < 0.0001 compared to baseline

Conclusion: Pamidronate appears to be effective treatment option for pts with uSpA with acceptable safety profile.

1926

Can Clinical Phenotype Identify Early Psoriatic Arthritis in an Early Arthritis Cohort? Laura C. Coates[3], Philip G. Conaghan[3], Paul Emery[3], Michael J. Green[4], Gamal Ibrahim[1], Helen MakIver[1] and Philip S. Helliwell[2]. [1]Bradford Hospitals NHS Trust, UK, Bradford, United Kingdom, [2]LIMM, Section of Musculoskeletal Disease, University of Leeds, Leeds, UK, [3]LIMM, Section of Musculoskeletal Disease, University of Leeds, UK, [4]York Hospital NHS Trust, York, UK

Background: The classification of psoriatic arthritis (CASPAR) criteria are increasingly used to identify psoriatic arthritis. However the initial stem of the CASPAR criteria states that patients must have inflammatory joint, entheseal or spinal disease. The aim of this study was to assess whether the phenotype of inflammatory disease differed between early PsA and other forms of early inflammatory arthritis.

Methods: Cases of early PsA (less than 24 months symptom duration) and controls with other forms of early inflammatory arthritis who were all disease modifying anti-rheumatic drug naive were recruited. Gold standard diagnosis was confirmed by a consultant rheumatologist. A 66/68 joint count, enthesitis count (Maastricht Ankylosing Spondylitis Enthesitis Score – MASES, Leeds Enthesitis Index – LEI and plantar fascia) and assessment of axial disease were performed to assess presence of inflammatory disease.

Results: 111 early PsA cases and 111 early arthritis controls (RA n=82, undifferentiated arthritis n=13, spondyloarthritis n=9, inflamm OA n=4, crystal arthritis n=3) were recruited. All but one of the controls had arthritis. The pattern of arthritis (oligoarticular vs polyarticular) and the average tender and swollen joint counts did not differ significantly between cases and controls. DIP joint involvement was significantly more common in PsA cases than controls (32% vs 16%, p=0.007). When comparing PsA cases only to controls with RA (n=82), PsA cases had significantly lower joint counts (p<0.008)

Presence of enthesitis was significantly more frequent in the PsA patients compared to controls (67% vs 52%, p=0.029). There was a trend towards higher enthesitis counts in PsA cases compared to control patients but this was not significant. Spondylitis appeared more frequent in the PsA patients but the difference was not significant due to small numbers (5% vs 1%, p=0.055).

	Cases (n=111)	Controls (n=111)	RA controls (n=82)
Proportion with arthritis (%)	100	99	100
Oligoarthritis (%)	30	24	15
Polyarthritis (%)	70	76	85
DIP joint involvement (%)	32	16	18
Median TJC (IQ range)	7 (13)	8 (15)	12 (16)
Median SJC (IQ range)	5 (7)	5 (9)	7 (11)
Proportion with enthesitis (%)	67	52	52
Median enthesitis count (IQ range)	2 (4)	1 (3)	1 (4)
Proportion with spondylitis (%)	5	1	0

Conclusion: Different clinical phenotype cannot be relied upon to identify early psoriatic arthritis. Enthesitis and DIP joint involvement are

more frequent in early PsA compared to other forms of inflammatory arthritis, however a significant proportion of controls (including a significant proportion of patients with RA) also have clinical enthesitis. Spondylitis is likely to be more frequent in PsA than in RA, however it cannot be relied upon to differentiate from other forms of inflammatory arthritis.

Clinical Improvement with Etanercept Versus Sulfasalazine Treatment in Patients with Ankylosing Spondylitis: Comparative Performance of Various Efficacy Measurements (ASCEND). Desiree M. Van Der Heijde[2], Juergen Braun[7], Maxime Dougados[1], Annette Szumski[4], Ronald Pedersen[6], Bonnie Vlahos[3], Bruce Freundlich[4] and Andrew S. Koenig[5]. [1]Hospital Cochin, Paris, France, [2]Leiden University Medical Center, Meerssen, The Netherlands, [3]Pfizer, Inc., Pottstown, PA, [4]Pfizer, Inc., Collegeville, PA, [5]Pfizer, Inc., Blue Bell, PA, [6]Prizer, Inc., Collegeville, PA, [7]Rheumazentrum Ruhrgebiet, Herne, Germany

Background: Ankylosing spondylitis (AS) is a form of spondyloarthritis characterized by inflammatory back pain, peripheral arthritis, enthesitis, and extra-articular features such as uveitis. The disease frequently has an early onset and can seriously impair patients' quality of life and ability to work. Sulfasalazine (SSZ) is commonly used for the treatment of predominantly peripheral as well as axial symptoms of AS. Etanercept (ETN), a fully human TNF soluble receptor, has demonstrated short- and long-term efficacy in patients with AS. Outcome measures used in clinical trials need to be highly responsive to help detect improvement and discriminate between treatment effects. The ASCEND trial, a randomized, double-blind study that compared the efficacy of ETN and SSZ in subjects with axial and peripheral manifestations of AS, did not include a placebo arm, which hampered assessment of the net benefits of treatment. To gain more insight, we compared the discriminatory capacity of several AS assessments used in the trial.

Methods: In the ASCEND trial, subjects with AS received ETN 50 mg once weekly (n=379) or SSZ titrated to a maximum of 3 g daily (n=187) for 16 weeks. Week-16 adjusted treatment differences and effect sizes of improvement from baseline of several outcomes were used to assess their ability to detect improvement and discriminate between the effects of ETN and SSZ. All randomized subjects who received ≥1 dose of study drug and provided data at baseline and Week 16 were included in this analysis.

Results: The adjusted treatment differences and effect sizes of improvement from baseline between treatment groups for several efficacy outcomes are shown in descending order based on their treatment effect size (Table). All measures detected a greater treatment effect with ETN than with SSZ after 16 weeks of treatment.

Adjusted Week-16 treatment differences and effect sizes of improvement from baseline for ETN vs SSZ

Outcome Measure	Adjusted Treatment Difference* (SD)	Adjusted Effect Size† (95% CI)	Outcome Measure	Adjusted Treatment Difference* (SD)	Adjusted Effect Size† (95% CI)
ASDAS	0.80 (0.88)	0.91 (0.72, 1.09)	BASMI	0.59 (1.33)	0.44 (0.26, 0.63)
CRP	8.61 (11.59)	0.74 (0.56, 0.93)	SF-36 PCS	3.70 (8.55)	0.43 (0.25, 0.61)
Noctumal back pain	16.41 (24.83)	0.66 (0.48, 0.85)	Modified Schober's test	0.49 (1.57)	0.31 (0.13, 0.50)
Back pain	14.73 (24.48)	0.60 (0.42, 0.79)	Swollen joint count (68 joints)	0.40 (2.37)	0.17 (−0.02, 0.36)
Physician Global Assessment of disease activity (0–100 mm VAS)	11.44 (19.35)	0.59 (0.41, 0.78)	Chest expansion	0.18 (3.05)	0.06 (−0.13, 0.25)
BASDAI	12.08 (20.93)	0.58 (0.39, 0.76)	Occiput-to-wall distance	0.28 (4.55)	0.06 (−0.12, 0.25)
BASFI	9.92 (20.89)	0.48 (0.29, 0.66)			

*Difference in improvement between ETN and SSZ, based on an ANCOVA model adjusted for the endpoint's baseline and pooled site.
†Adjusted difference between ETN and SSZ, divided by ANCOVA model-based SD estimate.

Conclusions: In this blinded head-to-head trial conducted in subjects with active AS, the ASDAS showed the best discriminatory capacity followed by the objective measure CRP. Overall, subjective outcome measures, such as nocturnal back pain, back pain, Physician Global Assessment of disease activity, and BASDAI, showed a somewhat lower discriminatory capacity than CRP. Including objective measures either as part of the ASDAS or alone as CRP improved the discriminatory capacity of the outcome assessments.

1928

Comparison of Comorbid Disease Burden in Psoriasis and Psoriatic Arthritis (PsA). Janice Husted[1], Arane Thavaneswaran[4], Vinod Chandran[4], Lihi Eder[4], Sutha Shanmugarajah[4], Cheryl F. Rosen[2] and Dafna D. Gladman[3]. [1]Department of Health Studies & Gerentology, University of Waterloo, [2]Division of Dermatology, Toronto Western Hospital, [3]Toronto Western Hospital, Toronto, ON, Canada, [4]University of Toronto Psoriatic Arthritis Clinic

Background: The purpose of this study was to determine whether the presence of psoriatic arthritis (PsA) is associated with a higher comorbid disease burden compared to psoriasis without arthritis.

Methods: In 2006, lifetime prevalence of comorbid physical and mental conditions was collected for 449 psoriasis patients (without PsA) and 611 PsA patients who attended clinics affiliated with teaching hospitals. All patients were confirmed to have psoriasis by a dermatologist. Patients classified as psoriasis had PsA excluded after evaluation by a rheumatologist. The information on comorbidities was ascertained by clinic physicians using a standard protocol. Descriptive statistics were used to compare frequency of: sociodemographic and illness characteristics; specific comorbid conditions; and health-related quality of life (HRQOL) between groups. We also calculated the Functional Comorbidity Index (FCI), a summary count of all comorbidities, modified for this study to exclude arthritis. Linear regression models were used to compare FCI scores between psoriasis and PsA, adjusting for age, sex, and psoriasis duration.

Results: PsA patients were significantly older than psoriasis patients (mean age (SD) = 50.0 yrs (13.4) versus 46.6 yrs (13.1), $p < 0.0001$) and experienced a longer psoriasis duration (mean duration (SD) = 22.3 yrs (13.4) versus 16.2 yrs (14.1), $p < 0.0001$). Males comprised 58% of both patient groups. There was no significant difference in psoriasis severity as measured by the body surface area affected by psoriasis and PASI score. PsA patients reported lower HRQOL as measured by both SF-36 and HAQ, but higher HRQOL on the Dermatology Life Quality Index (DLQI). PsA patients, on average, reported a higher number of comorbidities than psoriasis patients (mean FCI score=1.44 (1.4), range=0, 7 versus 0.75 (0.9), range=0, 6, $p < 0.0001$). This difference remained significant after adjusting for covariates (age, sex and psoriasis duration). In PsA 39% of patients reported a history of cardiovascular disease, including hypertension compared to 19.6 % of patients with psoriasis ($p < 0.0001$, adjusted for covariates). Respiratory illnesses, depression, diabetes and cancer were the next leading comorbidities in PsA (22.5%, 27.0%, 17.0%, 12.1% and 8.5% of patients, respectively) and were more frequent than that observed in psoriasis (4.9%, 4.2%, 7.9%, 7.9% and 4.2 % of patients, respectively). With the exception of gastrointestinal disease, diabetes and cancer, these differences were statistically significant ($p < 0.05$). PsA patients had a significantly higher mean BMI than psoriasis patients (31.0 (16.5) versus 27.8 (5.5), p=0.0005, adjusted for covariates). However, the frequency of autoimmune disease was significantly higher in psoriasis than in PsA (6.3% versus 3.0%, $p = 0.0027$, adjusted for covariates). Finally, the observed group differences in HRQOL remained after adjusting for FCI score and covariates.

Conclusion: Patients with PsA have a higher comorbid disease burden (excluding arthritis) than patients with psoriasis without arthritis. This is associated with a reduced quality of life.

1929

Continued Efficacy of Infliximab in the Treatment of HLA B27 Positive Very Early Ankylosing Spondylitis Following Its Discontinuation; Clinical and Imaging Results of the 40 Week Follow-Up Study of a Three Month, Randomised, Placebo-Controlled Trial. Nick Barkham[3], Helen Keen[4], Laura Coates[4], Phil O'connor[2], Elizabeth Hensor[4], Dennis McGonagle[4], Helena Marzo-Ortega[4] and Paul Emery[1]. [1]Chapel Allerton Hospital, Leeds, United Kingdom, [2]Leeda University, [3]Leeds University, Leeds, Yorkshire, United Kingdom, [4]Leeds University

Objective: Treatment of early inflammatory back pain (AS in evolution) with infliximab, was shown to be efficacious during a 3 month treatment period. The current report describes the clinical and imaging outcomes following discontinuation of infliximab treatment.

Methods: Following an initial randomised, placebo controlled trial, all patients who had received either infliximab or placebo for 3 months discontinued treatment and were followed up to week 40 or time of clinical flare (BASDAI>4).

MRI scans of the spine and sacroiliac joints were performed at baseline, week 16, and week 40 or time of clinical flare. MRIs were scored by 2 observers blinded to treatment group and order using the Leeds 0–3 MRI grading system.

Results: In the placebo group, 17/19 patients (89.5%) had a high BASDAI at some point between the end of treatment (12 weeks) and the end of observation (40 weeks), compared to 12/19 (60.0%) in the infliximab group (Chi-square=4.44, df=1, P=0.035). Time to BASDAI>4 was shorter in patients who had received placebo [median (IQR) 5.0 weeks (4.0 to 16.0)] than those who had received infliximab [20.0 weeks (7.9 to 28.0), Log-rank Chi-square=5.77, P=0.016]. Between baseline and endpoint (at first BASDAI>=4 or week 40), infliximab patients showed significantly greater improvements in ASQoL(p=0.05), BASFI (p=0.033) and BASDAI (p=0.045).

Considering MRI lesions >= grade 2 (lesions not seen in normal spine MRI scans), in the 10 patients who reached week 40 without clinical flare (8 infliximab treated, 2 placebo), there was only one lesion >= grade 2 present at week 16 and no new lesions developed on the follow-up scan. In the 11 patients who flared between wk 16 and week 40 (6 infliximab 5 placebo) there were 8 grade>1 lesions present at week 16 and 12 new lesions developed.

Conclusions: A short course of infliximab treatment results in prompt suppression of disease activity and improvement in quality of life in early AS, which is sustained on withdrawal of therapy. Fewer patients who had received active therapy flared by week 40, and those who did not flare demonstrated no progression of grade>1 lesions on MRI. This raises the possibility that the "remission induction" approach could work in a subset of patients with early AS. As previously reported for the SIJ, the prognostic value of persistent >=grade 2 lesions is demonstrated, and MRI could allow early identification of patients with subclinical disease prior to the onset of clinical flare.

1930

Correlation of Disease Activity, but Not Radiographic Progression, with Functional Outcomes in Adalimumab-Treated Patients with Active Psoriatic Arthritis. Arthur Kavanaugh[4], Philip Mease[3], Michele Olds[2] and Frederic Lavie[1]. [1]Abbott Laboratories, Rungis, France, [2]Abbott Laboratories, Abbott Park, IL, [3]Swedish Medical Center and University of Washington, Seattle, WA, [4]University of California San Diego, La Jolla, CA

Background: In patients with rheumatoid arthritis, physical function is correlated with both disease activity and radiographic progression[1]; these relationships are unexplored in patients with Psoriatic Arthritis (PsA).

Objective: To explore the association of disease activity and radiographic progression with physical function in PsA patients treated with adalimumab (ADA).

Methods: ADEPT was a 24-week, randomized, placebo-controlled trial of ADA for the treatment of active PsA[2]. Treatment groups were randomized following stratification of subjects with methotrexate usage (≥3 months duration, 51% of patients) and extent of psoriasis (≥3% BSA, 45% of patients). In this post hoc analysis, DAS28 was used to assess disease activity, physical function was assessed through the Health Assessment Questionnaire (HAQ), and radiographic changes were determined using the modified Total Sharp Score (mTSS). Longitudinal generalized linear modeling was used to characterize the dependence of the HAQ on concurrent DAS28 and mTSS, following adjustment for baseline age and gender, and for concurrent CRP.

Results: Physical function following 48 weeks of treatment with adalimumab was linearly related to DAS28 ($P<0.001$). Increasing disease activity scores were predictive of higher HAQ scores (figure 1).

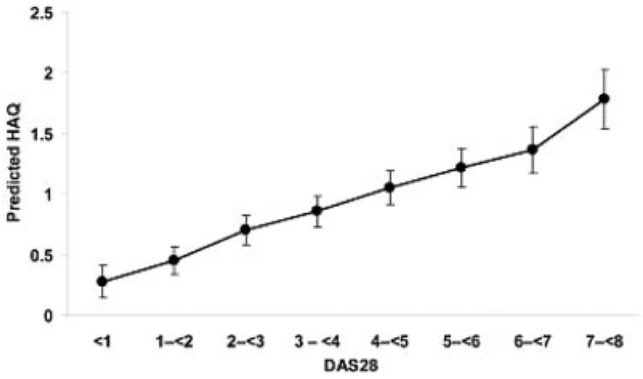

Figure 1.

However, there was no association between radiographic progression and HAQ score in PsA patients treated with adalimumab. The mean change from baseline to week 48 in HAQ score was not significantly different in adalimumab-treated patients with or without radiographic progression (ΔmTSS <0) through week 24. These results were consistent when analyzed by individual mTSS components (JSN and erosions). Radiographic progression measured by mTSS was not significantly associated with HAQ scores ($P=0.14$). However, HAQ scores appear to deteriorate at higher levels of radiographic damage (figure 2).

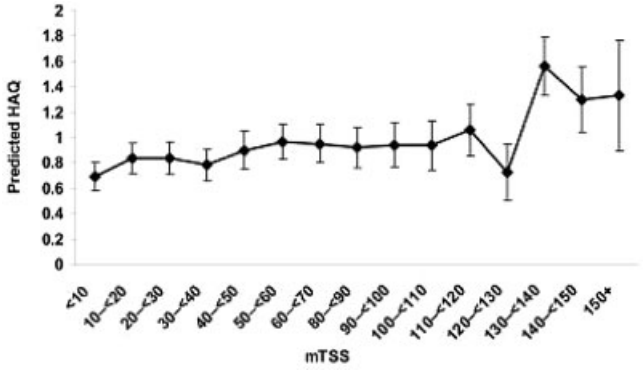

Figure 2.

Conclusion: In psoriatic arthritis patients recently treated with adalimumab, physical function is associated with resolution of disease activity, confirming the close relationship between HAQ and DAS28 early in the disease.[3] HAQ scores appear to relate to radiographic progression in patients with severe radiographic progression, supporting the hypothesis that HAQ is associated with radiographic progression at more advanced stages of the disease.

1931

CT Scan Facilitates the Diagnosis of Sacroiliitis in Patients with Suspected Spondyloarthritis, and without Proven Sacroiliitis on Pelvic X-Ray–Results of the ECHOSPA Cohort. Valérie Devauchelle-Pensec[1], Maria-Antonietta d'Agostino[8], Julien Marion[1], Sandrine Jousse-Joulin[2], Marie Lapierre[1], Daniele Colin[1], Isabelle Chary-Valkenaere[6], Christian Marcelli[3], Damien Loeuille[7], Philippe Aegerter[8], Sandrine Guis[5], Philippe Gaudin[4], Maxime Bréban[8] and Alain Saraux[1]. [1]CHU Brest, [2]CHU Brest, [3]CHU Caen, France, [4]CHU Grenoble, [5]CHU Marseille, France, [6]CHU Nancy, [7]CHU Nancy, [8]Hopital Ambroise Paré, France

Objective: To assess the performance of CT-scan for detecting sacroiliitis in patients with suspected spondylarthritis, and without obvious abnormalities of sacroiliac joints on X-ray.

Methods: 489 outpatients with suspected spondyloarthritis were recruited in a multicenter cohort study. At entry, they were submitted to clinical examination, pelvic X-ray, and HLA-B typing. Pelvic CT-scan was performed when rheumatologist was uncertain about the presence of sacroiliitis on X-ray. A set of 100 paired radiograph/CT-scan was read blindly by two radiologists, and the kappa coefficient was used to assess their reliability. One of them read the 173 pairs of X-ray/CT-scan available.

Results: After training, inter-reader reliability was moderate for sacroiliitis staging on X-ray (kappa = 0.52), excellent on CT-scan (kappa = 0.92), and perfect for diagnosing sacroiliitis on X-ray (New York criteria; kappa = 1). Quality was considered as good in 66, and 67 of 100 X-rays (kappa = 0.88), and in 93, and 92 of 100 CT-scans (kappa = 0.93), by readers one and two, respectively. Reliability between X-ray and CT-scan was low for sacroiliitis staging (kappa = 0.08), and diagnosing (kappa = 0.02). Sacroiliitis was retained in 6 (3.5%) patients on X-ray (4 confirmed by CT scan), and in 32 (18.5%) patients on CT-scan. Uveitis was associated with sacroiliitis on both X-rays (P :0.04) and CT-scan (P < 0.0001). Age, sex, HLA B27, arthralgia, enthesitis, rachialgia and buttock pain were not associated to sacroiliitis in our population.

Conclusions: Radiographic sacroiliitis was underestimated on X-ray, whereas CT-scan increased the detection of structural abnormalities leading to a proven diagnosis of sacroiliitis. CT-scan should facilitate the diagnosis of ankylosing spondylitis in patients with suspected spondyloarthritis.

1932

Dactylitis in Psoriatic Arthritis (PsA): Prevalence and Response to Therapy in the Biologic Era. Olga Ziouzina[2], Arane Thavaneswaran[2], Vinod Chandran[2] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto Psoriatic Arthritis Clinic

Background: Dactylitis is a common feature of PsA and one of the CASPAR criteria for the classification of PsA. It is associated with impaired function and is a marker of disease severity. Randomized clinical trials in PsA have shown remarkable response to treatment with biological agents with improvement in the active joint count, psoriasis, quality of life and function. However, the data on improvement of dactylitis has been sparse. Here we studied the prevalence and response of new acute dactylitis to treatment in a longitudinal PsA cohort.

Methods: Patients with PsA were followed at a PsA clinic January 2000 to January 2010 were included in this study. Patients were followed at 6 and 12 months according to a standard protocol. Acute dactylitis was defined as the presence of painful swelling of an entire digit. Response was defined as either complete resolution of dactylitis or > 50% improvement in the number of dactylitic digits. The prevalence of dactylitis in this cohort was determined. A multivariate generalized estimating equations analysis using a negative binomial model to account for repeated measures was conducted to determine predictors for response to treatment of dactylitis. The variables entered in the model were age, sex, duration of disease, treatment and intra-articular steroid use where treatment was categorized as no treatment, biologics (±DMARDs) and DMARDs.

Results: 294 patients of the 752 seen in clinic during this period had dactylitis at, at least one visit giving a prevalence of (39%). 252 patients (34% females, mean age 47 years, PsA duration 11 years, mean actively inflamed joint count 13.3, and mean damage joints 9.7, PASI score 5.6) with acute dactylitis and data available for response at 6 and 12 months were included in the study on predictors of response to treatment. Multivariate analysis showed only treatment type was a significant predictor of response to dactylitis at 12 months [relative risk 0.528, 95% CI (0.283, 0.985, p= 0.045]. There was a trend showing response at 6 months (p = 0.061). At 6 months, 77.3% of the patients responded to therapy when on biologics in comparison to 51.5% on DMARDs. Similarly, at 12 months, 87.2% of the patients responded to therapy when on biologics in comparison to 69.9% on DMARDs.

Conclusion: The prevalence of dactylitis on at least one visit during the period from January 2000 to January 2010 was 39%. Treatment was associated with improvement of dactylitis. Patients treated with biologics had better response to treatment compared to those treated with DMARDs alone.

1933

Decreased Recurrence Rate of Anterior Uveitis in Ankylosing Spondylitis Treated with Adalimumab—An Interim Analysis. Irene E. van der Horst-Bruinsma[2], J. Christiaan van Denderen[1], Ingrid Visman, Maria S. A. Suttorp-Schulten, Ben A. C. Dijkmans and Michael T. Nurmohamed. [1]Amsterdam, NH, The Netherlands, [2]VU University Medical Centre, Amsterdam, NH, The Netherlands

Introduction: A high percentage (30–40%) of patients with Ankylosing Spondylitis (AS) suffers from acute anterior uveitis (AAU) attacks. Local treatment with corticosteroids is a beneficial treatment and in addition, there are suggestions that TNF blocking agents also decrease the recurrence rate of AAU attacks. However, proper prospective studies investigating the of anti-TNF treatment on the recurrence rate of AAU attacks in AS are lacking.

Objective: To examine whether the use of adalimumab decreases the frequency of attacks of AAU in patients with AS, who receive this treatment due to their spinal disease activity.

Methods: Consecutive AS patients, who were treated with 40 mg of adalimumab every other week according to the international ASAS consensus statement, were enrolled. The number of attacks of AAU before and after treatment were assessed by patient history and ophthalmological controls at baseline and yearly thereafter.

Results: A total of 60 patients was enrolled. After 1 year of treatment 29 patients had their control visit, and follow up data were completed of 6 patients after 2 years. Fourteen out of these 29 (48 %) patients did not have any attacks of uveitis before and after treatment with adalimumab.

Fifteen patients (52 %) suffered from recurrent attacks of uveitis with a mean number of 3.8/year (range 1–12). After one year, the recurrence rate per year in these 15 patients was reduced to none attacks in 11 cases (73%), from 5 attacks to only one attack/year in 2 cases (13%) and remained the same in the other 2 patients (13%, one attack). Interestingly, even the patient with a very high number of attacks of AAU (12 per year) was completely free of attacks after the start of adalimumab, during 2 years of follow up. The recurrence rate decreased significantly (p=0.001) from 15/29 (52%) to 4/29(14%), with a 73% reduction in the recurrence of uveitis.

Conclusions: Our interim analysis revealed a significant reduction of recurrence rate of attacks of acute anterior uveitis during adalimumab treatment, even in patients with a high recurrence rate of the attacks.

1934

Direct Imaging Evidence That Adalimumab Induces Resolution of Inflammatory Lesions in AS Patients at Sites of Complete Spinal Ankylosis. Walter P. Maksymowych, Nathalie Morency and Robert G. W. Lambert. University of Alberta, Edmonton, AB, Canada

Purpose: Post-hoc analysis of clinical trial data has demonstrated that AS patients who have extensive spinal ankylosis on radiographs experience clinical improvement with adalimumab that is similar to patients without extensive ankylosis. This benefit has been documented by patient self-report and not objectively using imaging data. We aimed to assess the impact of treatment in AS patients where both radiographs and MR scans were available to analyze the fate of vertebral corner inflammatory lesions (CIL) that demonstrated syndesmophytes and ankylosis on the baseline radiograph.

Methods: MRI scans were performed at baseline, 12, and 52 weeks while radiographs were done at baseline and 104 weeks in 76 AS patients randomized to receive either adalimumab (ADA) 40 mg every other week or placebo (PBO) for 24 weeks in a, double-blind, Phase III study of active AS with an inadequate response to at least one NSAID or DMARD. After the week 12 assessment, patients not achieving an ASAS20 response were eligible for early escape therapy with ADA and after 24 weeks all patients received ADA. The anterior vertebral corners (VC) of the cervical (C2 lower to T1 upper) and lumbar (T12 lower to S1 upper) spine were examined for

syndesmophytes and ankylosis on lateral radiographs of the cervical and lumbar spine by 2 readers scoring independently. Anonymized MR scans were read independently by 2 readers who recorded the presence/absence of both typical CIL (Type A) and complex CIL (dimorphic) at the same anterior VC that were assessed by radiography. The primary analysis was based on concordant radiographic and MRI data. A CIL was defined as being persistent if it was recorded as being present on each MRI scan (baseline, 12, and 52 weeks) and as being completely resolved if either the baseline or 12 week MR scan showed a CIL that was no longer present at the 52 week final MRI examination.

Results: Ankylosis across the disc space was recorded on the baseline radiograph at 248 of 1736 (14.3%) VC that were assessed by both radiography and MRI. A syndesmophyte was recorded in 137 (7.9%) of VC at baseline. A CIL was observed significantly more frequently at VC without either ankylosis or syndesmophytes (212/1351 (15.7%)) as compared to those with ankylosis (13/248 (5.2%), p <0.0001) on baseline radiographs. Over half of CIL at VC with ankylosis at baseline resolved completely (7/13 (53.8%)) as compared to 157/212 (74.1%) of CIL at those VC without syndesmophytes/ankylosis at baseline (P = NS). For VC with baseline ankylosis, complete resolution was observed for almost all Type A CIL (5/6) but in only 2/7 dimorphic CIL.

Conclusion: Our data provide objective evidence for ongoing inflammation at sites of complete spinal ankylosis that can resolve completely with adalimumab, and that complete resolution of inflammation is observed more often in those CIL with a typical configuration than in more complex, dimorphic inflammatory lesions.

1935

Disconnect between Radiographic Progression and Clinical Outcomes in Psoriatic Arthritis Patients Treated with Adalimumab. Philip Mease[3], Christopher Ritchlin[4], Michele Olds[2] and Frederic Lavie[1]. [1]Abbott Laboratories, Rungis, France, [2]Abbott Laboratories, Abbott Park, IL, [3]Swedish Medical Center and University of Washington, Seattle, WA, [4]University of Rochester School of Medicine and Dentistry, Rochester, NY

Background: Treatment with adalimumab (ADA) diminishes disease activity and radiographic progression in subjects with active psoriatic arthritis (PsA)[1]. In subjects with rheumatoid arthritis (RA), inhibition of radiographic progression can occur independently of improvements in clinical symptoms following treatment with anti-TNF agents[2]; it is not known if such a disconnect in treatment responses exists in PsA patients.

Objective: To explore the relationship between disease activity and radiographic progression in subjects with active PsA following treatment with ADA or placebo (PBO).

Methods: ADEPT was a 24-week, randomized, placebo-controlled trial of ADA for the treatment of active PsA[1]. Treatment groups were randomized following stratification for methotrexate usage (≥3 months duration, 51% of patients) and extent of psoriasis (≥3% BSA, 45% of patients). In this post hoc analysis, disease activity was monitored by DAS28 and ACR response rates at week 12. The change in modified Total Sharp Score (ΔmTSS) was calculated from X-rays obtained at baseline and week 24; radiographic progression was defined as ΔmTSS >0.25.

Results: Radiographic progression occurred at a lower frequency following treatment with ADA; 84% of ADA-treated subjects were nonprogressors, while 62% of subjects in the PBO group had ΔmTSS ≤0.25 through week 24 ($P<0.001$). ADA-treated subjects were more likely to exhibit lower disease activity and improved ACR responses at week 12 (table). Even in subjects with active clinical symptoms at week 12, treatment with ADA resulted in significantly better radiographic outcomes at week 24 than treatment with PBO; for example, ADA subjects with moderate disease activity (DAS28 ≥3.2 – <5.1) still had reduced bone damage.

Conversely, subjects exhibiting radiographic progression from baseline to week 24 had higher mean DAS28 scores at week 12 in both treatment groups. PBO-treated subjects with ΔmTSS >0.25 had a mean±SD DAS28 of 5.0±1.3, while those showing no progression had a mean DAS28 of 4.3±1.3 at week 12 ($P=0.001$). Subjects treated with ADA with ΔmTSS >0.25 had a mean DAS28 of 3.9±1.6 at week 12, while those without radiographic progression had a mean DAS28 of 3.0±1.2 ($P=0.004$). DAS28 at week 12 showed a mild correlation with ΔmTSS at week 24 in the PBO group (correlation coefficient: 0.36) However, there was a weaker pattern of radiographic progression relative to DAS28 in the ADA group (correlation coefficient: 0.13).

Table. Pattern of radiographic progression (ΔmTSS) relative to disease activity

	PBO		ADA	
Week 12 DAS28	**N**	**ΔmTSS[a]**	**N**	**ΔmTSS[a]**
<2.6	7	0.2 ± 1.9	50	−0.1 ± 0.9
≥2.6–<3.2	23	0.1 ± 0.31	23	−0.2 ± 1.6
≥3.2–<5.1	65	0.5 ± 1.3	42	−0.5 ± 1.6
≥5.1	51	2.2 ± 4.6	14	0.9 ± 1.8
Week 12 ACR				
ACR90	0	n/a	9	−0.2 ± 0.59
ACR70, not ACR90	1	0.0	21	−0.2 ± 0.48
ACR50, not ACR70	5	0.0 ± 0.35	24	−0.7 ± 2.2
ACR20, not ACR50	16	1.1 ± 2.0	32	−0.3 ± 1.3
not ACR20	129	1.1 ± 3.2	54	0.2 ± 1.2

[a]baseline to week 24, mean ± SD.

Conclusions: Radiographic progression is lower in patients with active PsA who are treated with adalimumab compared with placebo, regardless of the treatment response in clinical symptoms. As in RA, it appears that a disconnect in the normal relationship between radiographic progression and disease activity can occur in subjects treated with adalimumab.

Environmental Risk Factors for Psoriatic Arthritis among Patients with Psoriasis—A Case-Control Study. Lihi Eder[3], Tamryn Loo[3], Vinod Chandran[3], Gideon Kalman-Lamb[3], Sutha Shanmugarajah[3], Richard Cook[1] and Dafna D. Gladman[2]. [1]Department of Statistics and Actuarial Science, University of Waterloo, Waterloo, ON, Canada, [2]Toronto Western Hospital, Toronto, ON, Canada, [3]University of Toronto Psoriatic Arthritis Clinic, Toronto Western Hospital, Toronto, ON, Canada

Aim: To investigate the association between potential environmental exposures and the development of psoriatic arthritis in patients with psoriasis.

Methods: In this case-control study, the cases were patients with recent onset psoriatic arthritis (PsA) of less than 7 years since the diagnosis. The control group was composed of psoriasis patients in whom arthritis was excluded after an evaluation by a rheumatologist. Patients and controls were matched by duration of psoriasis. The occurrence of the following environmental exposures was evaluated by a self administered questionnaire: infections, injuries and fractures, physically demanding occupational tasks, stressful life-events and vaccinations. The patients were asked to report any such event that occurred in the past 10 years and a positive exposure was defined as the occurrence of an event prior to the year of diagnosis. Participants in the control group were assigned a reference year corresponding to the year of PsA diagnosis in the matched case. The association between each exposure to environmental events and disease status were assessed through logistic regression after adjustment for age, sex and duration of psoriasis.

Results: There were 159 subjects in each group. There were no differences in age, sex, ethnicity, and severity of psoriasis as measured by PASI score between the 2 groups. The mean duration of PsA was 3.1 ± 2.2 years. The associations between each of the exposure variables and PsA are presented in Table 1 after adjustment for age, sex and duration of psoriasis.

Table 1. Proportion of environmental exposures

Exposure	Frequency PsA (%)	Frequency Psoriasis (%)	Adjusted P value*
Car accidents that required medical consult	6 (4%)	5 (3%)	0.95
Fractures	16 (10%)	14 (9%)	0.73
Any other injury	34 (21%)	17 (11%)	0.01
Infective diarrhea	20 (13%)	11 (7%)	0.23
Infections that required Ab	53 (34%)	37 (24%)	0.05
Infections that required hospitalization	11 (7%)	0 (0%)	0.0006
Vaccination - Hepatitis A	3 (3%)	4 (4%)	0.58
Vaccination - Hepatitis B	29 (23%)	19 (16%)	0.32
Vaccination - Pneumovax	30 (24%)	20 (17%)	0.35
Vaccination - Flu	59 (42%)	60 (45%)	0.92
Vaccination - Rubella	4 (3%)	5 (4%)	0.81
Vaccination - Tetanus	6 (5%)	4 (4%)	0.97
Death in the family	41 (27%)	44 (29%)	0.91
Divorce	17 (10.9%)	12 (8%)	0.33
Movehouse	74 (50%)	64 (41%)	0.62
Changed job	70 (47%)	56 (40%)	0.62
Becoming unemployed	34 (23%)	35 (23%)	0.80
Treated for anxiety/depression	21 (14%)	26 (17%)	0.55
Occupational risk: Prolonged standing	95 (65%)	85 (58%)	0.31
Squatting	45 (31%)	32 (22%)	0.12
Lifting heavy weights	44 (30%)	19 (13%)	0.0009
Pushing heavy weights	29 (20%)	18 (12%)	0.13
Using vibrating tools	7 (5%)	8 (6%)	0.66
Repetitive hand movement	88 (60%)	85 (58%)	0.96
Forceful gripping	28 (19%)	21 (14%)	0.48
Bending the wrist	65 (45%)	65 (45%)	0.85
Smoking - Current	28 (23%)	38 (35%)	0.05
Past	36 (27%)	51 (42%)	0.03

*Adjusted for age, sex, Ps duration.

The following exposures remained significantly associated with PsA following multivariate logistic regression: lifting cumulative loads of at least 100 pounds/hr (OR 2.9, $p<0.001$), infections that required antibiotics (OR 1.8, $p=0.04$), current smoking (OR 0.5, $p=0.03$) and past smoking (OR 0.5, $p=0.02$). Injury was significantly associated with PsA after adjustment for age, sex and duration of psoriasis, however it was no longer significant after inclusion in the full logistic regression model (OR 1.8, $p=0.07$). No association was found between PsA and vaccination, stressful life events and fractures.

Conclusion: Lifting heavy loads and infections that required antibiotics were associated with the occurrence of arthritis among patients with psoriasis. Smoking and past smoking were negatively associated with PsA. Further studies are necessary to determine whether these and other environmental factors are moderated by predisposing genetic factors.

Estimate of the Prevalence of Psoriatic Arthritis and Improvement with Etanercept Treatment in Moderate-to-Severe Plaque Psoriasis: PASE Results from the PRISTINE Trial. M. Elaine Husni[2], Abrar A. Qureshi[1], Deborah Robertson[4], Ronald Pedersen[4], Bruce Freundlich[4] and Charles T. Molta[3]. [1]Brigham and Women's Hospital, Boston, MA, [2]Cleveland Clinic Foundation, Cleveland, OH, [3]Pfizer, Inc., Paoli, PA, [4]Pfizer, Inc., Collegeville, PA

Background: Psoriatic arthritis (PsA) affects an estimated 30% of patients with psoriasis and may cause irreversible joint damage, underscoring the need for early PsA screening and prompt initiation of therapy. The Psoriatic Arthritis Screening and Evaluation (PASE) questionnaire is a validated tool that can be used to screen for active PsA among individuals with psoriasis and is being evaluated as a measurement of treatment response. We tested the PASE questionnaire in exploratory analyses in a large multinational study of etanercept (ETN), a biological agent approved for the treatment of PsA and psoriasis, to assess whether it is a useful tool for PsA screening and for evaluation of treatment effect in a clinical trial setting.

Methods: The PRISTINE trial evaluated the efficacy and safety of 2 ETN doses for the treatment of psoriasis. The PASE questionnaire was administered during the PRISTINE trial at baseline to estimate the prevalence of PsA using the PASE cutoff scores (absent if <47 or present if ≥ 47) and re-administered at 12 weeks to evaluate changes in PASE score with treatment. Participants were randomized to receive ETN 50 mg once weekly (OW) or 50 mg twice weekly (BIW) for 12 weeks double blind, followed by ETN 50 mg OW open label for 12 weeks in all subjects. Participants were ≥ 18 years old and had stable plaque psoriasis, with BSA $\geq 10\%$ or PASI ≥ 10. At baseline, the number of participants who self reported a history of PsA was assessed by medical history. Within-group p-values for comparison of PASE scores at baseline and week 12 were based on a paired sample T-test.

Results: A total of 273 subjects were enrolled (OW, n=137; BIW, n=136). Subjects were 70% male, and 64% Caucasian; mean age was 44 years, mean PASI was 21, and mean psoriasis duration was 17 years. At baseline, 31% had a self-reported history of physician-diagnosed PsA (mean duration, 8 years). Data from the PASE questionnaire at baseline and week 12 are shown (Table). Approximately 25% of subjects had a PASE total baseline score ≥ 47, meeting criteria for possible active PsA. After 12 weeks of ETN treatment, 13% had a score suggesting the presence of active PsA.

Results from the PASE questionnaire* at baseline and week 12 by treatment group†

PASE variable	ETN 50 mg OW/ETN OW		ETN 50 mg B/W/ETN OW*	
	Baseline	Week 12	Baseline	Week 12
Total score 247, nN (%) (95% CI)	37/136 (27.2%) (19.9%, 35.5%)	15/134 (11.2%) (6.4%, 17.8%)	30/132 (22.7%) (15.9%, 30.8%)	18/130 (13.8%) (8.4%, 21.0%)

Within-group p-value		*0.0007*		*0.0059*
Symptom score				
Mean (SD) (mean change from baseline [SD])	16.7 (7.5)	15.1 (6.3) (−1.6 [6.5])	16.4 (7.0)	14.8 (6.7) (−1.5 [6.5])
Median (min-max) (median change from baseline [min-max])	16.0 (7.0–32.0)	14.0 (7.0–34.0) (−1.0 [−18.0–15.0])	14.5 (7.0–35.0)	14.0 (7.0–35.0) (−1.0 [−26.0–22.0])
Within-group p-value		*0.0051*		*0.0095*

*Includes a total of 15 items, with symptom (7 items) and function (8 items) subscales, possible responses range from 1 (strongly disagree) to 5 (strongly agree). Total scores range from 15 to 75 points, symptoms scores from 7 to 35, and function scores from 8 to 40.
†In the modified intent-to-treat population, based on analysis of last observation carried forward.
‡P=NS, all between-group comparisons.

Conclusions: Consistent with previously published findings, nearly one third of participants in the PRISTINE study reported a physician diagnosis of PsA at baseline. PASE total, function, and symptom scores decreased from baseline to week 12 in both dose regimen groups. These results are generally consistent with clinical improvement with ETN treatment, but further analysis is needed. The findings suggest that PASE may be a useful tool for application in screening psoriasis patients for PsA in clinical trials and evaluating treatment response in a large dermatology setting.

1938

Evaluation of the New Akylosing Spondylitis Disease Activity Score (ASDAS) To Assess Disease Activity in Patient with Active Non-Radiographic Axial Spondyloarthritis Treated with Adalimumab and Retreated after Interruption of Therapy and Flare. Hildrun Haibel[3], Frank Heldmann[2], Joachim Listing[4], Hartmut Kupper[1], Jürgen Braun[2] and Joachim Sieper[3]. [1]Abbott GmbH & Co. KG, Ludwigshafen, Germany, [2]Centre of Rheumatology Ruhrgebiet, Herne, Germany, [3]Department of Rheumatology, Charité CBF, Berlin, Germany, [4]German Rheumatism Research Centre, Berlin, Germany

Background: The Spondyloarthritis International Society (ASAS) has recently developed a new disease activity score, the ASDAS, which includes

clinical measures and CRP and has a high discriminatory capacity for assessing disease activity in AS. Adalimumab has demonstrated good efficacy for 46 patients with active, non-radiographic, axial SpA during a 12-week, placebo-controlled trial and its 40-week, open-label extension [1].

Objective: To evaluate long-term efficacy after re-treatment with adalimumab for patients whose disease flared after treatment was discontinued at Week 52 using the ASDAS instrument.

Methods: All 46 enrolled patients discontinued therapy at Week 52 and 19 patients with a good response at week 52 had to be retreated because of a flare (defined as not longer reaching ASAS40 response compared to baseline). Patients were treated for up to two additional years (108 weeks of re-treatment). An ASDAS <1.3 was considered as 'inactive', 1.3–2.1 as 'moderate', 2.1–3.5 as 'high' and > 3.5 as very high disease activity. An ASDAS change ≥2 was defined as 'major improvement', as recently proposed.

Results: Of the 19 patients who had to be retreated, 52.6% were male; mean age was 32.5 years [range 24–45]; mean disease duration before treatment was 4 years [range 1–10]; and 74% were HLA-B27+). In these 19 patients, the mean ASDAS decreased from 3.4 at baseline to 1.2 ($p<0.001$) at week 52. At baseline of the retreatment period the mean ASDAS was 2.8 and after 1 and 2 years of retreatment 1.5 ($p=0.001$). For the percentage of patients reaching different disease activity categories see table 1.

Table 1. Percentage of patients (%) reaching different disease activity categories and mean ASDAS and BASDAI during treatment with adalimumab 40 mg eow.

ASDAS	Baseline	Week 52	R-Baseline	R-48	R-108
'Inactive' (%)	0	63.2	0	50	47.1
'Moderate' (%)	10.5	26.3	21.1	22.2	35.3
'High' (%)	47.4	10.5	52.6	22.2	17.6
'Very high' (%)	42.1	0	26.3	5	0
ASAS 40 (%)	NA	100.0	NA	52.6	73.7
ASAS p.R. (%)	NA	57.9	NA	47.4	63.2
ASDAS (Mean)	3.4	1.2	2.8	1.5	1.5
BASDAI (Mean)	6.1	1.4	5.1	2.8	2.4
ASDAS improvement > 1.1 (%)	NA	94.7	NA	50	64.7
ASDAS improvement ≥ 2.0 (%)	NA	36.8	NA	27.8	17.6

R=Retreatment, ASAS40=40% improvement according to the Assessments in SpondyloArthritis Society Criteria, p.R.=partial Remission.

Conclusions: All patients retreated reached a similar level of response as before interruption of adalimumab therapy, as judged by the percentage of patients reaching inactive or moderate ASDAS or ASAS pR. This was not well reflected in the ASAS 40 or ASDAS major improvement rates, probably because the baseline level of activity at retreatment was lower than before. Thus, the ASDAS and its definition of different levels of disease activity performed well in this analysis.

1939

High Prevalence of Psoriatic Arthritis in a Psoriasis Patients Cohort. Majed M. Khraishi[2], Trevor Newhook[1], Ian Landells[3], Jonathan Mong[3] and Kassem Aboushehde. [1]Nexus Clinical Research, St. Johns, NL, Canada, [2]Nexus Clinical Research, St Johns, NL, Canada, [3]Nexus Clinical Research

Objective(s): The prevalence of PsA is reported to range from 5 to 40% in individuals with psoriasis. We set out to detect the prevalence of PsA in psoriasis patients seen in a dermatology practice and define their characteristics utilizing a validated self-administered screening questionnaire, PASQ (the Psoriatic Arthritis Screening Questionnaire)

Method(s): Patients with definite Plaque psoriasis (as determined by the dermatologist) completed the PASQ, a validated screening tool which has an optimal cut-off of 9 in established PsA. To ascertain that all patients with PsA are captured, we chose a lower cutoff point of 7 on the questionnaire. All patients scored 7 and higher on the PASQ were assessed by a rheumatologist to ascertain the diagnosis of PsA according to the CASPAR criteria. Epidemiological, clinical and laboratory parameters were recorded in addition to the score of the PASQ. Statistical analyses were performed utilizing SPSS 17.0.

Result(s): Sixty six patients consecutive patients with confirmed diagnosis of psoriasis who were seen by the dermatologist were enrolled. The mean age (SD) was 45.6 (13.5) years, 30 (45.5%) were females. Average duration of psoriasis was 12.4 (10.1) years. 28 (42.4%) of the patients had baseline PASQ scores of 7 or higher and 17 of those patients were assessed by a rheumatologist where 12 were determined to have definite PsA, three had osteoarthritis, one had undifferentiated synovitis and one had ankylosing spondylitis. Of those 38 patients with a PASQ < 7, five had definite diagnosis of PsA which was reconfirmed by the rheumatologist resulting in 17 patients with PsA in this cohort. Assuming none of the remaining patients were later diagnosed with PsA, the prevalence of psoriatic arthritis in our psoriasis cohort is 25.8%. This would be an underestimate of the true prevalence since 11 of the patients with a PASQ ≥ 7 had not yet been assessed by a rheumatologist yet.

Khraishi et. al.11 determined that when using the PASQ as a screening tool on patients with early PsA (mean symptoms duration of 12 months) a cut-off point of greater or equal to 7 yielded a sensitivity and specificity of 82% and 75%, respectively. If the sensitivity is applied to those 11 patients with a PASQ ≥ 7that were not seen by a rheumatologist, approximately 9 (11*0.82) of these patients should eventually be diagnosed with PsA(assuming they have early PsA). This will result in a total of 26 PsA patients indicating that the estimated prevalence (95% CI) of PsA in patients with psoriasis is 39.4% (27.6%, 51.2%) in a dermatology setting.

Conclusion: Our estimated prevalence of PsA in psoriasis patients from a population of patients drawn from a dermatology practice is larger than most prior estimates. This fact illustrates the importance of screening for PsA in psoriasis patients as this comorbidity may affect the course of treatment and if left untreated may have a profound effect on the disability and quality of life of a large number of psoriasis patients.

1940

Improved Health-Related Quality of Life (HRQOL) with Apremilast (APR) Treatment in Psoriatic Arthritis (PsA): Results from a Phase 2 Randomized Controlled Study. Vibeke Strand[3], Adele Vessey[1], Angela Hu[2] and Victor S. Sloan[2]. [1]Celgene Corporation, Richlandtown, PA, [2]Celgene Corporation, Basking Ridge, NJ, [3]Stanford University, Portola Valley, CA

Purpose: PsA is a form of inflammatory arthritis with well-established deleterious effects on HRQOL. We evaluated the effect of APR on patient-reported outcomes (PROs) in subjects with PsA.

Methods: A phase 2, multicenter, randomized, double-blind, placebo (PBO)-controlled, efficacy/safety study was conducted in subjects with active PsA (duration >6 mo; ≥3 swollen joints; ≥3 tender joints). Subjects were randomized 1:1:1 to oral APR (40 mg QD or 20 mg BID) or PBO for 12 wk. PROs included Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), Health Assessment Questionnaire–Disability Index (HAQ-DI), global and pain visual analog scales (VAS), physical (PCS) and mental (MCS) component summaries and individual domain scores of Short-Form 36-item (SF-36) and Short-Form 6-Dimension (SF-6D) health utilities. Minimum clinically important differences (MCID) are 4.0 points for FACIT-F, −0.22 for HAQ-DI, 10.0 for VAS, 2.5 – 5.0 for PCS and MCS, and 5.0 – 10.0 for SF-36 domain scores. Minimally important differences (MID) for SF-6D are ≥0.041.

Results: 204 subjects were randomized (52.5% M; mean age 50.6 y). At 12 wk, statistically significant ($P<.05$) treatment-associated improvements in mean PCS (2.4) and MCS (3.4) scores that met or exceeded MCID in 20-mg BID group were observed vs PBO (0.8 and −0.8, respectively). Statistically significant ($P<.05$) mean changes in SF-36 domain scores were observed in 7 of 8 domains in the 20-mg BID group: physical functioning (PF), role physical (RP), bodily pain (BP), general health (GH), social functioning (SF), role emotional (RE), and mental health (MH). These changes were ≥MCID in the PF, BP, SF, RE, and MH domains. Endpoint domain scores in the 20-mg BID group differed from age/gender-matched US normative values by ≈20 points in physical domains, and <10 points in mental domains (except RE), indicating large and clinically meaningful improvements. Mean treatment-associated changes in PCS and MCS in the 40-mg QD group did not meet or exceed MCID and were not statistically significant vs PBO, with the exception of the BP domain ($P=.037$). Treatment-associated improvements in the 20-mg BID and 40-mg QD groups resulted in mean increases of 0.076 and 0.047 in SF-6D scores, respectively, both exceeding MID. More subjects in the 40-mg QD and 20-mg BID groups reported improvements in

HAQ-DI, FACIT-F, and VAS scores ≥MCID vs PBO. Moderate and statistically significant correlations were evident between VAS pain scores and BP, HAQ-DI and PF, and FACIT-F and vitality (VT) domains of SF-36.

Conclusions: Treatment of PsA with APR 20 mg BID was associated with statistically significant and/or clinically meaningful mean improvements vs PBO in PROs including FACIT-F, global/pain VAS, HAQ-DI, SF-36 PCS/MCS, and 7 of 8 domain scores.

Incidence of Tuberculosis in Korean Patients with Ankylosing Spondylitis Treated with Tumor Necrosis Factor Blockers. Eun-Mi Kim[2], Chan-Bum Choi[2], Yoon-Kyoung Sung[2], Wan-Sik Uhm[2], Jae-Bum Jun[2], Tae-Hwan Kim[2], Sang-Cheol Bae[1] and Dae-Hyun Yoo[1]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic of, [2]Hanyang University Hospital for Rheumatic Diseases

Objective: To assess the incidence rate and relative risk of tuberculosis (TB) in patients with ankylosing spondylitis (AS) and in patients with AS treated with tumor necrosis factor (TNF) blockers in Korea.

Methods: Using data from the Korean National Tuberculosis Association(KNTA) as a control and data from a single-center cohort of patients with AS, we conducted an evaluation of 987 patients with AS not exposed to TNF blockers and reviewed medical records of 57, 73 and 208 patients with AS treated with adalimumab, infliximab, etanercept, respectively, between 2002 and 2009.

Results: The mean incidence rate of TB, reported by the KNTA, was 69.8 per 100,000 person years (PS) from 2002 to 2009. In the TNF-blocker-naïve AS cohort, 10 cases of TB developed during 3247PY of followup (308 per 100,000 PY). In the adalimumab-treated AS group, 1 case of TB developed during 204 PY of followup (490 per 100,000 PY). In the infliximab-treated AS group, 2 cases of TB developed during 366 PY of followup (540 per 100,000 PY). In the etanercept-treated AS group, there was no case of TB during 1214 PY of followup. The risk of TB was higher in AS patients not treated with TNF blockers (risk ratio 4.3), in those treated with adalimumab (risk ratio7.0), and in those treated with infliximab (risk ratio 7.7) compared with the general Korean population.

Conclusion: The risk of TB infection is 4.3-fold higher in Korean patients with AS, 7.0-fold higher in AS patients treated with adalimumab and 7.7-fold higher in those treated with infliximab, compared with the general Korean population.

Long-Term Drug Survival of Anti-TNF Therapy in Ankylosing Spondylitis. Qiang Li[1], Michelle Y. Seah[2], John A. Burgess[3], Shyamali Dharmage[3], Belinda J. Martin[1], Russell Buchanan[1] and Lionel Schachna[1]. [1]Austin Health, Melbourne, Australia, [2]Austin Health, Melbourne, Australia, [3]University of Melbourne, Melbourne, Australia

Background: Unlike rheumatoid arthritis, the long-term efficacy and safety of TNF inhibitor (TNFi) therapy in ankylosing spondylitis (AS) is largely unknown. We examined drug survival (ie, continuation) rates of TNFis among a large cohort of AS patients.

Methods: All biologically-naive patients with active AS commencing TNFi therapy in a single center were followed to March 31, 2010. The effectiveness of treatment was examined by drug survival using life table analysis and multivariate Cox proportional hazards analysis.

Results: We examined 209 consecutive patients who received a total of 326 TNFi courses for active AS over 581.0 patient-years; the median treatment duration was 32.9 months (range: 0.4–68.3). The first TNFi was infliximab in 87 (41.6%), adalimumab in 66 (31.6%) and etanercept in 56 (26.8%). Men constituted 153 (73.2%) of the study sample and the mean age at inclusion was 42.4 (SD 11.9) years with disease duration of 19.1 (SD 11.3) years. At the end of follow-up, 128 (61.2%) remained on their first TNFi while 52 (24.9%) had switched to their second, and 24 (11.5%) to a third TNFi. The reasons for TNFi discontinuation were secondary inefficacy (34.6%), adverse event (24.1%), primary inefficacy (21.1%), convenience (12.0%) and other (8.3%). Treatment discontinuation due to adverse events occurred more commonly for infliximab 19 (17.0%) compared with adalimumab 6 (5.0%) (odds ratio (OR) 3.9, 95CI, 1.4–12.4) and etanercept 7 (7.5%) (OR 2.5, 95CI, 0.9–7.4). Only 13 patients (6.2%) had ceased TNFi therapy entirely (primary inefficacy (3), adverse event (5), planning to conceive (1), other (4)). Drug survival for the first TNFi therapy was 0.82, 0.72, 0.60, 0.53 and 0.43 at 6, 12, 24, 36 and 60 months, respectively. At similar time points, drug survival for the second TNFi was lower only for the first 12 months: 0.74, 0.64. 0.58, 0.52 and 0.44, respectively (p=0.32). For the second course of TNFi, primary inefficacy to the first TNFi was associated with drug survival at 6 months of only 0.50 compared with 0.84 for prior secondary inefficacy and 0.82 for adverse events (p=0.11). Survivor function was equivalent for all TNFis, by log rank test. Predictors for treatment discontinuation in multivariate analysis were absence of HLA-B27 (hazards ratio (HR) 2.0, 95CI, 1.1–3.8) and female sex (HR 2.0, 95CI, 1.3–3.0).

Conclusions: Switching to an alternative TNFi is common in AS but few patients entirely cease treatment. Primary inefficacy to initial TNFi is associated with low continuation rates of a second TNFi.

1943

Long-Term Radiographic Outcome in Psoriatic Arthritis Patients Treated with Golimumab: 104 Week Results from the GO-REVEAL Study. Arthur Kavanaugh[7], Desiree M. Van Der Heijde[4], Dafna D. Gladman[6], Philip J. Mease[5], Iain B. McInnes[8], Gerald G. Krueger[9], Weichun Xu[3], Neil Goldstein[2] and Anna Beutler[1]. [1]Centocor Research and Development, Inc, Collegeville, PA, [2]Centocor Research and Development, Inc, [3]Centocor Research and Development, Inc., [4]Leiden University Medical Center, Meerssen, The Netherlands, [5]Seattle Rheumatology Associate, Seattle, WA, [6]Toronto Western Hospital, Toronto, ON, Canada, [7]University of California-San Diego, La Jolla, CA, [8]University of Glasgow, Glasgow, United Kingdom, [9]University of Utah Health Sciences Center

Objectives: Golimumab (GLM), a human monoclonal anti-TNFα antibody administered as every 4 weeks subcutaneous injections demonstrated long-term clinical efficacy and acceptable safety through wk104. The effect of GLM on inhibition of progression of structural damage PsA pts has been shown through wk52. Week 104 radiographic results are being reported now.

Methods: Adult PsA pts with ≥3 swollen & ≥3 tender joints (SJC/TJC) were randomized to receive SC placebo (PBO) or GLM 50 mg or 100 mg q4 wks. At wk16, pts with <10% improvement in SJC/TJC's entered early escape (EE) in a double-blinded manner to GLM 50 mg

(PBO pts) or GLM 100 mg (GLM 50 mg pts). All pts randomized to PBO received GLM 50 mg from wk24 through wk104. Pts on GLM 50 mg could be dose-escalated based on the investigator's judgment to GLM 100 mg after unblinding at wk52. Radiographs of the hands and feet were read at wks 0, 52, and 104. Erosions and joint space narrowing were evaluated by two independent readers unaware of treatment and image time sequence using the van der Heijde-Sharp (vdH-S) method modified for PsA. Data was analyzed based on randomized groups. Due to lack of adequate control arm, no statistical comparisons were performed at wk52 or wk104.

Results: 405 pts were enrolled. Mean age was 46–48 yrs, median SJC/TJC's were 12–14/22–24, HAQ scores were 1.0–1.1, CRP levels were 0.6 mg/dL, and mean (median) total vdH-S scores were 16.34–22.99 (9.00–10.50).

Conclusions: GLM 50 mg and 100 mg treated patients with active PsA showed no to minimal evidence of radiographic disease progression through wk104.

1944

Low Doses of Etanercept Can Be Effective in Ankylosing Spondylitis Patients Who Achieve Remission of the Disease. Victoria Navarro Compán, Rafael Ariza Ariza, Carmen Vargas Lebrón, Blanca Hernández Cruz, Virginia Moreira Navarrete and Federico Navarro Sarabia. Hospital Universitario Virgen Macarena

Background: There is no evidence other than symptoms control to maintain the antiTNF therapy in patients with ankylosing spondylitis (AS). In this regard, low dose regimens could be considered in patients whose disease is clinically controlled. Moreover, the economic implications of this strategy can be important. However, although dose reduction can be common in clinical practice, the available data about it are scarce.

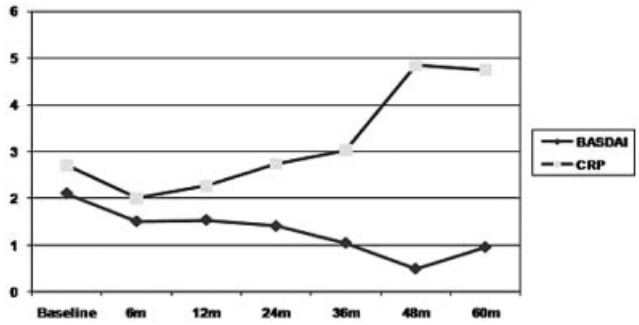
Objective: to explore the effectiveness of low dose of etanercept (ETN) in patients with ankylosing spondylitis (AS) who achieves a good control of their disease in daily clinical practice.

Methods: case series of AS patients treated with ETN. According to the judgment of the treating rheumatologist and patient′s preferences, a dose reduction was done in those patients who achieved a good control of their disease defined by BASDAI < 5 and C-reactive protein normal values. Descriptive statistics were calculated with mean, mode, median, ranges percents and lower and upper quartiles.

Results: 51 AS patients treated with ETN were identified and 16 of them (32%) were on dose reduction regimen.]

Group	Patients with low doses of Etanercept*	All
	n=16, 32%	n=51, 100%
Male n, %	14 (94%)	45 (91%)
HLA-B27 + n, %	14 (87%)	43 (84%)
Peripheral arthritis	3 (19%)	36 (71%)
Uveitis n, %	5 (31%)	41 (80%)
Sacroilitis n, %	4 (25%) II	12 (24%) II
	10 (62.5%) III	20 (39%) III
	2 (12.5%) IV	19 (37%) III
Previous DMARD treatment n, %	6 (31%)	34 (67%)
	Median (range)	Median (range)
Age, years	42.5 (30.5–57)	44 (32.53)
Disease duration, years	8 (3.5–14.7)	10 (6.5–18)
BASDAI	5.8 (4.5–7.7)	6.2 (4.7–7.9)
BASFI	5.9 (4.2–6.9)	6.5 (5–8.1)
ESR	34 (16–72)	29 (14–72)
CRP (mg/L)	17.9 (9.1–33.0)	18 (10–39)
PGA	55 (47–84)	62 (50–87)

Several regimens of dose reduction were used. Mean time receiving ETN before adjusting the dose was 17 ± 12 months. Mean follow up after dose change was 2 1±21 months. At this point all the patients in whom dose reduction was done remained in the low dose regimen. Median BASDAI (range) at starting the low dose regimen and 6 months later were 1.6 (0.9–2.4), and 1.4 (0.3–3.2), respectively. Median CRP values (range) at starting the low dose regimen and 6 months later were 1mg/l (0.1–2.8), and 1.3 mg/l (0.3–4.1), respectively. Other disease-related variables also remained unchanged. Patients with follow up at 12 and 24 months and longer remained in clinical remission with BASDAI values <2 and normal CRP values.



Conclusions: our data suggest that AS patients in clinical remission can use low doses of ETN without increasing disease activity. So, it can be a promising strategy but additional studies are needed to prove it.

1945

Methotrexate Does Not Influence Infliximab Pharmacokinetics and Concentration-Effect Relationship in Ankylosing Spondylitis. Emilie Ducourau[2], David Ternant[2], Francine Lauféron[2], Denis Mulleman[2], Daniel Wendling[1], Gilles Paintaud[2] and Philippe Goupille[2]. [1]Universite de Franche-Comte, Besançon, France, [2]Universite François Rabelais de Tours, Tours, France

Introduction: Methotrexate (MTX) was shown to modify IFX pharmacokinetics in rheumatoid arthritis (1). However, its combination with infliximab in the treatment of ankylosing spondylitis (AS) is not recommended. The objective of this study was to investigate the influence of MTX on IFX pharmacokinetics and pharmacokinetic-pharmacodynamics (PK-PD) in axial AS patients.

Methods: Patients with axial AS were randomized to receive infliximab alone (infusions of 5 mg/kg at week 0, 2, 6, 12 and 18) or infliximab combined with MTX (10 mg/week). A clinical and laboratory evaluation was performed at each visit. The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) was the primary endpoint of clinical response. The pharmacokinetics of IFX was described using a two-compartment model with

first order distribution and elimination constants. The relationship between IFX concentration and BASDAI score was described using an indirect response model with inhibition of BASDAI 'input'. A population approach was used and models were run simultaneously. The influence of MTX was tested as a covariate on each pharmacokinetic and PK-PD parameter.

Results: Twenty six patients were included (14 with MTX, 12 without MTX). A total of 507 blood samples were available for measurement of serum infliximab (2). The PK analysis showed an influence of body size and history of a previous anti-TNF failure on the distribution volume of the central compartment but did not identify any influence of MTX on the estimated parameters (3). The evolution of BASDAI, clinical measurements and biomarkers of inflammation were no different in both groups. Main pharmacodynamic parameters were the maximum inhibition of BASDAI input (Em) = 46%, (59%) and the concentration leading to 50% of Em (C50) = 6.3 mg/L. MTX did not influence any of pharmacokinetic or PK-PD parameters.

Conclusion: MTX influenced neither pharmacokinetics nor PK-PD of IFX. Our study does not support the combination of methotrexate with infliximab in axial AS.

1946

Nonsteroidal Anti-Inflammatory (NSAIDs) Drug-Sparing Effect and Sustained Clinical Improvement of Etanercept in Advanced Ankylosing Spondylitis. Results of an Open Label Extension Following a Randomized Double Blind Placebo-Controlled Study (SPINE). Maxime Dougados[2], Jürgen Braun[5], Sandor Szanto[6], Bernard Combe[1], Pal Geher[4], Veronique Leblanc[3] and Isabelle Logeart[3]. [1]Lapeyronie Hospital, Montpellier, France, [2]Paris-Descartes Univ, Cochin Hospital, Paris, France, [3]Pfizer France, Paris La Défense, France, [4]Polyclinic of the Hospitaller Brothers of St. John of God, Budapest, Hungary, [5]Ruhrgebiet Univ, Herne, Germany, [6]Univ of Debrecen, Debrecen, Hungary

Background: Etanercept (ETN) was showed to significantly improve rheumatic signs, symptoms and pulmonary function in patients with advanced ankylosing spondylitis during the randomized placebo-controlled trial (RCT) phase of SPINE study (1). A pre-planned open label extension (OLE) was aimed at assessing the sustained rheumatic effects of ETN for 3 additionnal months. In contrast to the RCT phase, the NSAID intake was at the discretion of the patients during this OLE phase. The purpose was to evaluate whether ETN therapy could be maintained with a concomitant NSAID treatment reduction.

Methods: *Patients*: Definite AS patients (modified New York criteria) with active (BASDAI ≥40), refractory (at least 2 NSAIDs), severe (at least 2, 3 or 2 inter-vertebral radiological consecutive bridges at the lumbar, thoracic or cervical level respectively), anti-TNF naive. *Study design*: Multicenter, double blind, RCT vs placebo of 12-week duration followed by a 12-week OLE. Patients who completed RCT phase entered the OLE and received etanercept (ETN). *Study drugs*: ETN 50 mg OW and identical placebo (PBO) during RCT phase and ETN 50 mg OW during the OLE phase. *Outcome measures*: BASDAI, BASFI, BASMI, and intake of NSAIDs using the ASAS-NSAIDs scoring system (2).

Results: Of the 82 randomized patients, 77 (males: 92%, age: 47.5±10.5 y, disease duration (since AS diagnosis): 16±10.7 y, B27 positive: 83.1%) entered the OLE phase (original ETN group: n=38; original PBO group, n=39). At baseline, patients had an active (BASDAI: 61.5±13.2, CRP: 20.5±26.1 mg/l) and severe (BASMI: 5.7±1.4, mSASSS: 37±20.2) disease and 83.1% of patients were receiving one NSAID at least at baseline. During the 12 weeks of the OLE trial, 3 patients discontinued the treatment (1 in the original PBO arm [due to withdrawal of consent] and 2 in the original ETN arm [due to withdrawal of consent: 1; due to lost to follow-up:1]). The mean change in BASDAI from baseline showed a sustained improvement reaching −15±20 and −27.4±23.8 at Week 12 and −28.6±24.3 and −37.6±22.4 at Week 24 in the original PBO group and ETN group, respectively.

Whatever the original group, the concomitant intake of NSAIDs significantly decreased during OLE phase in comparison to RCT phase: mean absolute change in ASAS-NSAID equivalent score between OLE and RCT was – 39.5 (−36%), p=0.005 and −20.9 (−17%), p=0.0005 in the original ETN and placebo group, respectively.

Conclusion: This prospective study conducted in advanced AS patients confirms the sustained symptomatic efficacy of ETN. Despite a relevant decrease in NSAIDs intake, such findings might be beneficial for the patients, not only in terms of long term symptomatic status but also in terms of prevention of long term NSAIDs toxicity.

1947

Periarticular Bone Changes in Psoriatic and Rheumatoid Arthritis Patients Following Anti-TNF-alpha Therapy. Agnes Szentpetery[2], Phil Gallagher[2], Susan Van der Kamp[2], Malachi J. McKenna[1], Douglas J. Veale[2] and Oliver FitzGerald[2]. [1]St. Vincent's University Hospital, Department of Endocrinology, Dublin, Ireland, [2]St. Vincent's University Hospital, Department of Rheumatology, Dublin, Ireland

Purpose: to examine the effect of anti-TNF-alpha therapy on periarticular bone mineral density (BMD) in patients with psoriatic arthritis (PsA) and rheumatoid arthritis (RA) prior to and 3 months, 1 and 3 years after receiving biologic treatment. Further, to explore associations between hand BMD and clinical responses in PsA and RA.

Methods: PsA and RA patients with active disease were selected following a decision to commence anti-TNF-alpha therapy. Global hand dual-energy × ray absorptiometry (DXA) including all hand bones distal to the wrist joint and 7 sub-regions of interests (ROI) were analysed at baseline, 3 months, 1 and 3 years. These included the carpus (R1) and the periarticular regions of 2nd (R2), 3rd (R3) and 4th (R4) MCPs and the 2nd (R5), 3rd (R6) and 4th (R7) PIPs. Clinical assessments including ESR, CRP, DAS28-CRP and HAQ were recorded at all time points.

Results: 62 patients (27 PsA, 35 RA) were recruited. Patients' median disease duration was 7 years (0.16–40). At baseline, global hand BMD (g/cm^2) was significantly greater in PsA than RA (0.349 v.0.327 p=0.025) and remained higher at all time points. BMD was higher in PsA than in RA in each ROI at all time points except in R2 at 3 years. BMD was significantly higher in PsA than in RA at baseline and at 3 months in R5 (0.316 v. 0. 292 p=0.035 and 0.316 v. 0.279 p=0.028) and R6 (0.331 v. 0.302 p=0.042 and 0.329 v. 0.293 p=0.04).

ESR remained significantly lower in PsA than in RA at all time points ($p<0.05$). In PsA CRP was lower at baseline and at 3 month whilst DAS28-CRP at 3 months and 12 months compared with RA ($p<0.05$). SJC, DAS28-CRP and HAQ remained lower in PsA during the study period.

In PsA, there were significant negative correlations between ESR and global hand BMD at 1 year (r = −0.6; p=0.028) and at 3 years (r = −0.6; p=0.008) and in RA between DAS28-CRP and global BMD at 3 years (r = −0.4; p= 0.025).

Conclusions: Periarticular bone density was higher in PsA at all time points but increased with anti-TNF-alpha treatment in both diseases. Higher periarticular bone density was associated with lower inflammatory activity in both diseases but earlier in PsA. Anti-TNF-alpha therapy reduces periarticular bone loss in patients with inflammatory arthritis.

Prediction of Early Response to Anti-TNF Therapy and Disease Activity State Using the Ankylosing Spondylitis Disease Activity Score (ASDAS). Nathan Vastesaeger[5], Yanxin Wang[6], Robert D. Inman[9], Atul A. Deodhar[7], Benjamin L. Hsu[1], Mahboob U. Rahman[2], B. A. C. Dijkmans[11], Juergen Braun[8], Piet P. Geusens[10], Joachim Sieper[3] and Desiree M. Van Der Heijde[4]. [1]Centocor Research and Development, Inc./Univ. of Pennsylvania School of Medicine, Wynnewood, PA, [2]Centocor Research and Development, Inc./ Univ. of Pennsylvania School of Medicine, Malvern, PA, [3]Charite Campus Benjamin Frankl, Berlin, Germany, [4]Leiden University Medical Center, Meerssen, The Netherlands, [5]Merck and Co., Inc., Whitehouse Station, NJ, [6]Merck and Co., Inc., [7]Oregon Health Sciences University, Portland, OR, [8]Rheumazentrum Ruhrgebiet, Herne, Germany, [9]Toronto Western Hospital, Toronto, ON, Canada, [10]University Hasselt, Genk, Belgium, [11]VU Medical Centre, Amsterdam, The Netherlands

Objectives: We previously reported that in the ASSERT and GO-RAISE studies, BASDAI50 response can be accurately predicted with a combination of baseline characteristics. This analysis compares the accuracy of predicted response rates and disease activity as measured by different assessments, including the ASDAS.

Methods: The ASSERT and GO-RAISE trial data were combined and baseline characteristics were used to predict the probability for achieving week 12 ASAS20, BASDAI50 and ASDAS major response and BASDAI and ASDAS scores at week 12. Univariate analyses identified baseline predictors for response. Variable associations were explored using Spearman correlation analysis. A stepwise selection procedure using logistic regression, ROC and correlation analyses was used to select a final set of predictors. Logistic regression was used to calculate the predicted week 12 BASDAI and ASDAS scores and the probability of week 12 response to anti-TNF or placebo respective to combined selected predictors at baseline. The accuracy of prediction between the different assessments was compared using ROC analyses and R-square.

Results: 479 AS patients (NY modified criteria) treated with anti-TNF and 156 patients treated with placebo with continued conventional therapy, with BASDAI and spinal pain assessment ≥ 4 were included. Age (mean 39.5; SD 11.3 yrs), BASFI, (mean 5.4; SD 2.2 cm), Berlin enthesitis-score (mean 2.4; SD 2.9), therapy (anti-TNF or placebo), CRP (mean 2.1; SD 2.4 mg/dL) and HLA-B27 genotype [(+) or (−)] were retained as final predictors of response. The area under the ROC curve of the model which included the six selected predictors (log transfer of CRP values) and interactions between predictors was 0.85, 0.79 and 0.75 and the R-square was 0.43, 0.33 and 0.24 for week 12 ASDAS major response, BASDAI50 response and ASAS20 response, respectively. This indicates good accuracy for prediction of BASDAI50 and ASDAS major response and fair accuracy for ASAS20 response. The R-squares of 0.49 and 0.27 for ASDAS and BASDAI scores respectively, indicate that the week 12 disease activity measured by ASDAS could be more reliably predicted. The figure shows the predicted change in ASDAS from baseline to week 12 versus actual changes.

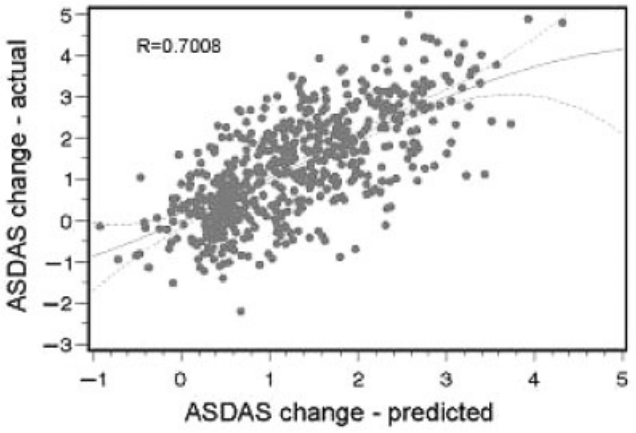

Figure. Change from baseline to week12 in ASDAS score.

Conclusion: Elevated CRP, lower age, lower enthesitis score, lower BASFI, and presence of HLA-B27 genotype are associated with a better treatment response at week 12 in ASSERT and GO-RAISE. The values of these characteristics at baseline allow calculating the predicted response rates and future disease activity of an individual patient. The accuracy of predicting ASDAS and ASDAS response is good and higher than that of other assessments.

Predictors of Radiographic Progression in Adalimumab-Treated Patients with Ankylosing Spondylitis. Walter Maksymowych[5], Desiree van der Heijde[3], Robert Landewe[4], Aileen Pangan[2], Steve Brown[2] and Frederic Lavie[1]. [1]Abbott Laboratories, Rungis, France, [2]Abbott Laboratories, Abbott Park, IL, [3]Leiden University Medical Center, Leiden, The Netherlands, [4]Maastricht University Medical Center, Maastricht, The Netherlands, [5]University of Alberta, Alberta, BC, Canada

Objective: To identify factors contributing to radiographic progression over 2 years in patients with Ankylosing Spondylitis (AS) who are treated with adalimumab (ADA).

Methods: The ATLAS trial randomized AS patients to treatment with ADA or placebo for a 24-wk double-blind period, followed by an open-label extension with ADA. Two independent blinded readers scored X-rays obtained at baseline and year 2 using the mSASSS method. Dependent variables were: 1) change in mSASSS ≥2 and ≥4 (severe progression) from baseline through 2 years, and 2) development of new syndesmophytes at year 2. Independent variables were age, disease duration, spinal mobility (cervical rotation and lateral lumbar flexion), area under the curve (AUC) from baseline to 2 years for CRP and ASDAS, and baseline ASDAS and mSASSS. Categorical variables were also included: HLA-B27, sex, peripheral synovitis at baseline (SJC>0), peripheral enthesitis at baseline (MASES>0), presence of baseline syndesmophytes, and history of uveitis. Associations were tested univariately; significantly associated variables were entered as explanatory variables in a multivariate analysis.

Results: This analysis includes 275 subjects with 2 years of exposure to ADA; at baseline, subjects had mean disease duration of 10.8 years, mean ASDAS of 3.7, and mean mSASSS of 20.3; syndesmophytes were present in 85% of patients at baseline. Radiographic progression (ΔmSASSS ≥2) was found in 61 subjects (22%), and severe radiographic progression (ΔmSASSS ≥4) was observed in 22 subjects (8%). New syndesmophytes were found by either reader in 106 subjects (39%).

Univariate analysis identified significant associations for age, mobility, and baseline bone damage with radiographic progression (Table). Linear regression revealed similar findings. Sex, HLA-B27, uveitis, peripheral synovitis or enthesitis, disease duration, baseline ASDAS, and CRP levels were not predictive in any analysis.

Table. Logistic regression for factors associated with radiographic progression

Variable	Odds Ratio (95% CI)		
	ΔmSASSS ≥2	ΔmSASSS ≥4	new syndesmophytes[a]
Age	1.04 (1.009, 1.062)†	1.04 (1.003, 1.084)†	1.02 (0.996, 1.040)
Syndesmophytes (BL)	3.87 (1.126, 13.301)*	n/a	6.45 (2.165, 19.200)*
mSASSS (BL)	1.03 (1.011, 1.039)*	1.03 (1.009, 1.049)*	1.01 (1.002, 1.026)†
Cervical rotation (BL)	0.98 (0.968, 0.995)*	0.99 (0.966, 1.006)	0.99 (0.974, 0.996)*
Lateral lumbar flexion (BL)	0.98 (0.890, 1.067)	0.64 (0.476, 0.859)*	0.91 (0.842, 0.992)†
ASDAS AUC (BL to 2 yr)	1.00 (0.997, 1.003)	1.01 (1.001, 1.009)†	1.00 (0.998, 1.003)

[a]identified by either Reader 1 or Reader 2; BL: baseline; n/a: not a valid logistic regression model; *$P \leq 0.01$; †$P < 0.05$.

Multivariate analysis was conducted using significant factors from univariate analysis, with the exception of mobility scores, which are intermediate variables. Only baseline mSASSS was consistently identified as a significant contributor to radiographic progression (ΔmSASSS ≥2 and ≥4, OR [95% CI]: 1.02 [1.005, 1.036], $P<0.01$ and 1.02 [1.001, 1.046], $P=0.04$) and only baseline syndesmophytes were predictive of the development of new syndesmophytes (OR [95%CI]: 7.63 [2.381, 24.476], $P<0.01$).

Conclusion: Clinical measures of disease activity were not related to radiographic progression. Only the presence of radiographic damage at initiation of therapy was consistently associated with the formation of new syndesmophytes through 2 years in AS patients treated with adalimumab. These results support previous studies suggesting a disconnect between disease activity and bone formation in patients with long-standing AS.

Prevalence of Psoriatic Arthritis in Thai Psoriasis at Ramathibodi Hospital. Bodin Butthum[4], Suphaneewan Jaovisidha[1], Pintip Ngamjanyaporn[3], Surachai Nithiketkul[2] and Suchela Janwityanujit[2]. [1]Department of Radiology Faculty of Medicine, Ramathibodi Hospital, Mahidol University, [2]Division of Allergy Immunology and Rheumatology, Department of Medicine Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand, [3]Division of Allergy Immunology and Rheumatology, Department of Medicine Faculty of Medicine, Ramathibodi Hospital, Mahidol University, [4]Naresuan University, Department of Medicine, Phitsanulok, Thailand

Objective: To determine the prevalence as well as the clinical features of psoriatic arthritis (PsA) in Thai patients with psoriasis. Factors highly associated with the diagnosis of PsA will also be identified.

Methods: Psoriatic patients who visited the dermatology clinic at Ramathibodi hospital during July 1 to December 31, 2009 were prospectively studied. A standard clinical protocol for PsA was used to assess patients for the actively inflamed joint count, dactylitis, enthesitis, nail change, range of body movement and the presence of back disease. X-ray films of the hands, feet, whole spine and the sacroiliac (SI) joints were taken. Based on the clinical and radiological information, the diagnosis of psoriatic arthritis was classified by CASPAR Classification Criteria for Psoriatic Arthritis (1) and the five clinical subsets defined by Moll and Wright (2) were assigned to each patient. Clinical variables indicative of PsA were also collected.

Results: Three hundred and two psoriatic patients (149 males and 153 females) who had complete X-ray studies as defined in the protocol were analyzed. The prevalence of PsA in psoriatic patients was 43.05% (130/302; 73 males and 57 females). Mean age, mean duration of disease and male to female ratio in patients with PsA were 51.3 years old, 12.2 years and 1.3:1 respectively, not differed from those with psoriasis alone. Spondylitis was the most common pattern of PsA (83.1%) followed by polyarthritis, oligoarthritis, DIP involvement and arthritis mutilans in our group of PsA patients. Interestingly, more than half of our psoriatic patients (150/179) had radiographic abnormalities without clinical criteria for PsA.

Conclusion: Radiological assessment gives additional arthritic findings not gained by clinical examination alone. Nail change, morning stiffness more than 1 hour, buttock pain and history of joint inflammation are suggestive of PsA in psoriatic patient.

1951

Psoriatic Arthritis and Onycholysis—Results from a Study of 1116 Patients with Psoriasis, and Follow-Up of Those with Psoriatic Arthritis over 1–6 Years. Thorvardur J. Love[2], Johann E. Gudjonsson[4], Helgi Valdimarsson[1] and Bjorn Gudbjornsson[3]. [1]Landspitali University Hospital, [2]Landspitali University Hospital, Boston, MA, [3]Landspitali University Hospital, Center for Rheumatology Research, [4]University of Michigan, Department of Dermatology

Psoriatic arthritis is an arthritis associated with the skin disease psoriasis. It is associated with nail changes, and small joint disease is associated with onycholysis. While 15% - 50% of patients with psoriasis have nail changes, up to 85% of patients with psoriatic arthritis do. However, subtypes of nail changes are rarely reported on. We studied the subtypes of nail changes in psoriasis patients and their associations with psoriatic arthritis, as well as the progression of nail changes over 1–6 years.

Methods: We performed a cross sectional analysis of the association between psoriasis and psoriatic arthritis and nail changes. We then followed those patients reporting psoriatic arthritis 1–6 years later, and re-evaluated their fingernails. Psoriasis cases were located from community sources, primarily a local psoriasis patient group, and only those cases with skin disease present, and 18 years of age or older, were included. Location and pattern of skin and nail involvement was recorded. Most patients had their HLA-C type determined. All patients were asked if they had been diagnosed with psoriatic arthritis by a rheumatologist. One to six years later, those patients who had reported psoriatic arthritis were asked to participate in a second study where they were evaluated for skin, nail and joint disease. We tested the location and pattern of skin findings, type of nail changes, and HLA-Cw06 status when available for an association with psoriatic arthritis using the chi-square test and univariate logistic regression. Those variables that were significantly associated with psoriatic arthritis on univariate analysis at a p value of 0.05 or less were further analyzed in a multivariate logistic regression model. Age and gender were included as covariates in all multivariate analyses.

Results: We recruited 1116 patients age 18 or older with active psoriatic lesions on physical examination. The mean age of onset of psoriasis SD was 20.8 +/− SD 12.5 and 56% were women. Chronic plaque psoriasis was present in 94%, with arms, scalp, and legs involved in 85%, 77%, and 71%, respectively. Nails were involved in 36% of patients, and the most common nail change was onycholysis. 183 patients or 16% reported having psoriatic arthritis. Onycholysis, subungual hyperkeratosis, and pitting were all associated with psoriatic arthritis on univariate analysis. Multiple logistic regression showed that onycholysis remained strongly associated with psoriatic arthritis with an OR of 2.02 while the other two types of nail changes no longer showed statistically significantly associations. On follow-up 122 of the 183 patients were evaluated again. All types of nail changes had increased in prevalence, with the overall prevalence of nail changes rising from 36% to 80%. Less than 4% of patients had all nail changes disappear from the first to the second visit.

Conclusions: Psoriatic arthritis is strongly associated with nail changes. Onycholysis may be more associated with arthritis than pitting or subungual hyperkeratosis. Nail changes tend to progress and rarely remit. More studies looking at the subtypes of nail changes in psoriasis and psoriatic arthritis are needed to confirm these findings.

1952

Psoriatic Arthritis: Oligoarticular or Polyarticular Presentation? Carlotta Nannini[1], Laura Niccoli[2], Emanuele Cassarà[2], Olga Kaloudi[2] and Fabrizio Cantini[2]. [1]Rheumatology Unit, Hospital of Prato, Prato, Italy, [2]Rheumatology Unit, Hospital of Prato, Italy

Background: Polyarthritis has been reported as the most frequent pattern in patients (p.) with Psoriatic Arthritis (PsA), with an estimated frequency of 60%.

Objectives: To determine the occurrence of the different PsA subgroups in a cohort of p. with early PsA selected using the CASPAR criteria.

Methods: We evaluated a cohort of 242 new consecutive outpatients with PsA observed between January 2000 and December 2009 at a secondary referral center. As controls 184 new consecutive early rheumatoid arthritis (RA) outpatients were used. Demographic, clinical, laboratory and radiological data were collected and stored in a computed database. In PsA p. the following clinical patterns were considered: peripheral (oligoarthritis $\leq$4 and polyarthritis $\geq$5 involved joints), axial (Calin's criteria for inflammatory spinal pain, radiologic or MRI evidence of sacroiliitis), mixed (concomitant axial and peripheral features). Involved joints were counted separately without grouping hand and foot small joints.

Results: Female gender (137/242; 57%) was significantly lower in PsA compared to RA (140/184; 78.2%) ($p<0.001$). Mean age was 50.33 $\pm$ 11.7 ys in PsA and 57.2 $\pm$ 13.55 years in RA ($p<0.001$). Mean disease duration of symptoms was 9.38 $\pm$ 2.0 mo. in PsA cohort and 10.1 $\pm$ 1.75 mo. in PsA cohort. At diagnosis, the total number of involved joints was significantly lower in PsA compared to RA ($p<0.001$). Table 1 summarizes the comparison between the demographic and clinical features of early PsA and early RA.

Table 1.

	PsA total	RA	P value
Total N of patients	242	184	-
Age at PsA or RA Dx (yrs)	50.3 ± 11.7	57.2 ± 13.55	<0.001
Female N(%)	137 (57%)	140 (78.2%)	<0.001
Duration of sympthoms (mo)	9.38 ± 2.0	10.1 ± 1.75	NS 0.8
Total N of involved joints at Dx	3 ± 3.5	16.2 ± 7.98	<0.001
ESR at Dx (mm1h)	31 ± 18	56.2 ± 25.03	<0.001
CRP at Dx (mg/dl)	1.83 ± 2.28	3.3 ± 3.37	<0.001
Low back pain N(%)	117 (48%)	NA	
Dactylitis N(%)	62 (26%)	NA	
Enthesitis N(%)	79 (33%)	NA	
Tenosinovitis N(%)	55 (23%)	NA	
Peripheral involvement N(%)	132 (51%)	NA	
Back involvement N(%)	41 (17%)	NA	
Mix involvement N(%)	69 (28%)	NA	
Sacroileitis N(%)	105 (43%)	NA	
Monolateral sacroileitis N(%)	41 (17%)	NA	
Bilateral sacroileitis N(%)	60 (25%)	NA	
HLA B27 N(%)	30 (12.4%)	NA	
HLA CW6 N(%)	58 (24%)	NA	
HLA B39 N(%)	9 (4%)	NA	

As shown in table 2, polyarthritis was present in 54 (22%) PsA p. and 164 (89.3%) RA p. (p<0.001), oligoarticular and monoarticular involvement in PsA was present in 188 patients (78%).

Table 2.

	PsA			
	PsA polyart	Non Polyart	RA polyart	P value
Total N of patients	54 (22%)	188 (78%)	164 (89.3%)	<0.001
Age at PsA or RA Dx (yrs)	54.1 ± 13.49	49.3 ± 11.07	57.2 ± 13.76	<0.001
Female N (%)	25 (54.3%)	88 (55.3%)	86 (78.9%)	<0.001
Duration of sympthoms (mo)	6 ± 5.12	10.0 ± 1.62	9.9 ± 1.74	NS 0.74
Total N of involved joints at Dx	6 ± 4.84	1.6 ± 1.54	17.6 ± 7.12	<0.001
ESR at Dx (mm1h)	33 ± 19.36	29.2 ± 18.62	39.3 ± 33.77	0.005
CRP at Dx (mg/dl)	1.7 ± 2.26	1.7 ± 2.31	2.0 ± 2.35	NA 0.48
Low back pain N (%)	12 (26.1%)	93 (58.5%)	NA	<0.001
Dactylitis N(%)	7 (15.2%)	47 (29.6%)	NA	NS 0.08
Enthesitis N(%)	4 (12.5%)	7 (6.4%)	NA	NS 0.25
Tenosinovitis N(%)	10 (21.7%)	44 (27.7%)	NA	NS 0.42

Conclusion: Differently from other reports we found oligoarthritis as the most frequent pattern of early PsA with a significant lower number of involved joints compared to RA. This may reflect possible selection biases due to the lack of validated criteria before CASPAR set availability and the referral of p. with more severe disease to tertiary centres.

Radiographic Progression Is Associated with Resolution of Systemic Inflammation in Patients with Axial Spondyloarthritis Treated with TNFα Inhibitors. Susanne Juhl Pedersen[8], Inge Juul Sørensen[13], Kay-Geert Hermann[4], Patrick Garnero[17], Julia S. Johansen[1], Ole Rintek Madsen[9], Annette Hansen[15], Michael Sejer Hansen[10], Gorm Thamsborg[9], Lis Smedegaard Andersen[18], Ole Majgaard[14], Anne Gitte Loft[16], Jon Erlendsson[11], Karsten Asmussen[7], Anne Grethe Jurik[3], Jakob Møller[5], Maria Hasselquist[5], Dorrit Mikkelsen[2], Thomas Skjødt[6] and Mikkel Østergaard[12]. [1]Dep. of Internal Medicine, Herlev Hospital, Copenhagen, Denmark, [2]Dep. of Radiology, Aabenraa Hospital, Aabenraa, Denmark, [3]Dep. of Radiology, Aarhus University Hospitals, Aarhus, Denmark, [4]Dep. of Radiology, Charité University Hospital, Berlin, Germany, [5]Dep. of Radiology, Herlev University Hospital, Copenhagen, Denmark, [6]Dep. of Radiology, Vejle Hospital, Vejle, Denmark, [7]Dep. of Rheumatology, Bispebjerg Hospital, Copenhagen, Denmark, [8]Dep. of Rheumatology, Gentofte and Herlev Hospitals, Copenhagen, Denmark, [9]Dep. of Rheumatology, Gentofte Hospital, Copenhagen, Denmark, [10]Dep. of Rheumatology, Herlev Hospital, Copenhagen, Denmark, [11]Dep. of Rheumatology, Horsens Hospital, Denmark, [12]Dep. of Rheumatology, Hvidovre and Glostrup Hospitals, Copenhagen, Denmark, [13]Dep. of Rheumatology, Hvidovre and Glostrup Hospitals and DANBIO, Copenhagen, Denmark, [14]Dep. of Rheumatology, Hvidovre Hospital, Copenhagen, Denmark, [15]Dep. of Rheumatology, Rigshospitalet, Copenhagen, Denmark, [16]Dep. of Rheumatology, Vejle Hospital, Denmark, [17]INSERM Unit 664, Lyon, and Cisbio Bioassays Bagnols/Cèze, France, [18]Rheumatism Hospital, University of Southern Denmark, Graasten, Denmark

Objectives: To explore the relation between radiographic progression and biomarkers of inflammation (C-reactive protein (CRP), interleukin-6 (IL-6), YKL-40), angiogenesis (vascular endothelial growth factor (VEGF)), cartilage turnover (CTX-II, matrix metalloproteinase 3 (MMP3), total aggrecan, cartilage oligomeric matrix protein (COMP)) and bone turnover (CTX-I, total osteocalcin) and MRI inflammation in patients with axial spondyloarthritis (SpA) treated with TNFα inhibitor.

Methods: Thirty-six patients (27 men, 9 women; median age 40 yrs (range 21–62); disease duration 15 yrs (1–45)) initiated treatment with TNFα inhibitors (infliximab (n=28), etanercept (n=7) and adalimumab (n=1)) and were followed for 46 weeks. Radiographs were evaluated according to the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) at baseline and week 46. Patients developing new syndesmophytes (0 vs. ≥1) or increased in mSASSS (0 vs. ≥1 unit) were compared with those who did not, regarding biomarker levels and MRI inflammation scores of the sacroiliac joints and lumbar spine (Berlin scores) and with biomarker levels of healthy subjects.

Results: The patients increased in mSASSS from median 13 (IQR: 6–24) at baseline to 15 (6–24) (p=0.005) at week 46 (p=0.005). Eighteen (50%) patients increased in mSASSS (i.e. progressed) and 11 (30%) developed new syndesmophytes. mSASSS and biomarkers did not correlate. Compared to mSASSS non-progressors, mSASSS progressors had higher pretreatment total aggrecan (666 ng/ml (537–820) vs. 507 (401–646), p=0.007) and higher time-integrated mean concentrations of total aggrecan from baseline to week 22 (743 ng/ml (612–849) vs. 602 (446–707), p=0.02) and 46 (746 ng/ml (636–895) vs. 638 (450–735), p=0.02). Patients developing new syndesmophytes also had higher time-integrated mean concentration of total aggrecan from baseline to week 22 and 46 as compared to patients without new syndesmophytes (results like above). Development of new syndesmophytes was associated with larger percentage decreases in CRP (−90% (−96;−78) vs. −58 (−88;−25), p=0.007) and IL-6 (−81% (−93;−75) vs. −67 (−89;−16), p=0.02) and increases in osteocalcin (20% (9;36) vs. 9% (−10;25), p=0.049). Radiographic progression was associated with normalization of CRP and IL-6 at week 22 (i.e. CRP ≤8 mg/l and IL-6≤3.3 ng/l) and decrease in MRI inflammation. Radiographic non-progression was associated with persistent systemic inflammation and unchanged/increased MRI inflammation scores (Table 1).

Conclusion: Radiographic progression in patients with axial SpA during treatment with TNFα inhibitors was associated with resolution of systemic inflammation and reduction in MRI inflammation but not with baseline inflammation.

Table 1. Changes in inflammatory parameters (CRP, IL-6 and MRI) versus radiographic progression

	Radiographic progression week 0–46					
	New syndesmophyte (≥1)			mSASSS progression (≥1)		
Changes from baseline to week 0–22	No N=25	Yes N=11	p-value	No N=18	Yes N=18	p-value
CRP decreased to ≤8 mg/l	11 (52)	10 (48)		7 (33)	14 (67)	
CRP remained >8 mg/l	7 (100)	0 (0)	0.03†	6 (86)	1 (14)	0.03†
CRP remained ≤8 mg/l	7 (87)	1 (13)	NS§	5 (63)	3 (38)	NS§

Reliability of Radiographic Scoring Methods in Axial Psoriatic Arthritis. Vinod Chandran[3], Bradley Biagioni[3], Richard Cook[1], Lihi Eder[3], Anupam Wakhlu[3], Michael Li[3], Hua Shen[1] and Dafna D. Gladman[2]. [1]Department of Statistics and Actuarial Science, University of Waterloo, [2]Toronto Western Hospital, Toronto, ON, Canada, [3]University of Toronto Psoriatic Arthritis Clinic, Toronto Western Hospital

Background: More than a third of patients with psoriatic arthritis (PsA) have axial arthritis. Although there are similarities, important differences exist between axial PsA (AxPsA) and Ankylosing Spondylitis (AS). The Bath AS Radiology Index (BASRI), modified Stokes AS Spinal Score (mSASSS) and Radiographic AS Spinal Score (RASSS) were developed to score AS, and Psoriatic Arthritis Spondylitis Radiology Index (PASRI) to score AxPsA. Our aim was to determine the reliability of these scoring systems in AxPsA.

Methods: A computerized scoring module that facilitated scoring radiographic features of axial arthritis on vertebrae, sacroiliac and cervical facet joints, and calculated total scores for all the available scoring methods for AS and AxPsA was developed. Four assessors all rheumatologists blinded to patient information were provided with an e-handbook and one hour training session. Spinal radiographs of 18 patients with AS (satisfying modified NY criteria) and 40 patients with AxPsA (defined as at least unilateral grade 2 sacroiliitis and/or inflammatory back pain and/or restricted spinal mobility) were duplicated, patient identifiers removed, and order randomized. Radiographs were read by the four assessors individually, data entered into the module and scores obtained. Intraclass correlation coefficient (ICC) estimates of the inter- and intra-assessor reliability of scores for each method were obtained. A consensus score for AxPsA patients was also obtained.

Results: The intra-and inter- assessor reliability for the radiographic scoring methods in AS are given in table 1.

Table 1. Inter-class and intra-class correlation coefficients and 95% confidence intervals of radiographic scores in AS (N=18).

Scoring System	Reliability	ICC	95% CI
Sacroiliitis grade (NY criteria)	Between Assessor	0.795	0.646, 0.905
	Within Assessor	0.908	0.837, 0.957
BASRI-spine	Between Assessor	0.861	0.746, 0.938
	Within Assessor	0.955	0.917, 0.98
mSASSS	Between Assessor	0.857	0.735, 0.938
	Within Assessor	0.982	0.967, 0.992
RASSS	Between Assessor	0.748	0.562, 0.888
	Within Assessor	0.961	0.929, 0.983
PASRI	Between Assessor	0.926	0.858, 0.968
	Within Assessor	0.985	0.971, 0.993

All methods had excellent inter- and intra- assessor reliability in AS. Scoring was completed by the assessors within an average duration of 7 minutes. The 40 patients with AxPsA (24 males, age 54 years, disease duration 18 years, mean cervical rotation of 61 degrees, Occiput to wall distance of 2.3 cm, Schober's test of 4.7 cm, Domjan lumbar lateral flexion of 15.5 cm, actively inflamed joint count of 5 and damaged joint count of 16 at the time of radiographic assessment) by consensus read had mean (± standard deviation) BASRI-spine score of 3.98 (2.38), mSASSS of 8 (13.4), RASSS 6.54 (14.1) and PASRI score of 12 (12.3) units. The intra- and inter- assessor reliability for the radiographic scoring methods in AxPsA are given in table 2.

Table 2. Inter-class and intra-class correlation coefficients and 95% confidence intervals of radiographic scores in AxPsA (N=40).

Scoring System	Reliability	ICC	95% CI
Sacroiliitis grade (NY criteria)	Between Assessor	0.67	0.544, 0.785
	Within Assessor	0.807	0.726, 0.875
BASRI-spine	Between Assessor	0.521	0.375, 0.669
	Within Assessor	0.771	0.688, 0.845
mSASSS	Between Assessor	0.652	0.488, 0.798
	Within Assessor	0.911	0.862, 0.949
RASSS	Between Assessor	0.68	0.513, 0.823
	Within Assessor	0.902	0.845, 0.946
PASRI	Between Assessor	0.88	0.817, 0.927
	Within Assessor	0.917	0.874, 0.95

Only PASRI had excellent intra- and inter-rater reliability in AxPsA.

Conclusions: Available radiographic scoring systems have at least moderate inter- and intrarater reliability when applied to AxPsA. The PASRI has the highest reliability in AxPsA and performs well in AS.

1955

Rituximab in Psoriatic Arthritis Provides Modest Clinical Improvement and Reduces Expression of Inflammatory Biomarkers in Skin Lesions. Philip Mease[2], Arthur Kavanaugh[3], Mark Genovese[1], Chris Ritchlin[4], Sanna Rosengren[3], Alex Quistberg[5] and David Boyle[3]. [1]Stanford Univ, [2]Swedish Medical Ctr, Univ. of Washington, [3]U of Calif San Diego, [4]Univ. of Rochester, [5]Univ. of Washington

Purpose: To determine the effect of rituximab (RTX) on clinical measures and inflammatory biomarkers in biopsies of psoriatic skin lesions compared to non-lesional skin before and after therapy with RTX in PsA patients (pts).

Methods: In this open-label study, 21 PsA pts received 1000 mg RTX + 100 mg solu-medrol on days 0 and 15. The primary clinical endpoint was ACR20 at week 24 and secondary endpoints included ACR50/70 and Psoriasis Area and Severity Index (PASI) 50/75 response. Lesional and non-lesional skin biopsies were collected from select patients pre-treatment and at week 8 for gene expression studies. mRNA levels were determined by quantitative PCR analysis and relative expression was determined using cell-based standard. Expression is reported as geometric mean and 95% confidence interval in relative expression units (REU). Paired t-tests were performed on log-transformed data.

Results: Sixty-four percent of patients were female and mean age was 52.7. Baseline tender and swollen joint count were 28.7 and 15.1. Fourteen of 21 subjects had been on anti-TNF previously. Of 21, 9 were on concomitant MTX, which did not have a significant impact on outcomes. Percent(%) ACR20/50/70 responders, by non-responder imputation (NRI) at 24 weeks, were 30/20/5. Percent PASI50/75 responders were 30/15. Subanalysis of response in anti-TNF inhibitor(i) naïve vs. experienced pts showed % ACR20 response by LOCF to be 50/29 and by NRI to be 33/29 and % PASI50 response by LOCF to be 67/36 and by NRI to be 67/14. One SAE occurred after 24 weeks, death due to pulmonary embolus, considered unrelated to investigational therapy.

Of 21 patients, 5 had evaluable pre and 8 week post-treatment skin biopsies. Few CD19 positive B cells were detected in pre and post lesional or non-lesional skin biopsies. However, IL1β, IL8, and Interferon γ (Table) were significantly elevated in lesional compared to adjacent non-lesional skin. These markers were all significantly reduced by rtx. Surprisingly, TNF expression was indistinguishable between non-lesional and pre and post lesional skin. IL6 trended higher in lesional and lower post treatment.

	Non-lesional skin: baseline*	Psoriasis lesion: baseline*	Psoriasis lesion: week 8*	P value†
IL1β	0.436 (0.112–1.69)	17.9 (5.74–55.8)	2.74 (1.33–5.65)	0.0019
IL6	0.109 (0.0505–0.236)	0.171 (0.0545–0.537)	0.0844 (0.0352–0.202)	NS
IL8	0.0886 (0.0600–0.131)	88.8 (38.4–205)	2.54 (0.327–19.8)	0.015
Interferon γ	1.11 (0.554–2.22)	17.2 (11.5–25.6)	7.22 (3.10–16.9)	0.0001
TNFi	14.0 (5.37–36.5)	27.8 (16.4–47.2)	30.7 (20.0–47.0)	NS

Conclusion: In this open label trial of 21 PsA pts treated with RTX, modest improvement in arthritis and psoriasis skin lesions was demonstrated, especially in anti-TNFi naïve pts. Therapy was well tolerated. Few B cells were found in lesional skin, however RTX significantly inhibited expression of certain cytokines, including T cells cytokines such as interferon γ. Skin TNF expression was not elevated in lesions nor was it affected by RTX. These data are consistent with a model wherein skin lesional pathobiology may be influenced by immunological activity in other sites.

1956

Smoking Is Negatively Associated with Development of Psoriatic Arthritis among Psoriasis Patients. Lihi Eder[3], Sutha Shanmugarajah[3], Arane Thavaneswaran[3], Vinod Chandran[3], Richard Cook[1] and Dafna D. Gladman[2]. [1]Department of Biostatistics and Actuarial Science, University of Waterloo, Waterloo, ON, Canada, [2]Toronto Western Hospital, Toronto, ON, Canada, [3]University of Toronto Psoriatic Arthritis Clinic, Toronto Western Hospital, Toronto, ON, Canada

Background: Smoking is a strong risk factor for seropositive rheumatoid arthritis. Smoking has also been associated with higher risk of psoriasis especially in patients with HLA-Cw6. There is no clear documentation of an association between smoking and PsA.

Aim: To determine whether smoking is associated with development of PsA among patients with psoriasis.

Methods: Data collected from two prospective cohorts, PsA and psoriasis uncomplicated with arthritis, was analyzed. In the psoriasis cohort, the presence of clinical inflammatory arthritis was ruled out by rheumatologic assessment. Smoking status was determined at the time of the diagnosis for PsA patients and at the first visit to the clinic for the psoriasis patients. Smoking status was defined as current or past smoker and lifetime non-smoker. A logistic regression model was constructed to determine the association between smoking status and PsA after adjusting for age, sex and duration of psoriasis. The prevalence of current smokers in each group was compared with data of smoking status in the general population from Statistics Canada through standardized prevalence ratios (SPRs).

Results: 791 PsA and 404 psoriasis patients were included in the study. The mean age and duration of psoriasis were: 46.3±13.1 and 16.1±14.1 years, respectively, for the PsA group and 36.7±13 and 8.5±10.2 years, respectively, for the psoriasis group. The proportions of females in the PsA and psoriasis groups were similar (41.6% vs. 43.8%, respectively). The proportion of lifetime non-smokers was higher compared to current smokers in the PsA group (54.7% vs. 43%, $p<0.001$), the proportion of past smokers was higher in the psoriasis group (30.2% vs. 23.4%, $p=0.001$). The number of pack years was similar in the psoriasis and the PsA patients (11.7±14 and 11.3±12.1 pack years respectively). On multivariate analysis after adjusting for age, sex and duration of psoriasis, current smoker status vs. lifetime non-smoker remained negatively associated with PsA (Odds Ratio (OR) 0.6, 95% Confidence Intervals (CI) 0.5–0.8, $p=0.003$), while past smoker vs. lifetime non-smoker status was no longer significantly associated with PsA (OR 0.8, 95% CI 0.6–1.1, $p=0.2$). The SPRs for current smoking for males with psoriasis and PsA were 1.12 (95% CI 1.00–1.26) and 1.0 (95% CI 0.91–1.11), respectively, while the SPRs for females with psoriasis and PsA were 1.29 (95% CI 1.12–1.47) and 1.18 (95% CI 1.13–1.23), respectively.

Conclusion: Active smoking is negatively associated with PsA among psoriasis patients. The prevalence of active smoking is higher in females with psoriasis and PsA compared to the general population.

The Dimorphic Vertebral Corner Inflammatory Lesion (CIL): A Magnetic Resonance Imaging Biomarker Associated with New Bone Formation in Patients with Ankylosing Spondylitis. Walter P. Maksymowych, Nathalie Morency and Robert G. W. Lambert. University of Alberta, Edmonton, AB, Canada

Purpose: One hypothesis proposed to explain the lack of impact of TNF blockers on radiographic progression in established AS is the activation of bone forming pathways in spinal lesions that have advanced from acute inflammation to more complex lesions. The latter may be visible on spinal MRI as a dimorphic corner inflammatory lesion (CIL) where the inflammatory signal at the vertebral corner (VC) on the STIR sequence does not itself extend all the way to the VC as in a typical CIL (Type A) but surrounds an area of decreased signal intensity at the VC which, on the T1 weighted images, may appear to be due to fat infiltration or erosion/bone sclerosis. It is proposed that the overall development of new bone during TNF blocker therapy may depend on the balance between the number of early and more mature inflammatory lesions. We tested the relative association between dimorphic or Type A CIL (lower and upper anterior VC in figure, respectively) and the subsequent development of new bone at the VC.

Method: MRI scans were performed at baseline, 12, and 52 weeks while radiographs were done at baseline and 104 weeks in 76 AS patients randomized to receive either adalimumab (ADA) 40 mg every other week or placebo (PBO) for 24 weeks in a, double-blind, Phase III study of active AS. After the week 12 assessment, patients not achieving an ASAS20 response were eligible for early escape therapy with ADA and after 24 weeks all patients received ADA. The anterior VC of the cervical (C2 lower to T1 upper) and lumbar (T12 lower to S1 upper) spine were examined for new syndesmophytes and ankylosis (baseline, 104 weeks) on lateral radiographs of the cervical and lumbar spine by 2 readers scoring independently. Anonymized MR scans were read independently by 2 readers who recorded the presence/absence of Type A and dimorphic CIL at the same anterior VC that were assessed by radiography. The primary analysis was based on concordant radiographic and MRI data and compared proportions developing new bone using the Pearson's chi square.

Results: Type A and dimorphic CIL were recorded in 155 (11.5%) and 56 (4.1%), respectively, of the 1351 VC analyzed both on MR and radiography. New syndesmophytes and/or ankylosis (from normal VC) was recorded in 45 (3.3%) of all VC. New bone developed significantly more frequently from VC that demonstrated dimorphic CIL (8 of 56 (14.3%)) as compared to Type A CIL (5 of 155 (3.2%), $p = 0.007$) or no CIL (32 of 1118 (2.9%), $p = 0.0004$) on the baseline MRI. This was also noted irrespective of whether the dimorphic CIL resolved or persisted at the 52 week follow up MRI.

Conclusion: Our data confirm previous studies that inflammation at VC on baseline MRI is associated with subsequent new bone formation in established AS. More importantly, we show that this entirely reflects the presence of more complex inflammatory lesions, visualized as dimorphic CIL on MRI, where the process of bone formation may be autonomous from inflammation.

1958

The Impact of Anti-TNF Therapy on Erosive Structural Changes in the Spine of Patients with Ankylosing Spondylitis. Xenofon Baraliakos[4], Joachim Listing[2], Martin Rudwaleit, Joachim Sieper[1] and Juergen Braun[3]. [1]Charite Campus Benjamin Frankl, Berlin, Germany, [2]German Rheumatism Research Center, [3]Rheumazentrum Ruhrgebiet, Herne, Germany, [4]Rheumazentrum Ruhrgebiet Herne

Background: Axial inflammation, potentially leading to osteodestructive and/or osteoproliferative bony changes is visualized by magnetic resonance imaging (MRI). The role of erosions, known to be important in RA, has not been extensively studied in AS to date, especially not in patients receiving anti-TNF therapy.

Objective: To study the course of osteodestructive changes and their relationship to spinal inflammation in AS by MRI.

Methods: T1 and STIR MR images of patients with active AS patients at baseline (BL, n=42), after 3 months (n=38) of therapy with TNF blockers or placebo and after 2 years (n=21) of continuous treatment with TNF blockers were analyzed by the ASspiMRI-a ('S1', scores inflammation and erosion) and its modification, the Berlin score ('S2', scores only inflammation), both scoring vertebral units (VU). Only patients with complete sets of images of BL and 3 months or 2 years of anti-TNF treatment were included in the study.

Results: At BL, 7.8% and 3.5% of the VUs showed active and inactive erosions, respectively, while 29% had signs of inflammation without erosions. In comparison, osteoproliferative changes were seen in 20% of all available VUs. On the patient level at BL, spinal inflammation was seen in 95% and active erosions in 73%, while inactive erosions were found in 38% of patients at BL.

At 3 months, the percentage of inflammed VUs decreased in the anti-TNF treated patients from 27.4% to 14.6%: inflammatory lesions without erosions decreased from 21.5% to 10% and with erosions from 5.9% to 4.6% of all VUs. In the placebo group, inflamed VUs decreased from 30% to 23.5%: without erosions from 22% to 15.5%, while inflammatory lesions with erosions (8%) did not show any change. There was similar improvement after anti-TNF with both scoring systems (56.7% for S1 and 54.7% for S2, both, $p<0.001$ as compared to BL) after 3 months, while inflammation changed by 13% with either system in the placebo group.

After 2 years of anti-TNF treatment, inflammatory lesions decreased from to 33.7% to 11.2% of all VUs: in VUs with inflammation only from 24.8% to 9.5% and in VUs with active erosions from 8.9% to 1.7%. On a patient basis, spinal inflammation was seen in all patients at baseline and in 76% after 2 years, while active erosions were found in 81% at BL and in 31% after 2 years. In contrast, the percentage of inactive erosions in all availble VUs increased from 3.5% at BL to 4.1% after 2 years. Overall 38% patients at BL and 52% at after 2 years had at

least 1 inactive erosion. There were no differences in the occurrence of erosions between the 3 spinal segments.

Conclusions: Erosions occur in the majority of AS patients but in less than 10% of the spinal structures analysed. The percentage of inflammatory lesions and active erosions was clearly reduced after 2 years of anti-TNF therapy. However, many patients still had spinal inflammation (76%) and about 30% still had active erosions. This suggests that the anti-inflammatory efficacy of anti-TNF treatment is not sufficient to completely eliminate inflammation. The Berlin MRI scoring system is sufficient for differentiation between different treatment strategies in the assessment of inflammatory activity in AS patients.

1959

TNF Blocking Agents Promote Resolution of Vertebral Erosions in Patients with Spondyloarthritis. Walter P. Maksymowych[2], Praveena Chiowchanwisawakit[1] and Robert Lambert[2]. [1]Mahidol University, Bangkok, Thailand, [2]University of Alberta, Edmonton, AB, Canada

Purpose: While the impact of anti-TNF agents on new bone formation remains unclear their impact on other structural lesions such as erosions has not yet been studied in SpA because these lesions are not commonly observed in the spine on radiography. Bone erosion is readily discerned on T1-weighted (T1W) MRI at vertebral corners (VC) and affecting the vertebral endplate. MRI can reliably detect these lesions and systematic study has demonstrated erosions in the majority of patients. It is possible that such lesions could be a secondary cause of symptoms in SpA. We aimed to assess the impact of both TNF blocking agents and standard treatment on the evolution of bone erosions using MRI.

Method: MRI scans were performed at baseline and 2 years in 61 AS patients of whom 28 received TNF blocking agents in open label follow up of clinical trials while 33 received either TNF blocking agents (n = 16) or standard therapy (n = 17) in an observational cohort. A bone erosion on MRI was defined as full-thickness loss of the dark appearance of cortical bone at its anticipated location and loss of the normal bright appearance of adjacent bone marrow on T1W MRI. Via televideoconference, reference images were developed in which erosions were assigned by consensus amongst an international MRI working group. Lesions were independently recorded dichotomously (present/absent) from lower C2 to the upper sacrum of the spine at both anterior and posterior vertebral corners and at each vertebral endplate. Anonymized MRI scans were assessed independently by 2 readers who were blinded to treatment and time point. The primary analysis compared the resolution of lesions according to treatment and was based on concordant data indicating agreement on resolution of erosions. Improvement or complete resolution was defined on the basis of ≥ 50% and complete restoration, respectively, towards a normal vertebral contour. Proportions were compared by Fisher's exact test.

Results: Analysis was based on concordant reads for 2801 VC and vertebral endplate sites. Complete resolution of VC erosions was recorded significantly more frequently in the TNF blocker treatment group (11 of 13 erosions (84.6%) whereas this was not observed in a single erosion in patients on standard therapy (p = 0.0002). Similar differences between treatments were noted for individual readers. Vertebral endplate erosions were more frequent than corner erosions but showed minimal resolution after 2 years regardless of treatment.

Table. Number (percentage) of vertebral erosions resolving.

	VC Erosion			Vertebral Endplate Erosion		
Treatment	**Resolved**	**Improved**	**No change**	**Resolved**	**Improved**	**No change**
Anti-TNF						
Concordant	11 (84.6)	0	2 (15.4)	2 (4.8)	2 (4.8)	40 (90.4)
Reader 1	26 (74.3)	2 (5.7)	7 (20)	8 (9.4)	23 (27.1)	54 (63.5)
Reader 2	19 (59)	0	11 (41)	17 (15.7)	3 (2.8)	88 (81.5)
Standard						
Concordant	0	0	8 (100)	0	0	17 (100)
Reader 1	1 (7.7)	4 (30.8)	8 (61.5)	0	6 (22.2)	21 (77.8)
Reader 2	7 (31.8)	4 (18.2)	11 (50)	4 (11.4)	4 (11.4)	27 (77.2)

Conclusion: Our preliminary data supports a beneficial effect of TNF blocker treatment on the resolution of vertebral erosions. The lack of impact on vertebral endplate erosions may reflect greater time dependence due to larger size and/or differences in etiology.

1960

TNF Switching in PsA Patients. Eliza F. Chakravarty[1], George Reed[5], Dennis Decktor[3], Susan Bolge[3], Rebecca Bolce[3], Michael Ingham[3], Raphael J. DeHoratius[2], Ying Shan[5] and Mark C. Genovese[4]. [1]Mountain View, CA, [2]Centocor Ortho-Biotech, Horsham, PA, [3]Centocor Ortho-Biotech, [4]Stanford University, Sunnyvale, CA, [5]University of Massachusetts Medical School

Purpose: To examine patterns of Anti-TNF switching in psoriatic arthritis (PsA) patients and patient factors associated with switching.

Methods: We identified biologic naïve PsA patients cared for by US rheumatologists participating in the CORRONA registry that initiated their first anti-TNF (Etanercept, Infliximab, Adalimumab) and followed for 2 years. Maintainers were defined as patients with no change of anti-TNF over two years. Switchers were defined as patients who discontinued and started another biologic within 6 months of discontinuation. Discontinuers were defined as patients who discontinued and did not initiate another biologic within 6 months. We defined early switchers as patients who switched within the first year and late switchers as patients who switched between 12 and 24 months. Maintainers were compared to switchers at time of switch using a comparable follow-up time point. Multivariable logistic regression estimated associations of characteristics with switching in early and late switchers.

Results: There were 139 biologic naive PsA patients who initiated an anti-TNF and had ≥2 years of follow up. Of these, 91 (65%) were maintainers, 18 (13%) were discontinuers, and 30 (22%) were switchers. Distribution of maintainers and switchers were significantly different between IV anti-TNF and subcutaneous (SC) anti-TNF with 85% maintainers, 9% discontinuers, 6% switchers in IV vs. 59% maintainers, 14% discontinuers and 27% switchers in SC anti-TNF (p=0.012). Among those patients who switched from any of the anti-TNFs the proportion achieving a Modified ACR 20 at 6 and 12 months was 23%, and 29%.

Table 1 compares characteristics among the patient groups. At initiation, switchers and discontinuers had higher disease activity as measured by patient pain, patient global and physician globas assessments. Switchers were more likely to be female, younger, have higher BMI and a shorter duration of disease. At the time of the switch, switchers and discontinuers had higher disease activity compared to maintainers.

In the multivariable analyses, Physician Global Assessment (OR=1.6 95%CI:[1.05, 2.41]) and duration of disease (OR=0.81 [0.67, 0.98]) were the best predictors for early switchers. In late switchers, Patient Global Assessment (OR=1.54 [1.14, 2.09]), Age (OR=0.92 [0.85, 0.98]), and being female (OR=10.7 [2.2, 52.5]) were the best predictors of switching.

Conclusions: Over a two year period the majority of patients started on a TNF inhibitor for PSA will remain on their original treatment. Fewer patients discontinued IV TNF inhibition (Infliximab) than SC TNF inhibition (Etanercept, Adalimumab), however the factors associated with this are unknown. In those who remained on initial therapy benefit appeared to be maintained, in those who switched there was a mild likelihood of improvement. A number of factors were associated with either early or late switch.

Table 1. Patient Characteristics (Mean ± SD)

Treatment of Active Ankylosing Spondylitis with Abatacept—An Open Label 24-Week Study. In-Ho Song[2], Frank Heldmann[1], Martin Rudwaleit[3], Hildrun Haibel[2], Anja Weiss[4], Jurgen Braun[1] and Joachim Sieper[2]. [1]Centre of Rheumatology, Herne, Germany, [2]Charite Campus Benjamin-Franklin, Medical Clinic I, Rheumatology, Berlin, Germany, [3]Charite Campus Benjamin-Franklin, Medical Clinic I, Rheumatology, Berlin, Germany, [4]German Rheumatism Research Center, Berlin, Germany

Background: An immunotherapy targeting T cells in ankylosing spondylitis (AS) might be of interest, given histological studies have shown T-cell clusters in facette joints and antigen-specific T cell response has been described in AS [1]. There is still an unmet medical need as some patients with AS may even not respond to anti-TNF agents.

Objective: To explore prospectively the short term efficacy and safety of abatacept in patients either naïve or with an inadequate response (IR) to anti-TNF agents.

Methods: In this open label (OL) pilot study, abatacept (10mg/kg) was administered intravenously on days 1, 15, 29 and every 28 days thereafter up to week 24 in 15 anti-TNF-naive patients (group 1) and 15 patients with IR to anti-TNF (group 2) with active AS. The primary end point was the proportion of patients with assessment of SpondyloArthritis international Society criteria (ASAS 40) in both groups at week 24 for which the likelihood of targeted minimum true response rates of 30% was investigated by estimating the 95% confidence interval [95% CI] of the observed response rates. Disease activity was assessed using ASAS and BASDAI responses, pain and CRP levels in the intent to treat population using LOCF analysis. Safety was assessed in patients who received at least 1 dose of OL abatacept.

Results: Of 15 patients enrolled in group 1 and group 2 respectively, each 12 completed 24 weeks (withdrawals for inefficacy each 2 in group 1 and 2) and SAE (each 1 in group1 and 2). In group 1 and 2, baseline characteristics were: 60% and 73% of males, mean disease duration of 14.5 (SD 10.3) and 20.5 (SD 10.8) years; 100% and 93% HLA-B27 positive and mean age of 38.0 (SD 7.2) and 45.3 years (SD 9.8), respectively.

At week 24, 13.3% [2.4%; 38.4%] of patients in group1 and 0% [0%; 21.3%] of group 2 achieved ASAS 40 (Table). The upper limit of the 95% CI in group 1 but not in group 2 exceeded the pre-specified minimum true response rates of 30%. We found no change of T cell function in regards of interferon-gamma (IFN-gamma) (% of IFN-gamma positive cells out of CD4 positive cells after stimulation with phorbol myristate acetate (PMA) ionomycin 14.8% at screening and 13.1% at week 24) or interleukin-17 secretion (% of IL-17 positive cells out of CD4 positive cells after stimulation with PMA ionomycin 1.5% at screening and 0.9% at week 24) supporting that T cell function is not suppressed but only modulated. Overall, abatacept was well-tolerated with 5 serious events (SAEs), including 1 gastroenteritis. Three mild to moderate acute infusion reactions were reported. There was no death, opportunistic infection, malignancy or TB reported.

Conclusions: In this pilot AS study, Abatacept was well tolerated. A major response was not observed in our study, but an efficacy cannot be excluded based on the limited sample size. Its short term therapeutic potential needs to be further evaluated.

Table: ASAS20/40/partial remission (PR) and BASDAI20/50 response rates in TNF-blocker naive and TNF-blocker failure patients at week 24

	TNF-blocker-naive patients (n=15)	TNF-blocker failure patients (n=15)
ASAS20	26.7%	20.0%
ASAS40	13.3%	0%
ASAS PR	6.7%	0%
BASDAI20	33.3%	20.0%
BASDAI50	6.7%	0%

Ultrasound (US) and × Rays (XR) Entheseal, Synovial and Sacroiliac Abnormalities in Early Psoriatic Arthritis (ePsA). Francesca Bandinelli[5], Diletta Bonciani[3], Francesca Prignano[3], Leonardo Giovannini[6], Giuliana Salvadorini[6], Ledio Collaku[1], Antonio Candelieri[4], Francesca Bartoli[6], Torello Lotti[2] and Marco Matucci Cerinic[6]. [1]Department of Internal Medicine of University of Tirana, Faculty of Medicine, Albania, [2]Dermatology Unit, University of Florence, Italy, [3]Dermatology Unit, University of Florence, Italy, [4]Laboratory of Decision Engineering for Health Care Delivery, Department of Electronics, Informatics and Systems, University of Cosenza Italy, [5]Rheumatology Division, University of Florence, Department of Biomedicine, Florence, Italy, [6]Rheumatology Division, University of Florence, Department of Biomedicine, Florence, Italy

Objective: To investigate entheseal/synovial and sacroiliac abnormalities in ePsA respectively with ultrasound (US) and traditional × rays (XR) and the correlation with ePsA features (familiarity, psoriasis, inflammatory markers, HLA) useful for diagnosis.

Methods: 92 ePsA patients (51±15 years old, 51 female and 41 male,), with duration of symthoms < 1 year, diagnosed according to CASPAR criteria (1) were consecutively studied with US (My Lab 70 XVG US Esaote 7–18 MHz linear array transducer) of entheses (Achilles, quadriceps, patellar and plantar fascia) and joints (radiocarpal, intercarpal, hands MCP, IFP and IFD, tibio-tarsal, feet MTP and IP) joints and with radiography (XR) of sacroiliac joints. Patients were scored respectively for entheses with Glasgow Ultrasound Enthesitis Scoring System (GUESS) (2) and Power Doppler signal (PD) (semiquantitative system, score 0–3), for peripheral joints with presence/absence of PD active synovitis, for sacroiliac joints with New York score (NYS) (3). We studied the correlation between GUESS and PD of entheses, active synovitis, NYS of sacroiliac joints with familiarity (for psoriasis and spondiloarthropathies), psoriasis area and severity Index (PASI), distribution -hand, feet, lower limbs- and characteristics -vulgaris, eritrodermic, pustulosus, guttata-, nail involvement, ESR, CRP, HLA aplotypes (B27, B35, B38, B39, CW6, CW7, DR4) were investigated.

Results: Abnormalities are present in high percentage: in entheses (GUESS>1:100%, PD 40,2%), in peripheral joints (40,2% PD active synovitis), in sacroiliac joints (NYS>1: 25%). GUESS and PD of entheses correlated with the presence of lower limb psoriasis (respectively $p<0,02$, $p<0,05$, Mann Whitney test) but not with PASI and entheses PD with ESR ($p<0,005$) (linear correlation Pearson). GUESS was higher ($p<0,05$ Mann Whitney test) in CW6 positive patients (29,6%) but not other significant difference were found in other aplotypes. Synovitis and sacroileitis didn't correlate with familiarity, psoriasis, ESR/CRP, HLA.

Conclusions: In ePsA patients, entheseal and synovial US and sacroiliac XR modifications are present in high percentage. Our data clearly indicate that a thorough US and XR investigations must be always perform in early phase.

Validation of the ASAS Definition of a Positive MRI in a Cohort of Patients with Early SpA Followed for Eight Years. Helena Marzo-Ortega[2], Alexander N. Bennett[2], Dennis McGonagle[2], Paul Emery[2] and Walter P. Maksymowych[1]. [1]University of Alberta, [2]University of Leeds, United Kingdom

Background: The Assessment of SpondyloArthritis International Society (ASAS) recently proposed a definition of a positive MRI for sacroiliitis based on the finding of bone marrow edema (BME) on STIR in subchondral or periarticular bone marrow of the sacroiliac joint (SIJ). MRI is considered positive for SpA if there are two BME lesions on the same coronal slice through the SIJ or a single BME lesion present on two consecutive slices. This

proposal requires validation, preferably in prospective cohorts to evaluate development of radiographic changes of sacroiliitis.

Objective: To compare the diagnostic utility of global assessment of MR scans versus the ASAS definition using a standardized approach to evaluation of the SIJ in an early SpA cohort followed over 8 years.

Method: Four rheumatologists blinded to patient and diagnosis independently assessed MRI scans (T1W and STIR) from 37 patients with SpA according to ESSG criteria (median symptom duration 24 weeks); 13 developed radiographic sacroiliitis after 8 years, 11 controls mechanical low back pain (mLBP), 11 healthy controls. Semi-coronal slices through the SIJ were read systematically according to a standardized online training module. BME, fat infiltration, erosions, and ankylosis was recorded using an online data entry system. Schematics of the SIJ divided into quadrants allowed recording of these lesions (yes/no) in each quadrant of each coronal slice. The ASAS definition was defined as met when BME was recorded in 2 SIJ quadrants on the same slice or when a single lesion in one SIJ quadrant was present in 2 consecutive slices. Readers also answered (yes/no) whether this SIJ scan confirmed the presence of SpA. Sensitivity, specificity, and LRs for individual and concordant data (at least 2 readers) were calculated according to clinical diagnosis at baseline and according to the development of radiographic sacroiliitis.

Results: MRI had high diagnostic utility for SpA according to global assessment by individual readers (mean for 4 readers (range) sensitivity/specificity: 66.9% (61.8–70.6)/94.4% (88.9–100), LR+ 11.9, LR- 0.2) as well as concordant data (sensitivity/specificity: 67.6%/94.4%, LR+ 12.1, LR- 0.3). By comparison, sensitivity for SpA of the ASAS definition was higher but there was reduction in specificity with 11.1% of control scans (3 mLBP) meeting the ASAS definition so that diagnostic utility was lower than for global assessment. Diagnostic utility of baseline MRI for radiographic sacroiliitis after 8 years follow up was even higher: global assessment (sensitivity/specificity: 100%/94.4%, LR+17, LR- not calculable (nc), ASAS definition (sensitivity/specificity: 100%/88.9%, LR+ 9, LR- nc).

Conclusion: The diagnostic utility of the ASAS definition resembles global evaluation by expert readers, the principle limitation being the finding of BME in patients with mLBP.

Global Assessment ASAS Definition

1964

Which Clinical Variables Predict Radiographic Progression in Spondyloarthritis? An Analysis of the Spondyloarthritis Research Consortium of Canada (SPARCC) Cohort. Walter P. Maksymowych[4], Nigil Haroon[6], Nathalie Morency[5], Richard Cook[7], Hua Shen[7], Proton Rahman[1], Dafna D. Gladman[2] and Robert D. Inman[3]. [1]Memorial University Newfoundland, St. Johns, NL, Canada, [2]Toronto Western Hospital, Toronto, ON, Canada, [3]Toronto Western Hospital, Toronto, ON, Canada, [4]University of Alberta, Edmonton, AB, Canada, [5]University of Alberta, Edmonton, Canada, [6]University of Toronto, Toronto, Canada, [7]University of Waterloo

Purpose: About a third of patients with SpA have been shown to exhibit radiographic progression over 2 years. There is limited prospective data on the factors that predict progression, even amongst clinical variables assessed in routine practice. Baseline radiographic score, measured with the modified Stoke AS Spine Score (mSASSS) method, and serum metalloproteinase 3 have been shown to predict progression but no evidence has yet implicated clinical measures of disease activity. We aimed to identify clinical variables contributing to radiographic progression over 2 years in patients with Ankylosing Spondylitis (AS).

Methods: The SPARCC cohort comprises patients with SpA followed prospectively with clinical and radiographic outcomes. Two readers scored X-rays obtained at baseline and year 2 using the mSASSS method. Dependent variables were: 1) raw change in mSASSS and >2 units from baseline through 2 years, 2) development of new syndesmophytes at year 2. Independent variables were age, sex, baseline Bath AS Disease Activity Index (BASDAI) and C-reactive protein (CRP), and baseline mSASSS score. Variables that associated significantly with the dependent variables in univariate analysis were also tested as explanatory variables in multivariate logistic and linear regression analyses.

Results: Baseline and 2-year radiographs were available on 279 patients with AS according to the modified New York criteria. At baseline there were 227 (81.7%) males, mean (SD) age 41.6 (13.3) years, mean (SD) age at onset of back pain 23.7 (8.4) years, mean (SD) BASDAI 4.8 (2.3), mean CRP 14.6 mg/L (20.8), and mean (SD)/median mSASSS 18.7 units (21.2)/8.0. Mean (SD) change in mSASSS over 2 years was 1.7 units (3.3) and 62 (22.2%) of patients had progression >2 mSASSS units. A new syndesmophyte was recorded in 27.7%. Uni- and multivariate logistic regression analysis where the dependent variable was mSASSS change >2 units showed that only baseline CRP was significantly associated with progression.

Baseline Covariates	Univariate Model OR	95%CI	P value	Multivariate Full Model OR	95%CI	P value	Multivariate Reduced Model OR	95%CI	P value
mSASSS	1.00	0.98, 1.02	0.90	1.00	0.98, 1.02	0.81			
CRP	1.02	1.00, 1.03	0.01	1.02	1.00, 1.03	0.02	1.02	1.00, 1.03	0.01
BASDAI	1.06	0.92, 1.22	0.45	1.01	0.87, 1.17	0.88			

Conclusion: Our data support the importance of inflammation, as reflected by CRP, as a factor influencing radiographic progression in SpA.

Ankylosing Spondylitis Macrophages Produce Greater IL-23 in Response to Lipopolysaccharide without Significant Unfolded Protein Response Induction. Ling Zeng, Mary Lindstrom and Judith Smith. University of Wisconsin

Purpose: Inflamed tissue from Ankylosing Spondylitis (AS) patients display a preponderance of macrophages. Previous work from an HLA-B27 transgenic rat model suggests that macrophages from arthritic animals develop an intracellular stress response called the Unfolded Protein Response (UPR) and as a result, secrete increased cytokines in response to Toll like receptor agonists such as lipopolysaccharide (LPS). Our objective was to determine if macrophages from AS patients undergo a UPR and secrete increased cytokines/chemokines in response to LPS.

Methods: Peripheral blood monocytes were isolated from 10 AS patients (median age 46.5y, 90% male, 70%HLA-B27+ and 2ND) and 10 controls (HC, median age 45y, 90%male, all HLA-B27-), and differentiated in vitro with M-CSF for 5 days. Select samples were then treated with 1000U/mL IFN-γ for 24h to up-regulate MHC class I prior to stimulation with LPS for 3h (for RNA collection), or 8–24h (supernatants). UPR induction was assessed by up-regulation of ERdj4, BiP and CHOP mRNA detected by quantitative PCR. Supernatants were analyzed for cytokine/chemokine production by ELISA or Luminex. Statistical analysis involved 2-sample Wilcoxon tests for cytokine data, and a linear mixed effect model following log transformation of gene expression data.

Results: In response to LPS alone, AS macrophages secreted more CXCL9, IL-10, IL-12p70, IL-23, and TNFα than HC macrophages ($p< \text{or} = 0.02$). We did not detect significant differences between AS and HC for IL-6, IL-8, CXCL10, IL-1β, IFN-β or MCP-1. IFN pre-treatment tended to minimize differences between AS and HC for all cytokines/chemokines except IL-12p70. The most striking difference between AS and HC macrophages was for IL-23 production (median HC 9pg/mL vs. AS 265 pg/mL at 24h, $p=0.0007$). 3h LPS treatment had no effect on UPR gene expression. Although IFN treatment up-regulated HLA-B expression by 2–3 fold, it did not enhance BiP or CHOP expression. ERdj4 expression weakly increased (2-fold, $p=0.03$–0.06) in IFN+LPS AS samples only.

Conclusions: Gene association studies and animal models have implicated the IL-23/Th17 pathway in pathogenesis. These results showing greater IL-23 production by AS patient macrophages in response to LPS further support the development of IL23-directed therapy. Since we were unable to detect significant UPR induction in AS macrophages, the relationship between UPR and inflammatory cytokine production remains unclear.

1966

Association between Killer-Cell Immunoglobulin-Like Receptor (KIR) Gene Polymorphisms and Psoriatic Arthritis (PsA). Vinod Chandran[2], Fawnda Pellett[2], Renise Ayearst[2], Remy Pollock[2] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto Psoriatic Arthritis Clinic, Toronto Western Hospital

Background: KIR genes within the leukocyte receptor complex on chromosome 19q are associated with PsA. We sought to further characterize this association and determine whether the associations are independent of HLA allele associations.

Methods: 685 cases of European ethnicity (295 females, mean age 43 years, PsA duration 7 years, psoriasis duration 15 years, actively inflamed joint count 11, PASI score 5.2) with PsA and 706 ethnically matched controls (273 females, mean age 53 years) were recruited for the study. Genotyping for 15 KIR genes was performed on genomic DNA obtained from peripheral blood using PCR-SSP and that for HLA-B, and -C alleles was performed using PCR-SSO reverse line blot. Phenotype frequencies (frequencies of individuals positive for each gene or allele) were calculated and differences between cases and controls determined using Fisher's exact test using a dominant model. Multivariate logistic regressions were performed, including all KIR genes present in <95% of cases or controls, and HLA alleles present in >5% of cases and controls and significant in univariate analyses. Association of KIR2DS1 and KIR2DS2 with PsA in the presence/absence of HLA-Cgrp2 (HLA-C*02, C*04, C*05, C*06) and Cgrp1 (HLA-C*01, C*03, C*07, C*08) ligands for their corresponding inhibitory KIRs (KIR2DL1 and KIR2DL2/2DL3 respectively) was also investigated using chi- square test and evidence of trend with combined risk genotypes determined using Mantel-Haenszel trend test.

Results: In univariate analyses, KIR2DS2 (Odds ratio 1.13 p = 0.028), KIR2DL2 (OR 1.13, p = 0.031), HLA-B*07 (OR 0.56, p<0.0001), B*13 (OR 1.73, p = 0.016), B*27 (OR 3.04, p <0.0001), B38 (OR 7.24, p <0.0001), B39 (OR 2.04, p = 0.008), B51 (OR 0.45, p <0.0001), B*57 (OR 1.81, p <0.0001), B*60 (OR 0.58, p =0.008), C*01 (OR 1.89, p =0.002), C*02 (OR 1.98, p <0.0001), C*03 (OR 0.64, p =0.002), C*04 (OR 0.74, p =0.027), C*06 (OR 1.65, p <0.0001), C*07 (OR 0.66, p<0.0001), C*12 (OR 2.38, p <0.0001) and C*15 (OR 0.48, P=0.005) were significantly associated with PsA. The results of the multivariate analysis using logistic regression with backward selection are given in Table 1.

Table 1. Results of multivariate logistic regression analyses using HLA alleles found significant in the univariate analyses as well as KIR genes present in <95% of the population as explanatory variables.

Allele/Genotype	Odds Ratio	95% Confidence Interval	P value
HLA-B*07	0.71	0.54, 0.94	0.0169
HLA-B*13	2.14	1.35, 3.4	0.0012
HLA-B*27	3.52	2.46, 5.03	<0.0001
HLA-B*38	8.22	4.66, 14.51	<0.0001
HLA-B*39	2.54	1.49, 4.34	0.0006
HLA-B*51	0.53	0.34, 0.81	0.0038
HLA-B857	2.30	1.61, 3.3	<0.0001
HLA-C*03	0.74	0.56, 0.99	0.0457
KIR2DS2	1.31	1.04, 1.64	0.0205

HLA-B*13, B*27, B*38, B*39 and B*57 were found to increase PsA risk whereas HLA-B*07, B*51 and C*03 were protective. Among the KIR genes only KIR2DS2 was found to significantly increase risk for PsA after adjusting for HLA-B and -C associations. Association between PsA and combined KIR2DS2 and HLA-Cgrp1 risk genotypes was demonstrated (trend p= 0.024). Although, chi square test using combined KIR2DS1 and HLA-Cgrp2 genotypes showed evidence of association (p = 0.025), no evidence of a trend could be demonstrated (trend p = 0.81).

Conclusions: KIR2DS2 is associated with PsA independent of HLA alleles. The risk for PsA increases with the presence of KIR2DS2 in the absence of ligands for KIR2DL2/2DL3 with risk being highest when KIR2DS2 is present in the absence of HLA-Cgrp1 alleles.

1967

Decreased TH17 Cells in the Peripheral Blood of Patients with Early Spondyloarthritis (ESpA). María Belén Bautista-Caro[2], Irene Arroyo-Villa[2], Concepcion Castillo-Gallego[2], Eugenio de Miguel-Mendieta[2], Emilio Martín-Mola[2] and María Eugenia Miranda-Carus[1]. [1]Hospital La Paz, Madrid, Spain, [2]Hospital La Paz

Background: Th17 cells may be implicated in the pathogenesis of Spondyloarthritides (SpA). Previous data regarding the percentage of Th17 cells in the peripheral blood of Early SpA (ESpA) patients are limited and contradictory.

Objective: To determine the frequency and phenotype of Th17 cells in the peripheral blood of patients with ESpA.

Patients: We studied 22 healthy controls and 22 patients with ESpA (who met ESSG or other accepted SpA Classification Criteria) from the "Esperanza" programme of the Spanish Rheumatology Foundation. The inclusion criteria were inflammatory back pain or asymmetric peripheral arthritis, duration of disease of three to 24 months and age of 18 to 45 years. At baseline visit, medical history, physical examination, ESR, CRP, HLAB27 and pelvis conventional x-Ray were recorded.

Methods: CD4 T cells were magnetically sorted from freshly isolated peripheral blood and cultured overnight in the presence of PMA and ionomycin. IL-17 was determined by ELISA of culture supernatants and by flow cytometry of monensin-treated cells. In addition the expression of CCR6, IL-23R and RORγT were examined by flow cytometry.

Results: ESpA patients were 7 females, 15 males. Age was (mean ± SD) 36 ± 7 years, duration of disease 17 ± 10 months. BASDAI index was 3.7 ± 2.2 (median 3.55, range 1.2–8.3) and BASFI was 1.82 ± 1.69 (median 1.65, range 0.3–6.1). CD4 T cells of ESpA patients secreted signficantly lower amounts of IL-17 into the culture medium (1134.9 ± 488.6, median 687.97, range 99.02–3156.33) when compared with controls (2059.3 ± 664.6 pg/ml, median 1719.67, range 448.11–6243.9), p<0.05. Likewise, the percentage of IL-17 producing CD4 T cells (Th17 cells) was significantly lower in ESpA patients: 0.93 ± 0.26, median 0.84, range 0.22–2.15 in patients vs 1.50 ± 0.56,median1.13, range 0.66–3.92 in controls, p< 0.05. Th17 cells expressed CCR6, RORγT and IL-23R. Disease activity as assesed by BASDAI index was negatively correlated with IL-17 concentration and with the percentage of Th17 cells. Likewise, BASFI function index showed a negative correlation with soluble IL-17 and with the percentage of Th17 cells.

Conclusion: Peripheral blood CD4 T cells from ESpA patients demonstrate a decreased secretion capacity of IL-17 together with decreased percentage of Th17 cells, that are related with disease activity as assessed by BASDAI index and with the functional index BASFI.

Distinctive Patterns of Gene Expression Post-Infliximab Therapy in Psoriasis, Rheumatoid and Psoriatic Arthritis. Christopher T. Ritchlin[3], Yahui Grace Chiu[2], Alexander Rosenberg[2], Darren Tabechian[2], Sharon Moorehead[2], Rick Barrett[2], Hangtao Fan[1], Fred Baribaud[1], H. Liu[1], Nancy Peffer[1], David Shealy[1] and Edward S. Schwarz[2]. [1]Centocor R&D, [2]University of Rochester Medical Center, [3]University of Rochester Medical Center, Rochester, NY

Background: Despite divergent phenotypes, psoriasis (Ps), rheumatoid (RA) and psoriatic arthritis (Ps) often improve after anti-Tumor Necrosis Factor (TNF) therapy but the comparative effect of TNF inhibition on gene expression in circulating CD14+ monocytes, synovium and skin in these disorders is not well understood.

Objectives: To compare gene expression profiles in RA and PsA monocytes and synovium and Ps monocytes and skin plaques following infliximab (IFX) therapy.

Methods: Microarray analyses with Affymetrix hg U133 plus 2.0 PM

(HT) chips were performed on CD14+ monocytes isolated from 10 Ps, 9 RA and 12 PsA patients (pts) at baseline and 10 weeks and plaque biopsies from 5 Ps pts at baseline and week 2 after IFX treatment. Synovial biopsies from RA (3) and PsA (5) pts were also analyzed at baseline and 10 weeks. Pathway characterization and analysis of functional annotation enrichments for genes with a significant change in expression at 2 (skin) or 10 weeks post-infliximab ($p<0.05$) were performed using DAVID 6.7 (NIAID/NIH web-based tool).

Results: A significant decline in the DAS28score was noted in the RA (5.9 to 4.1; $p<.005$) and PsA pts (4.6 to 3.3; $p<.001$) following IFX. In the Ps pts, a significant decrease in the PASI score (5.3 to 2.3; $p<.00008$) was observed 2 weeks after IFX. IFX was well tolerated in all pts. The number of genes that significantly changed expression from baseline to 10 weeks (either up or down) in CD14+ monocytes, skin and synovial tissues from Ps, RA and PsA pts differed between the 3 groups (shown in table).

	Ps	RA	PsA
CD14+ cells	141	104	267
Skin/synovium	1260	819	255

Number of genes that demonstrated a significant change in expression post-IFX treatment.

Only a single gene, GTP binding protein (GBP4), changed significantly in monocytes from all 3 groups. Based on gene-annotation enrichment analysis, the most significant changes in Ps monocytes were noted in immunoglobulin (Ig), antigen binding and immune response genes similar to RA monocytes in which both immune response and Ig genes showed the greatest change. In PsA monocytes, genes related to phosphoproteins, cell motion and migration and Sh2 domains showed the greatest change. In Ps plaques, genes associated with the cell cycle, cell division, the immune response and leucocyte activation showed the greatest change compared to RA synovium where genes that control cell adhesion, Wnt and G-protein signaling were most highly affected. Lastly, PsA synovium showed significant changes in gene expression associated with protein kinase A (PKA) and the following signaling pathways: IL-6, IL-17, IL-27 and JAK-STAT following treatment with IFX.

Conclusion: IFX was highly effective for skin and joint inflammation in this cohort yet the impact of TNF inhibition on gene expression was surprisingly distinctive in the 3 disorders. These data suggest the presence of unique pathophysiologic mechanisms in immune mediated disorders downstream of TNF. If so, disease biomarkers in Ps, RA, and PsA are likely to be disease-specific.

Endoplasmic Reticulum Aminopeptidase (ERAP) Deficiency Alters IL-17 Production and Host Response Following Yersinia Gastrointestinal Infection in B27-Transgenic Mice. Robert D. Inman[1] and Fei Zhu[2]. [1]Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada

Objective: Recent genetic studies have demonstrated that polymorphisms in ERAP are strongly associated with spondyloarthritis. But the mechanism of this interaction has not been resolved. In the present study we examine the host immune response to Yersinia enterocolitica (Ye) using mice with genetic alteration of class I MHC or ERAP.

Methods: The following mice (all on a B6 background) were compared: (i) deficient in endogenous class I MHC (DKO) (ii) transgenic for HLA B*2705 (B27) (iii) transgenic for B*2705/human β_2M (B27/β_2M) (iii) transgenic for HLA B*2705 *and* deficient in ERAP (B27/ERAP−/−). Mice were challenged intragastrically with 10^7 Yersinia enterocolitica 0:8. Survival curves were generated and cytokine responses were assessed by quantitative PCR on mesenteric lymph nodes and liver.

Results: Survival curve (figure1) indicated the following ranking: B27/β_2M> B27/ERAP−/− > B27> DKO. Only DKO showed significant effects (<3 days) on early survival, confirming that ERAP effects on host immune responses implicate adaptive immunity not innate immunity. With respect to cytokine profiles, the clearest differential was an elevated expression of IL-17 in B27/ERAP−/− mice, which coincided with the temporal course of mortality. There was no consistent impact of ERAP deficiency on IL-4, IL-23, IFN-γ, TGF-β, or TNF-α after Yersinia infection.

Conclusions: ERAP deficiency was associated with enhanced IL-17 production after gastrointestinal infection with Yersinia (figure2). These findings suggest that polymorphisms which affect ERAP function might play a deleterious role in IL-17-mediated immune responses to arthritogenic pathogens.

Evaluation of T Helper 17 Axis in Ankylosing Spondylitis. Ali Taylan, Ismail Sari, Didem Kozaci, Arif Yuksel, Safak Bilge, Yasar Yildiz, Gulten Sop, ISIL Coker, Necati Gunay and Nurullah AKKOC. Izmir Tepecik Training and Research Hospital, Department of Internal Medicine, Izmir, Turkey

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disorder which primarily affects the axial skeleton. Although the etiology of AS is unknown, available data strongly suggests the importance of genetic factors in the susceptibility to the disease. Recent studies suggest that interleukin-23 receptor (IL-23R) is one of the major generic factors involved in susceptibility to AS. In accordance with this observation, recent studies focused on the T helper 17 (Th17) axis in patients who have AS or spondylarthropathy (SpA).

Objectives: To evaluate T helper 17 (Th17) axis and its relation with tumor necrosis factor (TNF) alpha blockage and disease activity in ankylosing spondylitis (AS).

Methods: 127 AS patients (100M/27F) and 38 (27M/11F) controls were studied. Spinal mobility was assessed by the Bath Ankylosing Spondylitis Metrology Index (BASMI). Patients were also evaluated with the Bath Ankylosing Spondylitis Functional Index (BASFI) and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Serum sample measurement of cytokines including IL-6, IL-12, IL-17A and IL-23 were performed by using commercially available ELISA kits.

Results: Age, and sex distributions were similar between patients and controls ($p>0.05$). Cytokines including IL-6, IL-12, IL-17, and IL-23 were significantly higher in the AS patients than the controls ($p<0.05$; 3.06 [0.73–339,4] vs.1.42 [0.74–4]pg/mL, 4.65 [3,4–41,1] vs. 4.27 [3.47–57,8] pg/mL, 0.72 [0–31,6] vs. 0.15 [0–3.85]pg/mL, 98 (38–206) vs. 57 (36–160) pg/mL respectively).

Comparison of the patients who were on anti-TNF and conventional therapy revealed Th-17 related Cytokines were not different between the groups ($p>0.05$). Cytokines also were similar between the active vs. inactive patients' groups ($p>0.05$).

On correlation analysis, IL-17 was correlated with IL-23 and IL-12 ($p<0.05$). IL-23 showed correlations with IL-17, IL-12 and BASMI ($p<0.05$). Other correlations ($p<0.05$) were as follows:IL-6 with CRP, IL-12 with IL-17 and IL-23.

Table 1. Clinical and laboratory characteristics of the patients and controls

	AS Patients (n=127)	Controls (n=38)	P value
Age (years)	38 (16–64)	38 (23–56)	0.94
Sex (M/F)	100/27	27/11	0.38
BMI (kg/m2)	25.9 (16,3–36,7)	25,3 (18,2–34,3)	0.28
Disease duration (years)	10 (1–35)		
BASFI	3.6 (0–9,5)		
BASDAI	4.4 (0–9,2)		
BASMI	2 (1–9)		
CRP (mg/L)	7.5 (0.27–119,1)	1.15 (0.19–6,4)	<0.001
IL-6 (pg/mL)	3.06 (0.73–339,4)	1.42 (0.74–4)	<0.001
IL-12 (pg/mL)	4.65 (3,4–41,1)	4.27 (3.47–57,8)	0.04
IL-17 (pg/mL)	0.72 (0–31,6)	0.15 (0–3.85)	<0.001
IL-23 (pg/mL)	98 (38–206)	57 (36–160)	0.001
TGF-β (pg/mL)	26.4 (5.2–87)	22.1 (0,4–39)	0.01

Conclusions: In this study we found serum levels of Th-17 axis related cytokines to be significantly increased in the sera of AS patients. Disease activity, treatment type and history of peripheral arthritis(not shown) seem no effect on these cytokines. Targeting the cytokines related with the Th-17 axis may be a reasonable approach in AS patients who don't respond anti-TNF therapies.

Functional Significance of mTor in FLS Proliferation and Its Role in the Pathogenesis of Psoriatic Arthritis. Siba P. Raychaudhuri[2], Ankit Saxena[1] and Smriti K. Raychaudhuri[3]. [1]UC Davis, [2]UC Davis/VAMC Sacramento, Davis, CA, [3]UC Davis/VAMC Sacramento

Purpose: Hyperproliferation and impaired apoptosis of resident synoviocytes (FLS) are critical pathologic events in the pathogenesis of autoimmune inflammatory arthritis like in rheumatoid arthritis (RA) and psoriatic arthritis (PsA). Synovial hyperplasia leads to cartilage and bone damage in the inflamed joints. Increasing evidence places mammalian target of rapamycin (mTOR) as a central regulator of both cell growth (size) and proliferation, this is achieved in part by regulation of translation initiation. We hypothesize that mTOR signaling cascade proteins are upregulated in the FLS obtained from PsA patients and thus maintains proliferation and survival of these cells causing disease pathology. The aim of this study was to investigate the association of mTOR signaling proteins in regulating the proliferation and survival of these synoviocytes of psoriatic arthritis.

Methods: FLS were isolated and prepared from the synovial tissue collected from PsA patients (n=5). FLS obtained from OA (n=5) were used as control. Cell lysates were prepared from these FLS. By western blot assay denovo expression of mTOR and its phosphorylated downstream signaling protein p-mTOR was determined. Also effect of mTOR inhibitors were observed on the proliferation and survival of these FLS. FLS were cultured with rapamycin (10nM) and NVP-BEZ235 (50nM) for 3–5 days at 37°C in 5% CO_2. FACS based CFSE dilution and MTT assays were used for proliferation studies.

Results: We found enhanced expression of mTOR (relative intensity (R.I.)= 1.9 ± 0.1) and its downstream activated signaling protein p-mTOR (R.I.= $0.73\ \pm0.02$) in FLS obtained from PsA in comparison to the non inflammatory OA FLS (R.I.= $0.9\ \pm\ 0.05$; p-mTOR R.I.= 0.26 ± 0.05). The difference of mTOR and p-mTOR was found to be significant at $p<0.01$. Also the FLS proliferation was found to be significantly reduced when cultured in presence of rapamycin [proliferation index (PI)=$.35\pm0.04$) and NVP-BEZ 235 (PI=$0.28\pm\ 0.02$), in comparison to untreated cells (1.2 ± 0.035), data were found to be significantly different between treated and untreated groups at $p<0.01$.

Conclusions: We observed high expression of mTOR signaling cascade proteins in the FLS obtained from PsA in comparison to noninflammatory OA cells. We used FLS from RA patients as positive controls and observations were similar to that of FLS of PsA. Further inhibition of proliferation of these cells in presence of mTOR inhibitors rapamycin and NVP-BEZ235 substantiates the role of mTOR signaling pathway in regulating the proliferation of FLS cell. Proliferating FLS is the major component of the invading pannus in inflammatory arthritis. The novel observations described herein provide new insights for the molecular mechanism of FLS proliferation as well as provides new avenues for treatment of psoriatic disease and RA.

Genetic Studies of Ankylosing Spondylitis in Korean Confirm Associations with ERAP1 and 2p15 Reported in Caucasian Cases. So-Young Bang[5], Tae-Hwan Kim[5], Bitnara Lee[5], Eunji Kwon[5], Sang Hyun Choi[6], Ki Soo Lee[1], Seung Cheol Shim[2], Angela Pope[8], Proton Rahman[3], John D. Reveille[7] and Robert D. Inman[4]. [1]Cornell University, Republic of Korea, [2]Eulji University, Republic of Korea, [3]FRCPC, Memorial University of Newfoundland, [4]FRCPC, Toronto Western Hospital, University of Toronto, [5]Hanyang University Hospital for Rheumatic Diseases, Republic of Korea, [6]Korean Minjok Leadership Academy, Republic of Korea, [7]Rheumatology and Clinical Immunogenetics, University of Texas Health Science Center at Houston, [8]Senior Scientist, Newfound Genomics

Objective: Ankylosing spondylitis (AS) is a chronic disabling disorder and pathogenesis is not understood. Multiple genetic factors are thought to be important contributors to disease susceptibility and MHC, IL23R, ERAP1, 2p15 and 21q22 are known to be associated with AS. TASC investigators have recently reported additional genes associated with AS susceptibility including IL1R2, ANTXR2, and gene deserts at 2p15 and 21q22. We evaluated these new candidate genes in a large cohort of Korean AS cases.

Methods: A total of 1164 AS cases and 752 ethnically matched, healthy controls who are native Koreans were enrolled for this study. 8 SNPs were analyzed to define genetic association with Korean AS. The MassARRAY® system (Sequenom, San Diego, CA) was used to genotype each study participant in a two-well reaction designed using Assay Designer 3.1.

Results: Significant positive associations of AS with ERAP1 SNPs, rs27037 ($p = 1.31\times10^{-4}$) and rs27434 ($p = 4.59\times10^{-6}$), were observed. The SNP rs10865331 of gene desert at 2p15 also showed a significant association with AS ($p = 4.63\times10^{-5}$).

Table 1. Genotype and allele frequency of 8 SNPs in Korean AS cohort*

Chromosomal band	SNP	Gene	Allele 1	Allele 2	Cases (n=1164) Genotypes 11	12	22	MAF	Controls (n=752) Genotypes 11	12	22	MAF	OR (95%CI)	P
2p15	rs4672495	-	T	G	939	197	12	0.096	563	155	11	0.121	0.77 (0.63-0.95)	0.01
2p15	rs10865331	-	G	A	410	539	200	0.409	315	325	87	0.342	1.53 (1.16-1.52)	4.63×10^{-5}
2q11.2	rs2310173	IL1R2	C	T	605	515	125	0.334	353	301	72	0.306	1.14 (0.99-1.31)	0.05
4q21.21	rs4333130	ANTXR2	T	C	1039	113	2	0.051	666	77	5	0.059	-	-
5q15	rs27037	ERAP1	C	T	409	678	142	0.384	343	280	89	0.322	1.31 (1.14-1.51)	1.31×10^{-4}
5q15	rs27434	ERAP1	G	A	126	626	295	0.543	215	336	167	0.466	1.36 (1.19-1.56)	4.59×10^{-6}
6p22.2	rs3734523	-	C	T	1144	13	0	0.006	725	13	1	0.010	-	-
21q22.2	rs2836754	-	G	A	346	575	230	0.450	219	336	171	0.457	0.93 (0.82-1.06)	0.30

* 1016 subjects were genotyped (1164 cases and 752 controls) for SNPs with missing values. The rs3734523 SNP was rare and rs3734523 SNP was not common. Odds ratio (OR) and 95% confidence interval (95% CI) were calculated using chi-square test. SNP = single nucleotide polymorphism, MAF = minor allele frequency.

Conclusions: This is the first confirmation in a non-Caucasian population that genetic polymorphisms of rs27037, rs27434 and rs10865331 are associated with AS, implicating common pathogenetic mechanisms in Korean and Caucasian AS.

1973

HD6: A Novel Antibody That Recognises Cell Surface HLA-B27 Homodimers. Kirsty McHugh[3], Sravan K. Payeli[1], Simon Kollnberger[2], Markus Thiel[1], Jacqueline Shaw[2], Sascha Kleber[1], Andreas Wadle[1], Christoph Renner[1] and Paul Bowness[2]. [1]Department of Oncology, University of Zurich, [2]MRC Human Immunology Unit, Weatherall Institute of Molecular Medicine, Oxford, [3]MRC Human Immunology Unit, Weatherall Institute of Molecular Medicine, Oxford, Oxfordshire, United Kingdom

Background: Possession of HLA-B27 is strongly associated with development of the spondyloarthropathies, including Ankylosing Spondylitis (AS). The mechanism by which HLA-B27 confers this susceptibility is unclear. HLA-B27 forms both heterotrimers (B27) associated with peptide and beta-2-microglobulin, and also heavy chain homodimers (B272). A pathogenic role for these homodimers has been proposed. However, determination of the extent, distribution and triggers of B272 expression have been hampered by the lack of a specific detection reagent. In order to investigate the role of homodimers in AS, we generated an antibody to B272 using phage display technology.

Methods: Phage display technology was used to generate monoclonal antibodies specific for B272. Biotinylated recombinant B272 complexes were used for positive selection and heterotrimeric B27 for negative selection of a phage Fab library. One clone selected for further characterisation, HD6, was then sub-cloned to generate a chimeric antibody comprising human Fab2 and murine IgG1 Fc. ELISA was used to confirm its specificity for B272 complexes. For recognition of cell-expressed B272, human B cell lines transfected with HLA-B27 or control HLAs, and AS patient and control peripheral blood mononuclear cells were used and results analysed by FACS. Inhibition of the interaction of B272 with the immunoreceptors KIR3DL1, KIR3DL2 and LILRB2 was determined using transfected and FACS-sorted cell lines.

Results: 1) In ELISA, HD6 specifically recognised recombinant B272 but not HLA-A2, B7 or B27 heterotrimers. 2) HD6 bound in FACS to LBL721.220 cells transfected with HLA-B27, which express B272 cell surface homodimers, but not to LBL721.220 B7 or to B27 with Cys 67 mutated to serine (which do not express B272). HD6 also bound the C1R human B cell line transfected with HLA-B27 but not with HLA-A2. 3) Cell surface HD6-reactive HLA-B27 molecules were sensitive to treatment with papain (in 3 independent experiments). 4) HD6 bound in FACS to peripheral blood monocytes from AS patients but not controls. B272 expression on monocytes from AS patients ($n=7$) was significantly higher when compared to monocytes from B27+ ($p=0.01$, $n=4$) or B27- ($p=0.06$, $n=7$) healthy individuals, respectively. Low level binding to B27+ B but not T lymphocytes was also observed. 5) HD6 inhibited the binding of the immunoreceptors KIR3DL1, KIR3DL2 and LILRB2 to B272.

Conclusions: A novel phage display-derived monoclonal antibody recognises both recombinant and cell-expressed B272. HD6 stains monocytes from AS patients, implicating these cells in AS pathogenesis. HD6 will be a powerful tool to address the potential pathogenic role of B272 in SpA and may additionally have therapeutic potential.

1974

HLA- B*27 and Cw*06 Are Risk Alleles for Psoriatic Arthritis among Psoriasis Patients. Lihi Eder[2], Fawnda Pellett[2], Vinod Chandran[2], Sutha Shanmugarajah[2] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, Toronto, ON, Canada, [2]Toronto Western Hospital, Centre for Prognosis Studies in the Rheumatic Diseases, Toronto, ON, Canada

Aim: Genes that differentiate patients with Psoriatic Arthritis (PsA) from those with psoriasis alone serve as markers for the development of PsA in patients with psoriasis. We aimed to identify HLA alleles that are associated with PsA among psoriasis patients.

Methods: In this population based association study, we performed HLA typing in 3 groups: PsA, psoriasis without arthritis and healthy controls. The PsA group included adult patients satisfying the CASPAR criteria that were part of a large prospective PsA cohort. The psoriasis patients were recruited from a recently established psoriasis cohort that was confirmed by a dermatologist. These patients were examined annually by a rheumatologist to rule out the presence of inflammatory arthritis. Control DNA was from healthy Caucasian volunteers, cadaveric organ donors from laboratories of the University Health Network and from a commercial biobank. Extracted genomic DNA was amplified by PCR using locus specific primers for each of the HLA-A, -B, -C, -DR and DQ loci. PCR amplicons were identified by Sequence Specific Oligonucleotide probes using a reverse line blot technique. Caucasian subjects from the PsA and psoriasis cohorts were combined into a "Psoriatic disease" group that was compared to the healthy controls. The differences in allelic distributions for each of the HLA loci were compared using chi square test and Fisher exact test. Bonferroni corrected p values were calculated to adjust for multiple testing. A logistic regression analysis was performed to account for the strong linkage disequilibrium between the HLA alleles.

Results: 804 PsA patients, 412 psoriasis patients without arthritis and 719 healthy controls were included in the study. The mean ages for the psoriasis, PsA and control subjects were: 45.7 ± 13.1, 42.3 ± 12.6 and 43.6 ± 17.2 years respectively. The proportions of females were: 41.9%, 43.5% and 49.3% respectively. The following HLA alleles were found to be significantly different between the psoriatic disease group and healthy controls: A*03 (20% vs. 27.3%, Odds Ratio (OR) 0.6, $p=0.05$), B*07 (16.3% vs. 25.8%, OR 0.6, $p= 4*10^{-4}$), B*13 (9.7% vs. 4.7%, OR 2.2, $p=0.01$), B*27 (14.1% vs. 7.2%, OR 2.1, $3*10^{-4}$), B*38 (11.9% vs. 2.5%, OR 5.3, $p= 10^{-10}$), B*51 (5.7% vs. 10.7%, OR 0.5, $p= 3*10^{-5}$), Cw*03 (15.9% vs. 22.5%, OR 0.7, $p=0.05$), Cw*06 (32.8% vs. 18.1%, OR2.2, $p= 8*10^{-10}$), Cw*07 (44.2% vs. 56.6%, OR 0.61, $p= 4*10^{-5}$), Cw*12 (19.4% vs 10.2%, OR 2.1, $p= 2*10^{-5}$), DRB1*15 (19.2% vs. 26.5%, OR 0.7, $p=0.03$), DQB1*0602 (17% vs. 24.7%, OR 0.6, $p=0.009$). When the PsA group was compared to the psoriasis alone group the only HLA alleles that were found to be significantly different were: B*27 (17.7% vs. 4.1%, OR 5, $p= 4*10^{-9}$), Cw*02 (11.6% vs. 4.8%, OR 2.7, $p=0.01$) and Cw*06 (26.9% vs. 42.1%, OR 0.5, $p= 8*10^{-6}$). On logistic regression analysis only HLA B*27 (OR 4.6, 95% Confidence interval (CI) 2.5–8.3) and Cw*06 (OR 0.5, 95% CI 0.4–0.7) remained significantly associated with PsA compared to psoriasis.

Conclusions: HLA*B27 is a risk allele for PsA among psoriasis patients, while HLA-Cw*06 is a protective allele.

1975

HLA-Bw4 Alleles and HLA-C Alleles That Have High Cell-Surface Expression Are Associated with Susceptibility to Psoriatic Arthritis (PsA). Vinod Chandran[3], Fawnda Pellett[2], Renise Ayearst[2], Remy Pollock[3] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto Psoriatic Arthritis Clinic, Toronto Western Hospital, Toronto, ON, Canada, [3]University of Toronto Psoriatic Arthritis Clinic, Toronto Western Hospital

Background: Natural-Killer (NK) cells and NK-T cells are important in the pathogenesis of PsA. The killer-cell immunoglobulin-like receptors (KIRs) on NK cells regulate the inhibition and activation of NK-cell responses through recognition of HLA class I molecules on target cells. It was previously shown that individuals with KIR3DS1 and HLA-B alleles with the serological Bw4 epitope and amino acid isoleucine at position 80 (HLA Bw4 80Ile-B*1513, 1516, 1517, 1524, 2702, 3801, 4901, 51, 5201, 5301, 5302, 57, 58), as well as those with expressing HLA-C alleles that have high cell-surface expression (HLA-C Hi- C* 02, 05, 06, 08, 12, 15, 16) progress more slowly to AIDS. Given the important epidemiological relationship between PsA and AIDS we sought to determine whether these genotypes are associated with susceptibility to PsA.

Methods: 685 cases of European ethnicity (295 females, mean age 43 years, PsA duration 7 years, psoriasis duration 15 years, actively inflamed joint count 11, PASI score 5.2) with PsA and 706 ethnically matched controls (273 females, mean age 53 years) were recruited for the study. Genotyping for HLA-B, and -C alleles was performed using PCR-SSO reverse line blot and that for KIR genes was performed

using PCR-SSP on genomic DNA obtained from peripheral blood. Association between genotypes and PsA was investigated using chi square, Mantel-Haenszel trend test and logistic regression.

Results: HLA-Bw4 80Ile was associated with PsA with risk being higher in subjects with two Bw4 80Ile alleles compared to those with one or no alleles [Bw4 80Ile 2 copies vs. none OR = 1.91, p = 0.03; 1 copy vs. none OR = 1.61, p<0.0001, trend p <0.0001] independent of HLA-B*27. KIR3DS1 was not associated with PsA in univariate analysis (p=0.82), although in a multivariate logistic regression analysis including all KIR genes, KIR3DS1 was protective (OR=O.54, p = 0.038). Analysis for association of Bw4 80Ile and/or KIR3DS1 with PsA where the hierarchy of putative biological effects, namely, Bw4 80Ile absence and KIR3DS1 presence < absence of both Bw4 80Ile and KIR3DS1 < Bw4 80Ile presence and KIR3DS1 absence < presence of Bw4 80Ile and KIR3DS1 (highest risk group) was taken into account showed that the combined genotype was associated with PsA (p trend < 0.0003). HLA-C Hi alleles also were associated with PsA with risk being higher in subjects with two HLA-C Hi alleles compared to those with one or no alleles (C Hi two copies vs. none OR = 2.56, p <0.0001; 1 copy vs. none OR = 1.49, p=0.0012, trend p <0.0001) independent of HLA-C*06, KIR2DS1 and KIR2DS2. Multivariate regression analysis including both Bw4 80Ile and C Hi alleles in a logistic model revealed that both HLA-Bw4 80Ile and HLA-C Hi are independently associated with susceptibility to PsA.

Conclusions: HLA and KIR genes that are associated with better control of HIV/AIDS are independently associated with increased susceptibility to PsA.

1976

IL-17 Receptor and Its Functional Significance in Psoriatic Arthritis. Siba P. Raychaudhuri[2], Ankit Saxena[1] and Smriti K. Raychaudhuri[1]. [1]UC Davis, [2]UC Davis/VAMC Sacramento, Davis, CA

Purpose: The infiltration of T lymphocytes into the synovium involves a dynamic interaction between the subintimal endothelial cells and the fibroblast-like-synovial cells (FLS) in autoimmune arthritis. Overproduction of the pro-inflammatory cytokine, IL-17 has been reported in the rheumatoid arthritis(RA), psoriatic arthritis (PsA) synovium compared to osteoarthritis (OA) patients. Increased levels of IL-17 induce a multitude of factors contributing to the degradation of the articular cartilage and erosion of the underlying bone. In contrast to the restricted site of synthesis of IL-17, the IL- 17 receptor (IL-17R) is expressed ubiquitously. The IL-17R is a type-I membrane protein with no homologue to any of the known family of cytokine receptors. There is no study available about the IL-17R in PsA. To gain knowledge about the expression and function of IL-17R in patients with PsA we analyzed FLS from patients with PsA, RA and OA.

Method: FLS were isolated from the synovium of RA (n=5), PsA (n=5) and OA (n=5) patients. IL-17R expression in FLS was identified by western blotting (WB) and flowcytometry. We also measured IL-17 levels in the synovial fluid (SF) of PsA, RA and OA by ELISA. T lymphocytes derived from synovial fluid (SF) of these patients were studied to identify and phenotype the Th17 cells. Further we determined the functional significance IL-17R in respect to the production of proinflammatory cytokines and endopeptidase.

Results: We observed by flowcytometry that IL-17R expressing cells in FLS obtained from the synovium of RA, PsA and OA were 16.5%±5.37, 12.5%± 3.04, 0.3%±0.9 respectively. WB analyses showed that relative intenstity (RI) of IL-17R protein were higher in RA and PsA compared to OA. RI of IL-17R for RA, PsA and OA were 0.74±.034, 0.68± 0.02, 0.044±.01 respectively.The difference between the groups was found to be significant at p<0.01. The IL-17 level in SF was highest in the PsA group (288.5 pg/ml ± 85.2; n=12). In RA (n=12) and OA (n=12) the level of IL-17 were 225 pg/ml ± 55 and 52 pg/ml±16 respectively. A significant enrichment of IL-17-producing CD4+T cells (10%±3.2) was noticed in the SF of the PsA patients compared to the OA (p<.001). Compared to OA, recombinant IL-17 induced higher levels of IL-6, IL-8, and MMP-3 in PsA derived FLS. Further blockade of the IL-17 R inhibits production of IL-6, IL-8, and MMP-3.

Conclusion: This is the first report to demonstrate the functional significance of IL-17R in PsA. High expression of IL-17R in PsA correlates with the inflammatory outcome of the disease. Our results support the hypothesis that IL17/IL-17R interaction may contribute to an unbalanced production of cytokines and likely to play a significant role in the pathogenesis of PsA. Further our study provides evidence that IL-17R blocking agents/monoclonal antibodies likely to be effective in psoriatic arthritis.

1977

Increase of CD5+ 'Innate' B Lymphocytes with Regulatory Capacities in Spondyloarthritis. Tineke Cantaert, Gabriela FrancoSalinas, Jacky Paramarta, Yvonne Tiersma, Christine Teitsma, Paul P. Tak and Dominique Baeten. Academic Medical Center/University of Amsterdam

Background: B lymphocytes play a pivotal role in many autoimmune diseases by terminal differentiation to autoantibody-producing plasma cells, by antigen presentation to T cells, and by cytokine production. However, innate-like CD5+ B cells have recently been shown to down-regulate inflammation by IL-10 production in several colitis models. Considering the relationship between gut and joint inflammation as well as the unknown role of B cells in spondyloarthritis (SpA), we aimed to characterize the presence and function of CD5+ B cells in this seronegative disease.

Materials and Methods: Peripheral blood B cells were analyzed and sorted by flow cytometry in patients with SpA as well as in healthy controls (HC) and patients with rheumatoid arthritis (RA). Sorted cells were stimulated in vitro with either anti-IgM and CD40L or with CpG. Production of cytokines was measured by real-time PCR and ELISA. Synovial biopsies were obtained from actively inflamed joints by needle arthroscopy and were analyzed by double immunohistochemistry.

Results: B cell phenotyping revealed no alterations in naïve, memory, and extra-follicular B cells as well as plasmablasts in SpA. However, there was a significant increase of CD5+ B cells in SpA compared to HC in all B cell subsets (p<0.05). This was not due to increased B cell activation in SpA as the early activation marker CD69 was not increased and both HLA-DR (p<0.01) and CD40 (p=0.013) expression were even decreased on SpA versus HC B cells. Moreover, activation in vitro did not result in an upregulation of CD5. The increase of CD5+ B cells was also specific for SpA and not due to preferential migration of CD5- B cells to the inflamed target tissues as there was no increase in CD5+ B cells in RA peripheral blood and as CD5+ CD19+ B cells were detected in the inflamed synovial tissue. As to the function of the CD5+ B cells in SpA, they displayed not only lower levels of HLA-DR and CD40 but also lower expression of CD80 and CD86 when analyzed directly ex vivo as well as after in vivo activation, suggesting a decreased ability to fully activate T cells. Moreover, the CD5+ B cells produced increased levels of IL-10 but lower levels of IL-6 after BCR stimulation in vitro. This was not the case after innate immune activation by CpG.

Conclusion: CD5+ innate-like B cells are specifically increased in SpA. Their reduced expression of molecules involved in antigen-specific cross-talk with T lymphocytes as well as their ability to produce IL-10 indicate that this B cells subset has regulatory capacities. These data warrant further investigation of their potential contribution to the pathophysiology of SpA in vivo.

1978

Increased Expression of Carbonic Anhydrase I in the Synovium of Patients with Ankylosing Spondylitis. Xiaotian Chang[2], Yan Zhao, Xinfeng Yan and Yunzhong Zhang[1]. [1]China, [2]Shandong Acedemy of Medicinal Sciences, China

Background: The most distinctive features of ankylosing spondylitis (AS) is new bone formation and bone resorption at sites of chronic inflammation. Previous studies have indicated that the hyperplasia and inflammation of synovial tissues are significantly related to the pathogenic

process of AS. The present study applied a proteomics approach to identify novel AS-specific proteins by simultaneously comparing the expression profiles of synovial membranes from patients with AS, rheumatoid arthritis (RA) and osteoarthritis (OA).

Methods: Proteins extracted from synovial tissues (n=10 for each disease) were separated by 2-D electrophoresis, and the proteins with significantly increased expression in the AS samples were subjected to MALDI-TOF/TOF-MS analysis. The results were verified using western blotting and immunohistochemistry. The levels of candidate proteins in synovial fluids (n=40 for each disease) were measured using ELISA.

Results: Compared with RA and OA tissue samples, the proteomics approach revealed significantly increased expression of carbonic anhydrase I (CA1) in the synovial membrane of patients with AS. Immunohistochemistry and western blotting analysis confirmed the above finding.

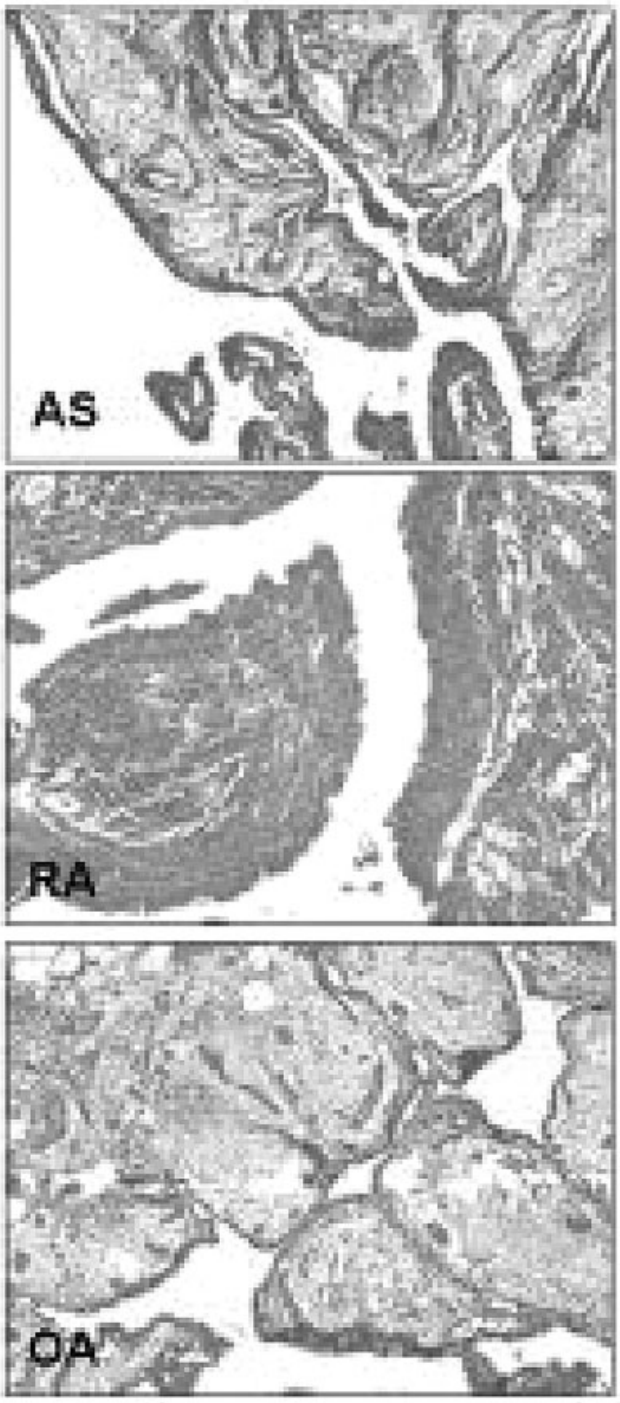

Figure 1.

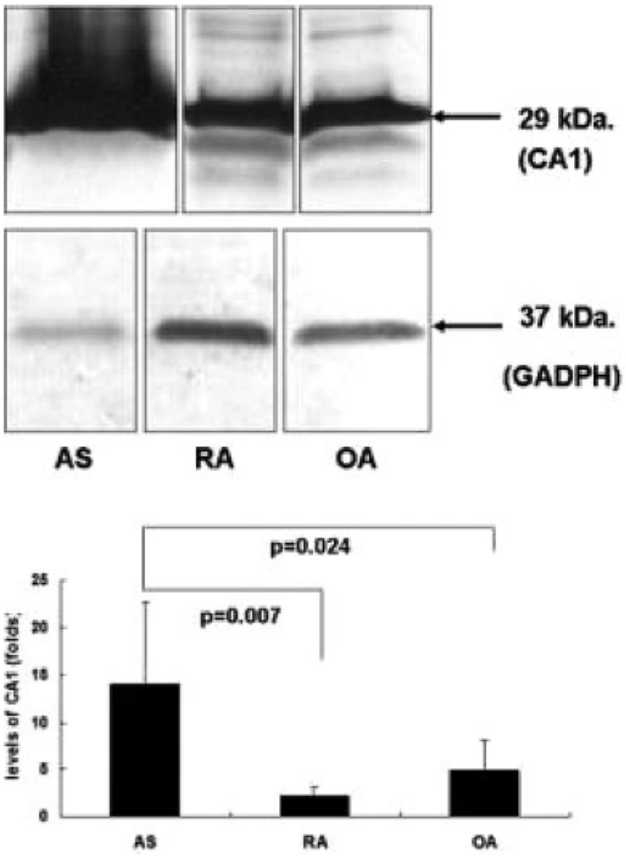

Figure 2.

ELISA detected a higher level of CA1 in synovial fluids from patients with AS than in RA and OA samples. The study also detected increased expression of alpha-1-antitrypsin in the synovial tissues from AS patients, which corresponds to other reports.

Conclusion: *In vitro* experiments by other groups indicated that CA1 catalyzes the generation of HCO_3^- through hydration of CO_2, which then combines with Ca^{2+} to form a precipitation of $CaCO_3$. Many evidences indicated that carbonic anhydrase also stimulates bone resorption. Hence, over-expression of CA1 in synovium of AS may promote improper calcification and bone resorption in AS.

1979

MICA*016 Allele Differentiates Skin and Joint Manifestations of Psoriatic Disease. Vinod Chandran[3], Remy Pollock[3], Jessica Barrett[1], Lihi Eder[3], Fawnda Pellett[3], Christopher Yao[3], Marsel Lino[3], Sutha Shanmugarajah[3], Vernon Farewell[1] and Dafna D. Gladman[2]. [1]MRC Biostatistics Unit, University of Cambridge Institute of Public Health, Cambridge, UK, [2]Toronto Western Hospital, Toronto, ON, Canada, [3]University of Toronto Psoriatic Arthritis Clinic, Toronto Western Hospital

Background: The Major Histocompatibility Complex Class 1 Chain-Related Gene A (*MICA*) is a multiallelic locus in the MHC region that encodes a 43 kDa cell-surface protein that functions to activate pathways in innate and adaptive immunity. Previous studies have shown associations between psoriatic arthritis (PsA) and MICA-A9 corresponding to MICA*00201 and MICA*017, and MICA-A4, corresponding to MICA*001, MICA*00701, and MICA*018, when compared to healthy controls. However, it is not clear whether the associations are with psoriasis or with PsA, and if the associations are independent of HLA alleles. Our purpose was to delineate the contributions of MICA alleles to susceptibility to skin and joint manifestations of psoriatic disease.

Methods: 249 unrelated Caucasian subjects with PsA (96 females, mean age 41 years, PsA duration 7 years, psoriasis duration 14 years, actively inflamed joint count 10, PASI score 5.3), 243 with psoriasis (100 females,

mean age 47 years, psoriasis duration 17 years, PASI score 5) and 248 healthy controls (141 females, mean age 49 years) were recruited for this study. Genotyping for 55 MICA alleles was done by PCR-SSP and for HLA-B, and -C alleles by PCR-SSO reverse line blot. Allele frequencies were calculated and univariate and multivariate logistic regressions performed, adjusting for HLA-B and C alleles previously shown to be associated with psoriasis and/or PsA.

Results: In univariate analyses MICA*00201/020, MICA*016 frequencies were significantly increased in psoriatic disease (PsA and psoriasis combined) compared to controls, while MICA*00801, MICA*018 and MICA*049 frequencies were decreased. MICA*00201/020 and MICA*00701/026 were increased in PsA compared to controls and MICA*004, MICA*00801 and MICA*018 were decreased. MICA*00201/020, MICA*016 and MICA*017 frequencies were significantly increased in psoriasis compared to controls, while MICA*00801 was decreased. Finally, MICA*00701/026 was increased in PsA compared to psoriasis, and MICA*016 was decreased. There was a significant effect of homozygosity for the allele MICA*00801. Results of the multivariate analyses are provided in the table.

Table. Results of multivariate logistic regression analyses using *MICA* alleles found significant in the univariate analyses as explanatory variables, as well as the results after the inclusion of HLA alleles that were found to be at least marginally significant in univariate analyses.

			After Adjustment for HLA	
Allele	**OR**	**P Value**	**OR**	**P Value**
Psoriatic Disease vs. Controls				
MICA*00201/020	1.694	0.012	1.505	0.078
MICA*00801	0.686	0.03	0.788	0.211
MICA*016	3.022	0.044	*3.628*	*0.021*
MICA*018	0.451	0.017	*0.494*	*0.041*
MICA*049	0.126	0.06	0.176	0.115
PsA vs. Controls				
MICA*00201/020	1.824	0.014	1.462	0.174
MICA*004	0.528	0.028	0.681	0.204
MICA*00701/026	2.602	0.002	0.333	0.115
MICA*00801	0.764	0.209	0.846	0.480
MICA*018	0.437	0.051	0.448	0.067
Psoriasis vs. Controls				
MICA*00201/020	1.836	0.011	1.473	0.135
MICA*00801	0.686	0.062	*0.638*	*0.036*
MICA*016	4.461	0.009	*4.388*	*0.011*
MICA*017	1.875	0.019	1.218	0.619
PsA vs. Psoriasis				
MICA*00701/026	5.074	<0.001	1.026	0.969
MICA*00801†	1.173	0.449	1.294	0.265
MICA*016	0.608	0.243	0.597	0.245

After adjusting for HLA-B*13, −27, −38, −57 and HLA-Cw*01, −02, −06, −12 alleles, no MICA alleles were associated with PsA, but MICA*016 remained significantly associated with psoriasis [Odds Ratio (OR) = 4.4, p = 0.011] and MICA*00801 remained protective [OR = 0.69, p = 0.036]. MICA*00801 homozygosity significantly increased susceptibility to PsA for patients with psoriasis.

Conclusions: MICA allele associations with psoriasis and PsA are dependent on linkage disequilibrium with HLA-B and HLA-C risk alleles. Independent of HLA, only MICA*016 and MICA*00801 influence the risk of developing psoriasis without arthritis, and homozygosity for MICA*00801 increases the risk of developing PsA.

Peripheral Joint Ankylosis in the Spontaneous Model of Arthritis in DBA/1 Mice Is Associated with a Locus on Chromosome 3 That Contains the BMP Receptor Type 1b. Rik Lories[2], Inge Derese[3], Shea Carter[3], Kirsten Braem[3], Ana Valdes[1] and Frank P. Luyten[2]. [1]King's College, [2]KU Leuven, Leuven, Belgium, [3]KU Leuven

Background: Progression of ankylosis in patients with ankylosing spondylitis is highly variable. Diseases such as diffuse idiopathic skeletal hyperostosis (DISH) and fibrodysplasia ossificans progressiva (FOP), show new bone formation with striking similarities to AS both at the histomorphological and molecular level. This suggests that ankylosis is at least partially due to genetic factors. We used the ankylosing enthesits model in DBA/1 mice to search for associated regions and genes.

Methods: Male DBA/1 were crossed with female BALB/c mice. Male F2 mice from different litters were studied by histomorphology at 26 weeks. 159 markers with sequence-length polymorphisms on the autosomes were selected. Median spacing between the markers was 6.9 cM. 162 F2 male mice were studied. Genes in regions of interests were linked to skeletal development, bone morphogenetic protein (BMP) and Wnt signaling pathways with the Gene Ontology database. The association was evaluated by Chi-square tests with a False Discovery Rate (FDR) algorithm.

Results: Incidence of ankylosing enthesitis was lower in the F2 generation as compared to wild-type DBA/1 males (42% vs. 72%; $p<0.0001$). When applying the FDR algorithm for 159 markers, associations with *D3MIT199* and *D3MIT160* were significant ($p<0.016$). Adjacent markers were additionally genotyped. In the associated region between markers *D3MIT42* and *D3MIT129*, 162 genes were found among which *Bmpr1b, Cxxc4, Lef1, Papss1, Pitx2*, and *Ube2d3*. Only BMP receptor type 1b (*BMPr1b*) was specifically upregulated in mice with spontaneous arthritis as demonstrated by quantitative RT-PCR.

Conclusion: By using F2 mouse genetics in the analysis of a specific phenotype of joint ankylosis, we identified a locus on chromosome 3 that shows association. Within this locus, several genes could play a role in ankylosis but the expression profile suggests that BMP receptor 1b is involved, further supporting a critical role for BMPs in this process.

1981

Phenotypic, Functional and Transcriptomic Analysis of Monocyte-Derived Dendritic Cells from SpA Patients Revealed Their Hypo-Stimulatory Capacity and Specific Molecular Response to LPS Compared to Healthy Controls. Maxime Breban[1], Nelly Bonilla[2], Badredine Mohand Oumoussa[2], Alice Talpin[2], Henri-Jean Garchon[2] and Gilles Chiocchia[2]. [1]AP-HP, [2]Inserm

Purpose: DCs from B27 transgenic rats have a diminished ability to interact with CD4+ T cells and to stimulate a proliferative response, as compared to control DCs. Such results raised the hypothesis that an altered interaction between antigen-presenting cells and CD4+ T lymphocytes might be critical in AS pathogenesis. Nevertheless, we need data in the human disease. Thus, it is of first importance to analyse the expression of HLA molecules and to evaluate the function and genes expression profiling of DCs in AS patients.

Objectives: To study HLA and accessory molecules expression in monocyte-derived DCs (MD-DC), to examine the functional capacity of MD-DC from patients compared to normal controls and the genes expression profiling in monocytes and their derived dendritic cells before and after stimulation.

Method: AS patients (11 HLA-B27+; mean age 44+12 years; BASDAI = 38+22; BASFI = 19+21) and 10 healthy controls were studied. Multi-colours FACS analysis of in vitro MD-DCs was used to compare the expression level of HLA-DR and a full set of cell markers: CD4, CD8, CD11c, CD14, CD40, CD80, CD83, CD86. In vitro derived DCs were obtained from purified CD14+ population cultured for 7 days in the presence of IL-4 and GM-CSF. HuGene 1.0 microarrays were used for genes expression profiling of both monocytes and their derived dendritic cells.

Results: The expression of HLA-DR was higher in AS patients than in controls ($p=0.009$) on monocyte-derived DCs obtained after 7 days of culture and activated with LPSWe observed that like it was reported in rat, the monocytes-derived DCs from AS patients exhibited a weaker stimulatory efficiency of CD4+ T cells than DCs from controls both on autologous and heterologous stimulation conditions. The analysis of genes differentiellyexpressed between CD14+ monocytes from AS patients and controls showed that inflammatory mediators genes transcrits such as CCL2 chemokine, IL-1b and IL-6 cytokines were significiently overexpressed on AS patients CD14+ cells. We also observed a specific molecular signature response to LPS by MD-DC from AS patients compared to controls.

Conclusions: Our findings revealed consistent differences in HLA expression on DCs from AS patients, as compared to healthy controls. We bring evidence that DC from SpA patients have a lower ability to stimulate CD4+ T cell proliferation, as compared to control DC. Transcriptomic analysis of monocytes CD14+ from patients compared with healthy controls showed an inflammatory signature in which genes of inflammatory mediators are significantly overexpressed in SpA. Furthermore, transcriptomic analysis of MD-DCs stimulated with LPS revealed a difference in molecular signature between patients and healthy controls.

1982

Plasma Cytokine Profles in Ankylosing Spondylitis. Brock E. Harper[4], Michael H. Weisman[1], Pravitt Gourh[5], Shervin Assassi[4], Laura A. Diekman[4], Michael M. Ward[2], John D. Reveille[3] and Sandeep K. Agarwal[4]. [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]NIH, NIAMS, IRP, Bethesda, MD, [3]Univ Texas Health Sci Ctr, Houston, TX, [4]Univ. of Texas Health Science Center Houston, Houston, TX, [5]Univ. of Texas Health Science Center Houston

Background: Ankylosing spondylitis (AS) is commonly treated with TNFα inhibitors (TNFi) with success; however, our understanding of the immunology of AS is limited. Identification of the genetic association of *IL23R* with AS susceptibility implicates involvement of the Th17 pathway in the pathogenesis of AS. This study aims to investigate the possible effects of TNFi use and patterns of lymphocyte activation in AS.

Methods: Plasma from 128 AS patients and 144 nonautoimmune controls were obtained from patients seen at the University of Texas Health Science Center at Houston Rheumatology Division within the PSOAS cohort. Levels of 13 cytokines were evaluated by electrochemiluminescent multiplex assays.

Results: AS patients had higher levels of IL-23 ($p=0.004$), IL-4 ($p=0.0007$), IL-6 ($p<0.0001$) and lower levels of IL-1β ($p=0.002$) and IL-8 ($p<0.0001$) compared to controls after adjustment for age and gender. Results of analysis of TNFi subsets are shown in Table 1. No differences were seen between either subset of AS patients and controls for IFNγ, IL-5, IL-12, IL-13 or IL-10.

Table 1. Comparison of Cytokine Levels in Patients On and Off TNF inhibitors. Cytokine values are listed as mean±SD in pg/mL. P-values are of data after log-transformation and adjustment for age and gender.

	Control (N=144)	AS Off TNFi (N=92)	AS On TNFi (N=36)	Adjusted P value Ctl vs Off	Adjusted P value Ctl vs On	Adjusted P value On vs Off
IL 17	1.85 ± 2.27	2.28 ± 2.66	0.61 ± 0	NS	<0.0001	<0.0001
IL 23	4.67 ± 12.38	7.65 ± 20.4	10.86 ± 36.97	0.003	NS	NS
IL 2	1.80 ± 6.98	1.40 ± 2.88	0.74 ± 0.56	NS	NS	0.008
IL 4	1.69 ± 3.08	3.30 ± 4.21	2.40 ± 3.47	<0.0001	0.08	0.05
IL 1β	4.93 ± 11.97	1.05 ± 1.98	1.05 ± 1.59	0.006	0.08	NS
IL 6	6.19 ± 11.79	15.06 ± 22.27	4.27 ± 7.38	<0.0001	NS	<0.0001
IL 8	76.99 ± 343.32	2.82 ± 8.10	4.19 ± 12.00	<0.0001	0.02	NS
TNFα	9.73 ± 7.00	11.45 ± 22.48	31.54 ± 31.66	0.0006	<0.0001	<0.0001

Significant correlations with clinical parameters were found with IL-6 and higher BASDAI, ESR, CRP and limited spinal movement. IL-2 and IL-4 were also associatied with higher BASDAI. IL-17, IL-23, IL-2, IL-4, IL-1β, IL-8 were associated with ESR and CRP.

Conclusions: Plasma cytokines differences between controls and patients with AS particularly with respect to TNFi use support the potential role of dysregulation of the Th17 pathway in AS.

1983

Stromal Cell Derived Mediators of Bone Remodeling in Psoriatic Arthritis: Implications for Disordered Osteoclastogenesis and Bone Erosion. Nicola Dalbeth[1], Bregina Pool, Timothy Smith, Karon Callon, Maria Lobo, William J. Taylor, Peter B. Jones, Jillian Cornish and Fiona M. McQueen[2]. [1]Univ Auckland, Auckland, New Zealand, [2]Univ of Auckland Sch of Med, Auckland, New Zealand

Background: Diverse bone pathologies are observed in patients with psoriatic arthritis (PsA). Uncoupling of bone remodeling with disordered osteoclastogenesis has been implicated in the pathogenesis of bone resorption in PsA. The aim of this study was to examine the role of stromal cell derived mediators of bone remodeling in PsA.

Methods: Patients with PsA (n=38), with psoriasis (n=10) and healthy controls (n=12) were studied. Serum was obtained for testing of Dikkopf-1 (Dkk-1), macrophage-colony stimulating factor (M-CSF), osteoprotegerin (OPG) and receptor activator of nuclear factor-κB ligand (RANKL) by ELISA. These stromal cell derived mediators were selected as all have been definitively implicated in bone remodelling in models of inflammatory arthritis. Patients with PsA also had bone densitometry, plain radiographs of the hands and feet, and assessment of peripheral blood osteoclast precursors. Radiographs were scored for erosion and joint space narrowing using the Sharp-van der Heijde (SvdH) method modified for PsA, and for the number of joints with new bone formation.

Results: Compared with psoriasis and healthy controls, patients with PsA had higher circulating concentrations of Dkk-1 and M-CSF (Figure). In patients with PsA, the SvdH radiographic scores correlated with M-CSF concentrations ($r=0.52$, $p<0.01$) and RANKL concentrations ($r=0.36$, $p<0.05$), but not Dkk-1 concentrations ($r=0.15$, $p>0.05$). Circulating mediators of bone remodeling did not correlate with the number of joints with new bone formation or with total hip bone mineral density. The radiographic SvdH scores correlated with the percentage of peripheral blood osteoclast precursors ($r=0.38$, $p<0.05$), the number of osteoclast-like cells ($r=0.37$, $p<0.05$) and resorptive pits ($r=0.47$, $p<0.01$) following culture with RANKL and M-CSF. Circulating M-CSF concentrations correlated with the percentage of peripheral blood osteoclast precursors ($r=0.40$, $p<0.05$).

Conclusions: Systemic expression of stromal cell derived factors that promote osteoclastogenesis and bone loss is disordered in patients with PsA. The data do not support a role for these factors in other bone pathologies of PsA, such as new bone formation.

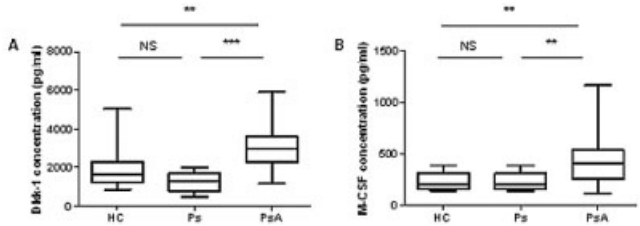

Figure. Stromal cell derived mediators of bone remodeling. Box and whisker plots showing concentrations of A. Dkk-1, and B. M-CSF in healthy controls (HC), patients with psoriasis (Ps) and patients with PsA. **p<0.01, ***p<0.001, one-way analysis of variance with Dunn's multiple comparison test.

1984

The Association of IL-13 Polymorphism with Psoriatic Arthritis among Psoriasis Patients. Lihi Eder[2], Vinod Chandran[2], Fawnda Pellett[2], Remy Pollock[2], Sutha Shanmugarajah[2] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, Toronto, ON, Canada, [2]Toronto Western Hospital, Centre for Prognosis Studies in the Rheumatic Diseases, Toronto, ON, Canada

Aim: The IL-13 cytokine is involved in T helper type 2 signaling pathway. IL-13 polymorphisms confer a risk for Asthma. Recently, these were found to be associated with a reduced risk for Psoriatic Arthritis (PsA) but not with psoriasis. Smoking was found to abrogate this effect. We aimed to study the association of IL-13 polymorphisms with PsA and psoriasis and their combined effect with smoking.

Methods: We genotyped three groups of Caucasian individuals: patients with PsA, patients with psoriasis without arthritis and healthy controls, for the following Single Nucleotide Polymorphisms (SNPs): rs20541 and rs848, an additional SNP, rs1800925, was genotyped only in the PsA and psoriasis groups. The PsA patients were recruited from a large prospective PsA cohort and satisfied the CASPAR criteria. The psoriasis patients were assessed by a rheumatologist to rule out inflammatory arthritis. The control DNA was from healthy volunteers, cadaveric organ donors from laboratories of the University Health Network and from a commercial bio-bank. Smoking status was defined as smoker ever for smokers and lifetime non-smoker. SNP genotyp-

ing was performed using TaqMan allelic discrimination assays and SDS 2.2.2 software was used for data collection and allele calling.

The differences in allelic distributions were compared by chi square test using PLINK software. The combined effect of genotype and smoking was tested by comparing the proportions of PsA and psoriasis patients and the different combination groups of rs1800925*CT/TT status and smoking status.

Results: 555 PsA patients, 342 psoriasis patients without arthritis and 216 healthy controls were included in the study. Smoking was negatively associated with PsA (258/492 (47.6%) in the PsA group and 139/342 (59.4%) in the psoriasis alone, $p<0.0008$). The minor alleles of rs20541*A and rs848*A were protective for PsA compared to controls (Odds Ratio (OR) 0.61, $p=0.0005$, OR 0.62, $p=0.0007$, respectively). The same alleles were not found to be associated with psoriasis alone (OR 0.75, $p=0.06$, OR 0.79, $p=0.11$, respectively). When PsA patients were compared to those with psoriasis alone, the minor alleles of rs1800925*T (OR 0.78, $p=0.04$) and rs848*A (OR 0.77, $p=0.05$) were found to be protective. A stronger protection was found with the rs1800925*T/ rs20541*A haplotype (OR 0.64, $p=0.007$). The combined effect of rs1800925*CT/TT status and smoking status is presented in Table 1. The combination of smoking and the protective genotype rs1800925*CT/TT was the most protective for PsA. Among non-smokers rs1800925*CT/TT was no longer associated with PsA.

Table 1. The combined effect of smoking status and rs1800925*CT/TT genotype status on the prevalence of PsA

rs1800925 - genotype	Smoking	PsA	Psoriasis	OR*	95% CI**	p value
CT/TT	Yes	82 (48.5%)	87 (51.5%)	0.49	0.33–0.73	0.0003
CC	Yes	146 (55.7%)	116 (44.3%)	0.66	0.46–0.93	0.02
CT/TT	No	69 (61.1%)	44 (38.9%)	0.82	0.52–1.29	0.39
CC	No	196 (60.7%)	127 (39.3%)	Ref.	Ref.	Ref.

*Odds ratio
**Confidence interval.

Conclusions: An IL-13 polymorphism is protective for PsA among psoriasis patients. This effect was not significant among non-smokers.

The Relationship of Biomarkers and Radiographic Progression in Patients with Ankylosing Spondylitis. X. Baraliakos[5], R. Landewe[4], D. Van Der Heijde[3], J. Listing[2], D. Baker[1], H. Benjamin[1] and J. Braun[6]. [1]Centocor Inc, R&D, [2]German Rheumatism Research Center, [3]LeidenUniversity Medical Center, Meerssen, The Netherlands, [4]Maastricht University Medical Center, Maastricht, The Netherlands, [5]Rheumazentrum Ruhrgebiet Herne, [6]Rheumazentrum Ruhrgebiet, Herne, Herne, Germany

Background: Structural damage in patients with ankylosing spondylitis (AS) is characterized by the development of syndesmophytes. How this is influenced by inflammation and bone metabolism is not entirely clear, and the role of biomarkers associated with new bone formation in this scenario remains to be clarified.

Objective: To determine the level of different biomarkers, analyse their relevance in correlation to clinical, MRI and radiographic measurements and define their role in the prediction of syndesmophyte formation in AS patients under anti-TNF treatment.

Methods: Data of AS patients who participated in ASSERT were retrospectively analyzed. Complete data from radiographs and of the following biomarkers (measured by ELISA) were available at baseline and after 2 years: interleukin-6 (IL-6), vascular endothelial growth factor (VEGF), transforming growth factor-β (TGFβ) for inflammation and osteocalcin (OC), bone alkaline phosphatase (BAP), C Telopeptide 1 (CTX), N Telopeptide (NTX), osteopro¬te¬gerin (OPG) and cartilage oligomeric matrix protein (COMP) for bone turnover.

Assessment of disease activity (BASDAI), function (BASFI), metrology (BASMI), laboratory parameters (CRP, ESR), radiographs and MRIs were available at baseline and after 2 yrs. Analyses were performed based on 'severe radiographic progression' (SRP, increase of $\geq$3 mSASSS units/year) and/or the development of new syndesmophytes at the 2-year follow-up.

Summary statistics were used for the baseline data, and linear and logistic regression to test for the association of serum markers with MRI activity, mSASSS scores, clinical indices and the development of new syndesmophytes. ROC analysis was used for cut-point determination.

Results: Data of 148 patients could be analyzed, 15% of those showed SRP and 19% syndesmophyte formation. Baseline characteristics and the mean serum levels of biomarkers were not significantly different in patients with and without syndesmophytes/radiographic baseline damage. By logistic regression analysis, only OPG serum levels correlated significantly with SRP. The best cut-off for OPG in discriminating between patients with and without SRP was 3.1 units (OR (95%CI): 8.0 (2.6–24), $p=0.001$), sensitivity 67%, specificity 71% (AUC 0.66, LR+: 1.7, LR−: 0.54). Furthermore, baseline radiographic damage (OR (95%CI): 31 (3.2–298), $p=0.003$) and female gender (OR 0.17 (0.033–0.77), $p=0.032$) were also predictive of SRP. HLA-B27 could not be investigated due to low prevalence of HLA-B27 negativity. No correlations with the development of syndesmophytes were found. Among the markers for inflammation, only IL-6 showed a trend towards higher levels for patients with (mean (SD): 14.7 (18.2)) vs. without (13.3 (23.6)) SRP.

Conclusion: Increased levels of OPG, an osteoclastogenesis inhibitory factor, were predictive of severe radiographic progression over 2 years on the group level only. In contrast to previous studies with AS patients and patients with active RA or OA, none of the biomarkers indicative of bone degradation or hyperproliferation were predictive of radiographic progression.

Pedro, Aveiro, Portugal, [8]Instituto de Biotecnologia e Bioengenharia, Centro de Genética e Biotecnologia, da Universidade de Trás-os-Montes e Alto Douro (IBB/CGB–UTAD), Vila Real, Portugal, [9]Instituto Português de Reumatologia (IPR), Lisboa, Portugal, [10]UTAD, Universidade de Tás-os-Montes e Alto Douro, Vila Real, Portugal

Background: The aetiopathology of ankylosing spondylitis (AS) is poorly understood. A number of genetic-association studies have identified genes contributing to AS susceptibility but such approaches provide little information as to the gene activity changes occurring during the disease process. Transcriptional profiling generates a "snapshot" of the sampled cells activity and thus can provide insights into the molecular processes driving the disease process. Several recent studies have defined transcriptional profiles generated from peripheral blood mononuclear cells (PBMCs) however PBMC isolation is not viable in multicentre studies and limits the viability of such an approach. An alternate approach is to use whole blood samples collected using PAXgene technology which preserves integrity of the RNA.

Objective: We undertook a whole-genome microarray approach to identify candidate genes associated with AS and validated these gene-expression changes in a larger sample cohort.

Methods: 18 active AS patients, classified according to the New York criteria. and 18 gender-and age-matched controls were profiled using Illumina HT-12 Whole-Genome Expression BeadChips which carry cDNAs for 48000 genes and transcripts. Class comparison analysis identified a number of differentially expressed candidate genes. These candidate genes were then validated in a larger cohort using qPCR-based TaqMan Low Density Arrays (TLDAs).

Results: 239 probes corresponding to 221 genes were identified as being significantly different between patients and controls with a p-value <0.0005 (80% confidence level of false discovery rate). Forty eight genes were then selected for validation studies, using the TLDAs. Thirteen of these genes were validated in the second patient cohort with 12 down-regulated (1.3–2-fold) and only 1 upregulated (1.6-fold).

	Array		TLDA	
Gene symbol	Parametric p-value	Fold-change	Parametric p-value	Fold-change
DNMT1	6,46E-05	0,71	1,30E-06	0,46
CDC25B	0,0002	0,67	2,50E-06	0,5
BCL11B	0,000588	0,70	2,90E-06	0,45
DOCK10	0,000173	0,70	1,81E-05	0,54
CLSTN1	0,000453	0,68	1,94E-05	0,52
SPOCK2	0,000307	0,65	0,000522	0,57
ITGB7	0,000563	0,68	0,001209	0,58
MCM3	0,000424	0,73	0,001398	0,61
PTPN1	1,50E-06	0,69	0,002644	0,67
EP300	0,000126	0,70	0,003489	0,68
PPP2R1A	0,000173	0,71	0,012503	0,71
CLEC4D	0,000347	1,52	0,018409	1,61
CX3CR1	0,000345	0,58	0,020676	0,66

A number of these genes, have well-documented inflammatory roles with PTPN1 and DOCK10 both involved in mediating IL4 action. Of specific interest to AS progression are the established roles of SPOCK2 (osteonectin) and EP300 in cartilage. DNMT1 and EP300 both mediate STAT3 functionality which has also been associated in genetic studies with AS.

Conclusion: We have validated a gene expression signature for AS from whole blood and identified strong candidate genes that may play roles in both the inflammatory and joint destruction aspects of the disease.

Background: The non-synonymous polymorphism rs763361 of the CD226 gene, which encodes the DNAX accessory molecule 1, involved in T cell co-stimulation pathways, has recently been identified as a genetic risk factor for autoimmunity.

Objective: To test for association the CD226 rs763361 polymorphism with systemic sclerosis (SSc) in European Caucasian populations.

Methods: CD226 rs763361 was genotyped in 3645 individuals comprising a discovery set (991 SSc patients and 1008 controls) and a replication set (999 SSc patients and 634 controls), all individuals being of European Caucasian origin.

Results: The CD226 rs763361 T allele was found to be associated with SSc in both discovery and replication samples providing the following results in the combined populations: OR 1.22 95%CI [1.10–1.34], $P=5.69\times10^{-5}$. The CD226 T allele was also associated with various SSc subsets highlighting a potential contribution in disease severity. The most remarkable associations of the CD226 TT risk genotype were observed with diffuse cutaneous subtype, anti-topoisomerase I antibodies positive and SSc-related fibrosing alveolitis subsets: OR 1.86 95%CI [1.42–2.43], $P=5.15\times10^{-6}$, OR 1.82 95%CI [1.38–2.40], $P=2.16\times10^{-6}$ and OR 1.61 95%CI [1.25–2.08], $P=2.73\times10^{-4}$, respectively.

1988

Characterization of Single Histone Deacetylase Isoforms in Endothelial Cells Derived from Progenitors in Systemic Sclerosis. Hossein Hemmatazad[1], Britta Maurer[1], Beat A. Michel[1], Renate E. Gay[1], Gay Steffen[1], Jèrome Avouac[2], Oliver Distler[1], Yannick Allanore[2] and Astrid Jüngel[1]. [1]Center of Experimental Rheumatology, University Hospital and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Department of Rheumatology A, Cochin Hospital, Universitè Paris Descartes, INSERM U781, Paris, France

Background and Objectives: Microvascular damage is a major concern in the pathogenesis of SSc with outcome depending on the extent and severity of vascular lesions. Considering reports which indicate a key role of specific histone deacetylase (HDAC) isoforms in angiogenesis, we investigate here the expression patterns of HDACs in endothelial cells derived from circulating progenitors (EPCs) from patients with SSc and from normal healthy controls, under basal and under hypoxic conditions.

Methods: Late outgrowth EPC-derived cells were obtained from the peripheral blood of 11 patients with SSc and 6 healthy individuals according to the EUSTAR recommendations on endothelial precursor cells in SSc. All patients fulfilled the ACR classification criteria for SSc. Gene expression patterns of HDACs (1–11) and HoxA9, the key transcription factor for endothelial cells, were analyzed under basal conditions and under hypoxic (1% oxygen for 6h) conditions by TaqMan Real-time PCR using 18S for normalization. To assess the expression on protein level, antibodies against HDAC1 and HoxA9 were used for western blot.

Results: Under basal conditions, the mRNA levels of HDAC1, 2 and 5 were significantly up regulated in endothelial cells from SSc patients by 4.33 ± 1.75, 7.40 ± 3.40 and 1.51 ± 0.54 (x-fold ± SD, $p<0.05$) respectively, as compared to normal healthy cells. Moreover, the expression of HDAC6 and HDAC10 were reduced by 44 ± 15 and 31 ± 20 (% ± SD, $p<0.05$) in SSc vs. healthy EPCs. After 6h of hypoxia, we observed a notable increase in the expression of mRNA levels for HDAC1 and 2 by 2.47 ± 0.92 and 3.08 ± 1.27 (x-fold ± SD, $p<0.05$) in SSc cells as compared to healthy controls. In contrast, the expression levels of HDAC6 and 7 were down regulated by 31 ± 20 and 36 ± 19 (% ± SD, $p<0.05$). It is known that HDAC1 activity is required for the expression of HoxA9 which regulates important genes in vascular formation. We observed a significant down regulation of HoxA9 mRNA by 95 ± 3 % in SSc endothelial cells vs. healthy cells. Using western blot we confirmed this data on protein level. Of interest, the protein expression of HDAC1 was in contrast to the mRNA level reduced

in SSc (n=3) as compared to healthy controls under basal conditions. It has been reported that some microRNAs regulate Hox genes. Therefore, we hypothesize that microRNAs prevent the transcription of HDAC1 mRNA and regulate thereby the expression of HoxA9.

Conclusions: We conclude that vasculopathy in SSc might be related to the different expression of HDACs in endothelial cells. Altered expression of HDACs could possibly regulate the expression of important genes involved in vascular formation via transcription factors like HoxA9 and contribute to altered angiogenesis in SSc.

1989

Circulating T Cell Polarization Is Associated with Respiratory Decline in Scleroderma Patients with Active Interstitial Lung Disease.

Francesco Boin[1], Fredrick Wigley[2], Robert Wise[2] and Antony Rosen[2]. [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University

Purpose: Immune activation plays a role in the pathogenesis of systemic sclerosis (SSc) and may be relevant for the initiation and propagation of target tissue injury. In particular, development of interstitial lung disease (ILD) is associated with lung inflammation. The presence of neutrophilia and/or eosinophilia (alveolitis) in the bronchoalveolar lavage (BAL) fluid of SSc patients has been considered indicative of active ILD. However, this measure has not consistently provided reliable prediction of lung disease outcomes. A pro-fibrotic type 2 (Th2/Tc2) T cell response has been detected in the periphery of SSc patients with ILD. In this study we investigated whether an abnormal distribution of polarized T cell subsets in the periphery or the bronchoalveolar lavage (BAL) fluid of SSc patients is associated with the presence of active ILD.

Methods: Peripheral blood and BAL were simultaneously obtained from 22 SSc patients undergoing bronchoscopy for suspected active ILD based on increasing respiratory symptoms, worsening lung volumes or abnormal imaging studies. Decline of the forced vital capacity (FVC) >10% of predicted within 6–10 months prior to the procedure was considered as significant for active ILD. The presence of active BAL alveolitis was defined as neutrophils >3% and/or eosinophils >2.2% on differential cell count. T cell subsets were characterized by flow cytometry using CD3, CD4, CD8, chemokine receptor CCR5 (Th1/Tc1 specific) and CRTH2 (Th2/Tc2 specific) surface markers. CCR5/CRTH2 ratio was used to determine polarization of the immune response towards a type 1 (high ratio) or type 2 (low ratio) phenotype.

Results: Active ILD (FVC decline >10%) was identified in 12 patients and was significantly associated with a relative Th2/Tc2 polarization in the peripheral blood based on a lower CD3+CCR5/CRTH2 ratio (3.9 vs. 11, $p<0.001$). This finding was mostly determined by a lower number of circulating CCR5+ T cells in active vs. non-active ILD patients (CD3 8.6% vs. 24.8%, $p<0.001$; CD4 7.7% vs. 19.4%, $p=0.005$; CD8 14.9% vs. 40%, $p<0.001$). Conversely, the presence of BAL alveolitis was not significantly associated with declining FVC volumes, nor it was correlated with any absolute or relative difference among polarized T cell subsets in the peripheral blood or BAL fluid.

Conclusions: Distinct polarized T cell subsets in the peripheral blood of SSc patients are associated with declining respiratory function and should be prospectively explored as a novel biomarkers to measure disease activity and predict outcomes in ILD and other clinical manifestations of scleroderma.

1990

Does Treatment with Imatinib Modify Gene Expression in the Skin and Peripheral Blood Mononuclear Cells of Patient with Systemic Sclerosis?

Jessica K. Gordon[1], Robert Spiera[2], Jamie N. Mersten[1], Horatio F. Wildman[4], Ziad Taimeh[3], Neil Hackett[4], Sasa Vukelic[3], Kyriakos A. Kirou[1] and Mary K. Crow[1]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgery, [4]Weill-Cornell Medical College

Background: Patients with Systemic Sclerosis (SSc) have been shown to have distinct patterns of gene expression in the skin and peripheral blood. In the skin these patterns correspond to clinical involvement. It is not known whether gene expression patterns in the skin correlate with those in the blood or if treatment leads to modulation of gene expression. We hypothesized that imatinib treatment would modulate gene expression in the skin and peripheral blood mononuclear cells (PBMC) of treated patients with diffuse cutaneous (dc)SSc.

Methods: We performed gene expression profiling with microarray on RNA from skin biopsy and PBMC samples of 8 patients with dcSSc from the Imatinib clinical trial at our center. Patients selected had improvements of ≥ 5 points in their Modified Rodnan Skin Scores (MRSS) over 12 months. RNA was hybridized to Affymetrix Human U133 2.0 gene chips. Paired t-tests were performed using Genespring GX11 and Ingenuity Pathways was used to evaluate pathways of interest.

Results: Patient characteristics: 63% female; median age: 44 [18, 71]; median disease duration: 1.8 years [0.3 to 8]; and median change in MRSS: −9 [−5 to −12]. In the skin treatment led to the differential expression of 433 genes at a p-value of 0.05 and a fold-change cut-off of 1.5 without multiple testing correction. In PBMC treatment led to differential expression of 534 genes at the same cut-off. In PBMC unsupervised hierarchical clustering demonstrated a primary separation of groups based on treatment status.

In both skin and blood we observed down-regulation of PI3K signaling with treatment. This included down-regulation of AKT2, PIK3R1, PIK3C2A, EEAl, and ITPRIPL2 in skin and down-regulation of AKT2, INPP4A, HIPK1, LIMK1, MAK, MAP2K6, and PTEN in blood. We were interested especially looking for changes in TGF-β and PDGFR signaling. In the skin there was down regulation of smad2 and AKT2, and in PBMC there was decreased expression the TGF-β Receptor 1, egr2 transcription factor, WNK1 and AKT2. In the skin there was increased expression of PDGFRL.

Other entities differentially regulated include in the skin down-regulation of NCOA3, ADAM10, ADAM17, vitamin D receptor, dihydrofolate reductase, Cxcl3, and integrin β1 as well as up-regulation for col1a1, col6a2, MAPK12, ADAMTS2, and the chemokines CCL 18, 26, 22, 13. In PBMC there was differential expression of the angiogenic mediators VEGFA (up) and flt1 (down.) There was also increased expression of thrombospondin1.

Conclusions: Treatment with imatinib may lead to modulation of gene expression in skin and PBMC. Hierarchical clustering in PBMC is supportive of a treatment effect. One common pathway affected in skin and blood is PI3K signal transduction which was not expected but which may be pathogenically relevant in the transdifferentiation of myofibroblasts. It is important to note that the changes seen are modest and do not stand up to statistical correction for multiple testing in this small number of patients. We plan to analyze this data in the context of several controls – treated patients without clinical improvement, longitudinal disease controls, and healthy controls. Validation of this microarray data by qPCR is planned.

Objective: Ephrins have emerged as essential regulators of angiogenesis and thrombospondins are inhibitors of angiogenesis and strong promoters of fibrosis that are both involved in systemic sclerosis (SSc). Our aim was to investigate whether ephrins and thrombospondins contribute to the dysregulation of angiogenic homeostasis related to systemic sclerosis (SSc) and to the pathologic activation of SSc dermal fibroblasts.

Methods: Skin biopsies were obtained from 8 patients with early diffuse cutaneous subset and from 4 healthy volunteers, matched for age and sex with SSc patients. SSc Skin biopsies were taken from both clinically involved and

non-involved skin. Dermal fibroblasts were cultured from control and clinically involved and non-involved SSc skin. Ephrin (EphB4 and EphrinB2) and thrombospondin (TSP-1 and 2) mRNA and protein levels were analyzed in skin tissue respectively by in situ hybridization and immunohistochemistry. EphB4/EphrinB2 and TSP-1/2 mRNA and protein levels were assessed in SSc and control dermal fibroblasts in basal conditions and after stimulation by TGFβ or 6 hours of hypoxic exposure. Ephrin and thrombospondin expression was also determined in SSc and control dermal fibroblasts cultured with a pan-specific TGFβ blocking antibody.

Results: Increased mRNA and protein levels of EphrinB2 and EphB4 were detected in clinically involved skin of SSc patients. EphrinB2, but not EphB4, was also upregulated in clinically non-involved skin. The expression of Ephrins was restricted to the vessels. Low levels of EphrinB2 and EPhB4 were detected in control and SSc cultured dermal fibroblasts, in basal conditions or after stimulation by TGFβ or hypoxia, suggesting that fibroblasts do not produce ephrins. TSP-1 and 2 were upregulated in SSc skin biopsies taken from both involved and non-involved skin. Their expression was mainly detected in the extracellular matrix located at the periphery of vessels. The overactivation of TSP-1 and TSP-2 persisted in cultured SSc dermal fibroblasts issued from involved and non-involved skin, and might contribute to the activated phenotype of SSc fibroblasts. Culture with TGFβ blocking antibody markedly reduced the upregulated expression of TSP-1 and TSP-2 in SSc dermal fibroblasts, but had little effect on healthy fibroblasts. Moreover, stimulation of healthy dermal fibroblasts with TGFβ, but not with hypoxic exposure, led to TSP-1 and TSP-2 activation.

Conclusion: We investigated for the first time the expression of EphB4/EphrinB2 and TSP-1/TSP-2 expression in the skin and in dermal fibroblasts of patients affected by SSc. EphB4 and EphrinB2 are upregulated in clinically involved skin of SSc patients, suggesting their participation in SSc perturbed angiogenesis. TSP-1 and 2 are upregulated in both clinically involved and non-involved SSc skin and are constitutively activated in a TGFβ dependent/hypoxia independent manner in SSc dermal fibroblasts. Further studies are now warranted to assess the role of TSP-1 and TSP-2 respectively in the early activation of TGFβ and in the assembly of extracellular matrix proteins accumulated under the overproduction of TGFβ.

Enhanced IL-17A and IL-22 Production by Peripheral Blood Mononuclear Cells Distinguish Systemic Sclerosis from Healthy Individuals. Nicolò C. Brembilla[1], Marie-Elise Truchetet[2], Elisa Montanari[1], Yannick Allanore[3] and Carlo Chizzolini[1]. [1]Immunology & Allergy, Geneva University Hospital, Geneva, Switzerland, [2]Immunology Allergy, Geneva University Hospital, Geneva, Switzerland, [3]Rheumatology, Cochin Hospital, Paris, Paris, France

In systemic sclerosis (SSc) inappropriate T cell responses are thought to participate in initiating events ultimately leading to excessive extracellular matrix deposition and fibrosis. The pattern of cytokine produced distinguish T cell subsets with distinct functional capabilities and the pattern of chemokine receptor expressed at the surface of T cells participate to the code used for homing in peripheral tissues, including the skin. Aim of the present work was to assess whether T cells present in the peripheral blood (PB) of SSc patients could be distinguished from those of healthy controls in terms of cytokine production and whether the chemokine receptor expression on T cells could further predict their functional subset and homing capability.

PB mononuclear cells and clinical characteristics were obtained from 19 immunosuppressant agents naive SSc and 18 healthy controls (Ctrl) upon informed consent and approval by the ethical committee. Multiparameter cytofluorimetric analysis was performed to assess the surface expression of CD4, CD45RA, CCR4, CCR6, CCR10, CXCR3, and CD161 as well the intracellular accumulation of IL-17A, IL-22, IFN-gamma, and IL-4 upon activation by CD3/CD28 crosslinking in PB mononuclear cells at time 0 and after 7 days of culture. The results were stratified according to the presence of SSc, limited (lSSc) or diffuse disease (dSSc). The results of the various patient populations were compared using the Mann Whitney U test and correlations between variables computed using the Spearman r test.

SSc individuals had higher frequencies of CD4+ T cells and higher frequencies of IL-17A and IL-22 producing CD4+ T cells both at time 0 and upon 7 days of culture when compared to Ctrl. A significant increase in IL-4 production was observed only in the dSSc subset. The intracellular levels of IL-17A and IL-22 with the exclusion of IFN-gamma were tightly correlated indicating co-production by the same CD4+ T cell in SSc and not in Ctrl. When the expression level of various chemokine receptors on CD4+ T cells was taken into account, the production level of IL-17A was positively correlated with the lack of CXCR3 expression ($p = 0.0009$) and particularly so in the CXCR3-CCR6+ subset ($p = 0.0006$). Furthermore, the frequency of CD161+ CD4+ T cells was higher in SSc than in Ctrl.

Our results for the first time show that increased IL-17A is accompanied by IL-22 but not IFN-gamma production in SSc CD4+ T cells, thus stressing a preferential Th17 cell expansion in SSc. Furthermore, the production of these cytokines correlates with the expression levels of chemokine receptors important for skin homing, strongly indicating that they may participate to dysregulated matrix deposition at least in this target organ. These results provide a rationale for targeting IL-17 and the Th17 differentiation pathway as novel approaches to harness the clinical course of SSc.

Gd Compounds Signaling through Toll-Like Receptors 4 and 7 in Normal Human Macrophages: Establishment of a Proinflammatory Phenotype and Implications for the Pathogenesis of Nephrogenic Systemic Fibrosis. Peter J. Wermuth[1] and Sergio A. Jimenez[2]. [1]Jefferson Institute of Molecular Medicine and Division of Connective Tissue Diseases, Thomas Jefferson University, Philadelphia, PA, [2]Thomas Jefferson Univ, Philadelphia, PA

Purpose: Nephrogenic Systemic Fibrosis (NSF) is a progressive and generalized disorder occurring in some patients with renal insufficiency following exposure to Gd based contrast agents (GdBCA). Previous studies showed that GdBCA induced, normal human macrophages to secrete increased levels of profibrotic and proinflammatory cytokines but the mechanisms involved are not known. Increased production of proinflammatory cytokines by macrophages is often triggered via signaling through Toll-like receptors (TLRs) or Nod-like receptors (NLRs), which recognize bacterial and viral components based on common molecular shapes. Here, we examined the hypothesis that GdBCAs can signal through one or more TLRs or NLRs.

Methods: Normal human differentiated macrophages were exposed to 50 mM Omniscan® or saline. RNA was isolated and examined employing Affymetrix human U133 2.0 Plus Microarrays and the data was analyzed by Volcano Plot and pathway analysis (DAVID; NIH). Human embryonic kidney 293 (HEK293) cells engineered to express one of seven different human TLRs (TLR2, 3, 4, 5, 7, 8 and 9) or two human NODs (NOD1 and 2) were exposed for 24 h to varying concentrations of Gd compounds Gd-DTPA, Dotarem®, MultiHance®, ProHance®, OptiMark®, Omniscan®, gadodiamide, Gd-EDTA or Gd-Citrate or to caldiamide, the chelate molecule present in Omniscan®. The signaling activity of each compound was evaluated on its ability to activate expression of a reporter gene under control of an NFκB promoter. Macrophages were pretreated with inhibitory and control peptides targeting the TLR downstream effector NFκB followed by exposure to Omniscan®. RNA was isolated and proinflammatory cytokine expression measured by real-time PCR.

Results: Pathway analysis of differential gene expression of normal differentiated human macrophages exposed to Omniscan® suggested the involvement of TLR signaling. Studies using engineered HEK293 cells each expressing one of a panel of human TLRs or NODs identified TLRs 4 and 7 mediating activation of the NFκB dependent reporter gene following exposure to 5 mM Omniscan® or gadodiamide. Subsequent testing in HEK293 cells expressing either TLR4 or TLR7 showed that Omniscan® and gadodiamide strongly activated TLR4 and TLR7-mediated reporter gene expression in a concentration dependent manner. No or miminal activity was observed for Gd-DTPA, Dotarem®, MultiHance®, ProHance®, OptiMark®, Gd-EDTA and Gd-citrate. Inhibition of activation of the TLR downstream effector molecule NFκB with specific inhibitory peptides in normal differentiated human macrophages strongly blocked Omniscan®-induced expression of proinflammatory cytokines.

Conclusions: We demonstrate that Omniscan® and gadodiamide induce expression of an NFκB dependent reporter via TLRs 4 and 7. Further, we demonstrate that blocking the TLR effector molecule NFκB greatly reduces the Omniscan® dependent expression of proinflammatory molecules in normal human macrophages. The ability of GdBCA to signal via TLRs resulting in increased production of proinflammatory/profibrotic cytokine and growth factor expression by normal human macrophages may be an important component in the pathogenesis of NSF.

1994

Genome-Wide Association Study in Systemic Sclerosis. Yannick Allanore[5], Mohammad Saad[2], Philippe Dieudé[4], Catherine Boileau[1], Maria Martinez[3] and GENESYS Consortium. [1]Biochimie A. Paré Hospital, Université VSQ, Boulogne, France, [2]INSERM U563 Université Paul Sabatier, Toulouse, France, [3]NSERM U563 Université Paul Sabatier, Toulouse, France, [4]Rhumatologie, Inserm u699, Bichat, Paris Diderot Universite, France, [5]Université Paris Descarte, Rhumatologie A, INSERM U781, Paris, Paris, France

Systemic sclerosis (SSc) is an orphan multi-organ disease affecting the immune system, the microvascular network and the connective tissue. SSc leads to major disability and premature death. Epidemiological data suggest a complex genetic etiology.

To dissect genetic susceptibility to SSc we have performed a genome-wide association study in 654 SSc patients of French Caucasian origin from the GENESYS study, and 2,543 French controls (subjects without SSc from GENESYS project and neurologically healthy subjects from the Three-City cohort- Lambert et al, Nat Genet. 2009;41:1094–9). Subjects were genotyped using the Illumina Human 610 QUAD bead chip. The final post-QC discovery (stage-1) sample comprised 564 SSc cases and 2,466 controls, and a total of 489,814 SNPs passed quality control criteria. Association was tested using logistic regression assuming additive genetic effects and adjusted for the two principal components to account for population substructure. The genome-wide association results revealed a number of SNPs with strong evidence ($P<10-5$) of association. Interestingly, in our discovery sample, stronger signals were detected for 6 non-HLA SNPs that spanned 5 distinct genomic loci. Two SNPs belong to a candidate gene previously reported associated to other autoimmune disease of high relevance with regards to SSc pathogenesis. Furthermore, the remaining 4 SNPs are located on 3 previously unreported putative SSc loci. 2 SNPs are close to genes coding for neuro-mediators and 1 SNP is close to a metabolic gene recently showed to deeply contribute to extra-cellular matrix remodeling. Follow-up and replication analysis (stage-2) of these promising and new association signals are under way in a second French/Italian/German/Eastern case-control sample (>1,750 SSc cases and 3,200 controls). Our preliminary GWAS results identified a tractable number of novel candidate genes for SSc that warrant further investigation. All top best associated SNPs will be reported in the meeting.

This work was supported by French, German and Italian research networks on systemic sclerosis and by ANR grant (Projet R08160KS), Association des Sclérodermies de France, Research grants from Institut Servier and Sanofi Aventis, France.

1995

High Resolution Magnetic Resonance Imaging for the Assessment of Dermal Fibrosis in a Pre-Clinical Model of Scleroderma. Helen Jones[1], Emma Derrett-Smith[1], Chris P. Denton[1], David Abraham[1], George Bou-Gharios[2] and Po-Wah So[3]. [1]Centre for Rheumatology, UCL Medical School, [2]Kennedy Institute of Rheumatology, Imperial College London, [3]Pre-clinical Imaging Unit, Institute of Psychiatry, King's College London

Introduction: Scleroderma (Systemic Sclerosis, Ssc) is a heterogeneous chronic multisystem rheumatological disorder. A hallmark of the disease is excessive dermal and organ scarring. Dermal biopsies have been extensively used to evaluate the degree of scarring and development of fibrosis. This invasive technique only allows a 'snapshot' of one region of the skin. Here we used a pre-clinical model of scleroderma to assess the potential for applying non-invasive magnetic resonance imaging for the analysis of dermal fibrosis. We analysed structural changes in the skin of mice harbouring mutations which resulted in modulation of the TGFβ signalling pathways ($T\beta RII\Delta k^{fib}$ mice) by histological staining and high resolution magnetic resonance imaging (MRI) scans to detect and compare changes in skin architecture and composition.

Methods: Full-thickness dermal biopsies were taken from the dorsal region of adult mice and fixed in formalin. Samples were placed within a customised holder containing Fomblin Perfluorosolv PFS-1, positioned within a quadrature volume coil, and MRI performed on a 7 Tesla VMRIS scanner using a gradient echo MRI sequence with the following parameters: repetition time, 250ms; echo time, 2.5ms; field of view, 10 × 10mm; matrix size, 128 × 128; 40° flip angle and 14 consecutive transverse, 1mm thick slices (in plane resolution 78μm). Thickness of the dermis and panniculus adiposus were measured using Image J with 7 measurements, distributed across the image, for each sample. After scanning, samples were embedded in paraffin and serial sections (3 microns) were stained with H&E for routine histology and an extracellular matrix stain for the degree of fibrosis (Picrosirius red). Images were captured at 10x magnification. Thickness of the dermis and panniculus adiposus were measured using Axioskop software with at least 30 measurements, distributed across the length, for each sample.

Results: Histological staining allows easy identification of the dermal and hypodermal compartments, namely the dermis, panniculus adiposus, panniculus carnosus, subcutaneous loose connective tissue, and subcutaneous muscle. Comparison with the MRI images showed that high resolution MRI can also distinguish between dermis, panniculus adiposus, panniculus carnosus, subcutaneous loose connective tissue, and subcutaneous muscle. By gradient echo MRI dermis, panniculus carnosus, and muscle have higher signal intensities than panniculus adiposus and loose connective tissue.

Thickness measurements of dermis and panniculus adiposus are consistent between histological and MRI images, however a better correspondence is observed for dermis than panniculus adiposus. $T\beta RII\Delta k^{fib}$ mutant mice were found to have thicker dermis than wildtype mice ($p<0.01$), which is consistent with the known increase in collagen in the skin of the mutant mice. Interestingly, thickening of the dermis is also accompanied by a thickening of the underlying panniculus adiposus ($p<0.01$).

Conclusion: High resolution MRI scanning is a promising non-invasive technique for assessing dermal fibrosis that warrants further optimisation in pre-clinical models prior to translation into a clinical setting.

IL-6 Overexpression in Early dcSSc Associates with Poor Clinical Outcome and May Drive Fibrotic Response. Korsa Khan[1], Shiwen Xu[1], Christopher P. Denton[2] and Voon Ong[1]. [1]Center for Rheumatology and Connective Tissue Diseases, UCL Medical School, Royal Free Hospital, London, United Kingdom, [2]Royal Free Hospital, London, United Kingdom

Introduction: We previously reported that thrombocytosis may identify a subgroup of diffuse SSc with elevated IL-6 and a high modified Rodnan skin score (mRSS). In this study, we explore the predictive value of IL-6 overexpression in dcSSc and its potential role in driving fibrosis.

Method: Expression levels of IL-6 were examined with immunohistochemistry and Western blot analysis. Skin biopsies from patients with early dcSSc and thrombocytosis (n=10, mean platelet count: 472×10^9/L, mean disease duration, Mean ± SEM: 35 ± 9.5 months), established dcSSc (n=8, mean platelet count:293×10^9/L, mean disease duration:128 ± 22) and healthy controls (n=12) were used in this study. IL-6 ligand and receptor levels were measured in the supernatant from cultured SSc fibroblasts and their effect on collagen production was studied in normal fibroblasts stimulated with recombinant IL-6.

To explore the potential link between IL-6 levels and clinical outcome in dcSSc, serum IL-6 from 39 patients (74 % female) was quantified by ELISA. The cases were categorised into high IL-6 (≥10pg/ml) and low (<10pg/ml) cohorts. Association between IL-6 levels at presentation and mRSS at 36 month from disease onset was determined by Pearson's correlation. Mean difference of mRSS between the cohorts of IL-6 expression over the 36 month period was compared by Student t-test. Difference in survival between cohorts was examined using Kaplan-Meier methods.

Results: There was significantly greater dermal IL-6 expression in patients with early dcSSc and thrombocytosis than patients with established dcSSc. Prominent staining for IL-6 was associated with dermal vascular structures and mononuclear inflammatory infiltrate in 8/10 (80%) patients with early dcSSc and with fibroblastic staining. Moderate vascular expression for IL-6 was observed in 4/12(33%) controls. Similar expression pattern was observed in 2/8 (25%) patients with established dcSSc with faint staining for IL-6 in some dermal fibroblasts and inflammatory infiltrates.

IL-6 ligand and receptor levels were elevated in supernatant from SSc fibroblasts (n=3) by 17-fold and 13-fold (Densitometric Image Unit, DIU $p<0.05$) respectively. Collagen was upregulated by at least 7-fold in SSc fibroblasts and similar induction by recombinant IL-6 (20 ng/ml) was observed in normal fibroblasts (17.94 ± 3.41 vs 2.18 ± 1.85 DIU control, $p<0.05$). This was partially abrogated with neutralising antibody against IL-6 receptor (4.26 ± 2.07 DIU, $p<0.05$).

Interestingly, serum IL-6 level at presentation positively correlated with mRSS at 36 months follow-up in dcSSc cases with available data ($r=0.81$, $p<0.01$, n=16). There was a significant difference in mean mRSS between the two groups based upon IL-6 expression (10.9, 95% Confidence interval, 3.8, 18.2, $p<0.01$). Kaplan-Meier analysis showed that the 5-year survival was 93% and 81% in the group with low and high IL-6 levels respectively ($p=0.02$, log rank test).

Conclusions: These results confirm overexpression of IL-6 in selected

cases of dcSSc and support the utility of IL-6 as a surrogate marker for outcome. Our study also provides strong support for the potential benefit of targeting the IL-6 axis in some cases of early dcSSc.

1997

Imatinib Mesylate and Rottlerin Abrogate Transforming Growth Factor-β Induction of Endothelial-to-Mesenchymal Transition in Primary Lung Endothelial Cells. Zhaodong Li and Sergio A. Jimenez. Jefferson Institute of Molecular Medicine, Thomas Jefferson Univ, Philadelphia, PA

Purpose: Tissue fibrosis, most prominent in the skin, lungs, and microvasculature, is the pathological hallmark of systemic sclerosis (SSc). The origin of the mesenchymal cells responsible for the tissue and vascular fibrosis in SSc has not been fully identified. Recent studies have shown that transdifferentiation of endothelial cells into myofibroblasts via endothelial-to-mesenchymal transition (EndoMT) may participate in the development of tissue fibrosis in various fibrotic diseases. Here we used small molecule kinase inhibitors to investigate the signaling pathways involved in TGF-β-induced EndoMT in murine pulmonary endothelial cells (EC) to identify potential therapeutic targets for the fibroproliferative vasculopathy characteristic of SSc.

Methods: Primary mouse pulmonary EC were isolated by immunomagnetic methods employing sequential anti-CD34 and anti-CD102 antibody selection. The induction of EndoMT was assessed by immunofluorescence and Western blot for α-smooth muscle actin (α-SMA) expression. Expression of the transcriptional repressor Snail-1 was examined by RT-PCR, Western blot of cell lysates and immunofluorescence staining of cultured cells. The signaling pathways involved were examined employing small molecule kinase inhibitors.

Results: 1) TGF-β1 induced α-SMA and type I collagen expression in primary pulmonary EC. The induction of α-SMA in pulmonary EC by TGF-β was mediated by a marked increase in Snail-1 expression, evidenced both at mRNA and protein levels. 2) The TGF-β-induced α-SMA and Snail-1 expression was abolished by treatment with either the c-Abl kinase inhibitor, imatinib mesylate or the PKC-δ inhibitor, rottlerin. Imatinib mesylate also inhibited Snail-1 mRNA expression (Figure) and α-SMA stress fiber organization. 3) The effects of imatinib mesylate and rottlerin were not mediated by PI-3 kinase or Smad-2 phosphorylation but were mediated by inhibition of GSK-3β serine 9 phosphorylation. 4) Inhibition of GSK-3β activity employing a potent and specific inhibitor (BIO) caused marked increase in α-SMA and Snail expression.

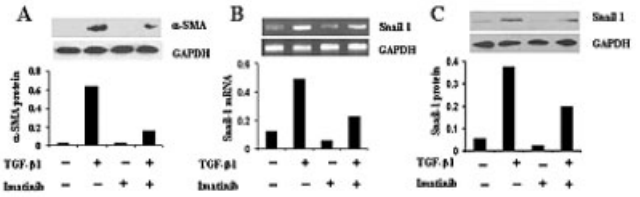

Figure. Inhibition of α-SMA and Snail-1 expression by imatinib mesylate.

Conclusion: These results indicate that c-Abl and PKC-δ participate in TGF-β-induced EndoMT in pulmonary EC. These effects are PI-3 kinase- and Smad2-ndependent and are mediated by GSK-3β. The results suggest that imatinib mesylate and rottlerin or similar inhibitor molecules may be effective therapeutic agents for SSc-associated tissue and vascular fibrosis and may also be effective in other fibroproliferative vasculopathies. Supported by NIH Grant RO1 AR055660 to SAJ.

1998

In Systemic Sclerosis, Cooperation between B-Cells and Skin Fibroblasts Promotes Fibrogenic Cytokines and Collagen Production. Antoine Francois[3], Dominique Wachsmann[3], Jean Sibilia[1] and Jacques E. Gottenberg[2]. [1]Strasbourg Hospitals, Illkirch Graffenstaden, France, [2]Strasbourg Hospitals, Strasbourg, France, [3]Universite de Strasbourg, Illkirch Graffenstaden, France

Background: B-cells might play a role in the induction of skin and pulmonary fibrosis in systemic sclerosis. BAFF and APRIL, key cytokines for B-cell activation, are increased in serum and skin from patients with systemic sclerosis. The role of B-cells in fibrosis has been demonstrated in several studies (Novobrantseva, 2005, Komura, 2008) but the mechanisms implicated in B-cells and fibroblasts collaboration as well as the role of BAFF remains unclear. We therefore cocultivate B-cells and fibroblasts and assessed the release of soluble collagen and fibrogenic cytokines.

Methods: We performed cocultures of blood B cells and SSc skin fibroblasts stimulated with BAFF. IL-6, IL1β, TGF-β1, and CCL2 mRNA expression was determined by quantitative RT-PCR. Cytokine release was evaluated by ELISA. We also analysed the release of soluble collagen in cell culture supernatants using the Sircol Collagen Dye.

Summary of the Results: Coculture of skin fibroblasts isolated from SSc patients with blood B-cells induced IL-6 (35ng/mL), TGF-β1 (2000pg/mL) and CCL2 (6300pg/mL) release in culture supernatants. IL1β, which is a strong inducer of collagen, was not detected. Interestingly, BAFF stimulation increased IL-6 (315ng/mL) and CCL2 (17ng/mL) release in cell culture supernatants but TGF-β1 was not modified. We also showed that coculture of SSc fibroblasts with B-cells increased the production of soluble collagen by fibroblasts (from 25μg/mL for fibroblasts alone to 113μg/mL with B-cells) but this effect was not enhanced in presence of BAFF.

Conclusion: Taken together, these data suggest that interaction of B-cells with SSc fibroblasts promotes the production of fibrogenic cytokines and soluble collagen. We found that BAFF enhanced the release of cytokines but had no direct effect on collagen synthesis.

1999

Inhibition of Glycogen Synthase Kinase (GSK)-3β Downregulates Collagen I Gene Expression in Normal and Scleroderma Fibroblasts and Abrogates the Profibrotic Effects of Transforming Growth Factor β (TGF-β). Jolanta Fertala and Sergio A. Jimenez. Jefferson Institute of Molecular Medicine, Thomas Jefferson University, Philadelphia, PA

Background and Purpose: GSK-3β is a ubiquitously expressed, highly conserved serine/threonine protein kinase which phosphorylates numerous substrates including enzymes and transcription factors and it is a core component of many important cell signaling pathways. Recently, GSK-3 has emerged as an important participant in wound healing and fibrosis. In particular, it has been shown that mice harboring a fibroblast-specific deletion of GSK-3β displayed accelerated wound closure, increased fibrogenesis, and excessive scarring. Fibroblasts isolated from those mice showed increased expression of a-smooth muscle actin and contraction of extracellular matrix. Thus, these results suggested that the presence of the active GSK-3 played a crucial role in maintaining physiological levels of extracellular matrix proteins and normal wound healing. The specific way in which GSK-3 participates in regulation of fibrosis is currently not well understood. Here, we studied the effects of GSK-3β activity modulation on the expression of COL1A1 in human dermal fibroblasts derived from patients with systemic sclerosis (SSc). Thus, the fundamental purpose of this study was to define whether GSK-3 should be considered a target to treat SSc and other fibrotic disorders.

Methods: Normal and SSc dermal fibroblasts were treated with various concentrations of two different GSK-3β inhibitors: (i) Inhibitor XV (EMD4 Biosciences) and (ii) inhibitor IX (BIO, Cayman Chemical). In addition, normal dermal fibroblasts treated with TGF-β were also analyzed. Following treatment with the GSK-3 inhibitors the expression of collagen I at protein and mRNA levels was analyzed by Western blot assays and RT-PCR, respectively.

Results: Quantitative Western blot assays demonstrated that, in comparison to non-treated cells, both normal and SSc dermal fibroblasts cultured in the presence of either GSK-3β inhibitor produced significantly less collagen I. Furthermore, GSK-3 inhibitors also abrogated the stimulation of COL1A1 expression induced by TGF-β. A similar decrease was also observed at the level of expression of COL1A1.

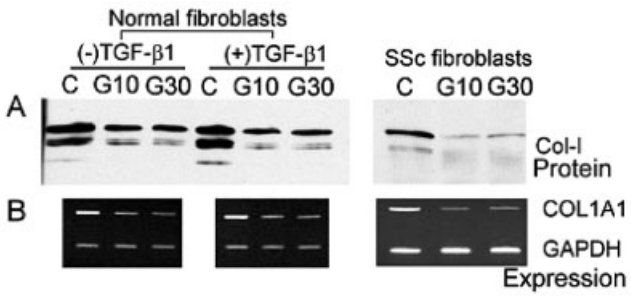

Figure. Analysis of expression of collagen I in normal and scleroderma fibroblasts treated with a GSK-3 inhibitor.

Conclusion: These data demonstrate that inhibition of GSK-3β activity results in a significant decrease in the expression and production of collagen I. These data are in contrast with the previously published study demonstrating that conditional GSK-3 knock-out in mice was associated with accelerated fibrosis. Our observation that inhibiting GSK-3 activity in SSc fibroblasts is associated with a substantial decrease of production of collagen I suggests that this enzyme may be a potential target for treatment of SSc and other fibrotic disorders.

2000

Insights into the Pathogenesis of Systemic Sclerosis Vasculopathy Based on Gene Expression Profile of Endothelial Cells Issued from Progenitors. Jerome Avouac[5], Nicolas Cagnard[1], Jorg H. W. Distler[6], Yoland Schoindre[2], Barbara Ruiz[2], Catherine Boileau[2], Gilles Chiocchia[3] and Yannick Allanore[4]. [1]INSERM U567, Cochin Hospital, APHP, Paris, France, [2]INSERM U781, Necker Hospital, Paris, France, [3]NSERM U567, Cochin Hospital, APHP, Paris, France, [4]Paris Descartes University, Rheumatology A Department, Cochin Hospital, APHP, Paris and INSERM U781, Necker Hospital, Paris, France, [5]Paris Descartes University, Rheumatology ADdepartment, Cochin Hospital, APHP, Paris and INSERM U781, Necker Hospital, [6]University of Erlangen, Erlangen, Germany

Objective: To determine the pattern of gene expression in endothelial cells (ECs) derived from late outgrowth endothelial progenitor cells (EPCs), in basal conditions and after hypoxic exposure, in patients with systemic sclerosis (SSc).

Methods: Late outgrowth EPCs were isolated from the peripheral blood of 10 SSc patients (5 limited and 5 diffuse cutaneous subset) and 5 healthy controls matched for age and sex. Total RNA was extracted and amplified from these cells in basal conditions and after 6 hours of hypoxic exposure. Affymetrix Human Genome HGU133 plus 2.0 Array microarray were used. The data were analyzed in the GeneSpring program, and potential pathways were identified with the Ingenuity software. Validation of genes of interest was performed by quantitative RT-PCR. Protein expression of identified mediators was then assessed in SSc and control skin sections by immunohistochemistry.

Results: Signals from 92 probe sets (33 known genes) were different from controls in basal conditions. The largest group of transcripts included 9 genes related to cell-to-cell interaction. Within this group, was identified in SSc-EPC-derived cells a downregulation of tumor necrosis factor ligand superfamily member 10 (TNFSF10, odds ratio, OR: 0.5, $p=0.04$), which prevents the interaction between PBMCs and ECs. Signals from 188 probe sets (53 known genes) were different from controls after hypoxic exposure. The largest group of transcripts included 5 genes involved in the regulation of vascular remodeling. Within this group, was identified in SSc-EPC-derived cells a downregulation of homeobox gene HOXA9 (OR: 0.5, $p=0.02$), which play a role in the activation of ECs. A respective 2 and 1.5-fold downregulation of TNFSF10 mRNA levels in basal conditions and HOXA9 mRNA levels after hypoxic exposure in SSc-EPC-derived cells further validated these observations. In SSc and control skin sections, no differential expression of TNFSF10 and HOXA9 was found.

Signals from 221 and 307 probe sets (75 and 79 known genes) were different between patients with the diffuse and the limited cutaneous subset, in basal conditions and after hypoxic exposure respectively. Included among these were transcripts for a group related to inflammatory response. In particular, was identified after hypoxic exposure, in EPC-derived cells from patients with diffuse SSc, an upregulation of tumor necrosis factor alpha-induced protein-3 (TNFAIP3, OR:1.5 $p=0.04$) and prostaglandin-endoperoxide synthase-2 (PTGS2, OR:1.75, $p=0.02$). Quantitative RT-PCR analysis confirmed the upregulation of these two genes (respectively 1.5 and 2-fold). TNFAIP3 and PTGS2 were also overexpressed in the skin of patients with the diffuse cutaneous subset.

Conclusion: Our data reveal important gene expression changes in EPC-derived cells from SSc patients, characterized by a proadhesive and activated profile. Our results also support a proinflammatory profile of these cells in the diffuse cutaneous subset. These results emphasize the presence of an endothelial signature in SSc and point to novel mediators in this disease that warrant more in-depth exploration to increase the understanding of the pathogenesis of this incurable disease.

PDGF Receptor as Therapeutic and Diagnostic Target in Systemic Sclerosis. Gianluca Moroncini[4], Antonella Grieco[5], Chiara Paolini[5], Giulia Nacci[3], Massimiliano Cuccioloni[2], Matteo Mozzicafreddo[2], Cecilia Tonnini[5], Katarzyna Pozniak[5], Silvia Svegliati[5], Mauro Angeletti[2], Enrico Avvedimento[1], Ada Funaro[3] and Armando Gabrielli[5]. [1]Dipartimento di Biologia e Patologia Molecolare e Cellulare, Università Federico II, Napoli, Italy, [2]Dipartimento di Biologia Molecolare, Cellulare e Animale, Università di Camerino, Italy, [3]Dipartimento di Genetica, Biologia e Biochimica, Università di Torino, Italy, [4]Dipartimento di Scienze Mediche e Chirurgiche, Clinica Medica, Università Politecnica delle Marche, Ancona, Italy, [5]Dipartimento di Scienze Mediche e Chirurgiche, Clinica Medica, Università Politecnica delle Marche, Ancona, Italy

Background: Systemic sclerosis or scleroderma (SSc) is a disease characterized by fibrosis of skin and visceral organs. We have provided evidence that the serum of SSc patients contains stimulatory auto-antibodies (auto-abs) directed to the PDGF receptor (PDGFR) that elicit Ha Ras-ERK 1/2 signaling and collagen production in normal human fibroblasts *in vitro* (Baroni SS et al, NEJM 2006). A recent study (Olson LE, Soriano P, Dev Cell 2009) has confirmed the central role of increased PDGFR activation and signaling in driving systemic fibrosis *in vivo* in transgenic mice.

Objectives: To identify the epitopes of PDGFR extracellular domains bound by stimulatory auto-abs. This information will be used to generate i) PDGFR selective inhibitors and ii) binding assays for detection of functional auto-abs in serum.

Methods and Results: IgG-positive memory B cells obtained from peripheral blood of SSc patients were immortalized by EBV infection. Supernatants of individual lymphocyte clones were screened by immunofluorescence and flow cytometry for the ability to react selectively with F alpha cells (mouse fibroblasts expressing the human PDGFR alpha), but not with F−/− cells (mock-transfected mouse fibroblasts). Positive clones were further screened for the production of antibodies stimulating reactive oxygen species (ROS) generation in normal human fibroblasts *in vitro*. Positive clones were expanded in serum-free medium, IgG were purified from supernatants and tested to confirm both binding and biological activity on fibroblasts. mRNA was obtained from such positive B cell clones for sequencing and cloning of antibody variable regions into a human IgG expression vector. Human IgG constructs were expressed in CHO cells, recombinant (rec.) monoclonal antibodies (mAbs) were purified from medium and tested by immunoprecipitation and stimulation experiments. These rec. monoclonal human IgG showed different extents of PDGFR binding and stimulation. Few mAbs displayed the properties identified in total IgG pools purified from serum of SSc patients, since they bound to PDGFR and induced ROS, p-ERK and type I collagen gene expression in normal human fibroblasts. Molecular docking simulation indicated that the PDGFR epitopes bound by stimulatory mAbs differ from those of non-biologically active mAbs. Epitope mapping was confirmed by binding competition experiments using a rec. PDGFR immobilized onto a biosensor. A peptide library is under construction to further define the map of PDGFR epitopes targeted by the different mAbs.

Conclusions: We identified the specific epitopes bound by functional PDGFR auto-abs that trigger PDGFR signaling. This information is shedding light on the structure of active PDGFR domains, on SSc pathogenesis, and can be used to devise new therapeutic strategies to block PDGFR signaling and, specifically, the progression of SSc. Moreover, synthetic polypeptides corresponding to these functional PDGFR domains will be employed to selectively detect stimulatory auto-abs in serum, possibly implicated in the early phases of SSc pathogenesis.

2002

Proteomic Analysis of Systemic Sclerosis Serum Identifies the Toll-Like Receptor Agonists S100A8/A9 as a Novel Possible Pathogenic Marker. Lenny van Bon[3], Arnoud Loof[3], Helmut Wittkowski[1], Waander van Heerde[3], Madelon Vonk[3], Johannes Roth[1], Wim B. Van Den Berg[2], Peter van Lent[3] and Timothy Radstake[3]. [1]Interdisciplinary Centre for Clinical Research University of Muenster, [2]Radboud Univ Nijmegen Med Cntr, Nijmegen, The Netherlands, [3]Radboud University Medical Centre Nijmegen, The Netherlands

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by fibrosis of the skin and the internal organs. The etiology is still unknown but prominent features are vascular injury and chronic inflammation resulting in fibrosis. Except for anticentromere and anti-topoisomerase I antibodies there are no markers available that predict SSc susceptibility and/or prognosis. This study is the first study that exploits a proteome-wide profiling to identify new targets in the pathogenesis of SSc.

Method: 40 SSc patients were included for initial proteomic identification. Patients were stratified as having diffuse SSc (dSSc) (n= 19) or limited SSc (lSSc) (n=21) according to the extent of skin involvement. As controls 20 healthy donors were included. Blood was drawn and serum was stored before analyzing with the SELDI-TOF-MS. In the first run 10 difSSc patients, 10 limSSc patients and 10 healthy controls were measured as a training set. The rest of the samples were then use as a validation of the training results. SELDI-TOF-MS technology consists of three major components: the ProteinChip array, a mass spectrometer and the data analysis software. For replication a cohort compromising 30 difSSc patients and 60 limSSc was available.

Results: Analysis revealed a list of 29 masspeaks of interest of which 21 could be predicted using Tagident. Six peaks were increased in difSSc and three peaks in limSSc, 18 peaks were increased in both disease subtypes. One of the main significant peaks was S100A8. Since accumulating evidence points to a crucial role of toll like receptors in SSc, and S100A8 is reported to ne an endogenous TLR ligand, we next aimed to replicate the increased expression of S100A8. Further stratification for SSc disease phenotype reveals it to be increased solely in limSSc patients with lungfibrosis. This finding is replicated with an ELISA in 60 limSSc patients S100A8/A9 being 415 pg/ml in limSSc without lungfibrosis and 659 pg/ml in limSSc with lungfibrosis ($p<0.05$) (fig 1). Futhermore we show an increased presence of S100A8 in SSc skin sections.

Conclusion: This is the first study identifying new targets in SSc using proteome wide profiling in serum. S100A8 revealed to be increased in limSSc patients with lungfibrosis specifically. As S100A8 is an important protein in inflammatory processes it is interesting to further investigate its contribution to the pathogenesis of SSc and more specifically lung fibrosis.

2003

Role of Agonistic Autoantibodies Directed to the Angiotensin II Type 1 and the Endothelin-1 Type A Receptors in Systemic Sclerosis. Angela Kill[2], Jeannine Günther[2], Mike Oliver Becker[1], Gerd-Rüdiger Burmester[1] and Gabriela Riemekasten[1]. [1]Charité Berlin, Berlin, Germany, [2]Charité/DRFZ, Berlin, Germany

Background: In addition to their vasoconstrictive functions, angiotensin II and endothelin-1 have been shown to play an important role in vascular inflammation. We have identified autoantibodies against the angiotensin II type 1 receptor (anti-AT_1R- autoantibodies) and the endothelin-1 type A receptor (anti-ET_AR-autoantibodies) in patients with systemic sclerosis (SSc). The presence of these autoantibodies is predictive for a higher degree of pulmonary and cutaneous fibrosis as well as for a higher degree of mortality and the development of pulmonary arterial hypertension (PAH) in SSc.

Objectives: To analyze the role of anti-AT_1R- and anti-ET_AR-autoantibodies on the regulation of the pro-inflammatory mediator interleukin-8 (IL-8) in endothelial cells and collagen-1 production in human fibroblasts.

Methods: Using the human endothelial cell line human microvascular endothelial cells-1 (HMEC-1), we analyzed *in vitro* the effect of anti-AT_1R- and anti-ET_AR-autoantibodies on RNA and protein expression levels of IL-8. Collagen-1 production was measured using immunocytochemistry on human dermal fibroblasts of healthy donors. Cells were treated with immunoglobulin G (IgG) containing anti-AT_1R- and anti-ET_AR-autoantibodies. In some experiments receptors were blocked prior to treatment and IgG of healthy donors served as a negative control.

Results: IgG from patients with SSc upregulated the expression of IL-8 in endothelial cells compared to negative control on the RNA level and expression of IL-8 was verified by analysis on protein level expression using sandwich ELISA. These effects were partly blocked through specific antagonism of the angiotensin II type 1 receptor and/or the endothelin-1 type A receptor. Collagen-1 production was elevated as shown by immunocytochemistry compared to negative control treatment and receptor antagonism.

Conclusions: Our findings suggest a role of the anti-AT_1R- and anti-ET_AR-autoantibodies in the regulation of the inflammatory chemokine IL-8 mediated by the angiotensin II type 1 receptor and the endothelin-1 type A receptor. Furthermore the production of collagen-1 is regulated upon treatment of fibroblasts with anti-AT_1R- and anti-ET_AR-autoantibodies. Anti-AT_1R- and anti-ET_AR-autoantibodies thus might play a role in vascular inflammation and fibrosis of SSc.

2004

Skewed X-Chromosomal Inactivation Impacts T Regulatory Cell Function in Systemic Sclerosis. Jasper Broen[4], Ingrid Wolvers-Tettero[2], Lenny Geurts-van Bon[4], Madelon Vonk[4], Marieke Coenen[3], Robert A. Lafyatis[1], Timothy Radstake[4] and Anton Langerak[2]. [1]Boston University School of Medicine, Arlington, MA, [2]Department of Immunology, Erasmus MC, University Medical Center, Rotterdam, The Netherlands, [3]Radboud University Medical Center, Dept. of Human Genetics, Nijmegen, Netherlands, [4]Radboud University Medical Center, Dept. of Rheumatology, Nijmegen, Netherlands

Objectives: To investigate the role of × chromosomal inactivation (XCI) in systemic sclerosis and its effects on Foxp3 expression in T regulatory cells.

Methods: A total of 217 female SSc patients and 107 female healthy controls were included. From these subjects DNA was isolated from total PBMCs, plasmacytoid dendritic cells, T cells, B cells, myeloid dendritic cells and monocytes after magnetic bead separation. All samples were assessed for skewed XCI patterns with the HUMARA assay. Outcome was assessed with linear regression. Next, CD4+CD25+ cells were isolated and intracellular Foxp3 expression was assessed by flowcytometry.

Results: Skewing is not associated with increased age in SSc, in contrast to the controlpopulation ($r=0.45$, $P<0.0001$). Taking this into account, we found a significantly higher frequency of skewed XCI in SSc patients ($P=0.001$) compared to controls. No difference in skewing was observed between the immune cell subsets. In addition, we found a higher concentration of Foxp3+ cells, exhibiting a lower Foxp3 MFI in the SSc patients with profound XCI skewing (both $P<0.001$), associated with less efficient suppressive activity ($P=0.012$).

Conclusions: Skewed XCI plays a role in susceptibility to SSc, is not restricted and influences Foxp3 expression and suppressive capacity of Tregs.

2005

Structural and Vasomotor Dysfunction in the Thoracic and Pulmonary Vessels of the Tight-Skin 1 (Tsk-1/$^+$) Mouse: Role of Endogenous Nitric Oxide. Audrey Dooley[1], Emma C. Derrett-Smith[1], Xu Shiwen[1], Nelson N. Orie[2], Korsa Khan[1], Christopher P. Denton[4], Lucie Clapp[2], Richard Bruckdorfer[3] and David Abraham[5]. [1]Center for Rheumatology and Connective Tissue Diseases, UCL Medical School, London, United Kingdom, [2]Centre for Pharmacology, UCL Medical School, Rayne Institute, London, United Kingdom, [3]Institute of Structural and Molecular Biology, UCL Medical School, London, United Kingdom, [4]Royal Free Hospital, London, United Kingdom, [5]University College London, London, United Kingdom

Background: Systemic sclerosis (SSc) is a disease that features excessive collagen overproduction, fibrosis, as well as large and small vessel dysfunction. Previously we have shown that nitric oxide (NO), an important physiological signalling molecule and vasodilator, has abnormal metabolism in the skin of SSc patients and in the scleroderma-like syndrome of the tight-skin 1 (Tsk-1/$^+$) mouse, an experimental model predisposed to the development of a connective tissue disease (CTD). The present study investigates contractile function and also the role of NO, in the thoracic aorta and pulmonary artery of the Tsk-1/$^+$ mouse.

Methods: Thoracic aortae and pulmonary arteries from heterozygous TSK-1/$^+$ mice (age: 4, 8, 12 months) were compared with pallid littermates as control. Histology was used to stain sections for collagen or elastin expression. Vessel wall structure was further assessed by EM microscopy, and soluble collagen quantified by Sircol assay. Vascular isometric tension measurements of contractile function were studied using an organ bath or small vessel myograph. Potassium chloride (KCL; 30 mM and 80 mM) or phenylephrine (PE; 1 nM–50 μM) agonists were used to induce vasoconstriction in endothelium-dependant or independent vascular rings. Vascular rings were also pre-incubated with L-NAME (100 μM), a non-specific NO synthase (NOS) inhibitor, or 1400W (5 μM), a specific inducible NOS inhibitor. The NO donor sodium nitroprusside (SNP; 1 nM–50 μM) was used to assess endothelial-independent relaxation.

Results: In Tsk-1/$^+$ thoracic aorta, using histological staining and EM microscopy we observed thickening of the aortic arch wall, disruption of the elastic fiber architecture, and elevated levels of collagen in the aortic adventitia. Aortic soluble collagen content was greater in the Tsk-1/$^+$ group compared to controls. Isometric tension measurement revealed that both KCL and PE-induced contractions were reduced in aortic Tsk-1/$^+$ vessels at all ages studied. PE-induced maximal responses (E_{max}) at 4 months were (Tsk-1/$^+$ 217.2 $\pm$ 6.3 mg; control 411.0 $\pm$ 10.1 mg), at 8 months (Tsk-1/$^+$ 322.5 $\pm$ 32.4 mg; control 618.1 $\pm$ 17.9 mg), and at 12 months (Tsk-1/$^+$ 319.4 $\pm$ 44.7 mg; control 576.2 $\pm$ 31.0 mg). Similarly, at 4 months in pulmonary Tsk-1/$^+$ vessels, PE-induced maximal responses were reduced. Inhibition of endogenous NO production in aortic control vessels, by either pre-treatment with L-NAME or removal of the endothelium, increased PE-induced contractions by 61% but had no significant effect in the aortic Tsk-1/$^+$ group, indicating reduced basal NO bioavailability. Pre-treatment with 1400W had no significant effect on either group. SNP-induced endothelium-independent relaxations, completely dilated PE-induced contraction of both control and Tsk-1/$^+$ aortas, indicating no difference in smooth muscle sensitivity to NO.

Conclusion: The pathogenesis of the Tsk-1/$^+$ mouse model of CTD exhibits vasomotor dysfunction of the thoracic aorta that could be associated with increased collagen deposition and reduced NO bioavailability.

2006

Th1 and Th17 Cytokine Signatures in Early Pediatric Localized Scleroderma. Kathryn S. Torok[3], Thaschawee Arkachaisri[1], Thomas A. Medsger[2] and Carol A. Feghali-Bostwick[4]. [1]KK Women's and Children's Hosp, Singapore, Singapore, [2]Univ of Pittsburgh, Pittsburgh, PA, [3]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [4]University of Pittsburgh, Pittsburgh, PA

Purpose: Pediatric localized scleroderma (LS) is an autoimmune disease characterized by fibrosis of skin and underlying tissues, including subcutaneous tissue, tendons, and muscles. Infiltration of the skin with T cells is a key feature in both LS and systemic sclerosis (SSc). Specifically, T-helper (Th) cell subsets and their associated cytokines have been identified as contributing to the pathogenesis of scleroderma. Previous studies in both SSc and LS support a primary Th2 response, but more recent reports implicate the Th17 subset and associated cytokines. This study was designed to evaluate serum cytokines representative of all three Th cell lineages (Th1, Th2, Th17) in active pediatric LS.

Methods: Serum samples from 71 pediatric LS patients and 49 healthy pediatric controls were obtained. All of the LS patients had active disease, defined as having new lesion(s), expanding lesion(s) and/or erythematous skin lesion(s), and were naive to systemic medications. Two independent luminex assays were performed to evaluate the Th1, Th2, and Th17 serum cytokine profiles. Statistical analysis was completed using Wilcoxon-rank sum tests and chi-square tests with a p-value <0.05 as significant.

Results: The ranks of the individual cytokines were not significantly different between LS patients and controls using Wilcoxon-rank sum tests. However, the p-value did trend toward significance ($p = 0.05 – 0.30$) with higher serum concentrations in the LS group for IL-1β, IL-6, IL-12p70, IL-17F, IL-22 and IFN-γ. Among LS patients with a greater than 10-fold increase in one or more cytokine compared with the upper IQR level for that cytokine in healthy controls, there were correlations between individual cytokines and disease duration. High levels of IL-12p70, IFN-γ, IL-1β, and IL-6 were significantly more frequently detected in LS patients with short disease duration (<24 months) compared with intermediate duration (24–48 months), who had elevated IL-17F and IL-22 levels, and those with long duration (>48 months), who had no elevated cytokine levels ($p<0.05$). Higher cytokine levels correlated with the presence of linear scleroderma, positive ANA, anti-ssDNA and anti-histone antibodies ($p<0.05$).

Conclusions: Th1 and Th17 related cytokines were elevated in the sera of pediatric LS patients with active disease with short to intermediate duration. Th1 associated cytokines appeared early and Th17 associated cytokines appeared later in disease course. Patients with greater elevations of these cytokines more often had linear LS, ss-DNA and anti-histone antibodies, all previously recognized predictors of more severe disease. Understanding and targeting the immune elements involved in the active early stages of LS is critical to designing novel therapies to prevent long-term complications such as thick fibrotic skin, loss of adipose tissue, joint contractures and limb-length discrepancies, which are associated with physical and psychological morbidity.

2007

The Effect of Oxidative Stress on Protein Tyrosine Phosphatase 1B in Scleroderma Fibroblasts. Pei-Suen Tsou[5], Nadin N. Talia[6], Sonsoles Piera[2], Sergio A. Jimenez[1], James R. Seibold[3], Kristine Phillips[4] and Alisa E. Koch[7]. [1]Thomas Jefferson Univ, Philadelphia, PA, [2]Thomas Jefferson University, Philadelphia, PA, [3]University of Connecticut Health Center, Farmington, CT, [4]University of Michigan, Ann Arbor, MI, [5]University of Michigan Medical School, Ann Arbor, MI, [6]University of Michigan Medical School, [7]Unversity of Michigan, Ann Arbor, MI

Purpose: Skin fibrosis is a main characteristic of systemic sclerosis (SSc). Platelet-derived growth factor (PDGF) and its receptor (PDGFR) have been shown to play key roles in promoting fibrosis in SSc. Upon PDGF stimulation, the PDGFR is phosphorylated, and its downstream signaling pathways, including ERK1/2, are activated. The PDGFR is dephosphorylated by phosphatases, including protein tyrosine phosphatase 1B (PTP1B), and the signaling cascade is hence terminated. In addition, increased superoxide production is observed in SSc dermal fibroblasts compared to normal fibroblasts (NL). In this study we sought to determine whether the thiol-sensitive PTP1B is affected by oxidative stress in these cells, enhancing the ERK1/2 signaling pathway of PDGFR. The effect of the thiol antioxidant n-acetylcysteine (NAC) on PTP1B activity was also investigated.

Methods: SSc and NL fibroblasts were isolated from skin biopsies. Cells were stimulated with 30 ng/ml PDGF and phosphorylation of ERK1/2 as well as PTP1B levels were measured by Western blotting. A phosphate release assay was used to determine PTP1B activity. Superoxide was measured by dihydroethidium.

Results: Activation of PDGFR by PDGF resulted in phosphorylation of ERK1/2. In NL fibroblasts, ERK1/2 phosphorylation was maximal at 45 min (3 fold increase vs. unstimulated [US], $p<0.05$, $n=5$) and returned to baseline at 4 hr. In contrast, in SSc cells, ERK1/2 was significantly phosphorylated at 10 min and remained phosphorylated at 4 hr (2 fold increase vs. US, $p<0.05$). PDGF increased PTP1B protein expression significantly at 45 min and 2 hr in NL. In contrast, PTP1B expression in SSc fibroblasts remained the same, and at 45 min the level of PTP1B in NLs was significantly higher than that in SSc

($p<0.05$). PTP1B activities were 20.1 ± 2.7 and 11.9 ± 1.3 nmoles (phosphate released, $p<0.05$) in NL and SSc fibroblasts, respectively. In the presence of NAC, PTP1B activity was restored in SSc fibroblasts (from 11.9 ± 1.3 nmoles without NAC to 19.2 ± 2.1 nmoles with NAC, $p<0.05$). In contrast, the activity of PTP1B was unaffected with NAC treatment in NLs (20.1 ± 2.7 nmoles without NAC vs. 16.2 ± 0.4 nmoles with NAC, $p>0.05$). Superoxide was significantly higher in SSc than in NL dermal fibroblasts, and the level in SSc cells was reduced significantly after incubation with NAC ($p<0.05$).

Conclusions: The profile of ERK1/2 phosphorylation, which indicated PDGF-induced PDGFR activation, was different in NL and SSc dermal fibroblasts. The inability to dephosphorylate ERK1/2 in SSc fibroblasts suggests that the phosphatases that are responsible for ERK1/2 dephosphorylation are deficient in SSc. The ability to produce PTP1B after PDGF stimulation, and hence terminate PDGFR signaling, was hampered in SSc dermal fibroblasts. PTP1B activity was significantly inactivated in SSc fibroblasts, which may have resulted from higher levels of superoxide than in NL. NAC treatment both restored the low PTP1B activity and decreased superoxide levels in SSc dermal fibroblasts. Thus, we introduce a new class of proteins dysregulated in SSc. Our study also provides a novel molecular mechanism by which NAC therapy may act on these proteins to benefit SSc patients.

2008

The Wnt Signalling Inhibitor Gene, WIF1, Expression Is Downregulated in Fibroblasts Derived from Systemic Sclerosis Patients by a Persistent Oxidative Stress. Silvia Svegliati[2], Giusi Marrone[3], Antonella Grieco[2], Tatiana Spadoni[2], Lucia De Gennaro[2], Gianluca Moroncini[2], Enrico Avvedimento[1] and Armando Gabrielli[2]. [1]Dipartimento di Biologia e Patologia Cellulare e Molecolare, Università Federico II, Napoli, Italy, [2]Dipartimento di Scienze Mediche e Chirurgiche, Università Politecnica delle Marche, Ancona, Italy, [3]Oncogenomic Center, NOGEC, CEINGE, Italy

Background: Systemic sclerosis is an autoimmune disease characterized by extensive fibrosis and vascular lesions. Primary fibroblasts derived from systemic sclerosis (SSc) patients contain high level of cytoplasmatic and peri-nuclear free radicals (ROS) and breaks in the genomic DNA.

Stimulatory IgG auto-antibodies to the PDGF receptor were identified in sera from systemic sclerosis patients. These autoantibodies were capable of converting normal fibroblasts into SSc-like cells inducing excessive oxygen species (ROS) production by activating membrane NADPH oxidase complex. Wnt family constitutes a large group of highly conserved glycoproteins that are implicated in developmental processes and recently in carcinogenesis, aging and fibrosis. Wnt signaling is tightly controlled by several groups of negative regulators that interfere either with receptor-ligand binding or with intracellular signaling.

Wnt inhibitor factor 1, WIF1, is frequently silenced in human cancer by DNA methylation. Recently, its inhibition has been associated to ageing of mesenchymal stem cells and fibrosis, induced by unrestrained Wnt signaling. In order to identify specific markers of the disease, we have decided to analyze WIF1expression in cells derived from patients affected by systemic sclerosis and explore the mechanism of WNT signaling regulation.

Materials and Methods: Human skin fibroblasts were obtained from punch biopsies taken from normal volunteers and from the involved skin of scleroderma patients. We have investigated WIF-1 expression by reverse transcription and quantitative real-time PCR. Total RNA isolation was performed with total RNA mini kit (BioRad) and reverse transcription PCR was performed using iScript cDNA synthesis kit from BioRad. Quantitative PCR was performed in triplicate with SYBR Green (Biorad).

Results: WIF gene expression was significantly down-regulated in cells derived from systemic sclerosis patients. Moreover, the gene was not methylated, as in breast cancer cells, and its expression was reactivated by inhibiting histone de-acetylase enzymes, trichostain (TSA). PDGF in 24 hours robustly stimulated WIF-1 expression and this effect was prevented by inhibiting NADPH oxidase. Prolonged oxidative stress induced by IgG SSc silenced WIF1 by triggering DNA damage. Inhibition of ATM kinase by the specific inhibitor KU-55933 rescued WIF expression in fibroblasts exposed to long term oxidative stress.

Conclusions: These data indicate that in SSc fibroblasts a persistent oxidative stress, triggered by PDGF or anti PDGF receptor autoantibodies, induce WIF-1 downregulation and possibly altered WNT signaling. Our data indicate that the ultimate cause of silencing WIF-1 is DNA damage.

2009

Alveolar Hemorrhage (AH) in ANCA-Associated Vasculitis: Characteristics and Prognostic Factors in 65 Patients. Alex M. Kostianovsky[2], Thomas Hauser[2], Christian Pagnoux[2], Pascal Cohen[2], Eric Daugas[3], Luc Mouthon[2], Jean-Francois Cordier[4] and Loic P. Guillevin[1]. [1]Hopital Cochin-Paris Univ, Paris, France, [2]Internal Medicine, Hopital Cochin, APHP, Universite Paris Descartes, Paris, France, [3]Nephrology, Assistance Publique de Paris, Paris, France, [4]Pulmonology, Hopsice Civils de Lyon, Lyon, France

AH can be a mild or a life-threatening sign of ANCA-associated vasculitis, but its prognostic impact and specific characteristics have not been determined. To do so, we retrospectively analyzed AH episodes that occurred, between 1991 and 2010, in patients with ANCA-associated vasculitis entered in the FVSG database.

Patients and Methods: We selected confirmed AH cases, as assessed by the presence of hemoptysis and ground-glass images on X-rays or CT scans and/or bloody bronchoalveolar lavage fluid. Renal insufficiency was defined as creatininemia >150 mmol/l. Severity criteria were: hypoxia, Hb decline >1 g/dl over 48 h after AH occurred and requiring mechanical ventilation.

Results: For the 65 cases (35 men and 30 women) analyzed, their mean age at the 1st AH episode was 53 years. ANCA-associated vasculitis diagnoses were: 55% Wegener's granulomatosis (WG), 34% microscopic polyangiitis (MPA) and 9% Churg–Strauss syndrome (CSS). Pre-AH hemoptysis occurred in 41 (63%) patients: 39% the week preceding, 29.3% 2–4 weeks before and 19.5% >1 month prior to AH diagnosis, which led to ANCA-associated vasculitis diagnosis for 45 (69.2%) patients. Among 10 (15.4%) patients (4 WG, 4 MPA, 2 CSS) requiring mechanical ventilation, 4 had hemoptysis previously. Twenty-three (35%) patients were hypoxic and 23 (35%) had major Hb decreases; 36 (55%) had concomitant renal insufficiency (pulmo-renal syndrome): 18 WG (51% of all WG) and 18 MPA (81% of all MPA). Paucimmune glomerulonephritis was seen in 31/33 kidney biopsies. Intriguingly, no CSS patient had renal impairment when AH occurred.

Treatments included a combination of corticosteroids and intravenous cyclophosphamide (CYC) for 55 (85%) patients; oral CYC was used in 5, methotrexate in 4 and plasma exchange in 7. Rituximab and remicade were prescribed to 1 patient each. Mean time between AH and treatment onset was 5.87 (range 0–60) days. Mean follow-up was 8.3 years (range 1 month–19 years). Follow-up information was not available for 8 patients. A total of 38 (58%) patients relapsed: 7 with AH and other organ involvement, 21 with non-AH manifestation(s) and 10 with AH alone. Three patients underwent kidney transplantation.

The 13 (20%) deaths (6 WG and 7 MPA) were attributed to: septic shock for 4, lung cancer for 2, and 1 each of the following: bladder cancer, AH, sudden death, hemorrhagic stroke, ARDS due to misplaced nasogastric tube and probably drug-related (methotrexate). Although 9/13 patients with pulmo-renal syndrome died, no death resulted directly from the initial AH.

Conclusion: These findings highlight the importance of recognizing premonitory hemoptysis as an early sign of AH in ANCA-associated vasculitides, since 63% of the cohort patients had bloody sputum before AH was diagnosed. Also, patients with AH and renal insufficiency have poorer survival prognoses. As demonstrated by the five-factor score, AH alone is not predictive poor prognosis; conversely, kidney involvement dictates a poor outcome.

2010

Baseline Characteristics of Patients with Non-Infectious Mixed Cryoglobulinemia Vasculitis: Results from the French Nationwide CryoVas Survey. Benjamin Terrier[8], Isabelle Marie[9], Adeline Lacraz[2], David Launay[5], Emmanuelle Plaisier[11], Jean-Emmanuel Kahn[10], Luc de Saint-Martin[3], Fabrice Bonnet[2], Guillaume Le Guenno[4], Elisabeth Diot[12], Patricia Rullier[6], Raphaël Seror[1], Estabaliz Lazaro[2], Olivier Hermine[7], Jean-Marc Léger[8], Patricia Senet[11], Xavier Mariette[1] and Patrice Cacoub[8]. [1]Bicêtre, [2]Bordeaux, [3]Brest, [4]Clermont-Ferrand, [5]Lille, [6]Montpellier, [7]Necker, [8]Pitié-Salpéterière, [9]Rouen, [10]Suresnes, [11]Tenon, [12]Tours

Background: Hepatitis C virus infection is the main cause of mixed cryoglobulinemia vasculitis (CryoVas). Data are lacking regarding demographical, clinical and biological features of patients with non-infectious mixed CryoVas.

Objectives: To analyze the baseline features of patients with non-infectious mixed CryoVas included in the French CryoVas survey. The objective of this survey is to describe the presentation and evaluate efficacy and tolerance of treatments in patients with non-hepatitis C virus CryoVas, in the absence of large series and therapeutic guidelines.

Methods: Fifty-four French centres of Internal Medicine, Nephrology, Rheumatology, Hematology, Dermatology and Neurology from Universitary and general hospitals have included 211 patients with non-infectious mixed CryoVas diagnosed between January, 1995 and June, 2010. Demographical, clinical and biological data, as well as first line therapy, were assessed.

Results: Hundred and forty-five women and 60 men (sex ratio F/M 2.4), mean age 63.2 ± 14.6 years were included. Main causes of CryoVas included autoimmune disorders in 66 patients (31%) [mainly primary Sjögren syndrome in 56 and systemic lupus erythematosus in 4], and B-cell lymphoma in 44 (21%). Mixed CryoVas was essential in 101 patients (49%). At inclusion, clinical manifestations included purpura (74%), peripheral neuropathy (52%), glomerulonephritis (36%), Raynaud's phenomenon (27%), arthralgia/arthritis (41%), skin ulcers (17%), skin necrosis (14%), gastrointestinal (6%), central nervous system (2%) and pulmonary involvement (2%). Immunochemical characterization and quantification of cryoglobulinemia were available in 200 (95%) and 140 (66%), respectively. Cryoglobulinemia was type II in 175 patients (88%) and type III in 25 (12%). Median cryoglobulin level was 0.36 g/L (0.05–10.0), and median C3 and C4 complement levels were 0.82 (0.14–1.94) and 0.04 g/L (0.01–0.44). Histological confirmation of vasculitis was available in 74%.

Most patients (n=194) were treated and received as first-line therapy corticosteroids in 85% [median dose of 57.5 mg/day (5–180)], cyclophosphamide in 24%, rituximab in 19%, plasma exchange in 14% [median number of 9 (2–46)], and colchicine in 4%. Seventeen patients (8%) were not treated because of mild symptoms attributable to CryoVas (n=8), spontaneous remission without relapse (n=5), or because patients were lost to follow-up before starting therapy (n=3) or refused treatment (n=1).

Conclusion: Our study is the largest clinical and epidemiological survey describing the features of mixed cryoglobulinemia vasculitis to date. This provides interesting findings for further comparisons. The analysis of response to therapy will be helpful to determine the best therapeutic strategies.

2011

Baseline Characteristics of Patients with Type I Monoclonal Cryoglobulinemia Vasculitis: Results from the French Nationwide CryoVas Survey. Benjamin Terrier[8], Isabelle Marie[9], Jean-Emmanuel Kahn[10], Guillaume Le Guenno[4], Alexandre Karras[5], Adeline Lacraz[2], Olivier Hermine[7], Luc de Saint-Martin[3], Elisabeth Diot[12], Philippe Modiano[6], Véronique Leblond[8], Patricia Senet[11], Jean-Marc Léger[8], Emmanuelle Plaisier[11], Xavier Mariette[1], David Saadoun[8] and Patrice Cacoub[8]. [1]Bicêtre, [2]Bordeaux, [3]Brest, [4]Clermont-Ferrand, [5]HEGP, [6]Lille, [7]Necker, [8]Pitié-Salpéterière, [9]Rouen, [10]Suresnes, [11]Tenon, [12]Tours

Objectives: To analyze the baseline clinical and biological features of patients with type I monoclonal cryoglobulinemia vasculitis (CryoVas) included in the French CryoVas survey. The objective of this survey is to describe the presentation and to evaluate efficacy and tolerance of treatments in patients with non-hepatitis C virus CryoVas.

Methods: Twenty-three French centers of Internal Medicine, Nephrology, Rheumatology, Hematology, Dermatology and Neurology from Universitary and general hospitals have included 51 patients with type I monoclonal CryoVas diagnosed between January, 1995 and June, 2010. Demographical, clinical and biological data, as well as first line therapy, were assessed.

Results: Twenty-seven women and 24 men (mean age: 66 ± 12 years) were included. B-cell lymphoproliferative disorders were present in all patients, including monoclonal gammopathy of unknown significance (n=25), Waldenström macroglobulinemia (n=9), multiple myeloma (n=6) and other low grade B-cell non Hodgkin lymphoma (n=11).

At inclusion, clinical manifestations of type I CryoVas included purpura (72%), peripheral neuropathy (45%), Raynaud's phenomenon (35%), skin necrosis (29%), arthralgia/arthritis (29%), glomerulonephritis (25%), skin ulcers (25%), livedo (8%), urticaria (6%), angioedema (2%) and nasal septal perforation (2%). Most patients had a severe clinical presentation as only 13 patients (25%) had mild to moderate manifestations (i.e. Raynaud's phenomenon, skin purpura without ulcers/necrosis, or sensory peripheral neuropathy). Median cryoglobulin level was 1.55 g/L (0.1–10.43), and median C3 and C4 complement levels were 0.87 (0.3–1.93) and 0.06 g/L (0.01–0.34). Histological confirmation of vasculitis was available in 71%.

Seventeen patients received specific chemotherapy of B-cell lymphoma. The remaining treated patients (n=28) received as first-line therapy corticosteroids in 89% [median dose of 60 mg/day (20–120)], rituximab in 20%, cyclophosphamide in 16% and plasma exchange in 12%. Only 6 patients were not treated because of mild symptoms attributable to CryoVas and absence of underlying malignant lymphoproliferative disorder.

Conclusion: Our study is the largest clinical and epidemiological survey describing the features of type I monoclonal cryoglobulinemia vasculitis to date. Type I CryoVas was always associated with B-cell lymphoproliferative disorders, including malignant B-cell lymphoma in almost 50% of cases. Cutaneous manifestations were the most frequent manifestations, and CryoVas presentation was considered as severe in 75% of cases.

2012

Circulating Markers of Vascular Injury in ANCA-Associated Vasculitis. Paul A. Monach[1], Ronald D. Snyder, Ulrich Specks, John H. Stone[8], David Cuthbertson, Linna Ding, Fernando C. Fervenza, Barri J. Fessler[10], Gary S. Hoffman[4], David Ikle, Cees G. M. Kallenberg[11], Carol A. Langford[3], Mark Mueller, Philip Seo[7], E. William St Clair[5], Robert Spiera[6], Nadia Tchao, Steven R. Ytterberg[9] and Peter A. Merkel[2]. [1]Boston University, Boston, MA, [2]Boston University School of Medicine, West Newton, MA, [3]Cleveland Clinic Foundation, Cleveland, OH, [4]Cleveland Clinic Foundation, Pepper Pike, OH, [5]Duke University Medical Center, Durham, NC, [6]Hospital for Special Surgery, New York, NY, [7]Johns Hopkins Bayview Medical Center, Baltimore, MD, [8]Massachusetts General Hospital, Sudbury, MA, [9]Mayo Clinic, Rochester, MN, [10]UAB Rheumatology, Birmingham, AL, [11]Univer Med Center Groningen, Groningen, The Netherlands

Background: There is a need for biomarkers associated with ANCA-associated vasculitis that are associated with disease activity, are useful in guiding clinical care, and reflect underlying pathophysiology. We investigated multiple markers of vascular injury and angiogenesis before and after induction of remission in a large clinical trial.

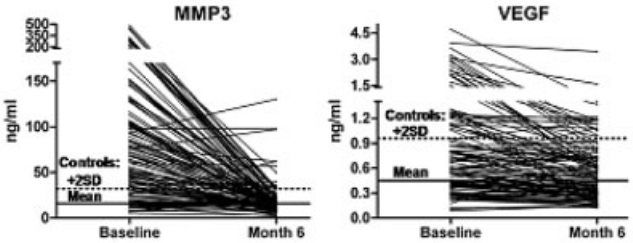
Methods: Subjects (n=127) enrolled in the Rituximab in ANCA-Associated Vasculitis (RAVE) trial were selected if they were in remission (BVAS/WG = 0) at 6 months after starting treatment with glucocorticoids and either rituximab or cyclophosphamide. Serum levels of E-selectin, ICAM-3, MMP1, MMP3, MMP9, P-selectin, thrombomodulin, and VEGF were measured by immunoassays (Meso Scale Diagnostics). ESR and CRP levels were used for comparison. Change in marker level from baseline to 6 months was analyzed by paired T-test. Marker levels in subjects with AAV were compared to marker levels in a group of 20 healthy controls (T-test). Correlations were calculated using Pearson coefficients.

Results: All subjects had highly active vasculitis (mean BVAS/WG score 8.6 +/− 3.2 SD) at baseline; 49% (n = 62) had active renal disease, and 27% (n = 34) had pulmonary hemorrhage. All subjects were clinically in remission (BVAS/WG = 0) at month 6; only 7 subjects were still receiving prednisone for minor flares that occurred before month 6. All markers levels except E-selectin and MMP9 were significantly elevated at baseline compared to controls, and all except E-selectin declined significantly by 6 months

(Table). MMP3 and VEGF, as well as ESR, were the only markers whose mean values at remission were no longer significantly elevated relative to controls (Table). MMP3 was both elevated at baseline and normal at 6 months in 70% of subjects; 18% showed such a trend for VEGF levels (Figure). There were modest correlations among VEGF, P-selectin, MMP1, MMP9, and ESR (maximum r = 0.48). MMP3 correlated with thrombomodulin (r = 0.40) but poorly with all other markers including ESR and CRP.

Marker	Active (Baseline) Mean ± SD	Remission (Month 6) Mean ± SD	Healthy Controls Mean ± SD
CRP	3.29 +/− 5.19*	1.25 +/− 2.20*†	Ref < 0.5
ESR	**44 +/− 31***	**18 +/− 16†**	**Ref < 20**
E-selectin	14.0 +/− 5.9	13.7 +/− 5.6	14.7 +/− 7.7
ICAM3	2.29 +/− 0.96*	1.88 +/− 0.76*†	0.55 +/− 0.30
MMP1	40.4 +/− 38.8*	22.8 +/− 17.2*†	10.6 +/− 6.9
MMP3	**99 +/− 95***	**22 +/− 32†**	**16 +/− 8.3**
MMP9	409 +/− 267	154 +/− 102*†	465 +/− 227
P-selectin	124 +/− 43*	107 +/− 34*†	87 +/− 24
Thrombomodulin	5.76 +/− 2.58*	5.18 +/− 2.10*†	2.60 +/− 0.69
VEGF	**0.93 +/− 0.85***	**0.56 +/− 0.41†**	**0.45 +/− 0.26**

*P<0.01 compared to healthy controls.
†P<0.001 compared to Baseline.
Markers that were elevated vs. controls at Baseline, reduced vs. Baseline at 6 months, and not significantly elevated vs. controls at 6 months are in bold.



Conclusions: Many markers of vascular injury and angiogenesis are elevated in highly-active ANCA-associated vasculitis and decline with treatment. Further study of MMP3 and VEGF is warranted to determine their clinical utility in combination with conventional markers of inflammation.

This research was performed with the support of the Immune Tolerance Network.

2013

Clinical and Autoimmune Manifestations of Levamisole-Adulterated Cocaine Abuse. Korey R. Ullrich[3], Sterling G. West[4], Whitney High[5], Robert J. Koval[3], Erin Koval[5], Srinivas Bapoje[2] and Joel M. Hirsh[1]. [1]Denver Health Hospital Authority, Louisville, CO, [2]Denver Health Hospital Authority, [3]University of Colorado-Denver Medical School, Denver, CO, [4]University of Colorado-Denver Medical School, Aurora, CO, [5]University of Colorado-Denver Medical School

Background: Levamisole (LVS) has been detected as an adulterant in cocaine with increasing frequency, and has been implicated as a cause of neutropenia in cocaine users. Here we describe a novel syndrome of a cocaine-associated vasculopathy likely secondary to LVS, and suggest possible mechanisms to explain this association.

Materials and Methods: Patients presented consecutively between August 2009 and April 2010. We prospectively followed all patients on inpatient consultation and in the rheumatology clinic at our public health hospital. It was possible to perform human neutrophil elastase (HNE) testing on 2 patients.

Results: Patient characteristics are detailed in Table 1.

5 patients with a history of crack cocaine use presented with arthralgias and purpuric skin lesions affecting the ears and extremities. There was no definable systemic autoimmune process or evidence of infection. Rapid skin improvement occurred in all with cessation of cocaine. Patient 5 was treated with cyclophosphamide (CYC) and prednisone for suspected systemic vasculitis, but therapy was discontinued once the association with LVS was identified. Patient 2 initially received no immunosuppression, but was subsequently treated with CYC and steroids after developing ILD with features of desquamative interstitial pneumonia and hypersensitivity pneumonitis on biopsy.

Table 1: Patient characteristics

Patients	Skin Histology	ANCA	aPL	Levamisole	Outcome
1	Erythema nodosum-like nodules Patient refused biopsy of purpura	pANCA 1:5120 MPO 59 PR3 21 HNE positive	DRVVT IgM ACL	Positive	Purpura improved, but continues to have nodules. aPL improved, but ANCA remain elevated after 3 months.
2	Vascular thrombosis with rare perivascular neutrophil and karyorrhectic debris	cANCA 1:1280 MPO neg PR3 3.9 HNE positive	Hex	Negative (checked 8th hospital day)	ANCA and aPL improved. CYC and steroids for ILD.
3	Leukocytoclastic vasculitis with evidence of thrombosis	pANCA 1:640 MPO 56 PR3 34 HNE not done	Hex IgM ACL IgM B2-GP1	Not checked	Subsequently developed arthritis responsive to a short steroid course. Symptoms recurred with crack relapse. No follow-up labs.
4	Not performed	pANCA 1:1280 MPO 23 PR3 180 HNE not done	DRVVT Hex IgM ACL	Negative	Persistent arthralgias. aPL improving, but ANCA remain elevated after 2 months.
5	Leukocytoclastic vasculitis with prominent intravascular thrombosis	pANCA 1:10240 MPO 235 PR3 31.5 HNE not done	PTT prolonged IgM ACL	Positive	Lost to follow-up.

ACL: anticardiolipin antibodies; ANCA: antineutrophil cytoplasmic antibodies (N: < 1:20); aPL: antiphospholipid antibody assays; B2-GP1: beta-2 glycoprotein 1 antibody; cANCA: cytoplasmic ANCA; DRVVT: dilute Russell viper venom time; Hex: hexagonal phase phospholipid neutralization; HNE: human neutrophil elastase; MPO: myeloperoxidase antibodies (N: < 20); pANCA: perinuclear ANCA; PR3: proteinase 3 antibodies (N: < 3.5); PTT: partial thromboplastin time

Discussion: We have described a novel syndrome of a cocaine-associated cutaneous vasculopathy likely secondary to LVS. Cardinal features include antiphospholipid (aPL) positivity, polyspecific ANCA, the tendency for purpura to involve the ears, and a lack of evidence of systemic vasculitis. Interestingly, HNE reactivity was detected in both of the patients tested.

Several lines of evidence support the role of LVS in the pathogenesis of this syndrome, but the most noteworthy is the similarity to previous descriptions of levamisole-associated purpura of the ears in children with nephrotic syndrome. We suspect the pathogenesis of this syndrome is multifactorial, related to the vascular and immunogenic effects of cocaine, the presence of pro-thrombotic aPLs, the immunoenhancing properties of LVS, and the effects of LVS on peripheral sympathetic activity.

It is important for clinicians to recognize LVS exposure through adulterated cocaine as a cause of a cutaneous vasculopathy that can be mistaken for a systemic ANCA-associated vasculitis. Owing to its short half-life of approximately 5 hours LVS may be undetectable in the urine in as little as 48 hours after ingestion, so negative test results do not exclude the diagnosis. As demonstrated by our patients' diverse courses, the natural history of this disorder and the relationship to lung disease are unclear at this time. The role of immunosuppression also remains uncertain, but may be warranted in severe cases. Cessation of cocaine is necessary, and relapses of the syndrome do occur with ongoing use.

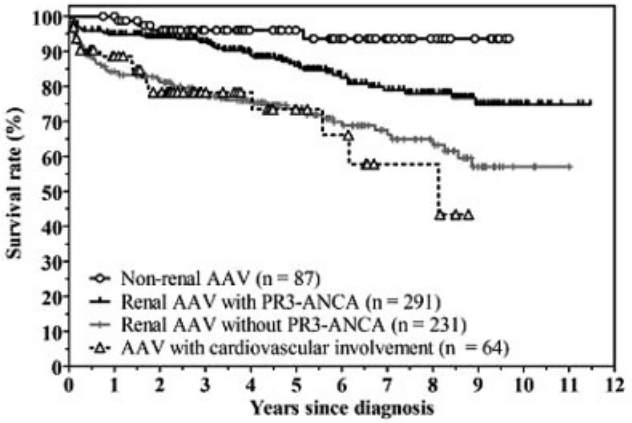
2014

Cluster Analysis and Clinical Phenotypes of ANCA-Associated Vasculitis. Alfred Mahr[3], Sandrine Katsahian[1], Loïc Guillevin[4], E. Christiaan Hagen[5], Peter Höglund[2], Peter A. Merkel[9], Christian Pagnoux[4], Niels Rasmussen[8], Kerstin Westman[6] and David Jayne[7]. [1]Clinical Epidemiology and Biostatistics, Hospital Saint-Louis, Paris, France, [2]Clinical Pharmacology, Department of Laboratory Medicine, Lund University, Lund, Sweden, [3]Internal Medicine, Hospital Cochin, Paris, Paris, France, [4]Internal Medicine, Hospital Cochin, Paris, France, [5]Internal Medicine, Meander Medical Center, Amersfoort, Netherlands, [6]Nephrology and Transplantation, Skane University Hospital Malmö, Lund University, Sweden, [7]Nephrology, Addenbrooke's Hospital, Cambridge, United Kingdom, [8]Otolaryngology, Rigshospitalet, Copenhagen, Denmark, [9]Rheumatology and Clinical Epidemiology Unit, Boston University School of Medicine, Boston, MA

Background: Wegener's granulomatosis (WG) and microscopic polyangiitis (MPA) have widely overlapping clinical, serological, and histological features and are increasingly considered phenotypic variants of a single entity termed "ANCA-associated vasculitis (AAV)". Applying current definitions to distinguish between WG and MPA is sometimes problematic, and physicians' and researchers' disease classifications are heterogeneous. In addition, clinical practice and observational study findings suggest that WG and MPA clinical forms may not reflect the full range of AAV expressions. This study applied cluster analysis of a large combined cohort to explore the clinical phenotyping spectrum of AAV.

Methods: A large dataset of patients with newly diagnosed WG and MPA originally enrolled in 5 clinical trials on AAV was analyzed. Eleven baseline variables, including 9 clinical variables (age at diagnosis, sex, ear/nose/throat, ocular, lung, renal, neurological, skin and cardiovascular manifestations), PR3-ANCA, and MPO-ANCA, served as primary variables for the cluster analysis. The clinical relevance of the generated clusters was analyzed by describing their summary characteristics and their patient outcomes.

Results: The dataset comprised 673 subjects, diagnosed as follows: 396 (59%) WG and 281 (41%) MPA. Over a mean follow-up of 4.4 years, 136 (20%) patients died. The analyses yielded 4 distinct phenotypic classes: 87 (13%) non-renal AAV, 291 (43%) renal AAV with PR3-ANCA, 231 (34%) renal AAV without PR3-ANCA, and 64 (10%) AAV with cardiovascular involvement. The distribution of WG-diagnosed patients into those 4 respective classes was 95%, 79%, 18% and 64%. Those 4 classes represented highly distinct mortality rates ($P < 0.0001$, log-rank test) (Figure) and frequencies of patients relapsing ≥ 1 times (range: 20–53%; $P < 0.0001$, χ^2 test). Using 3 of the 9 variables (presence or absence of renal involvement, cardiovascular involvement, and PR3-ANCA), 651 of the 673 subjects (97%) were accurately allocated to 1 of the 4 classes.



Conclusion: Our cluster analysis results suggest that AAV encompasses 4 phenotypic classes: non-renal AAV, renal AAV with PR3-ANCA, renal AAV without PR3-ANCA and AAV with cardiovascular involvement, associated with different outcomes. Compared to the traditional WG–MPA separation, this new classification might better reflect the phenotypic groupings within the AAV spectrum and more accurately stratify patients into homogeneous disease groups for clinical, epidemiological and basic research.

2015

CpG Stimulation of Neutrophils; a Possible Role for Bacterial DNA in Neutrophil-Mediated Pathogenesis of ANCA-Associated Vasculitis?
Henko Tadema[2], Cees G. M. Kallenberg[2], Sandra E. Thamerl[2], Nikola Lepse[2], Coen A. Stegeman[1] and Peter Heeringa[3]. [1]University Medical Center Groningen, Dept of Nephrology, Groningen, The Netherlands, [2]University Medical Center Groningen, Dept of Rheumatology and Clinical Immunology, Groningen, The Netherlands, [3]University Medical Center Groningen, Dept Pathology and Medical Biology, Groningen, The Netherlands

Background: Bacterial infections are often associated with autoimmunity, and CpG-motifs from bacterial DNA are suggested to play a role in the pathogenesis of anti-neutrophil cytoplasmic autoantibodies (ANCA) associated vasculitides. Binding of ANCA to autoantigens on pre-activated (primed) neutrophils results in full activation, causing the release of lytic enzymes and reactive oxygen species, thereby contributing to vascular inflammation. Here we investigated effects of CpG-motifs on ANCA-mediated neutrophil responses.

Methods: To study if CpG could prime neutrophils, we stimulated neutrophils from healthy controls and AAV patients *in vitro* with TNF-α, CpG, or both. Membrane expression of PR3 (mPR3), before and after stimulation, was analyzed by flowcytometry, and interleukin-8 release was measured by ELISA. Full activation of neutrophils in response to anti-PR3 and anti-MPO monoclonal antibodies after priming with CpG, TNF-α, or the combination, was studied by measuring superoxide production and degranulation.

Results: Both CpG and TNF-α induced increased mPR3 expression by neutrophils. Most donors have a $mPR3^-$ and a $mPR3^+$ subset within the neutrophils. TNF-α generally increased mPR3 expression on the $mPR3^+$ subset, whereas CpG increased mPR3 expression on both the $mPR3^-$ and $mPR3^+$ subsets. TNF-α primed neutrophils for full activation with anti-PR3 or anti-MPO antibodies, resulting in superoxide production, whereas CpG alone did not. Priming with the combination of TNF-α and CpG resulted in increased superoxide production and IL-8 release, compared to TNF-α priming. Furthermore, forward-sideward scatter plots of TNF+CpG primed and activated neutrophils indicated rapid degranulation, which was confirmed by preliminary data showing increased MPO release.

Conclusions: Although CpG-stimulation increased mPR3 levels on neutrophils, it did not prime neutrophils for full activation with anti-PR3 or anti-MPO antibodies. Preliminary data indicate that combined priming with TNF-α and CpG induced strong neutrophil responses including enhanced oxidative burst and degranulation. These data indicate that unmethylated CpG-motifs of bacterial origin may be of importance in ANCA-associated vasculitis, as it influences mPR3 expression and neutrophil responses. Bacterial DNA may prime neutrophils for rapid activation by ANCA in the presence of additional pro-inflammatory stimuli such as TNF-α, and may therefore contribute to the pathogenesis of ANCA-associated vasculitis.

2016

CXCL16 Antagonist Ameliorates the Progression of Vasculitis in McH5/lpr Mice.
Hitoshi Hasegawa[1], Jin Lei[2], Takuya Matsumoto[2], Masaki Yasukawa[2], Tatsuhiko Miyazaki[2] and Masato Nose[2]. [1]Ehime University Graduate School of Medicine, Toon, Ehime, Japan, [2]Ehime University Graduate School of Medicine

Background: Several chemokines associate with the initiation and progression of vasculitis. A recombinant congenic strain, McH5/lpr, was established by rearrangement of the genetic background of MRL/lpr mice by hybridization with C3H/lpr mice. McH5/lpr mice developed severe granulomatous polyarteritis but not glomerulonephritis, referred as a mouse model of periarteritis nodosa. CXCL16 is expressed at low levels by macrophages and vascular endothelial cells, but it undergoes marked up-regulation after stimulation of TNF-alpha and IFN-gamma. We investigated the expression of CXCL16 during the process of granulomatous polyarteritis in McH5/lpr mice and the therapeutic effect of CXCL16 antagonist (CXCL16-AT) on vasculitis.

Methods: The NH_2-terminally truncated CXCL16 analogs were converted to secreting forms by addition of signal sequence of IFN-beta, inserted into the pCXN2 expression vector and transfected into a non-metastatic fibroblastoid cell line, MRL/N-1. These transfectants were injected subcutaneously into McH5/lpr mice.

Summary of the Results: CXCL16 analogs (secreting form) truncated by 4 or more amino acid residues from N-terminus failed to induce chemotaxis by CXCR6-expression cells. Significantly increased expression of CXCL16 was induced mainly endothelial cells, epithelial cells, and infiltrating macrophages in the perivascular region at 8–10 weeks of age. CXCL16-AT-transfected MRL/N-1 cells were injected subcutaneously into McH5/lpr mice aged 8 wk (at the early stage of polyarteritis). CXCL16 antagonist was present in the serum of mice 2 wk after injection. After 8 weeks, inoculation of CXCL16-AT into McH5/lpr mice significantly reduced infiltrating mononuclear cells and destruction of the vessel wall associated with the formation of granulomatous lesions

compared with control mice. This seemed to be due to a marked reduction in macrophage and activated T-cell accumulation.However, there were no significant differences in serum anti-DNA antibodies and circulating immune complex at low levels among control, and CXCL16-AT-bearing McH5/lpr mice.

Conclusion: CXCL16 antagonist may provide a new therapeutic approach to vasculitis.

School of Medicine, Nashville, TN

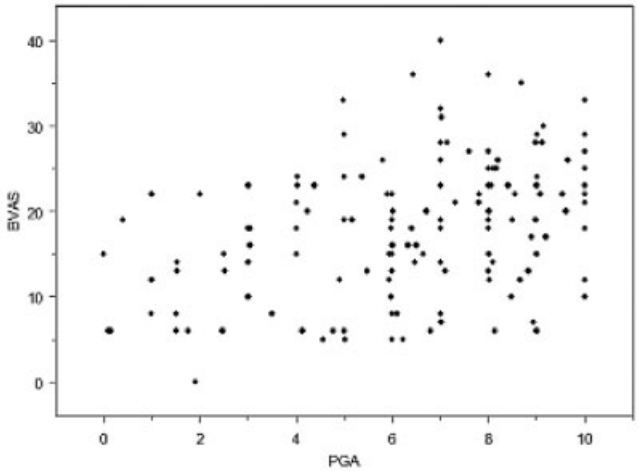
Background: There are no validated paediatric assessment tools for measuring disease activity in chronic vasculitis. The BVAS, a valid and reliable assessment tool for measuring disease activity in adults with vasculitis, may not necessarily capture the clinical features or components of disease activity assessment that might be unique to, or more characteristic of, the growing and developing child. In adult vasculitis, BVAS correlates highly (rho = 0.91) with physician's global assessment of disease activity (PGA).

Objectives: To describe the performance of BVAS applied at the time of diagnosis in children with AAV in relationship to PGA.

Methods: Eligible patients were those diagnosed since 2004 with an AAV, according to expert site rheumatologist (MD-diagnosis) at 37 ARChiVe centers. Data collection items in the registry included all elements of BVAS and a PGA for patients at the time of diagnosis. After BVAS items were extracted and individual patient scores calculated, the association between BVAS (version 3) and PGA scores was assessed using the Spearman rank correlation coefficient. The statistical analysis was performed using SPSS statistical software.

Results: 155 patients with an AAV were recruited into the ARChiVe cohort between January 2004 and March 2010. Five patients were excluded from analysis because data was insufficient to score BVAS. The MD-diagnosis of the remaining 150 patients were Wegener's granulomatosis (n = 98), microscopic polyangiitis (n = 25), Churg-Strauss syndrome (n = 3), ANCA-positive pauci-immune glomerulonephritis (n = 5), and unclassified vasculitis (n = 19). The correlation between BVAS and PGA scores was weak in children (rho = 0.379, 95% CI 0.233 to 0.509, p < 0.0001) (Figure).



Conclusion: The poor correlation of BVAS with PGA suggests either that BVAS requires significant paediatric specific modification, or, that there is no uniformity or standards of disease activity assessment among paediatric rheumatologists. The tool may also perform better measuring change of activity between visits rather than quantifying disease activity at diagnosis. Development of a standardized tool to enable clinical trials in children to improve outcomes is essential.

Differences between PR3 and MPO-ANCA Associated Vasculitis—Population Based Study from Southern Sweden. Aladdin Mohammad[1] and Mårten Segelmark[2]. [1]Helsingborg Hospital, Helsingborg, Sweden, [2]Skåne University Hospital

Background: Antineutrophil cytoplasmic antibodies (ANCA) are useful serologic markers for diagnosis of small vessel vasculitis. Two main specificities are recognized by ELISA; proteinase 3 (PR3-ANCA) and myeloperoxidase (MPO-ANCA). Even though PR3-ANCA is usually found in patients with Wegener's granulomatosis (WG) and MPO-ANCA in microscopic polyangitis (MPA), there are many exceptions to this rule. The lack of diagnostic criteria for WG and MPA make distinction between these disease phenotypes difficult, especially early during the disease course. A separation based on serology is, however, simple and reproducible.

Objectives: To study differences at disease presentation and outcome based on ANCA type among patients diagnosed with ANCA associated systemic vasculitis (AASV) from a defined population in southern Sweden.

Method: Demographic, clinical and laboratory data at presentation in patients with AASV diagnosed during 13 years period (1997–2009) retrieved from a defined population in southern Sweden were compared by ANCA type (PR3- vs. MPO-ANCA). Organ involvement was recorded using the definitions of the Birmingham Vasculitis Activity Score. Differences in renal and patients survival were studied by Kaplan-Meier analysis.

Results: A total of 163 patients for whom positive test for either PR3- (n=92) or MPO-ANCA (n=71) was available were included in the study. The demographics, clinical and laboratory characteristics are listed in Table 1. Among patients with PR3-ANCA 56 (61%) were men compared with 31 (43%) for MPO-ANCA, p=0,029. Patients with PR3-ANCA have had significantly higher inflammatory activity and larger number of organ involvement at diagnosis. Ear-Nose-Throat involvement was more common in patients with PR3-ANCA while renal disease was more prevalent in

MPO-ANCA disease (Table 1). Among patients with MPO- ANCA and renal involvement at diagnosis, nineteen (32%) went in End Stage Renal Disease compared to 10 (16%) of PR3-ANCA (p=0.032). There were no differences in the mortality rates between the 2 groups.

Conclusions: In this population based cohort of patients with AASV, statistically significant differences in clinical and laboratory characteristics at presentation were clearly evident. In term of outcome, renal survival was worse for patients with MPO-ANCA. These findings should be taken in consideration when stratifying patients with AASV in different therapeutic strategies.

Table 1.

	PR3-ANCA N. 92	MPO-ANCA N. 71	p-value
Sex, Male (87), N. (%)	56 (61%)	31 (43%)	0,029
Age at diagnosis, median (range), years	65 (20–88)	70.5 (32–92)	0,203
Diagnosis delay, median (range), months	2 (0–12)	2 (0–62)	0,037
Laboratory results, median (range)			
C-Reactive Protein g/l	119 (13–294)	50 (1–328)	<0,001
Erythrocyte sedimentation rate mm/hr	80 (4–126)	55 (8–150)	0,029
Hemoglobin g/l	111 (75–155)	107 (72–142)	0,012
Thrombocytes	410 (150–838)	324 (90–652)	<0,001
White Blood Cells	12 (7–26)	9.5 (2–20)	0,002
Creatinine μmol/l	134 (41–1214)	205 (43–1369)	0,024
N. of patients with >=3 organ systems involved	70 (76%)	40 (56%)	0,008
N. (%) of patients went in ESRD[1]	10 (16%)	19 (32%)	0,032
N. of patients died during follow-up[2]	26 (28%)	25 (35%)	0,423
Organ systems involved at diagnosis N. (%)			
General	86 (93%)	60 (84%)	0,063
ENT	56 (61%)	12 (17%)	<0,001
Chest	48 (52%)	27 (38%)	0,072
Nervous	12 (13%)	7 (10%)	0,530
Cutaneous	4 (4%)	4 (6%)	0,706
Mucocutaneous and eyes	10 (11%)	2 (3%)	0,051
Cardiovascular	4 (4%)	4 (6%)	0,706
Abdominal	5 (5%)	7 (10%)	0,284
Renal	62 (67%)	59 (83%)	0,023

Early Predictors of Neurological Long-Term Deficits in Children with Primary CNS Vasculitis. Gordon S. Soon, Ivanna Yau, Gabrielle Deveber, Derek Armstrong, Pascal Tyrrell, Jeffrey Templeton, Suzanne Laughlin and Susanne M. Benseler. The Hospital for Sick Children

Purpose: Childhood non-progressive primary CNS vasculitis (NPcP-ACNS) accounts for the majority of strokes in children. The aims of the study were 1) to report the neurological long-term outcome of NPcP-ACNS and 2) to determine early risk factors of long-term deficits in childhood vasculitis and stroke.

Methods: A single-centre cohort study of consecutive children diagnosed with cPACNS based on Calabrese criteria between January 1990 and December 2009 was performed. Patients were included if they 1) had non-progressive cPACNS (unilateral proximal stenoses and no evidence of progression >3 months) and 2) had serial clinical assessments and neuroimaging. The study excluded progressive cPACNS and angiography negative cPACNS. Data collection: 1) Demographics, preceding chickenpox; 2) Clinical characteristics, diffuse and focal neurological deficits recorded by two independent investigators, recurrence of ischemic events, 3) laboratory tests including inflammatory and prothrombotic markers and CSF analysis; 3) neuroimaging: serial Magnetic Resonance Imaging (MRI), MR angiography (MRA) and conventional angiography were blindly reviewed by two independent neuroradiologists following a previous developed protocol; 5) treatment with initial anticoagulation, antiplatelet and adjunctive immunosuppressive therapy. Outcome: Neurological deficit impacting on function as determined by Pediatric Stroke Outcome Measure (PSOM) at last follow-up. Analysis: putative early predictors of long-term deficits were tested in univariate and multivariable regression analyses.

Results: A total of 44 children with NP-cPACNS were included; were 32 were boys and 12 were girls; median age at diagnosis was 5.5 years (range 0.5–16.4 years) and median follow-up was 6.4 years; 25 (57%) had preceding chickenpox <12 months. All children presented with arterial ischemic stroke, 28 (64%) had right-sided symptoms. Headache was seen in 17 (39%), 16 (36%) had diffuse deficits and only 6 (14%) seizures. Recurrent ischemic events were observed in 13 (30%). Inflammatory markers were elevated 23 (52%). All patient had unilateral ischemic MRI lesions, including 21 (48%) with isolated basal ganglia lesions. The majority (58%) had vessel stenoses of >50%. Initial therapy: Anticoagulation in 61%, antiplatelet in 31%, both in 6% and adjunctive corticosteroids in 13 (30%). Outcome: Neurological long-term deficits were seen in 20 (45%). Children presenting with seizures (p=0.006), evidence of MRI beyond the basal ganglia (p=0.001) and/or high degree of vascular stenosis (p=0.04) were at highest risk for long-term deficits.

Conclusions: The long-term outcome of childhood vascular stroke is devastating: Neurological deficits impacting on function can be found in 45% of children with non-progressive primary CNS vasculitis, the most common cause of childhood stroke. Early predictors including seizures at diagnosis, evidence of extensive MRI lesions and high degree of vascular stenosis can identify children at highest risk for long-term deficits. Innovative, tailored treatment strategies have to target high risk patients to prevent long-term neurological damage.

2020

Effects of Imatinib Mesylate on Pulmonary Vascular Remodeling of Allergic Vasculitis in Murine Mode. Nobuhito Sasaki[2], Kohei Yamauchi[2] and Takashi Sawai[1]. [1]Department of Pathology, Iwate Medical University School of Medicine, Morioka, Iwate, Japan, [2]Division of Pulmonary Medicine, Allergy and Rheumatology, Department of Internal Medicine, Iwate Medical University School of Medicine, Morioka, Iwate, Japan

Objectives: We investigated the effects of imatinib mesylate (IM) on vascular remodeling using the murine model of allergic vasculitis with eosinophil infiltration (Exp. Lung Res. 2009. in press).

Methods: C57BL/6 mice (6–8 weeks) were sensitized with ovalbumin (OVA) and alum. The positive controls (n=12) were exposed to aerosolized OVA daily for 7 days. The other group of mice (IM treated mice) were administered with IM (4.5mg/kg, p.o.) in parallel with daily exposure to aerosolized OVA for 7 days (n=12). On 7th day, bronchoalveolar lavage (BAL) was performed and the lungs were excised for pathological analysis. Cell differentials were determined and concentrations of IL-2, IL-4, IL-5, IFN gamma and TNF-alpha in BAL fluid were measured.

Results: While there was no significant difference of total cell number in BAL fluids in between the control and the IM treated group, the ratio of eosinophils reduced significantly in the IM treated group. (control *vs* IM treated; 64.8±2.1 vs 37.6±4.3 %, p=0.004). There was no significant difference of concentrations of IL-2, IL-4, IL-5, IFN gamma or TNF-alpha in BAL fluids or serum in between the control and the IM treated group. The pathological scores reduced significantly in the IM treated group compared to the control group (control *vs* IM treated; 3.67±0.2 *vs* 2.20±0.2, p=0.0043). Intra luminal infiltration and proliferation of myofibroblasts in pulmonary arteries were reduced dramatically in the IM treated group compared to the control group. Intra luminal infiltration and proliferation of MIB1 positive myofibroblasts in pulmonary arteries were reduced dramatically in the IM treated group compared to the control group.

Conclusion: IM suppressed pulmonary vascular remodeling in the murine model of allergic vasculitis with eosinophil infiltration.

Immunostaining for MIB-1

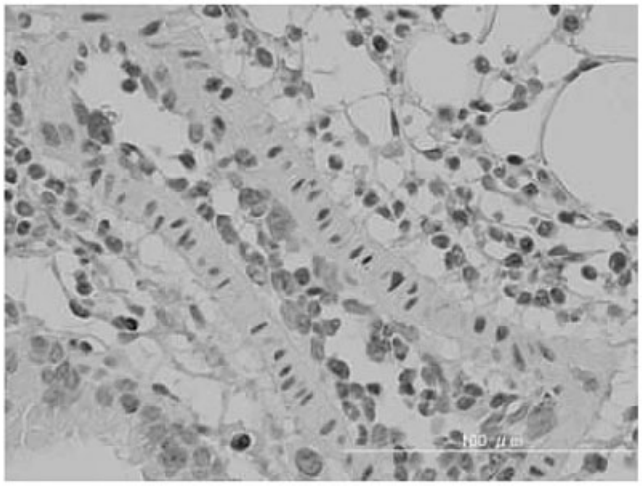

Figure 1. IM treated

MIB-1 positive inflammatory cells were seen in vascular lumen

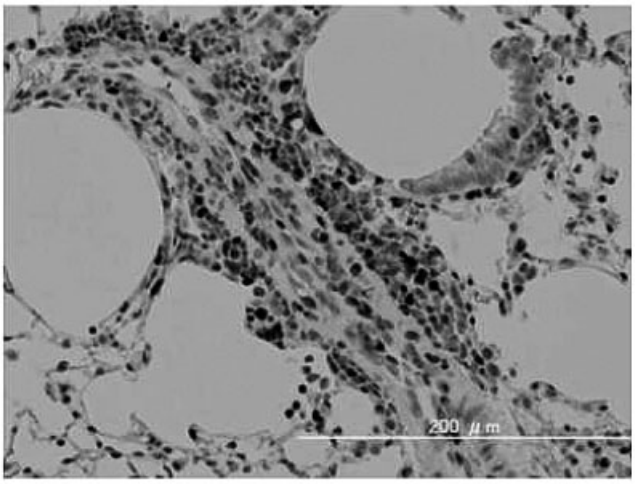

Figure 2. Control

Intra-luminal space was occluded by MIB-1-positive myofibroblasts.

2021

Endothelial Lineage Impairment and Increased PR3 Expression on Peripheral Cells of Endothelial Phenotype in Wegener's Granulomatosis. Susann Patschan, Daniel Patschan, Elvira Henze, Johannes Wessels, Sabine Blaschke and Gerhard Anton Müller. Department of Nephrology and Rheumatology, University Hospital Göttingen

Wegener's Granulomatosis (WG) is characterized by microvascular endothelial damage and by alterations of the endothelial progenitor cell (EPC) system. Interactions between anti-Proteinase 3 antibodies and their respective antigens (PR3) on neutrophils are pathogenetically relevant in WG. Aim of this study was (I) to analyze total circulating EPCs and regenerative activity of blood-dereived EPCs, and (II) to evaluate PR3 expression patterns on circulating myelomonocytic and endothelial cells in WG.

Blood samples from WG patients were analyzed for total and for Flk-1+ myolomonocytic cells (cytometric analysis). Healthy donors served as controls. For evaluating the proliferative activity of EPCs, a colony forming unit assay (CFU) was performed. PR3 expression by the cells was quantified by cytometric analysis. Serum Angiopoietin 1 and serum TNF-α were measured by ELISA technique.

A total of 21 healthy donors (12 female, 9 male [40.3 ±9.2 years]) and 31 WG patients (13 female, 18 male [59.2 ±15.3 years]) were included into the study. The total percentages of EPCs were not different between the two groups. WG patients displayed lower proliferate activity of EPCs (22.3 ±4.1 vs. 45.9 ±6.8, CFU-ECs, p=0.0027). In addition PR3 expression was significantly higher in the total as well as in the Flk-1+ (sub)population of myelomonocytic cells in WG (10.4 ±14.4% vs. 0.3 ±0.4%, p=0.02 bzw. 0.3 ±0.3% vs. 0.1 ±0.1%, p=0.04). Finally, WG patients showed lower mean serum levels of Angiopoietin 1 and higher mean serum levels of TNF-α as compared to controls (689 ±224 pg/ml vs. 1542 ±315 pg/ml, p=0.034 and 13 ±1 vs. 8.9 ±0.5 pg/ml, p=0.04), the serum levels of both cytokines did not linearily correlate with either clinical activity or the total number of circulating EPCs or the numbers of colonies formed (EPC regeneration).

In addition to reduced EPC regeneration and decreased serum levels of Angiopoietin 1, both indicating impairement of the endothelial system, patients with WG show significantly increased expression of PR3 in the total and in the Flk-1+ myelomonocytic cell population. These data imply, that PR3 could be involved in the pathogenesis of microvascular endothelial damage in patients with WG.

2022

Epidemiology of Lupus Nephritis (LN) and ANCA Associated Nephritis (AAN)—Comparison Study from a Defined Population. Aladdin Mohammad[1], Christina Ståhl-Hallengren[3], Ola Nived[3], Gunnar K. Sturfelt[3], Anders Bengtsson[3] and Mårten Segelmark[2]. [1]Helsingborg Hospital, Helsingborg, Sweden, [2]Skåne University Hospital, Lund, Sweden, [3]Skåne University Hospital, Lund, Lund, Sweden

Purpose: The aims of this study were to compare incidence rates, renal and patients' survival between Lupus Nephritis (LN) and ANCA Associated Nephritis (AAN) during a 12 year-period in a well defined population in southern Sweden.

Method: The study was carried out over a 12 year period (1997–2008) in a health care district in southern Sweden with a total population (> 95% Caucasian) of 238 069. Patients were retrieved from two existing cohorts of patients with systemic lupus erythematosus (SLE) and ANCA Associated Vasculitis (AAV). To be included in the study, patients had to (i) reside within the study area at the time of diagnosis, (ii) have a clinical diagnosis of either SLE or AAV and (iii) experience a first flare of biopsy proven nephritis during the study period. The indications for kidney biopsy were the same in both cohorts; and includes rising s-creatinine, excessive proteinuria and /or urinary sediment consistent with active nephritis. The clinical diagnosis of all patients was verified by review of case records. All patients with SLE fulfilled the American College of Rheumatology (ACR) classification criteria 1987. For AAV patients, classification was made according to an algorithm based on the ACR criteria 1990 and the Chapel Hill Consensus Conference definitions 1994.

Results: We identified a total of 43 patients with AAN (33 microscopic polyangitis, 10 Wegener's granulomatosis) and 13 patients with LN, with new onset of biopsy proven nephritis (Table 1). The annual incidence per million of the population (95 % Confidence Interval) was estimated to be 15.1(10.6–19.6) for AAN and 4.6 (2.1–7.0) for LN. 42 patients with AAN tested positive for ANCA (20 with pos. c-/PR3-ANCA and 22 with p-/MPO-ANCA). One patient with MPA was ANCA-negative. Eight patients (62%) with LN tested positive for anti-ds-DNA and 11 had complement consumption. Patients were followed until June, 1st, 2010 (median 48 months; range 1–144). During follow up 19 patients died [AAN 18; LN 1 (p=0.049)], and 13 patients went into ESRD (all with AAN). Among patients who were alive and not on renal replacement therapy at the end of follow up, 41 % of the AAN patients had an estimated GFR <50 mL/min/1.73 m^2 compared to 8.3% for the LN patients (p=0.046). The 1-, 5-, and 10-year survival for patients with AAN was 84%, 59% and 53% respectively.

Table 1.

Disease	n. of patients	Sex F/M	Age at diagnosis, median yrs (range)	s-creatinine at diagnosis µmol/l, median (range)	Incidence/10^6 (95% CI)	Mortality (n.)	ESRD (n.)
AAN	43	17/26	70 (20–88)	267 (66–1369)	15.1 (10.6–19.6)	18	13
MPA	33	16/17	71 (29–88)	339 (79–1369)	11.6 (7.6–15.5)	16	12
WG	10	1/9	58.5 (20–88)	203 (66–419)	3.5 (1.3–5.7)	2	1
LN	13	10/3	43 (25–72)	78 (51–173)	4.6 (2.1–7.0)	1	0

AAN: ANCA associated nephritis; LN: lupus nephritis; MPA: microscopic polyangiitis; WG: Wegener's granulomatosis; CI: confidence interval; ESRD: end stage renal disease.

Conclusions: In our area, AAN was three times as common as LN, and outcome was considerably worse. SLE is often diagnosed before the onset of nephritis; active and centralized follow-up at our hospital may contribute to a low incidence and benign course for LN in our area, while AAN is still often diagnosed at a later stage.

2023

Expression of Toll-Like Receptors 2, 4 and 9 by Peripheral Blood Leukocytes in Patients with ANCA-Associated Vasculitis. Henko Tadema[3], Wayel H. Abdulahad[3], Coen A. Stegeman[1], Cees G. M. Kallenberg[3] and Peter Heeringa[2]. [1]University Medical Center Groningen, Dept of Nephrology, Groningen, The Netherlands, [2]University Medical Center Groningen, Dept of Pathology and Medical Biology, Groningen, The Netherlands, [3]University Medical Center Groningen, Dept of Rheumatology and Clinical Immunology, Groningen, The Netherlands

Background: Bacterial infections have been linked to the pathogenesis of ANCA-associated vasculitis (AAV), and nasal carriage of *Staphylococcus aureus* is associated with an increased risk for relapses. Toll-like receptors (TLRs) are important sensors of pathogen associated molecular patterns, and these receptors may be important during the development of relapses in AAV. Here, we characterized the expression of TLRs 2, 4, and 9 by peripheral blood leukocytes from AAV patients in remission. We compared TLR expression in patients who were nasal carriers of *S. aureus* and non-carriers. Furthermore, we studied the effect of *in vitro* ANCA-priming on TLR expression by monocytes.

Methods: Expression of TLRs was determined using 9-color flowcytometry. Whole blood from 29 AAV patients (17 PR3-ANCA and 12 MPO-ANCA) and 19 matched healthy controls was stained for membrane markers CD3, CD14, CD16, CD19, CD27, and CD56 to distinguish between cell populations, and expression of membrane toll-like receptors (mTLR) 2, 4, and 9, and intracellular levels of TLR9 were determined. We compared TLR expression in AAV patients who were nasal carriers of *S. aureus* (n=9), and non-carriers (n=20). Peripheral blood mononuclear cells were stimulated *in vitro* with monoclonal anti-PR3 or PR3-ANCA IgG, and mTLR2 and mTLR4 expression by monocytes was determined.

Results: Membrane expression of TLRs 2, 4, and 9 by B lymphocytes and T lymphocytes was comparable in AAV patients and controls. In AAV patients, we observed increased percentages of $mTLR2^+$ (median=0.46% in AAV *vs* 0.18% in HC, $p=0.01$), and $mTLR4^+$ (median 0.37% in AAV *vs* 0.22% in HC, $p=0.02$) NK cells. Monocytes from AAV patients expressed increased levels of mTLR2, compared to HC (median ΔMFI=31.7 in AAV *vs* Δ19.8 in HC, $p=0.01$). mTLR-expression by granulocytes was comparable in patients and controls. Intracellular levels of TLR9 (iTLR9) were decreased in B lymphocytes, T lymphocytes and NK cells from AAV patients, whereas monocytes and granulocytes expressed comparable iTLR9 levels. Within AAV patients, we observed increased mTLR4 expression by monocytes from nasal carriers of *S. aureus*, compared to non-carriers (mean ΔMFI=12.6 in $Aureus^+$ *vs* mean ΔMFI=5.8 in $Aureus^-$, $p=0.02$). Priming with PR3-ANCA *in vitro* did not influence mTLR2 and mTLR4 expression by monocytes.

Conclusions: We observed increased TLR expression by a proportion of NK cells and monocytes in AAV patients in remission, compared to healthy controls. It has been suggested that ANCA trigger monocytes to increase TLR expression, but we did not observe increased TLR expression after priming with PR3-ANCA *in vitro*. Interestingly, monocytes from nasal carriers of *S. aureus* expressed increased mTLR4 levels compared to non-carriers, indicating proinflammatory conditions. Increased TLR levels on NK cells and monocytes may reflect increased activation of these cells in AAV patients, but whether relapses can be triggered via TLRs will need further investigation.

2024

Hepatitis C Virus-Associated Polyarteritis Nodosa. David Saadoun, Benjamin Terrier, Damien Sene, Thierry Maisonobe, Lucile Musset, Zahir Amoura, Mathieu Resche Rigon and Patrice Cacoub. Pitie Salpetriere Hospital

Objective: To analyse the main characteristics and outcome of polyarteritis nodosa (PAN)-type vasculitis associated with hepatitis C virus (HCV).

Methods: We reported characteristics and outcome of 31 patients chronically infected with HCV who satisfied American College of Rheumatology and Chapel Hill criteria of PAN, seen between 1990 and 2009, in a university center.

Results: Among a cohort of 161 patients with HCV-related vasculitis, 31 (19.2%) were diagnosed as having PAN. The median (Q1,Q3) age was 64.5 (49.5, 70.5) years with 54.8% of female. Compared with HCV-mixed cryoglobulinemia (MC) vasculitis, HCV-PAN displayed a more severe and acute clinical presentation with more frequent fever and weight loss ($p<0.0001$), severe hypertension ($p=0.0006$), gastrointestinal tract involvement ($p<0.0001$), severe acute sensory-motor multifocal mononeuropathy ($p<0.0001$), kidney and liver microaneurisms ($p=0.0002$) and increased C-reactive protein ($p<0.0001$). Complete clinical remission of vasculitis was achieved in 79.3% of HCV-PAN compared to 57.5% HCV-MC ($p=0.050$). In multivariate analysis, skin involvement (OR, 2.81; 95% CI 1.27 to 6.33), and PAN type vasculitis (OR, 3.01; 95% CI 1.16 to 8.96) were independently associated with a complete clinical response of HCV-vasculitis. A glomerular filtration rate lower than 70 ml/min (OR 0.54; 95% CI 0.24 to 1.21) was negatively associated with a complete clinical response of HCV-vasculitis. Clinical relapse rate was higher in HCV-PAN compared to HCV-MC (75% versus 12%, $p=0.002$, respectively under rituximab). Five-years survival rate was 86% in the whole cohort, regardless of the vasculitis type.

Conclusion: HCV-PAN account for 19.2% of our cohort of HCV vasculitis. HCV-PAN dysplay a more severe and acute clinical presentation and higher rate of clinical remission.

IL-25: A Cytokine Linking Eosinophils and Adaptative Immunity in Churg-Strauss Syndrome. Benjamin Terrier[1], Ivan Bieche[2], Thierry Maisonobe[1], Ingrid Laurendeau[2], Michele Rosenzwajg[1], Marie-Claude Diemert[1], Lucile Musset[1], Michel Vidaud[2], Damien Sène[1], Nathalie Costedoat-Chalumeau[1], Du Le Thi Huong[1], Zahir Amoura[1], David Klatzmann[1], Patrice Cacoub[1] and David Saadoun[1]. [1]Pitié-Salpétrière, [2]UMR745 INSERM

Background: Churg-Strauss Syndrome (CSS) is characterized by systemic vasculitis, and blood and tissue eosinophilia. Blood eosinophils correlate with disease activity. Activated T cells from CSS patients are predominantly Th2. IL-25 has been shown to license innate and adaptive immunity by enhancing Th2 cytokines production.

Objective: To analyze whether eosinophils could elicit a Th2 mediated immune response in CSS, we sought to determine the implication of IL-25 and its receptor IL-17RB in the pathogenesis of CSS.

Methods: We performed quantitative measurement of serum human IL-25 by ELISA, analysis of cell surface markers and cytokine production by flow cytometry and Luminex. Immunohistochemical analysis and gene quantification with mRNA on peripheral nerve biopsy samples of active CSS patients, patients with microscopic polyangiitis (MPA; disease controls) and controls with non-inflammatory axonopathy.

Results: We found increased level of IL-25 in the serum of active patient with CSS (952±697 vs. 75±49 pg/ml in inactive patients and 47±6 pg/ml in healthy donors). IL-25 correlated with disease activity and eosinophils blood level. Eosinophils were the main source of IL-25, whereas activated CD4 memory T cells were the main IL-17RB (IL-25 receptor) expressing cells in CSS. IL-25 enhanced the production of IL-4, IL-5 and IL-13 by activated peripheral blood monocytes. IL-25 and IL-17RB were observed within the vasculitic lesions of patients with CSS, and IL-17RB co-localized with T cells. Increased expression of IL-17RB, TRAF6 and JunB in vasculitic lesions of CSS underscored the IL-25-mediated activation, whereas up-regulation of GATA3 and IL-10 supported Th2 differentiation.

Conclusion: Our study is the first to demonstrate the implication of IL-25 in the pathogenesis of CSS and its correlation with disease activity. Eosinophils, through the production of IL-25, may exert a critical role in promoting Th2 responses in peripheral blood and target tissues in CSS, and represent a potential target for novel therapy.

Incidence and Predictors of Urotoxic Adverse Events in Cyclophosphamide-Treated Patients with Systemic Necrotizing Vasculitides. Guillaume Le Guenno[3], Alfred Mahr[2], Christian Pagnoux[3], Robin Dhote[1] and Loïc Guillevin[3]. [1]Internal Medicine, Hospital Avicenne, Bobigny, France, [2]Internal Medicine, Hospital Cochin, Paris, France, [3]Internal Medicine, Hospital Cochin, Paris, France

Background: Cyclophosphamide (CYC) is widely used to treat systemic necrotizing vasculitides (SNV) but its urotoxic side effects, i.e., hemorrhagic cystitis (HC) and urinary tract cancer (UTC), have raised important concerns. However, reported UTC incidence rates in CYC-treated SNV patients varied according to the study. In addition, while the cumulative CYC dose was identified as a major determinant of urotoxicity, it is not clear whether a cutoff exists below which cumulative CYC has no urotoxic effect and whether oral or intravenous CYC administration affects the urotoxic risk. Moreover, no information is available on CYC-related urotoxicity for SNV other than Wegener's granulomatosis (WG). To address these questions, we undertook a study that aimed at assessing the frequencies and predictors of HC and/or UTC in CYC-treated SNV patients.

Patients and Methods: The French Vasculitis Study Group database, which contains longitudinal data on SNV patients, was searched for UTC and/or HC occurrences in SNV patients diagnosed with WG, microscopic polyangiitis, Churg–Strauss syndrome or polyarteritis nodosa. The observed UTC incidence was compared to that expected in the French general population by calculating age- and sex-standardized incidence ratios (SIR). UTC and/or HC relationships with 10 variables, including CYC dose and administration route, were investigated by uni- and multivariate Cox proportional hazard models for a nested subgroup of patients with detailed information on CYC exposure; the variables "prior HC episode" and "cumulative CYC dose" were analyzed as time-varying covariates.

Results: Among the 805 patients analyzed (mean follow-up: 5.3 years), 22 HC and 7 UTC (6 bladder cancers, 1 ureter cancer) were identified in 27 patients. SIR for UTC was 5.00 ($P = 0.001$) and 5.96 for WG-diagnosed patients ($P = 0.03$). Based on 467 patients with detailed CYC information (mean cumulative CYC dose: 25.1 ± 38.0 g), cumulative CYC dose (hazard ratio [HR] for 10-g increments: 1.08; $P = 0.03$), ever-oral CYC administration (HR: 5.69; $P = 0.001$) and WG (HR: 2.98; $P = 0.01$) independently predicted UTC and/or HC development. Results of analyses using the effect of cumulative CYC doses as a categorical variable suggested that UTC and/or HC risk increased steadily with increasing cumulative CYC doses. Ever-tobacco smoking (HR: 7.64; $P = 0.02$) and a prior HC episode (HR: 10.91; $P = 0.006$) significantly predicted UTC.

Conclusion: CYC treatment of SNV is associated with a 5-fold higher risk of developing UTC. The urotoxicity risk for SNV patients is determined by the cumulative CYC dose and its oral intake, and might be higher for WG patients. This study's findings also support that HC should be recognized as a precursor of UTC and plead for sustained heightened awareness when prescribing this drug to tobacco smokers.

Inflammatory Aortitis: Diagnostic Performance of Aorta Wall Thickness CT-scan Measuring. Maia Forgues[8], Jacques Giron[12], Anne Hitzel[11], Anne Julian[11], Pierre Payoux[11], Daniel Adoue[10], Frédéric Degraeve[2], Serge Madaule[1], Laurent Prudhomme[3], Yann Leveneur[4], Francis Gaches[6], Xavier Delbrel[5], Leonardo Astudillo[9], Bruno Marchou[7], Philippe Arlet[10] and Laurent Sailler[8]. [1]CHG, Albi, France, [2]CHG, Auch, France, [3]CHG, Castres, France, [4]CHG, Lannemezan, France, [5]CHG, Pau, France, [6]Hôpital J Ducuing, Toulouse, France, [7]Hôpital Purpan, Infectious Diseases Department, Université de Toulouse, [8]Hôpital Purpan, Internal Medicine Department, Université de Toulouse, Toulouse, France, [9]Hôpital Purpan, Internal Medicine Department, Université de Toulouse, Toulouse, [10]Hôpital Purpan, Internal Medicine Department, Université de Toulouse, [11]Hôpital Purpan, Nuclear Medicine Department, Université de Toulouse, [12]Hôpital Purpan, Radiology Department, Université de Toulouse

Background: The measure of the aorta wall thickness (AWT) by computed tomography (CT-scan) is often used as diagnostic criteria for inflammatory aortitis. However, its diagnostic performance has not been studied.

Objective: to describe the diagnostic performance of AWT for inflammatory aortitis.

Method: This was a retrospective study from January 2005 to March 2010 including only patients who 1) had received a diagnosis of aortitis (expert diagnosis); 2) had performed a CT-scan and a PET-scan. For each case, one control was selected among patients who had performed a CT-scan and a PET-scan for the diagnosis of lymphoma in our institution. Cases and controls were matched for gender and age. Maximal AWT was measured by the same physician (JG) using a standardized procedure at the ascending aorta, descending thoracic aorta and abdominal aorta. AWT increase was validated only when it was circumferential and extended in the absence of obvious calcified atheroma plaque. The diagnostic performances of three different aortitis definitions were tested. Definition 1: at least one AWT value above the 99° percentile observed in the control group at one of the following site: ascending aorta, thoracic descending aorta and abdominal aorta; definition 2: increase of AWT above the 99° percentile of the maximal value observed in the control group whatever the aorta portion; definition 3: increase of AWT at one site or more above the more discriminating threshold determined using ROC curves.

Results: Thirty-one aortitis patients (24 women and 7 men) were recorded. Mean age was 58.1 years (range: 20 – 82). They suffered from giant cell arteritis (GCA; n=16), Takayasu arteritis (TA; n=8), ANCA-vasculitis (n=2), spondylarthritis (n=1) or unclassified aortitis (n=4). Among controls, the 99° percentile of AWT was 3 mm at the ascending aorta, 2.6 mm at the descending aorta and 2.7 mm at the abdominal aorta; the 99° percentile of maximal AWT was 3.2 mm. The best discriminating threshold determined by the ROC curves analysis was 2.6 mm, 2.2 mm and 2.4 mm respectively for the ascending, the descending and the abdominal aorta.The diagnostic performances of each definition are reported below.

Table 1. Diagnostic performance of three inflammatory aortitis definitions based on the measure of the aorta wall thickness using computed-tomography.

	Se	Sp	PPV	NPV
Definition 1	71	100	100	77.5
Definition 2	61	100	100	72
Definition 3	91,7	71	75,7	91.7

Se: sensibility; Sp: specificity; PPV: positive predictive value; NPV: negative predictive value

The diagnosis of aortitis had not been mentioned on the routine CT-scan report in 11 patients despite an increased AWT, an arterial wall contrast enhancement and/or peri-aortic edema. All these patients had a clearly abnormal PET-scan vessels imaging. All patients with a maximal AWT below 2 mm had a normal vessel's PET-scan.

Conclusion: The diagnosis of aortitis is frequently missed on routine CT-scan despite clear abnormalities. PET-scan seemed especially useful when the AWT was thicker than 2 mm and thinner than 3 mm at the ascending aorta, 2.6 mm at the descending aorta and 2.7 mm at the abdominal aorta.

2028

Interleukin-32 and Its Autoantibody Are Elevated in Patients with Wegener's Granulomatosis and Correlated with Treatment Response. Suyoung Bae[3], Yong-Gil Kim[2], Siyoung Lee[4], MinWook So[2], Chang-Keun Lee[2], Bin Yoo[1], Yong-Beom Park[5] and Soohyun Kim[3]. [1]ASAN Medical Ctr, Seoul, Korea, Republic of, [2]ASAN Medical Ctr, [3]Konkuk University, Seoul, Korea, Republic of, [4]Konkuk University, [5]Yonsei University

Background: Wegener's granulomatosis (WG) is a primary small systemic vessel vasculitis, involved prominently the respiratory tract and the kidneys. However, the etiology and pathogenesis are currently not characterized precisely. Human proteinase 3 (PR3), the major autoantigen, and anti-neutrophil cytoplasmic antibody to PR3 (PR3-ANCA) are associated with the pathogenesis of vascular damages in WG and cytokines including IFNγ and TNFα have been thought to be pivotal signal transmitters in granulomatous lesions due to recruiting lymphoid cells and activating macrophages in WG. PR3 has the ability to bind and activate IL-32, which has been recently described as a novel cytokine that induces proinflammatory cytokines (IL-1β, IL-6 and TNFα) and chemokines (IL-8 and MIP-2).

Objective: To evaluate the role of IL-32 in WG patients and the relationship between IL-32 and disease activity.

Methods and Results: The blood samples were collected from nine WG patients and the disease activity was assessed using Birmingham Vasculitis Activity Score (BVAS). We investigated the plasma levels of PR3, IL-32, TNFα, and IL-6 in WG patients using ELISA. Among them, we observed that IL-32 and PR-3 level of WG patients were increased significantly compared with healthy volunteers and each was tightly associated ($p < 0.01$). Northern blot analysis revealed that the mRNA level of IL-32 was significantly elevated in leukocytes of WG patients. The intracellular colocalization of IL-32 and PR3 in leukocyte from WG patients versus healthy volunteers was verified by immunofluorescence staining. Furthermore, the specificity in plasma concentration of IL-32 and IL-32 autoantibodies between healthy controls and WG patients was more noticeable than that in plasma levels of PR3 and PR3-ANCA. Although the significant relationship between IL-32 level and BVAS was not found, the change of IL-32 levels between pre- and post-treatment sample of three WG patients was well correlated with the change of BVAS.

Conclusion: In WG patients, the plasma level of IL-32 was increased and the decrease of this might imply the good response of treatment. Our results suggest that IL-32 could be a helpful index in WG patients and may have an important role in the disease pathogenesis.

2029

Investigation of the Effect of Histone Deacetylase 2 Function on Wegener's Granulomatosis. Dai Takagi[1], Yuji Nakamaru[2], Shigeru Akazawa[2] and Satoshi Fukuda[2]. [1]Department of Otolaryngology and Head & Neck Surgery Hokkaido University Graduate School of Medicine, Sapporo, Hokkaido, Japan, [2]Department of Otolaryngology and Head & Neck Surgery Hokkaido University Graduate School of Medicine

Background: Wegener's Granulomatosis (WG) is a systemic vasculitic disease characterized by necrotizing granulomas and vasculitis of arterioles and venules. It has been reported that anti-neutrophil cytoplasmic antibodies (ANCA) activate neutrophils result in induction of glomerulonephritis in WG by released hydrogen peroxide.

Histone deacetylase (HDAC) deacetylates histone and deacetylation of histone associates with gene repression or gene silencing. Even more importantly, HDAC2 is also key molecule of steroid action, and this reduction causes steroid insensitive inflammation, which is seen in COPD, severe asthma, rheumatoid arthritis.

In this study, we investigated whether HDAC2 function decreased in WG patients, and effect of oxidative stress on function of HDAC2.

Patients and Methods: A549 cells (lung epithelial cells) were stimulated by H_2O_2 (200 μM) to induce oxidative stress and expression of HDAC 2 were measured. We also measured HDAC 2 activity.

Six patients of WG (mean $\pm$ S.D. age $62 \cdot 5 \pm 17 \cdot 5$) diagnosed according to American College of Rheumatology criteria were examined.

Fresh PBMCs were isolated from heparinized blood by Ficoll-Conray separation and then whole cell protein was prepared. Target proteins were detected by Western blot analysis. We also measured HDAC 2 activity of PBMCs on patients.

Results: Treatment of A549 cells with H_2O_2 did not suppress expression of HDAC2. However, treatment of H_2O_2 significantly decreased total HDAC2 activity ($p < 0.05$).

We found that HDAC 2 activity was significantly decreased in WG patients compared to those from healthy subjects (HS), 75.5 ± 7.4 Arbitral Units at HS, 35.2 ± 12.3 Arbitral Units at WG ($p < 0.05$). Furthermore, we found negative correlation between HDAC 2 activity and titer of c-reactive protein and titer of PR3-ANCA. However, expression of HDAC2 did not decreased in WG patients.

Discussion: These results suggest that function of HDAC 2 is reduced in WG and that this reduction affects inflammation and vasculitis of WG. We have also confirmed that oxidative stress suppressed HDAC activity in lung epithelial cell line. Oxidative stress may worsen the disease via reduction of HDAC2 function without reduction of HDAC2 expression.

Thus, HDAC2 may serve therapeutic targets by modulating the function, which eventually regulates the development of WG.

2030

Low 25-OH Vitamin D Serum Levels Correlate with Extra-Hepatic Manifestations in Chronic Hepatitis C Virus Infection. Benjamin Terrier[2], Jean-Claude Souberbielle[1], David Saadoun[3], Guillaume Geri[3], Yoland Schoindre[3], Damien Sène[3], Lucile Musset[3] and Patrice Cacoub[4]. [1]Necker, [2]Pitié-Salpéterière, Paris, France, [3]Pitié-Salpéterière, [4]Pitié-Salpétrière

Background: Recent studies have suggested the critical role of vitamin D in the regulation of the immune system, in promoting the development of regulatory T cells and decreasing pro-inflammatory cytokines and B cell differentiation. Correlation between low levels of 25-OH vitamin D and disease activity have been reported in various autoimmune disorders. The beneficial role of vitamin D administration was also suggested in chronic HCV infection.

Objective: To evaluate the association between serum 25-OH vitamin D levels and the presence of extra-hepatic manifestations and immunological abnormalities during chronic HCV infection.

Patients and Methods: Ninety-four HCV+ RNA+ untreated patients [36 without mixed cryoglobulinemia (MC), 10 with asymptomatic MC and 48 with MC-vasculitis) were included. Clinical and biological characteristics were recorded and compared according to vitamin D status. Vitamin D status was classified as: deficiency if serum 25-OH vitamin D level < 12, insufficiency between 12 and 30, and sufficiency > 30 ng/ml. Kruskal-Wallis test was used to compare groups. Correlations between serum 25-OH vitamin D levels and biological and immunological features were analyzed using nonparametric Spearman correlation.

Results: Overall, 84 (89%) patients had hypovitaminosis D (< 30 ng/ml). Patients were distinguished according to vitamin D status: sufficiency (n=10), insufficiency (n=52), and deficiency (n=32). Demographical and HCV infection characteristics were similar between groups. Patients with vitamin D deficiency vs. insufficiency vs. sufficiency had more frequently: vasculitis (75 vs. 42 vs. 20%; P=0.002), arthralgia (50 vs. 31 vs. 20%; P=0.11), neuropathy (59 vs. 38 vs. 20%; P=0.048), purpura (63 vs. 35 vs. 10%, P=0.004), and renal involvement (28 vs. 12 vs. 10%, P=0.11). Biologically, patients with vitamin D deficiency vs. insufficiency vs. sufficiency had more frequently type II MC (77 vs. 46 vs. 10%; P=0.002) and low C4 serum levels (86 vs. 47 vs. 0%; P<0.0001). A negative correlation was found between 25-OH vitamin D and C4 serum levels (r^2=0.20; P=0.001) and the level of marginal zone B cells (r^2=0.24; P=0.001), and a positive correlation with regulatory T cells (r^2=0.23; P=0.005).

Conclusion: In chronic HCV infection, low 25-OH vitamin D serum levels correlate with clinical and biological immune extra-hepatic manifestations. These findings suggest the potential benefit of vitamin D supplementation in HCV infected patients with extra-hepatic manifestations.

2031

Patulous Eustachian Tube: A Novel Form of Damage in Wegener's Granulomatosis. Philip Seo[1] and Howard W. Francis[2]. [1]Johns Hopkins Bayview Medical Center, Baltimore, MD, [2]Johns Hopkins University

Background: The patulous eustachian tube (PET) is an uncommon syndrome caused by intermittent inappropriate patency of the eustachian tube that results in autophony. We explored whether this disorder might be more common among patients with Wegener's granulomatosis.

Methods: Symptoms associated with the patulous eustachian tube were elicited from patients with a known diagnosis of systemic vasculitis using a standardized survey form. Demographics, vasculitis type, and treatment history were also recorded. Descriptive statistical analyses were performed based on patients who reported symptoms commonly associated with this disorder. Pearson chi-square analysis was used for group comparisons.

Results: One hundred fifty-two surveys were sent to patients evaluated at the Johns Hopkins Vasculitis Center; 123 subjects (80.9%) completed the survey and returned for tabulation. The respondents were comprised of 43 men and 80 women (1:2 ratio), who had a median age of 50 years (range: 17–85). One hundred twenty (97.6%) of subjects had autoimmune disease. One hundred thirteen subjects (91.2%) had a diagnosis of vasculitis that had been confirmed by a rheumatologist; these patients carried a diagnosis of vasculitis for a median of 7 years. 64.2% of subjects had ANCA-associated vasculitis (i.e., Wegener's granulomatosis, microscopic polyangitis, or the Churg-Strauss syndrome).

Of the patients who had been diagnosed with vasculitis, 2/113 had been diagnosed previously with patulous eustachian tube; neither subject had received treatment for this diagnosis. Fifty-four subjects (47.8%) reported at least one symptom associated with PET, most commonly ear fullness (44.2%). Forty subjects (35.4%) complained of an increased awareness of his or her own voice. Based on their reported symptoms, 16 subjects were considered "highly probable" for having PET. These patients had symptoms for a median of 5 years, and 11/16 (68.6%) are still symptomatic. On a Likert scale of 0–5, where 5 represents "intolerable" symptoms, these subjects rated their current symptoms with a median score of 2. Nine patients report having developed symptoms prior to or at the time they were diagnosed with vasculitis; 3 patients report developing symptoms only after they had been in remission.

Of the 60 patients surveyed who had Wegener's granulomatosis, 36 (60%) had at least one symptom attributable to PET. Eleven patients with Wegener's granulomatosis (18.3%) were "highly probable" for having PET.

Conclusions: Symptoms attributable to PET are common among patients with Wegener's granulomatosis, possibly due to direct involvement of the eustachian tube. The majority of these patients are both symptomatic and undiagnosed. In many cases, these symptoms predate the diagnosis of vasculitis, implying that this may be a presenting symptom of Wegener's granulomatosis in some patients.

2032

Phase 1 Clinical Safety, Pharmacokinetic and Pharmacodynamic Evaluation of the Novel C5aR Antagonist CCX168, a Potential Therapeutic for ANCA-Vasculitis. Daniel J. Dairaghi, Juan C. Jaen, Kara Deshayes, Daniel A. Johnson, Manmohan R. Leleti, Shichang Miao, Jay P. Powers, Lisa C. Seitz, Yu Wang, Thomas J. Schall and Pirow J. Bekker. ChemoCentryx

Purpose: A single and multiple-ascending dose Phase 1 study has been conducted in healthy volunteers (HVs) to establish the safety, tolerability, pharmacokinetic (PK) and pharmacodynamic (PD) profile of the orally administered C5aR antagonist CCX168. This compound has been shown to completely block anti-MPO induced glomerulonephritis (GN) in mice. This work has paved the way for clinical evaluation of CCX168 in patients with ANCA-associated vasculitis/glomerulonephritis.

Methods: In the Phase 1 program, 40 male or female HVs received either placebo or 1–100 mg CCX168 orally, in a single-dose or a multiple-dose (7 days) regimen. Blood was collected at pre-specified time points for PK and PD analyses. Ex vivo analysis of C5aR receptor coverage on blood neutrophils was performed based on C5a-induced chemotaxis and CD11b expression. A similar PD assay was performed on blood samples from mice dosed orally with CCX168. PK/PD requirements were defined for complete inhibition of C5aRmediated neutrophil activation and anti-MPO induced GN by CCX168 in transgenic C5aR knock-out mice expressing human C5aR.

Results: CCX168 potently blocks C5a-mediated chemotaxis of human neutrophils in human blood (IC_{50} 2 nM) and CD11b upregulation (IC_{50} 4 nM). CCX168 was well tolerated, with excellent oral bioavailability and dose-proportional increases in exposure in both periods of the Phase-1 clinical study. No serious adverse events or withdrawals due to adverse events were observed. Plasma levels of CCX168 of 197 ng/mL (~400 nM) were reached after a 100-mg dose. These levels of CCX168 far exceed those required in the anti-MPO mouse model for near-maximal GN prevention. Twelve hours following a 100-mg single dose of CCX168 in HVs, there was a 94% reduction in C5a-induced CD11b upregulation on blood neutrophils (*ex vivo* PD assay). At this dose, plasma distribution half-life was 7.8 hours and terminal half-life was about 29 hours.

Conclusions: CCX168 showed an excellent safety and tolerability profile in HVs. PK and PD data indicate that 30–50 mg CCX168 bid in humans should result in greater than 90% C5aR coverage in blood at all times, considered optimal for CCX168 evaluation in Phase 2 trials in vasculitis.

Predictors of Outcome in Juvenile Polyarteritis Nodosa: A Multicenter Study. Fernanda Falcini[1], Francesco La Torre[7], Giorgia Martini[7], Fabio Vittadello[7], Antonella Boncompagni[10], Fabrizia Corona[6], Maria Alessio[3], Elisabetta Cortis[2], Silvia Magni-Manzoni[8], Giuseppina Calcagno[5], Luciana Breda[4], Matilde Beltramelli[6], Manuela Pardeo[9], Serena Capannini[1], Marco Matucci Cerinic[1] and Francesco Zulian[7]. [1]Dpt of BioMedicine, Division of Rheumatology, Transition Unit, University of Florence, [2]Dpt of Medicine, Division of Rheumatology, Ospedale Pediatrico, [3]Dpt of Pediatrics, Rheumatology Unit, Ospedale Federico II, [4]Dpt of Pediatrics, University of Chieti, Chieti, [5]Dpt of Pediatrics, University of Messina, [6]Dpt of Pediatrics, University of Milan, [7]Dpt of Pediatrics, University of Padua, [8]San Matteo Hospital, Pavia, [9]Scientific Institute Bambino Gesu, Rome, [10]Scientific Institute G. Gaslini, Genoa

Background: Polyarteritis nodosa (PAN) is a necrotizing vasculitis, seldom reported in childhood and adolescence. The disease is more frequent in Asian populations but it has been reported in all ethnical groups.

Aims: 1.To describe the clinical features, at onset and during the disease course; 2.To look for possible predictive factors related with outcome or persistent damage in a cohort of Italian pts with paediatric onset PAN.

Method: A retrospective data collection of demographic, clinical and therapeutic characteristics from 50 Caucasian pts (21M, 29F) fulfilling EULAR/PRES criteria for the diagnosis of PAN, from 8 Paediatric Rheumatology Units and 1 Transition Unit, were collected. Mean age at onset was 7.9 yrs (range 2–16 yrs) and the mean follow up 6.2 yrs (range 0.3–16.4 yrs).Correlation among symptoms and internal organs involvement at onset, during the disease course and final outcome or persistent damage was made.

Results: At onset, skin involvement and systemic symptoms were the most common findings in 36/50 pts (72%); nodules the main cutaneous manifestation (40%), fever the most frequent systemic symptom (66%). Other early clinical manifestations were musculo-skeletal symptoms (54%), renal (12%), CNS involvement (10%), peripheral nervous system (6%), cardiac involvement (6%), and gastrointestinal manifestations (4%). All pts received corticosteroids either oral or IV, 16 pts (32%) azathioprine, 20 pts cyclophosphamide (20%, 15 oral and 5 iv), 9 (18%) thalidomide, 7 (14%) IVIG, 5 (10%) methotrexate, 4 (8%) mycophenolate mofetil, and 2 (4%) biological agents (etanercept and infliximab). At the last follow up visit, 25 pts (50%) were in remission off therapy, 17 (34%) were under control on immunosuppressive drugs and 6 (12%) had persistent relapsing course. Two pts deceased because of ischemic cerebral infarction. At onset, the presence of renal involvement and fatigue significantly correlated with a bad outcome. CNS involvement, as seizures and paralysis, and nephrogenic hypertension, during the disease course, significantly correlated with the development of persistent damage.

Conclusion: The present study shows that in Caucasian children, PAN is quite severe despite the use of immunosuppressive drugs. Renal and CNS involvement seem to be the main factors affecting the final outcome.

Pregnancies in Systemic Necrotizing Vasculitides: Report on 12 Women and Their 20 Pregnancies. Christian Pagnoux[3], Véronique Le Guern, François Goffinet[1], Elisabeth Diot, Nicolas Limal, Emmanuelle Pannier, Ursula Warzocha, Vassilis Tsatsaris, Robin Dhote, Alexandre Karras, Pascal Cohen, Richard Damade, Luc Mouthon and Loic P. Guillevin[2]. [1]Gynecology and Obstetrics, [2]Hopital Cochin-Paris Univ, Paris, France, [3]Hopital Cochin-Paris Universite Descartes, APHP, Paris, France

Objective: To describe pregnancies of women with systemic necrotizing vasculitides (SNV), i.e., polyarteritis nodosa (PAN), Wegener's granulomatosis (WG), Churg–Strauss syndrome (CSS) or microscopic polyangiitis (MPA), followed over the past 15 years at 4 French centers.

Methods: Retrospective analysis of women whose SNV appeared during pregnancy or who became pregnant after SNV diagnosis.

Results: Among the 12 women identified, 1 had rupture of pancreatic artery microaneurysms at 27 weeks of gestation revealing PAN, leading to surgical hemostasis and cesarean delivery. Other 11 had 19 pregnancies after SNV diagnosis (8 in 4 WG, 6 in 3 CSS, 1 each in 3 PAN, and 2 in 1 MPA); 14 conceived during vasculitis remission. Two ended in first-trimester

abortions, 4 miscarried; the remaining 13 yielded 14 live newborns (1 twin pregnancy), with 7 preterm births. Life-threatening complications occurred during 3 of these latter 13 pregnancies and required cesarean deliveries. The twin pregnancy (in a CSS patient with initial vasculitis-related cardiac involvement, but in remission at conception) was complicated by transient maternal cardiac failure at 32 weeks. One WG patient with vasculitis-related renal damage developed thrombotic microangiopathy-associated renal impairment at 32 weeks, and another WG patient had severe pneumonia at 37 weeks. Other pregnancies were uneventful or with minor vasculitis manifestations.

Conclusion: Pregnant SNV patients should be closely monitored, since miscarriages and preterm births are not uncommon. Pregnancy does not seem to have a major impact on vasculitis activity. However, life-threatening manifestations can occur, especially in patients with vasculitis-related cardiac or renal damage.

Pregnancy Related Morbidity and Mortality in Patients with Systemic Vasculitis—A Single Centre Controlled Study. Shirish R. Sangle[1], Periklis Vounotrypidis[2], Ahlem Chaib[2], Veronica Salas-Manzanedo[2], Annette I. Briley[1], Simon Angel[1], Andrew Shennan[1], Munther A. Khamashta[1] and David P. D'Cruz[1]. [1]St Thomas' Hospital, London, United Kingdom, [2]St Thomas' Hospital

Objective: To study the outcome of pregnancy and effect of pregnancy on disease activity in patients with systemic vasculitis (SV) compared to age and ethnicity matched controls

Patients and Methods: We retrospectively studied 20 SV patients and 25 pregnancies attending the clinic since 1998. There were 4 with Wegener's WG), 3 Churg-Strauss syndrome (CSS), 3Takayasu arteritis (TA), and 2 ANCA positive vasculitis with renal involvement and 1 Henoch Schonlein purpura (HSP). All fulfilled the Chapel Hill Consensus Criteria and/ or ACR Criteria for SV. Two others had Behcet's disease, 3 urticarial vasculitis (UV), 1 adult onset Still's disease (AOSD) and 1 primary cerebral vasculitis (PCV). Two patients with WG had 2 pregnancies each and each patient with CSS, TA and UV had 2 pregnancies. Details regarding the duration of SV, antibody and hepatitis profile, disease activity—Birmingham vasculitis disease activity score (BVAS) and vasculitis damage index (VDI) were retrospectively evaluated from the notes during the pregnancy. Pregnancy outcome along with maternal and foetal complications were documented. Data regarding 19 healthy women who were matched for age, ethnicity and year of delivery formed the control group which was collected from the Obstetrics database of St Thomas' Hospital.

Results: The median age of the patients at the conception was 36 (24–46) and in the control group 36 (25–43) years. There were 16 Caucasian, 3 Asian and 1 Afro Caribbean in the SV group and 16 Caucasian, 2 Asian and 1 Afro Caribbean in the control subjects. The mean duration of SV was 3 (0–14) years. Six patients were receiving prednisolone, 10 azathioprine, 3 hydroxychloroquine and 2 no treatment during the pregnancy.

In the SV group, there were 19 successful pregnancies. There were 16 miscarriages in 7 patients. Median age of the gestation in SV was 38 (34–42) and in the controls 40 (37–42) weeks. Median birth weights in the SV group was 3.0 (2.0–5.2) and in the control subjects was 3.5 (2.28–4.32) kgs (p = NS). Six patients had pregnancy morbidity: 2 had pre-eclamptic toxemia (PET), 2 each had still births and premature deliveries and 1 patient had a post partum haemorrhage (she received heparin during pregnancy). In the control group 2 had miscarriages and 1 had PET. One patient with WG and HSP flared during the pregnancy and one other with WG required surgery in the 3rd trimester for subglottic stenosis. Eight patients with SV (2 WG, 1 each of HSP, CSS, TA, UV, AOSD and ANCA positive) flared after delivery. Four women were positive for antiphospholipid antibodies (aPL) and 2 had previous miscarriages. Three patients in the SV and 4 in the control groups were smokers. The median BVAS during pregnancy was 2 (range 1–5) and VDI was 2 (range 1–3).

Pregnancies	Miscarriages	PET*	Still birth	Premature	Postpartum bleed	Smoking	Med Gest age*	Medn Birth wt**	Median age
Vasculitis N=25	16 in 7 patients	2	2	2	1	3	38	3.0	36
Control N=21	2	1	0	0	0	4	40	3.5	36

*+PET: Pre-eclamptic toxaemia
+*Median gestational age
**Median birth weight

Conclusions: Patients with systemic vasculitis are likely to flare during pregnancy and the post-partum period and may have significant pregnancy morbidity.

Scarlato Hospital, Scafati, Salerno, Italy, [23]Section of Internal Medicine and Clinical Oncology, Department of Biomedical Sciences and Human Oncology, University of Bari, Medical School, Bari, Italy

Objectives: To develop international classification criteria for the CS.

Methods: The study was proposed by the GISC (Italian Study Group on Cryoglobulinemia), discussed between European EULAR experts, and divided in Part I, developing a questionnaire to be included in the formal, second part of the study (Part II). Positivity of serum cryoglobulins was defined as a "condition sine qua non" for CS classification. In Part I experts agreed on 17 questions putatively more sensitive and specific for CS. The questionnaire was administered to CS patients and controls (with diseases to be differentiated from CS). Study Part II involved 16 Centres from Italy and Europe. A dedicated chart included 1) a questionnaire for CS (with the discriminant questions identified by study Part I); 2) the pattern of organ involvement; 3) laboratory tests; 4) instrumental tests, as agreed. New patients with the CS (Group A) and controls, i.e., subjects with serum cryoglobulins but lacking a CS based on the golden standard judgment (Group B) and subjects without serum cryoglobulins but with clinico-laboratory features which can be observed in the course of CS (Group C)), were studied. Monovariate and multivariate analyses, additive or multiplicative combinations of items in terms of sensitivity and specificity, and the best combination

among the set of questions, clinical features and laboratory tests, were analyzed.

Results: In Part I, among 472 questionnaires (188 cases, 284 controls), a positive response to at least 2 of 3 selected resulted the best combination, showing a sensitivity of 81.9% and a specificity of 83.5% for CS. Study Part II included 272 patients in Group A, 228 controls in Group B, and 425 controls in Group C (173 C1 and 252 C2). The questionnaire developed in study Part I was validated, showing 83.8% $CI_{95\%}$ [79.4–88.2] sensitivity and 93.8% $CI_{95\%}$ [90.7–97.0] specificity for CS. The final Classification Criteria for CS, by pooling Group A and Group B data, are shown: at least 2 out of the following three anamnestic, clinical and laboratory items (questionnaire+ clinical; questionnaire + laboratory; or clinical + laboratory) provided a sensitivity of 88.5% $CI_{95\%}$ [84.3–92.8] and a specificity of 93.6% $CI_{95\%}$ [89.5–97.7] for CS. The same criteria proved also useful for the comparison of group A vs. C, to suspect a CS in patients cryoglobulin-negative by initial testing, since sensitivity for CS was 88.5% $CI_{95\%}$ [84.3–92.8]) and specificity 97.0% $CI_{95\%}$ [94.6–99.4] (a sensitivity of 88.5% [84.3–92.8] and a specificity of 95.4% [90.9–99.8] respectively, when comparing A only with the C1/ systemic vasculitis subgroup).

Preliminary Classification Criteria for the CS

satisfied if at least 2 of the 3 items (questionnaire, clinical , laboratory) are positive

i. Questionnaire item: at least 2 out of the following

- Do you remember one or more episodes of small red spots on your skin, particularly involving the lower limbs?
- Had you ever had red spots in your lower extremities which leave a brownish color after their disappearance?
- Did a doctor ever tell you that you have viral hepatitis?

ii. Clinical item : at least 3 out of the following 4 (present or past)

• Constitutional symptoms	Fatigue
	Low grade fever (37-37.9°C, >10 days, no cause)
	Fever (>38°C, no cause)
	Fibromyalgia
• Articular involvement	Arthralgias
	Non erosive arthritis
	Erosive arthritis
• Vascular involvement	Raynaud's phenomenon
	Purpura
	Necrotizing vasculitis
	Skin ulcers
	Hyperviscosity syndrome
• Neurologic involvement	Peripheral neuropathy
	Cranial nerve involvement
	CNS involvement
	Autonomic dysfunction

iii. Laboratory item : at least 2 out of the following 3 (present)

- Reduced serum C_4
- Positive serum rheumatoid factor
- Positive serum M component

Conclusion: International classification criteria for the CS were developed, including items easily accessible, and showing a very high specificity and a good sensitivity. A validated questionnaire is available for epidemiologic studies.

2037

Primary Central Nervous System Vasculitis Presenting with Intracranial Hemorrhage. Carlo Salvarani[1], Robert D. Brown, Jr[3], Kenneth T. Calamia[2], Teresa J. H. Christianson[3], John Huston III[3], James F. Meschia[2], Caterina Giannini[3] and Gene G. Hunder[3]. [1]Hospital of Reggio Emilia, Italy, [2]Mayo Clinic, Jacksonville, FL, [3]Mayo Clinic, Rochester, MN

Objective: Primary Central Nervous System Vasculitis (PCNSV) is an uncommon and heterogeneous condition that affects the brain and spinal cord. This study was undertaken to evaluate the clinical features and outcomes of patients who presented with intracranial hemorrhage (IH) in the context of the largest cohort of consecutive patients with PCNSV studied to date.

Methods: We identified 131 consecutive patients with PCNSV seen over the 25 year period of 1983 to 2007. PCNSV diagnoses were based on findings from a central nervous system (CNS) biopsy or conventional angiography (or both). We compared patients presenting with IH (within 3 months of the date of PCNSV diagnosis) to those without. We evaluated data on demographics, clinical findings, laboratory studies, imaging, biopsy of brain or spinal cord (or both), treatment and neurologic outcome.

Results: 16 (12.2%) cases had IH at presentation.12 patients had intracerebral hemorrhage (ICH), and 4 subarachnoid hemorrhage. Cerebral angiography was performed in 13 patients and showed multiple-vessel vasculitic changes in all. CNS biopsy findings were positive in 4 patients. Three patients had an acute necrotizing pattern, one had a granulomatous inflammatory pattern. Amyloid angiopathy was observed in 2 biopsy-positive specimens.

Compared with the 115 patients without, the 16 patients presenting with IH were more frequently females (100% versus 50.4%, $p < 0.001$), persistent neurological deficit or stroke (12.5% versus 42.6%, $p = 0.027$) and altered cognition (25% versus 56.5%, $p = 0.030$) occurred less frequently, and the frequency of patients who had discontinued therapy by the last follow-up visit was higher (37.5% versus 14.2%, $p = 0.031$). MRI and angiographic findings (excepted the presence of ICH), type of therapy (corticosteroids only or associated to immunosuppressive agents), therapy duration, frequencies of relapses, cerebrospinal fluid abnormalities, and Rankin disability score at last follow-up were similar. The survival curves of patients with and without IH were not different.

Conclusion: IH is not a rare presenting finding of PCNSV. These patients are predominantly females. The higher frequency of patients not requiring therapy at last follow-up suggests a more favorable response to therapy. An association with amyloid angiopathy may be present

Disclosure: C. Salvarani: None; **R. D. Brown, Jr:** None; **K. T. Calamia:** None; **T. J. H. Christianson:** None; **J. Huston III:** None; **J. F. Meschia:** None; **C. Giannini:** None; **G. G. Hunder:** None.

2038

Primary Central Nervous System Vasculitis: Analysis of 131 Patients. Carlo Salvarani[1], Robert D. Brown, Jr[3], Kenneth T. Calamia[2], Teresa J. H. Christianson[3], John Huston III[3], James F. Meschia[2], Caterina Giannini[3] and Gene G. Hunder[3]. [1]Hospital of Reggio Emilia, Reggio Emilia, Italy, [2]Mayo Clinic, Jacksonville, FL, [3]Mayo Clinic, Rochester, MN

Purpose: To analyze the clinical findings, response to therapy, outcome, and clinical subsets of primary central nervous system vasculitis (PCNSV) in a large cohort from a single center.

Methods: In the present study we use our updated cohort of 131 consecutive patients with PCNSV seen over the 25 year period of 1983 to 2007 at Mayo Clinic, Rochester, MN. The diagnosis of PCNSV was based on brain/spinal cord biopsy or cerebral angiography. The modified Rankin scale was used to evaluate the functional status. CNS tissue specimens from 63 cases were examined histologically. Clinical findings and outcomes were compared among patients categorized by method of diagnosis, response to therapy, survival, and degree of disability.

Results: Ninety patients were diagnosed by angiography and 41 by CNS biopsy. A granulomatous inflammatory histologic pattern was found in 23 patients (accompanied by vascular deposits of amyloid beta peptide in 11), a granulomatous and necrotizing pattern in 1, an acute necrotizing pattern in 9, and a lymphocytic pattern in 6. Headache (61.8%), altered cognition (52.7%), hemiparesis (40.5%), and persistent neurologic deficit or stroke (38.9%) were the most common initial symptoms. Intracranial hemorrhage occurred 16 cases (12.2%) within 3 months of the date of PCNSV diagnosis. Erythrocyte sedimentation rates at diagnosis were normal in most of the patients (median: 8 mm/hr, range: 0–110 mm/hr). Cerebrospinal fluid specimens showed 1 or more abnormal findings for 81/101 (80.2%) patients. Of the 97 patients with angiograms showing vasculitic changes, multiple-vessel abnormalities were bilateral in 94.8%. Magnetic resonance imaging (MRI) was performed initially in 118 patients and showed abnormal findings in 113 (95.8%). Infarctions were seen in 65 (55.1%). Bilateral multiple infarctions were found in 48 of the 65 (73.8%) patients. Gadolinium-enhanced intracranial lesions were observed in 39% of the patients. Glucocorticoid therapy was prescribed for 128 of the 131 patients. In 55 patients, glucocorticoids were the only therapeutic agents used, while 73 patients received medication in addition to glucocorticoids (cyclophosphamide in 60 patients). A favourable response to glucocorticoid alone was observed in 78% and to glucocorticoid plus cyclophosphamide in 76%. 26% had relapses that led to a change in therapy. Survival of patients with PCNSV was significantly reduced. The reduced survival rate was due to 10 patients who died for stroke-related fatalities within 6 months after the diagnosis. These patients more frequently had paraparesis/quadriparesis at presentation, angiographic presence of bilateral, larger-vessel vasculitis, and MRI evidence of multiple and bilateral cerebral infarctions.

Conclusions: PCNSV is a rare disease that may result in serious neurological outcomes or death. Angiography and brain biopsy may complement each other when determining the diagnosis. Early recognition and treatment may reduce poor outcomes.

2039

Prognostic Factors in Hepatitis C Virus Patients with Systemic Vasculitis. Benjamin Terrier[1], Oren Semoun[2], David Saadoun[1], Damien Sène[1], Matthieu Resche-Rigon[2] and Patrice Cacoub[1]. [1]Pitié-Salpéterière, [2]Saint-Louis

Objective: Hepatitis C virus (HCV)-related systemic vasculitis can cause significant morbidity and mortality. Most of the prognostic studies reported in the literature are derived from old heterogeneous studies performed before the antiviral therapy era.

Methods: 151 consecutive HCV RNA+ patients with systemic vasculitis prospectively followed-up between 1993 and 2009 were analyzed for clinical, biological and therapeutic factors associated with survival.

Results: After a median follow-up of 54 months, 32 patients (21%) died, mainly of infection (n=10) and end-stage liver disease (n=10). One-year, 3-year, 5-year and 10-year survival rates were 96, 86, 75 and 63%, respectively. Baseline factors associated with a poor prognosis were the presence of severe liver fibrosis (Metavir score $\geq$ 3) [hazard ratio (HR) 5.31], central nervous system (HR 2.74), kidney (HR 1.91), and heart involvement (HR 4.2). The Five Factor Score (FFS), a vasculitis scoring system, was significantly associated with outcome in HCV-related systemic vasculitis patients. In multivariate analysis, the Metavir liver fibrosis score (HR 10.8) and the FFS (HR 2.49) were significantly associated with a poor prognosis. During the follow-up, the use of the Peg-interferon plus ribavirin combination was associated with a good prognosis (HR 0.34). on the contrary, the use of immunosuppressant agents was associated with a poor outcome after adjustment for vasculitis severity (HR 4.05). In patients without severe liver fibrosis, the FFS was a good predictor of outcome, while in those with severe fibrosis, the vasculitis severity no longer had prognostic value.

Conclusion: In HCV-related systemic vasculitis patients, at the time of vasculitis diagnosis, severe liver fibrosis and vasculitis severity are the main prognostic factors. Use of antivirals is associated with a good prognosis, whereas immunosuppressants have a negative impact.

Risk Factors for Aortitis among Patients with Pathological Examination after Resection of the Thoracic Aorta in Denmark 1997–2009: A 12-Year Nationwide Population-Based Cross-Sectional Study. Jean Schmidt[1], Kaare Sunesen[2], Jette Kornum[2], Pierre Duhaut[1] and Reimar Thomsen[2]. [1]Amiens University Hospital and RECIF, Amiens, France, [2]Department of Clinical Epidemiology, Aarhus University Hospital, Aalborg, Denmark

Background: Population-based data on prevalence and risk factors for aortitis are scarce. The aim of our study was to assess them in a nationwide population-based cross-sectional study in Denmark.

Patients and Methods: We identified all adults hospitalized for first surgery of the thoracic ascending aorta between January 1, 1997 and March 1, 2009. Aortic inflammation was ascertained by linkage with nationwide pathology databases. We used logistic regression to examine whether sex, age at surgery, cardiovascular risk factors, cancer, and infectious diseases were associated with aortitis.

Results: During the study period, 1,210 adults underwent a resection of the ascending part of the aorta, and 610 (50.4%) had a pathological examination. Aortitis was found in 37 (6.1%). Ten of the 37 patients were diagnosed with conditions associated with aortitis or aortic aneurysm: five with temporal arteritis, one with Crohn's disease, one with rheumatoid arthritis, one with systemic lupus erythematosus, one with infectious aortitis, and one with Marfan's disease. Twenty-seven patients had idiopathic aortitis. Predictors of aortitis included a history of connective tissue disease (adjusted OR 4.7, 95 % CI 1.6 to 13.6), diabetes (OR 5.2, 96% CI 0.9–29.7), age > 67 years (OR 2.5, 95% CI 0.8–7.6), and aortic valve pathology (OR 2.3, 95% CI 1.1–4.9).

Conclusions: Aortitis was present in 6.1 % of adults with ascending aorta resection. This highlights the relevance of systematic pathological examinations of aorta. Predictors of inflammation included connective tissue disease, with a tendency for diabetes and advanced age.

2041

Rituximab Maintenance Therapy for Relapsed Wegener's Granulomatosis and Microscopic Polyangiitis. Claire Roubaud-Baudron[3], Christian Pagnoux[3], Julien Le Guen[3], Mathilde de Menthon[3], Sandra Camps[1], Jessie Aouizerate[3], Véronique Le Guern[3], Pascal Cohen[3], Luc Mouthon[3] and Loic P. Guillevin[2]. [1]Department of Pharmacy, Hopital COchin, APHP, Universite Paris Descartes, [2]Hopital Cochin-Paris Univ, Paris, France, [3]Internal Medicine, Hopital Cochin, APHP, Universite Paris Descartes, France

Background: After induction therapy, 50% of Wegener's granulomatosis (WG) and 33% of microscopic polyangiitis (MPA) patients relapse. Rituximab (RTX) effectively induced remission of 1st relapses and refractory disease, but its place in remission maintenance is unknown. In this study, we retrospectively analyzed RTX efficacy as maintenance therapy.

Methods: Patients entered in our department database who had received $\geq$2 RTX maintenance infusions, regardless of induction regimen, between 2003 and 2010, were selected. Their main characteristics (diagnosis, clinical and biological data (ANCA, CD19 and Ig levels) and treatment histories), RTX maintenance details (number, dose and periodicity), tolerance and outcomes were analyzed.

Results: Four MPA and 24 WG patients (median age 55.5 (range 18–78) yr; 18 (58%) men) were included. The cumulative median cyclophosphamide (CYC) dose was 48 (range 10–250) g. At last relapse, patients had several organ involvements: 19 ENT, 17 lung, 11 arthralgias, 11 fever, 9 nephropathy, 3 neuropathy and/or 4 eyes.

Induction treatment had been RTX for 21, conventional corticosteroid (CS)+CYC for 5, and IVIg for 2 (1 also with methotrexate). RTX maintenance (375 mg/m^2 biannually for 15 patients, 1 g biannually for 4, 1 g yearly for 3 and different regimens for 6) was chosen because RTX had obtained remission for 21, cytotoxic agent side effects for 2, persistent manifestations after >4 yr of azathioprine (AZA) or mycophenolate mofetil (MMF) for 1 each, previous relapse(s) under cytotoxic maintenance therapy for 2, or renal failure for 1. Patients had received 4 (range 2–10) RTX infusions at 38 (range: 21–97) months of follow-up since their last relapses. Cotreatments included CS for 23 (82%) patients and other cytotoxic agents (AZA for 5, MMF for 5, leflunomide for 1 and/or MTX for 4) for 14 (50%). At the last assessment, 5 (17%) patients were still taking cytotoxic agent(s); median CS dose was 5 (range: 2–20) mg/day. RTX infusions were well-tolerated; 3 patients developed infections (1 cutaneous abscess, 1 otitis and 1 H1N1-flu death).

Two major pulmonary relapses (at follow-up months 48 & 6) and 2 minor ENT relapses (at follow-up months 108 & 34) occurred. Fifteen patients had hypogammaglobulinemia (predominantly IgM). Notably, the 3 patients not CD19-depleted did not relapse. Nine (including 3/4 who relapsed) patients' CD19 levels rose before their biannual RTX infusion. Five patients ANCA-negative at vasculitis onset, remained so. ANCA levels increased before reinfusion in 7 (including 3/4 who relapsed) patients. Overall, at their last assessment, mean ANCA titers for all 28 patients had declined significantly since the last relapse and the last RTX infusion (ANOVA, $p<0.0001$).

Conclusions: RTX effectively maintained remission and was well-tolerated. It can be indicated, especially for noncompliant patients or when cytotoxic drugs are contraindicated. Only 2 major relapsed occurred. It is too early to conclude as to the place of CD19 and ANCA levels as indicators to determine infusion periodicity. The ongoing randomized controlled "MAINRITSAN" trial was designed to compare RTX to AZA maintenance therapy for ANCA-associated vasculitides.

Safety and Efficacy of Rituximab in Non-Viral Cryoglobulinemia Vasculitis: Prospective Data from the French AIR Registry. Benjamin Terrier[15], David Launay[6], Gilles Kaplanski[10], Arnaud Hot[9], Claire Larroche[1], Pascal Cathebras[12], Bernard Combe[11], Jean-Pierre Jaureguiberry[14], Olivier Meyer[3], Thierry Schaeverbeke[8], Alexandre Somogyi[5], Leila Tricot[13], Thierry Zenone[4], Philippe Ravaud[3], Jacques-Eric Gottenberg[7], Xavier Mariette[2] and Patrice Cacoub[15]. [1]Avicenne, [2]Bicêtre, [3]Bichat, [4]CH Valence, [5]CHI Saint-Germain, [6]CHRU Lille, [7]CHRU Strasbourg, [8]CHU Bordeaux, [9]CHU Lyon, [10]CHU Marseille, [11]CHU Montpellier, [12]CHU St Etienne, [13]CMC Foch, [14]HIA Toulon, [15]Pitié-Salpétrière

Background: Therapeutic management of non-hepatitis C virus cryoglobulinemia vasculitis (CryoVas) has still to be defined, although it is traditionally based on a combination of corticosteroids and immunosuppressants or plasmapheresis. Rituximab (RTX) has emerged as a novel and promising therapeutic alternative, but data are scarce since only few case reports have been reported in the literature.

Objectives: To evaluate safety and efficacy of RTX in non-viral CryoVas in off-trial real life patients.

Methods: Prospective data from the French AutoImmunity and Rituximab (AIR) registry, which includes patients with autoimmune disorders treated with RTX, were analyzed. The epidemiologic, clinical, and biologic data from every patient were collected at baseline, 3 and 6 month follow-up and then every 6 months. Toxicity and side effects were recorded on the standardized e-CRF.

Results: Twenty-three patients received treatment with RTX for non-viral CryoVas. Tolerance was marked by the occurrence of side effects in almost half of patients, including severe infections in 6/23 (26%), with a rate of 14.1/100 patient-years. These infections occurred in a particular subset of patients with age $>$ 70 years, essential type II mixed cryoglobulinemia, renal failure with GFR $<$ 60 mL/min and using high dose corticosteroids. Three of these patients died. In contrast, clinical and immunological efficacy was noted in all evaluable patients. Clinical relapses occurred in half of patients after a median time of 13.5 months following RTX administration and were more frequent in patients refractory to previous immunosuppressive therapy than in previously untreated patients.

Conclusion: Data from the AIR registry show a dramatic efficacy and a steroid-sparing effect of RTX, but the occurrence of severe infections in aged patients with renal failure and high dose steroids. The role of RTX in non-viral CryoVas remains to be defined in well designed randomized controlled trials.

2043

Seasonal- (SFV) and H1N1-Flu Virus (HFV) Vaccination for Patients with Autoimmune Diseases (AID): The Prospective MAIVAX Trial on 174 Patients. Alex Kostianovsky[2], Michele Goulet[2], Jean Francois Alves[2], Veronique Le Guern[2], Christian Pagnoux[2], Pascal Cohen[2], Alice Berezne[2], Anne Krivine[2], Luc Mouthon[2], Odile Launay[2] and Loic P. Guillevin[1]. [1]Hopital Cochin-Paris Univ, Paris, France, [2]Internal Medicine, Hopital Cochin, APHP, Universite Paris Descartes, Paris, France

Objective: The theoretical risk for AID and immunosuppressed patients exposed to the new H1N1 flu pandemic in June 2009, along with the historical debate on the role of vaccination in the context of AID relapses, led us to evaluate the efficacy and safety of SFV and HFV vaccinations in AID patients treated or not with immunosuppressants (IS).

Patients and Methods: A monocenter vaccine phase III prospective open study on 174 patients was conducted from September 2009 to June 2010. Subjects received SVF (1 dose, Mutagrip®) and/or non-adjuvant HFV (Panenza®, 2 doses at a 3-wk interval) vaccines. Due to their dates of commercial availability, SFV was administered 3 wk before HFV. The primary judgment criterion was the seroprotection rate: the % patients with positive anti-hemagglutinin–Ab titers (PAT) $\geq$1/40: 3 or 9 wk after SFV and 3 wk after the 2nd HFV shots. Secondary outcome measures were seroconversion rates, vaccine tolerance (no fever $>$37.8°C and/or local signs during the 3 days postinoculation), and numbers of flu syndromes (fever + cough and/or throat pain) and AID flares throughout the pandemic.

Results: AID included were: 62 systemic vasculitides (polyarteritis nodosa, microscopic polyangiitis, Wegener's granulomatosis, Churg–Strauss syndrome (CSS), Behçet's disease and cryoglobulinemia), 32 progressive systemic sclerosis (PSS), 29 systemic lupus erythematosus (SLE), 23 Sjögren syndrome (SS, with detectable autoAb) and 28 others. After SFV inoculation, 79.13% of the patients were seroprotected (110/139, 106 tested 3 wk and 4 tested 9 wk postvaccination, had PAT), 64 (46%) seroconverted (prevaccination PAT rose 4-fold for 14), 37 (26.6%) had prevaccination PAT; 2 (1.4%) became febrile and 27 (19.4%) developed local signs post-vaccination. After HFV immunization, 65% of the patients (113/174 with PAT) were seroprotected, 94 (54%) seroconverted (prevaccination PAT rose 4-fold for 7), 19 (10.9%) had prevaccination PAT; 6 had become HFV-positive after SFV immunization; 8 (4.6%) developed a fever (6 after the 1st dose and 2 after the 2nd dose) and 39 (22.4%) had local signs.

Concerning adverse events occurring during the study, among 12 patients developing 15 flu syndromes, 2 were temporally related to both vaccines (same patient); 1 patient died of septic shock and 2 AID flares were temporally related to inoculation: polyneuritis in a CSS patient (3 days after the 1st HFV dose), and severe myalgias and arthralgias in a PSS patient (10 days post SFV injection); 4 temporally unrelated AID flares occurred (2 PSS, 1 SLE and 1 SS).

Conclusion: Given the low rates of temporally associated events, tolerance of both vaccines was acceptable. The seroprotection rate was higher after SFV than HFV immunization, for similar seroconversion rates. Potential relationships between these data and ongoing IS are being analyzed. Notably, SFV induced PAT against the H1N1 virus in a minority of patients. Our findings demonstrated the safety and efficacy of SFV and HFV vaccination in AID patients.

2044

Small-Vessel Vasculitis Surrounding an Uninflamed Temporal Artery: A Population-Based Italian Study. Giovanna Restuccia, Luigi Boiardi, Alberto Cavazza, Luca Magnani, Maria Grazia Catanoso, Gianluigi Bajocchi, Fulvia Rossi, Pierluigi Macchioni, Ilaria Chiarolanza, Andrea Caruso, Nicolò Pipitone and Carlo Salvarani. Arcispedale S Maria Nuova, Reggio Emilia, Italy

Purpose: Small-vessel vasculitis (SVV) surrounding an uninflamed temporal artery (TA) is an often neglected pathological form of giant cell arteritis (GCA). A recent study showed a strong association between SVV and polymyalgia rheumatica (PMR). The aim of this study was to evaluate the prevalence and clinical significance of SVV surrounding an uninflamed temporal artery (TA) in an Italian population-based cohort of patients who received TA biopsy for a suspected diagnosis of GCA.

Methods: All TA biopsies performed in our Hospital between January 1986 and December 2005 were reviewed by a pathologist (AC) who was blinded to the clinical diagnosis. SVV was defined as aggregates of mononuclear inflammatory cells surrounding a capillary, distant from an uninflamed temporal artery. 180 patients residing in Reggio Emilia area with biopsy-proven GCA and 44 with SVV were identified. The identified patients with SVV were randomly matched to an equal number of biopsy-proven GCA patients. All inpatient and outpatient medical records were reviewed. Demographic, clinical, and laboratory data of patients in SVV group (n = 44) were compared with data of control group with biopsy proven GCA (n = 47).

Results: The table shows the comparisons between the patients with SVV and those with biopsy proven GCA.

Table. Characteristic of the patients with SVV compared to those of the patients with biopsy proven-GCA

	Patients with SVV (N=44)	Patients with biopsy proven GCA (N=47)	P
Male/female	18 (40.9%)/27 (59.1%)	13 (27.7%)/34 (72.3%)	0.194
Age at disease onset, Years mean ±	72 ± 11	75 ± 7	0.285
Headache	17/43 (39.5%)	33/47 (70.2%)	0.006
Scalp tenderness	1/42 (2.4%)	14/45 (31.1%)	0.000
Abnormalities of temporal arteritis	10/21 (47.6%)	29/33 (87.9%)	0.002
Visual loss	6/43 (14.0%)	7/47 (14.9%)	1.000
Jaw claudication	2/43 (4.7%)	14/47 (29.8%)	0.002
Systemic signs/symptoms	25/43 (58.1%)	37/47 (58.1%)	0.042
Polymyalgia rheumatica	24/43 (55.8%)	22/47 (46.8)	0.408
ESR at diagnosis, mm/hour; mean ± SD	84 ± 32	102 ± 21	0.008
CRP at diagnosis, mg/dl; mean ± SD	6.4 ± 6.4	9.9 ± 5.7	0.001
Initial prednisone dose, mg/day; mean ± SD	31.4 ± 17.5	65.1 ± 84.8	0.0001
Duration of prednisone therapy, months; mean ± SD	30.84 ± 35.60	35.14 ± 48.02	0.639
Cumulative prednisone dose, mg; mean ± SD	5,997 ± 7,610	9,459 ± 7,627	0.006
Duration of follow-up, months; mean ± SD	68.51 ± 52.56	48.30 ± 39.54	0.068
Relapse/recurrences	7/24 (29.2%)	14/40 (35.0%)	1.000

Conclusion: SVV appears to be a less severe form of GCA characterized by a reduced frequency of cranial manifestations, lower values of ESR at diagnosis, and lower cumulative prednisone dose. Differently from previous findings, SVV was not associated with PMR.

Systemic Necrotizing Vasculitides in the Elderly: Baseline Data on the 101 Patients ≥65 Years Old Enrolled in the CORTAGE Multicenter Trial. Christian Pagnoux[8], Florence Rollot[9], Thomas Quemeneur[7], Jacques Ninet[4], Elisabeth Diot[3], Xavier Kyndt[7], Benoît de Wazières[12], Jean-Luc Reny[2], Xavier J. Puechal[1], Pierre-Yves Leberruyer[13], Olivier Lidove[11], Pascal Godmer[10], Aimé Albath-Sadiki[14], Severine Poignant[14], Pascal Cohen[8], Luc Mouthon[8], Loic P. Guillevin[6] and The FVSG[5]. [1]Centre Hospitalier Du Mans, Le Mans, France, [2]CH Béziers - Narbonne, [3]CHRU TOurs, Medecine Interne, [4]CHU de Lyon - Hôpitale Edouard Herriot, Médecine Interne-Pathologie Vasculaire, [5]France, [6]Hopital Cochin-Paris Univ, Paris, France, [7]Internal Medicine, CH Valenciennes, [8]Internal Medicine, Hopital Cochin, APHP, Universite Paris Descartes, [9]Internal Medicine, Hopital Cochin, APHP, Universite Paris Descartes, [10]Medecine Interne, Centre Hospitalier Bretagne-Atlantique, BP 70555 56017 VANNES, [11]Medecine Interne, CHU Bichat, Paris Diderot, [12]Medecine Interne, CHU de Nimes, [13]Service de Medecine Interne. CHU Robert Debré. Avenue du Général Koenig. 51092 REIMS, [14]URC Cochin Tarnier, Paris Descartes

Objective: To analyze baseline characteristics of patients with systemic necrotizing vasculitides (SNV; polyarteritis nodosa (PAN), Wegener's granulomatosis (WG), microscopic polyangiitis (MPA), Churg–Strauss syndrome (CSS)) enrolled in the corticosteroid-based treatment for SNV patients aged ≥65 yr (CORTAGE) trial.

Methods: We analyzed their baseline clinical and biological manifestations, i.e., at diagnosis. At that time, patients were classified according to their prognostic five-factor score (FFS) and randomized to receive conventional treatment (corticosteroids alone for ~28 months for CSS or PAN patients with FFS=0; or combined with 500-mg/m2 cyclophosphamide pulses every 2 wk for the first 3 pulses then every 3 wk until remission, for WG or MPA patients, and CSS or PAN patients with FFS≥1, then switched to azathioprine or methotrexate for maintenance) or the experimental regimen (for all patients, corticosteroids for ~9 months, combined with cyclophosphamide pulses at a fixed 500-mg dose every 2 wk for the first 3 pulses then every 3 wk until remission, and switched after a maximum of 6 pulses to azathioprine or methotrexate for maintenance). The CORTAGE primary endpoint is morbidity at 3 years.

Results: Between July 2005 and February 2008, 108 patients were randomized; 7 were excluded (early consent withdrawn, protocol violation, wrong diagnosis). Mean age at diagnosis of the 101 analyzed patients (54 males, 47 females; 8 PAN, 12 CSS, 34 WG, 47 MPA) was 75.3 ± 6.3 yr, with a maximum of 92 years for 1 MPA patient. Sixteen PAN or CSS patients had FFS=0 (7/8 PAN, 9/12 CSS). Complete data on clinical features at diagnosis were comparably distributed between arms: 50 (50%) with fever, 36 (36%) arthralgias, 58 (57%) lung (15 nodules, 16 alveolar hemorrhages, 4 ARDS), 37 (37%) ENT, 20 (20%) GI, 18 (18%) heart (4 severe cardiac insufficiencies), 16 (16%) skin purpura, 13 (13%) ophthalmological (5 episcleritises), 24 (24%) PNS and 3 (3%) CNS manifestations. Mean creatinine was 236±210 μmol/l (61 microscopic hematuria, 8 initially required dialysis). Mean hemoglobin level was 10.2±2.0 g/dl, neutrophils 8538±4098/mm3, lymphocytes 1452±674/mm3, C-reactive protein 103±89 mg/l, albumin 28.0±6.3 g/l.

Seven (6.9%; 4 conventional-arm, 3 experimental-arm) patients died during induction. All had received cyclophosphamide: 4 (3 MPA, 1 WG) died of SNV progression, 2 (WG) of sepsis and 1 (MPA) of previously unknown cholangiocarcinoma.

Conclusion: Despite having severe disease, as reflected by their high mean creatinine level at diagnosis, mortality of SNV patients ≥65 years old included in the CORTAGE trial was relatively low during induction. Treatment-related morbidity and relapse rate remain to be determined (end of trial follow-up: April 2011).

Systemic Vasculitis in Patients with Hepatitis C Virus Infection with and without Detectable Mixed Cryoglobulinemia: Towards a Unique Entity. Benjamin Terrier[1], Damien Sène[1], Agnès Dechartres[2], David Saadoun[1], Lucile Musset[1], Matthieu Resche-Rigon[2], Thierry Maisonobe[1] and Patrice Cacoub[1]. [1]Pitié-Salpéterière, [2]Saint-Louis

Background: More than 80% of mixed cryoglobulinemia (MC) are associated with hepatitis C virus (HCV) infection. Some patients develop symptomatic MC, a systemic vasculitis that mainly affects the small and, less frequently, medium-sized vessels. MC vasculitis leads to clinical manifestations ranging from the so-called MC syndrome (purpura, arthralgia, and asthenia) to more serious lesions with neurologic and renal involvement. It has been described few patients with peripheral neuropathy occurring with HCV infection without detectable MC.

Objectives: To describe HCV-related systemic vasculitis without detectable MC and to compare them to typical HCV-MC vasculitis.

Methods: The study population consisted of 60 patients with HCV infection (HCV RNA+) and chronic active liver disease. The 12 cases (men/women 5/7, mean age 60±17 years) were defined as patients with histologically proven systemic vasculitis who had not shown evidence of MC on numerous occasions during a follow-up of 55±38 months. Each case was matched for age and sex with 4 controls. The 48 controls (men/women 20/28, mean age 60±14 years) were randomly selected from our data base of patients with typical HCV-MC, i.e. patients who had serum MC levels > 0.05 g/L on at least on two occasions associated with the triad of purpura/arthralgia/asthenia and sometimes renal or neurological involvement.

Results: The main epidemiological and virologic features were similar between cases and controls. No clinical difference was found, except for lower rates of arthralgia (33% vs. 71%, p=0.02) and purpura (50% vs. 83%, p=0.03) in cases. Cases compared to controls showed higher mean serum C3 (1.17 ± 0.21 vs. 0.93 ± 0.23 g/L, p=0.01) and median C4 levels (0.25 vs. 0.04 g/L, p<0.001), lower median serum IgM levels (0.6 vs. 1.9 g/L, p<0.001), and lower rates of rheumatoid factor positivity (8% vs. 82%, p<0.001). Main pathologic features were similar between cases and controls. After treatment, overall clinical response of vasculitis (75% vs. 83%) and sustained virological response (40% vs. 64%, p=0.3) were similar between cases and controls, except for higher complete clinical response (42% vs. 73%, p=0.05) in controls.

Conclusions: Practitioners should be aware of the occurrence of systemic vasculitis during HCV infection in the absence of detectable serum MC. Systemic vasculitis without MC showed quite similar epidemiological, clinical, biological, virologic and pathological features as MC vasculitis. Therapeutic management and response to therapy were also comparable between patients with and without MC. Such similarities suggest that vasculitis induced by chronic HCV infection, whatever the presence or the absence of MC, should be considered as a unique entity.

2047

The Correlation between Circulating Microparticles and Platelet Aggregation and Disease Activity in Wegener Granulomatosis. Rula Hajj-Ali[3], Roy Silverstein[1], Gary Hoffman[1], Li Zhang[1], Peter Imrey[1] and Carol A. Langford[2]. [1]Cleveland Clinic, [2]Cleveland Clinic Foundation, Cleveland, OH, [3]Clevelnad Clinic, Cleveland, OH

Background: The objective of this study is to determine whether there are correlations between platelet aggregation and/ or circulating microparticles (MP) and disease activity in Wegener's granulomatosis (WG)

Methods: Eligible consenting adult patients who met the ACR 1990 classification criteria for WG were enrolled from the Cleveland Clinic Center for Vasculitis Care and Research. Controls were subjects who did not have WG or other chronic inflammatory diseases. Exclusion criteria for patients and controls included acute or chronic infection within the past 3 months, NSAID or aspirin use within a week of platelet and MP studies, or diagnosis of a chronic inflammatory diseases, an autoimmune disease, or thrombophilia. Data on WG disease activity was captured by BVAS-WG.

Platelet aggregation was assessed turbidometrically with a dual channel aggregometer using graded doses of ADP (1, 2, 5, and 10 μM). The change in light transmission after addition of ADP was recorded and expressed as a percentage of maximum deflection. MP counts were assessed by flow cytometry from platelet poor plasma. MP were stained by Annexin V and further characterized for cellular origin using specific antibodies to endothelial cells (CD105, CD144), platelets (CD41), leukocytes (CD18), neutrophils (CD16b) and monocytes (CD14). Each marker was assessed separately.

Results: 46 patients were included; 38 in remission and 8 during acute disease relapse. The two groups did not differ in age or gender. Subjects in relapse had

1- a significant increase in leukocyte derived MP compared to those in remission, and

2- platelets with increased sensitivity to activation by ADP (Table 1).

Table 1. Comparison of MP counts and platelet aggregation between flare and remission groups

Factor	Flare (N=8)	Remission (N=38)	P value
Age (years)	61 ± 13	54 ± 13	0.20
Female	5 (63)	17 (45)	0.45
CD14 - MP counts	477 (386, 797)	249 (67, 409)	0.030*
CD16 - MP counts	182 (127, 219)	56 (26, 100)	0.006*
CD18 - MP counts	257 (210, 314)	63 (36, 106)	0.002*
Platelet aggregation (1μM ADP)	28 (18, 38)	5 (2, 10)	0.005*
Platelet aggregation (2 μM ADP)	49 (43, 71)	19 (7, 26)	0.005*
Platelet aggregation (5 μM ADP)	82 (78, 98)	36 (26, 57)	0.009*
Platelet aggregation (10 μM ADP)	87 (78, 92)	51 (38, 70)	0.008*

Normally distributed data were expressed as mean ± SD and analyzed with the P from the T-test; Non-normally distributed data were expressed as median (25th, 75th) percentiles and analyzed with the P from the Wilcoxon rank sum test. N and percentage for categorical variables with Fisher exact test.

We also assessed the association of MP levels to platelet aggregation in WG vs. healthy controls (N=21). There were moderately positive linear relationships between levels of CD14, CD16 and CD18 expressing MP and platelet aggregation responses in WG patients. There were no statistically significant associations in the control group (Table 2).

Table 2. Correlation of Platelet aggregation and MP counts in WG and healthy controls

	Platelet aggregation	MP	N	rho	95%CI	P value
WG Patients	ADP 1μM	CD14	41	0.43	(0.14, 0.65)	0.006
		CD16	41	0.47	(0.19, 0.68)	0.002
		CD18	41	0.64	(0.41, 0.79)	<0.001
	ADP 2 μM	CD14	44	0.38	(0.09, 0.61)	0.011
		CD16	44	0.40	(0.12, 0.63)	0.007
		CD18	44	0.54	(0.28, 0.72)	<0.001
	ADP 5 μM	CD14	44	0.35	(0.06, 0.58)	0.021
		CD16	44	0.31	(0.01, 0.55)	0.042
		CD18	44	0.45	(0.18, 0.66)	0.002
	ADP 10 μM	CD14	41	0.32	(0.02, 0.57)	0.039
		CD16	41	0.30	(−0.01, 056)	0.058
		CD18	41	0.43	(0.14, 0.65)	0.005
Controls	ADP 1 μM	CD14	19	0.31	(−0.11, 0.84)	0.13
		CD16	19	0.25	(−0.18, 0.79)	0.13
		CD18	19	0.28	(−0.21, 0.77)	0.25
	ADP 2 μM	CD14	21	0.25	(−0.21, 0.72)	0.27
		CD16	21	0.18	(−0.29, 0.65)	0.43
		CD18	21	0.28	(−0.18, 0.74)	0.22
	ADP 5 μM	CD14	21	0.41	(−0.03, 0.85)	0.067
		CD16	21	0.37	(−0.08, 0.81)	0.1
		CD18	21	0.44	(0.01, 0.87)	0.046
	ADP 10 μM	CD14	20	0.08	(−0.41, 0.58)	0.73
		CD16	20	0.07	(−0.43, 0.56)	0.78
		CD18	20	0.15	(−0.33, 0.64)	0.52

Conclusions: Levels of leukocyte derived MP and sensitivity of platelets to ADP-induced aggregation correlate with disease flares in WG. The correlation between MP counts and platelet reactivity seen in WG but not controls suggest that elevated levels of leukocyte-derived MP generated during chronic inflammation may sensitize platelets to activation and contribute to athero-thrombotic complications. Whether these events also contribute to injury in WG is worthy further studies.

The Human C5a Receptor (hC5aR) Antagonist CCX168 Effectively Ameliorates a Model of ANCA Glomerulonephritis (GN) in hC5aR Knock-in Mice. Hong Xiao[2], J. C. Jennette[3], D. J. Dairaghi[1], L. Ertl[1], T. Baumgart[1], S. Miao[1], J. P. Powers[1], L. C. Seitz[1], Y. Wang[1], P. Hu[3], R. J. Falk[3], T. J. Schall[1] and J. C. Jaen[1]. [1]ChemoCentryx, [2]University of North Carolina, Chapel Hill, NC, [3]University of North Carolina

Purpose: Intravenous injection of mouse anti-myeloperoxidase (anti-MPO) IgG causes GN and vasculitis in mice that mimics antineutrophil cytoplasmic autoantibody (ANCA) disease in patients. We have shown that alternative pathway complement activation and resultant C5a are involved in pathogenesis. Here we study the effects on this model of CCX168, an orally active antagonist of human C5a receptor (hC5aR) that has completed Phase 1 trials. We also evaluated CCX168 pharmacokinetic, pharmacodynamic and therapeutic endpoints in mice using the same assays of hC5aR blockade used in the human Phase 1 trial.

Methods: Humanized mice with knock-in of human C5aR and knock-out of mouse C5aR (hC5aR KI mice) were injected with anti-MPO IgG; and received CCX168 doses ranging from 0.1–30 mg/kg qd, or vehicle alone. The potency of CCX168 for C5aR in hC5aR KI mice was assessed by 125I-C5a binding and chemotaxis assays. C5a-induced neutrophil CD11b expression was used to assess CCX168 C5aR blockade in mice and compared to results using the same assay in humans.

Results: CCX168 had similar C5aR antagonist potency on human and hC5aR KI mouse neutrophils (inhibition of C5a-mediated chemotaxis in blood, IC50 2 nM; inhibition of C5a-induced CD11b upregulation in blood, IC50 4 nM). 30 mg/kg CCX168 markedly reduced the severity of anti-MPO induced GN. Glomerular crescent formation was reduced from 29.3% with vehicle alone to 3.3% with CCX168 ($p<0.0001$) and glomerular necrosis from 8.2% to 1.1% ($p<0.0001$). Urine protein, leukocytes and RBCs, and serum BUN and creatinine also were reduced in mice receiving CCX168. 0.1 mg/kg/d CCX168 caused 30% reduction in crescents. The lowest dose that produced a near-maximal therapeutic benefit was 4 mg/kg CCX168 bid (with plasma levels from 35 to 200 ng/mL throughout the day, and C5aR blockade ranging from 95 to 99%). As reported in

a separate meting abstract, plasma CCX168 levels of 197 ng/mL (~400 nM) were reached with a 100-mg dose in a human Phase 1 trial.

Conclusions: Orally active human C5aR antagonist CCX168 markedly suppresses the induction of GN by anti-MPO IgG in mice with knocked-in human C5aR. CCX168 doses that induce a near-maximal therapeutic benefit in mice produce CCX168 plasma levels and C5aR blockade that were attainable and well tolerated in Phase I human trials. These results support an important role for C5aR engagement by C5a in the pathogenesis of anti-MPO induced GN, which is a model for human ANCA GN, and thus support the possible therapeutic benefit of C5aR blockade in human ANCA disease.

The Relationship between Disease Status in Wegener's Granulomatosis with the Development of Subclinical Atherosclerosis. Rula Hajj-Ali[5], Roy Silverstein[2], Douglas Joseph[1], Peter Imrey[2], Gary S. Hoffman[4], Li Zhang[2] and Carol A. Langford[3]. [1]Cleevland Clinic, [2]Cleveland Clinic, [3]Cleveland Clinic Foundation, Cleveland, OH, [4]Cleveland Clinic Foundation, Pepper Pike, OH, [5]Cleveland Clinic, Cleveland, OH

Background: A role for inflammation in the development of accelerated atherosclerosis in patients with chronic inflammatory disease has been proposed. However, the pathophysiology of this process is not fully understood. The objective of this study was to asses the relationship between inflammatory disease in Wegener's granulomatosis (WG) with the development of subclinical atherosclerosis.

Methods: Eligible consenting adult patients who met the 1990 ACR classification criteria for WG were enrolled from the Cleveland Clinic Center for Vasculitis Care and Research. Exclusion criteria included history of coronary heart disease, heart failure, stroke, peripheral vascular diseases, acute or chronic infection within the past 3 months, NSAID or aspirin use within a week of MP and platelet studies, or diagnosis of chronic inflammatory disease, an autoimmune disease, or thrombophilia. Disease status was measured by BVAS-WG, VDI, disease duration and numbers of relapses (from onset of disease diagnosis until enrollment in the current study). Classic atherosclerotic risk factors and other co-morbidities were recorded in addition to platelet aggregation responses and circulating microparticle (MP) levels. All patients underwent ultrasound of the carotid arteries to assess intima media thickness (IMT) as an outcome for subclinical atherosclerosis.

Results: 45 WG patients were included. In univariate analyses, systolic and diastolic blood pressure, creatinine, and age at onset of disease were significantly associated with a higher IMT with rho values of 0.37, 0.38, 0.35 and 0.54 respectively ($p < 0.02$ for all), determined by Spearman rank correlation (Table 1).

Table 1. Spearman rank correlation between IMT and patient characteristics

Outcome	Variable	N	rho	95%CI	P value
IMT	BMI	44	0.19	(−0.12, 0.49)	0.23
IMT	Systolic blood pressure	45	0.37	(0.09, 0.66)	0.012
IMT	Diastolic blood pressure	45	0.38	(0.09, 0.66)	0.011
IMT	Creatinine	45	0.35	(0.06, 0.64)	0.019
IMT	HDL	45	−0.21	(−0.51, 0.10)	0.18
IMT	LDL	45	−0.19	(−0.50, 0.11)	0.2
IMT	FBG	45	0.12	(−0.18, 0.43)	0.42
IMT	Age at onset of disease	45	0.54	(0.28, 0.80)	<0.001
IMT	Disease Duration	45	0.23	(−0.07, 0.53)	0.13
IMT	Azathioprine Duration	45	−0.24	(−0.53, 0.06)	0.12
IMT	Methotrexate Duration	45	0.11	(−0.20, 0.41)	0.48
IMT	Cyclophosphamide Duration	45	−0.13	(−0.43, 0.18)	0.41
IMT	Cumulative Dose of cyclophosphamide	45	−0.15	(−0.45, 0.16)	0.34
IMT	Total MP counts	45	−0.18	(−0.48, 0.12)	0.23
IMT	Annexin counts	45	−0.2	(−0.50, 0.10)	0.18
IMT	CD_14 MP counts	45	−0.04	(−0.34, 0.27)	0.81
IMT	CD_16 MP counts	45	−0.12	(−0.42, 0.19)	0.45
IMT	CD_18 MP counts	45	0	(−0.31, 0.31)	0.99
IMT	CD_41 MP counts	45	−0.16	(−0.47, 0.14)	0.29
IMT	CD_105 MP counts	45	−0.21	(−0.51, 0.09)	0.16
IMT	CD_144 MP counts	45	0	(−0.31, 0.31)	0.99
IMT	CD_235 MP counts	43	−0.05	(−0.37, 0.26)	0.73
IMT	Platelet aggregation	40	0.24	(−0.08, 0.56)	0.14

When all variables were considered in a multiple regression model that included the total number of disease relapses, and after adjusting for the other significant factors, higher relapse number, older age at onset of disease, and higher diastolic blood pressure were found to be associated with higher IMT as shown in Table 2.

Table 2. Multiple regression model for assessing the association between IMT and sum of Flares

Outcome	Parameter	Estimate (%95 CI)	P value
IMT	Flare sum	0.0119 (0.0001, 0.0236)	0.003
	Age at onset of disease	0.005 (0.003, 0.008)	<0.001
	Diastolic blood pressure	0.0033 (0.0003, 0.0064)	0.031

Conclusion: This is the first study that addresses disease status as it relates to atherosclerosis in WG. Our data suggests that total number of disease relapses, but not disease duration, is a more important risk factor for atherosclerosis and implies that the cumulative inflammatory events contributes to the development of atherosclerosis.

'Specialized Generalists': How Do Rehabilitation Therapists Practice in Rural Areas? Robin K. Roots, Linda C. Li, Lesley Bainbridge and Helen Brown. University of British Columbia, Vancouver, BC, Canada

Background: The health disparity between rural and urban residents, including higher rates of arthritis and other chronic diseases, necessitates innovative practice models for rehabilitation professionals, who are already in short supply in rural areas. The **purpose** of this research is to better understand the barriers and facilitators to rehabilitation practice from the perspectives of occupational therapists (OTs) and physical therapists (PTs) working in rural regions.

Methods: OTs and PTs living and working in rural communities within a provincial health authority were recruited through a mail out to workplaces. Using purposive sampling, therapists were selected according to their range of experience in rural practice and the health care setting, source of funding and service delivery model in which they worked. Following a semi-structured interview guide, therapists were asked to describe how the rural context shapes their practice using an example of service provision for a patient with arthritis. Face-to-face interviews were recorded and transcribed. Guided by the methodological approach of interpretive description, data was analysed inductively to identify concepts of rural practice and extrapolate practice insights and exemplary strategies used by therapists. An analytic framework was used to map relationships between themes, concepts and cases. Rural rehabilitation practice paradigms will be interpreted to consider implications for practice change.

Results: Of the 43 eligible clinicians, 11 PTs, 6 OTs and 2 combined trained OT/PTs agreed to participate. Consistent with the literature, rural therapists described themselves as 'specialized generalists' referring to the broad scope of practice deemed essential to providing service to the diversity of their caseloads. While maintaining competency in a large number of practice areas presents significant challenges, therapists articulated strategies based on the unique context and features of rural practice. Skills and knowledge listed by therapists as essential to rural practice included: 1.) waitlist priority setting; 2.) drawing upon a large network of professional and community resources; 3.) recognizing boundaries to competency through reflective practice; and 4.) the importance of collaborating with other practitioners. Collaborative practice was seen as optimal in providing client centred care but not always achievable given limited resources, isolation and professional barriers. When asked what supports would be beneficial for practitioners new to rural practice, participants highlighted the importance of practice education placements in rural communities during training, formal mentoring programs, and a greater emphasis on interprofessional education.

Conclusion: Despite the growing interest in professional specialization, rural therapists appear to maintain general practice and interprofessional collaborative service delivery models in order to equitably meet the demands of the rural population and transcend the limited local health resources and services.

Background: In 2001 the *Royal Dutch Society for Physical Therapy (KNGF) Guideline for hip and knee osteoarthritis (HKOA)* was developed. Since then, many scientific papers on physical therapy interventions as well as national and international guidelines were published.

Objectives: To update the physical therapy guideline based on current evidence and best practice.

Methods: Topics concerning the three guideline chapters: initial assessment, treatment and evaluation were selected by a guideline development committee consisting of 10 expert physical therapists. With respect to treatment a systematic literature search (up to June 2009) within various databases was performed aiming to identify reviews and randomized controlled trials (RCTs) on the effectiveness of physical therapy interventions and the evidence was graded (1–4). For initial assessment and evaluation mainly review papers and textbooks were used. Based on evidence and expert opinion, recommendations were formulated (5 consensus meetings and 8 feedback rounds) and graded (A-D). A first draft of the guideline was reviewed by 17 experts from different professional backgrounds (2 feedback rounds). A second draft was field-tested by 45 physical therapists.

Results: For the initial assessment, a description of relevant health related topics in HKOA was made according to *the International Classification of Functioning, disability and health (ICF) core set for osteoarthritis (OA)*. Concerning treatment, 22 systematic reviews and 74 RCTs were reviewed. Recommended were: exercise therapy, education and self management interventions, a combination of exercise and manual therapy, and postoperative exercise therapy in HKOA, and taping of the patella in knee OA. Neither recommended nor advised against were: balneotherapy, hydrotherapy, and preoperative physical therapy in HKOA; thermotherapy, TENS, and Continuous Passive Motion in knee OA. Not recommended were: massage, ultrasound, electrotherapy, electromagnetic field and Low Level Laser Therapy. For the evaluation of treatment goals the use of one or more of the following measurement instruments was recommended: daily activities and participation: Lequesne index, Western Ontario and McMaster Universities osteoarthritis index questionnaire, Hip and Knee disability and Osteoarthritis Outcome Scores, 6 Minute Walk test, Timed Stand Up and Go test and Patient Specific Complaint list; body functions and structures: Visual Analogue Scale for pain, Intermittent and Constant OsteoArthritis Pain questionnaire, goniometry, Medical Research Council for strength, Handheld Dynamometer.

Conclusions: This update of the Dutch physical therapy guideline on HKOA included recommendations on the initial assessment, treatment and evaluation. The revised guideline will be launched in February 2010 and published on www.kngf.nl (including an English translation).

Clinical Measures Associated with Self-Reported Knee Instability in Knee Osteoarthritis (KOA). G. Kelley Fitzgerald, Sara R. Piva and Stephen R. Wisniewski. University of Pittsburgh

Background: Self-reported knee instability is a common symptom that can affect physical function in people with KOA. Very little has been reported concerning factors that may be associated with self-reported knee instability in KOA. Understanding factors associated with knee instability is the first step in understanding how to treat this symptom. The purpose of this study was to examine the association between clinical assessment variables and self-reported knee instability in subjects with KOA.

Method: 158 subjects (107 female) with KOA participated in the study. Person specific measures of independent clinical variables included age, gender, body mass index, fear of physical activity, anxiety, and depression. Knee specific variables were taken on the index knee (most symptomatic knee as reported by the subject) and included radiographic severity of the medial, lateral, and patellofemoral compartments, knee pain, quadriceps muscle strength, lower extremity muscle flexibility (hip flexors, quadriceps, hamstrings, gastrocnemius) knee range of motion, frontal plane and sagittal plane passive knee laxity, and knee alignment. The dependent measure was the Knee Outcome Survey Self-Reported Instability item (KOS-SRI)(5 = no instability, 4 = instability present but does not affect function, 3 = instability minimally affects function, 2 = instability moderately affects function, 1 = instability severely affects function) participated in the study. Subjects were dichotomized as stable if the KOS-SRI score was ≥ 4 and unstable if ≤ 3. A stepwise, forward (likelihood ratio), logistic multiple regression analysis was performed to identify which clinical variables were associated with the KOS-SRI score.

Results: Table 1 summarizes the results of the regression analysis. Medial compartment radiographic severity, knee pain, depression, and hamstring flexibility were associated with the KOS-SRI score.

Table 1. Results of Stepwise Linear Regression. Nagelkerke $R^2=0.45$

Variable	beta	Odds Ratio	95% CI	p
Medial Compartment Knee OA				.054
Severity (KL grade)				
KL=1	−2.62	0.07	0.01; 0.87	.04
KL=2	2.76	15.77	0.95; 290.99	.054
KL=3	−0.29	0.75	0.22; 2.49	.63
KL=4	−0.20	0.82	0.27; 2.51	.73
Knee Pain (VAS)	−0.39	0.68	0.56; 0.82	< .001
Depression (CES-D)	−0.09	0.91	0.86; 0.97	.01
Hamstring Tightness	0.07	1.07	1.03; 1.11	<.001

Conclusion: The results indicate that a medial compartment Kellgren and Lawrence (KL) grade < 2, lower numeric knee pain rating, less depression, and tighter hamstring muscles are protective against self-reported knee instability in our sample of subjects with KOA. Longitudinal study is needed to determine if changes in these variables mediate the progression of self-reported knee instability over time.

Disclosure: G. K. Fitzgerald: None; **S. R. Piva:** None; **S. R. Wisniewski:** None.

2053

Describing the Pattern of Outpatient Physical Therapy Utilization Following Total Knee Replacement (TKR). Carol A. Oatis[1], Jessica M. DiRusso[1], Mindy J. Hoover[1], Katherine K. Johnston[1], Monika Kasinova[1] and Patricia D. Franklin[2]. [1]Arcadia University, Glenside, PA, [2]Univ of MA Med Schl, Worcester, MA

Purpose: Incidence of TKR is projected to rise 673% by 2030 to 3.48 million from 450,000 procedures in 2005. According to the 2003 NIH Consensus Statement, post-operative rehabilitation is the most understudied aspect of the management of TKR. The purpose of this study was to examine outpatient physical therapy (PT) utilization by patients who have undergone primary TKR surgery.

Methods: PT records from TKR patients participating in a NIAMS-funded clinical trial at the University of Massachusetts Medical Center were included in the study. Patients who attended outpatient PT, completed their course of care and the study's 6-month assessment were eligible for review. Records from 65 patients who underwent primary TKR were eligible for review. Forty-four outpatient PT records were reviewed from 18 facilities. Twenty-one records were not reviewed because the facilities did not respond to requests for the records. Of these 21 records, 14 were from facilities that had sent at least 1 other record. Frequency and duration of physical therapy and total number of visits were recorded. "Usual care" was operationally defined as more than 50% agreement in PT delivery. "Consensus" was operationally defined as more than 85% agreement in delivery. Univariate regression analysis assessed the associations between PT utilization and patient baseline characteristics that could be associated with greater PT need (e.g., poorer pre-op function or self-care).

Results: No agreement or consensus existed regarding timing of initiation of outpatient PT (2–8 weeks postoperatively). There was no agreement on the total number of outpatient visits (7–34) or on when to discontinue outpatient PT (7–30 weeks postoperatively). The average number of visits was 15 (SD 6.3). Although there was a trend toward correlation between time to start of post-operative outpatient PT and age ($p = .08$; $r^2 = .07$), no other relationship existed between PT utilization and baseline characteristics, including function (PCS scale of the SF36, WOMAC), emotional health (MCS scale of SF36), arthritis self-efficacy, depression (CESD) or BMI.

Conclusions: Considerable variability exists in outpatient PT utilization despite the prevalence of the procedure. Utilization appears unrelated to preoperative patient characteristics that could be associated with greater PT need. People who undergo a primary TKR still have varied functional gains one year after the surgical intervention. Research is needed to determine if the variability in post-operative outpatient PT utilization contributes to sub-optimal patient outcomes. Better understanding of outpatient PT utilization may lead to rehabilitation practices that yield optimal outcomes and are cost efficient.

Disclosure: C. A. Oatis: NIAMS-NIH, 2; **J. M. DiRusso:** None; **M. J. Hoover:** None; **K. K. Johnston:** None; **M. Kasinova:** None; **P. D. Franklin:** NIA, 2, NIAMS-NIH, 2, Robert Wood Johnson Foundation, 2.

2054

Describing the Pattern of Physical Therapy Intervention Following Total Knee Replacement (TKR). Jessica M. DiRusso[1], Mindy J. Hoover[1], Katherine K. Johnston[1], Monika Kasinova[1], Patricia D. Franklin[2] and Carol A. Oatis[1]. [1]Arcadia University, Glenside, PA, [2]Univ of MA Med Schl, Worcester, MA

Purpose: The incidence of TKR is projected to rise 673% by 2030 to 3.48 million from 450,000 procedures in 2005. According to the 2003 NIH Consensus Statement, post-operative rehabilitation is the most understudied aspect of the management of TKR. Quadriceps strength remains diminished one year after surgery and aggressive quadriceps strengthening has been shown to improve functional outcomes. The purpose of this study was to describe the outpatient physical therapy (PT) provided to patients who have undergone primary TKR surgery.

Methods: PT records from patients participating in the Joint Action clinical trial at the University of Massachusetts Medical Center were included in the study. Only records from patients who had attended outpatient PT, completed their course of care and their 6-month study assessment were eligible for review. Records from 65 patients who underwent primary TKR were eligible for review. 44 records were reviewed from 18 facilities. 21 records were not reviewed because the facilities did not respond to requests for the records. Of these 21 records, 14 were from facilities that had sent at least 1 other record. Outpatient PT records were reviewed to identify all interventions provided. Physical therapy exercise interventions were classified into open chain, functional mobility, closed chain, and advanced closed chain. Progression was operationally defined as one or more exercises that increased resistance or difficulty. "Usual care" was operationally defined as interventions used with more than 50% of patients. "Consensus" was operationally defined as interventions used with more than 85% of patients.

Results: No agreement was reached regarding strength progression. 9% of records reported no exercise progression. 30% of patients progressed in only 1 exercise (5/13 progressed straight leg raising). Specific quadriceps strength progression reached usual care (60%). Step-up exercises were the only closed chain activity that reached consensus. Step-downs reached usual care. There was no agreement on bridging or wall slides. No agreement existed in the use of advanced closed chain activities (squats was the closest at 48%). Balance and coordination training reached usual care (59%). The only modalities that reached usual care were cold packs (68%) and patellar mobilizations (57%).

Conclusions: Little uniformity exists in the post-acute outpatient physical therapy treatment of patients following TKR. Patients who undergo a primary TKR have varied functional outcomes one year after the surgical intervention. Research is needed to determine if the variability in post-operative physical therapy interventions contributes to patient outcomes.

Disclosure: J. M. DiRusso: None; **M. J. Hoover:** None; **K. K. Johnston:** None; **M. Kasinova:** None; **P. D. Franklin:** NIA, 2, NIAMS-NIH, 2, Robert Wood Johnson Foundation, 2; **C. A. Oatis:** NIAMS-NIH, 2.

2055

Factors Associated with the Use of Physical Therapy by People with Hip and Knee Osteoarthritis. Renata T. B. Jorge[1], Eric C. Sayre[4], Jacek Kopec[2], Jolanda Cibere[2], John M. Esdaile[2], Sherry Bar[3] and Linda C. Li[2]. [1]Arthritis Research Centre of Canada, Vancouver, BC, Canada, [2]Arthritis Research Centre of Canada, [3]BC Ministry of Health Services, [4]University of British Columbia

Background: Current guidelines recommend exercise as a first-line management for hip and knee osteoarthritis (OA). Physical therapists (PTs) are trained to prescribe exercise for managing arthritis; however, little is known about the factors associated with the use of physical therapy services by people with OA. This study aimed to assess factors associated with the use of physical therapy by people with hip and/or knee OA.

Methods: Eligible participants were those identified from a provincial administrative database between 1992 and 2006 as meeting the case definitions for OA, and had two or more medical visits or one hospitalization for OA within a 365-day period. We collected information on the WOMAC, use of healthcare service such as physical therapy in the past 12 months, and sociodemographics. Logistic regression was used to assess the factors associated with PT visits. Guided by the Andersen Model of Health Services Use, the dependent variables were grouped into *predisposing characteristics* (age, sex, body mass index), *enabling factors* (education, employment status, health authority region), and *need factors* (duration of diagnosis, number of comorbid conditions, estimated baseline WOMAC score). Because WOMAC was collected after the PT visits, we penalized the WOMAC scores of those who visited a PT by 15% (i.e., assuming that those who saw a PT improved by 15% after treatment). Sensitivity analyses were done by varying this assumption from 10 to 20%. Contribution of the enabling factors to PT visits was estimated by the difference of 100 minus the ratio of R^2 of the reduced model (with predisposing and need factors only) versus the R^2 of the full model.

Results: 1,349 participants completed the survey and reported having knee/hip OA (knee OA only=700; hip OA only=261; knee and hip OA=388). The mean age was 67.1 (SD=11.1), 816 (60.5%) were females, and 921 (68.3%) were diagnosed with OA 6 years ago or longer. They had an average of 1.8 (SD=1.5) comorbid conditions. 325 participants (24.1%) visited a PT in the past 12 months. Mean estimated baseline WOMAC score was 34.3 (SD=20.4). Higher education (OR=3.17, 95% CI=2.02, 4.97), living in the Fraser Health Authority (OR=0.62, 95% CI=0.40, 0.96) or Northern Health Authority (OR=0.46, 95% CI=0.29, 0.74), and having an estimated baseline WOMAC score $\geq$50 vs. $\leq$10 (OR=3.57, 95% CI=2.07, 6.16) were significant predictors for seeing a PT. Assuming physical therapy improved the WOMAC score by 15%, enabling factors accounted for 68.3% of the variance for seeing a PT that the full model accounted for. Sensitivity analyses indicated that this percentage ranged from 61.4% to 77.1%.

Conclusion: Enabling factors, rather than patients' needs, appeared to be the largest driver of the use of physical therapy by people with hip/knee OA. The findings indicated potential inequity in the use of physical therapy for the management of hip/knee OA.

2056

Impaired Knee Frontal Plane Neuro-Muscular Stabilization in Persons with Knee Osteoarthritis (KOA): A Biomechanical Study. Alison H. Chang[1], Song Joo Lee[1], Yupeng Ren[4], Heng Zhao[3] and Li-Qun Zhang[2]. [1]Northwestern University, [2]Northwestern University; Rehabilitation Institute of Chicago, [3]Rehabilitation Institute of Chicago, [4]Rehabilitation Institute of Chiicago

Purpose: Persons with KOA often report instability during activities. Lower passive capsulo-ligamentous stiffness or poor muscular stabilization in the frontal plane may compromise knee stability and lead to excessive varus-valgus (V-V) motions during walking. Understanding these frontal plane neuro-mechanical properties in KOA will help elucidate the factors contributing to knee instability and aid in the development of targeted intervention strategies. The objectives of this study were to quantify knee frontal plane passive and active stiffness and muscle strength in persons with medial KOA.

Method: 28 subjects: 14 with symptomatic radiographic medial KOA and 14 age- and gender-matched healthy controls (8 women/6 men in each group) were evaluated. A joint driving device (JDD) with a customized motor and a 6-axis force sensor measured knee frontal plane neuro-mechanical parameters. With the participant sitting on a custom built chair at knee extension, the JDD moved the knee into varus and valgus with controlled external torques, and recorded joint angle and torque outputs. For passive tissue V-V stiffness, the motor moved the knee into varus and valgus at 1 degree/sec with a maximum torque limit of 12 Nm in each direction and recorded the hysteresis curves of passive knee tissues for 12 cycles. Varus stiffness was analyzed by the ratio of the applied external torques to the resulting varus angular motion at the range of 0 to 1 degree (deg) varus. Valgus stiffness was computed similarly. For active muscle contribution to V-V stiffness, similar protocol described above was used; expect the participant was asked to contract his/her muscles to stiffen the knee and stabilize the knee against V-V motion imposed by the motor. Contribution of active muscle activity on V-V stiffness was computed by the difference in stiffness with vs. without voluntary muscle contraction. For V-V muscle strength, the participant performed knee adductor (varus) and abductor (valgus) maximal voluntary contractions, 3 trials in each direction. Visual feedback of torque output was displayed to facilitate muscle torque generation. Body weight normalized maximal V-V torque was used for analysis. We used ANCOVA with BMI as a covariate to test for differences between OA and control groups with $p < 0.05$ as significant.

Results: The mean age was 60 ± 8 (OA) and 58 ± 9 years (control); BMI 30 ± 8 (OA) and 24 ± 3 kg/m2 (control). There were no between-group differences in passive tissue V-V stiffness (varus: 3.57 ± 1.47 vs. 3.96 ± 1.25 Nm/deg, $p > 0.05$; valgus: 4.11 ± 1.83 vs. 4.07 ± 1.07 Nm/deg, $p > 0.05$). OA group had a significantly smaller change of V-V stiffness with voluntary muscle contraction (OA: 4.67 ± 2.86 vs. control: 8.26 ± 5.95 Nm/deg, $p < 0.05$), decreased varus muscle strength (0.013 ± 0.008 vs. 0.018 ± 0.008, $p < 0.05$), and a trend toward decreased valgus muscle strength (0.013 ± 0.007 vs. 0.019 ± 0.010, $p = 0.054$).

Conclusion: Persons with medial KOA had impaired active neuromuscular control in the frontal plane, including diminished ability to actively stabilize the knee in the frontal plane and to generate varus and valgus muscle torques; but did not show comprised stiffness in the passive capsuloligamentous tissues.

Physical Activity Level and Poor Disability Profile: A Population-Based Study of US Adults with Arthritis. Jennifer M. Hootman[2] and David Brown[1]. [1]CDC, [2]Centers for Disease Control, Kennesaw, GA

Background: Physical activity (PA) has been shown to improve pain and function among adults with arthritis but the relationship between PA and an overall disability profile based on the International Classification of Function (ICF) is unknown.

Methods: Data were from the 2009 Behavioral Risk Factor Surveillance System, an annual telephone health survey conducted in all 50 states and the District of Columbia (n = 424,592 adults). Arthritis (ARTH; n= 151,120) was defined as a 'yes' response to "Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?". Three outcome measures, based on ICF domains, were created: 1) impairment = severe pain (PAIN), 2) limitation = activity limitation (AL) and 3) restriction = social participation restriction (SPR). PAIN was defined as 7 or higher on a 0–10 point scale. AL was defined as a limitation in usual activities due to arthritis. SPR was defined with a question asking about the extent that arthritis interfered with social activities such as shopping, going to movies or social gatherings. Respondents reporting "A lot" (versus "A little/Not at all") were defined as having SPR. Persons who reported PAIN, AL, and SPR were classified as having a POOR disability profile. Respondents were asked how often (frequency) and for how long (duration) they did moderate and vigorous intensity PA outside of their occupation for at least 10 minutes at a time (minimum value 10 minutes/week). Minutes per week of moderate and vigorous intensity self-reported PA were summed (1 vigorous minute = 2 moderate minutes) and categorized as: Inactive (0 min/wk = referent group), Insufficient (10–149 min/wk), and Recommended (150+ min/wk). Logistic regression was used to estimate the relationship (odds ratio = OR, 95% confidence interval = CI) between PA level and each ICF domain separately and overall POOR disability profile adjusting for age, sex, race/ethnicity, education, body mass index, and self-rated health status. All analyses used statistical weights to account for the complex sample design.

Results: Among adults with arthritis, 26.3% reported PAIN, 45.6% AL, 16.8% SPR, and 11.9% were classified as having a POOR disability profile. The prevalence of having a POOR disability profile by PA level was 26.2% (CI 25.2–27.2) inactive, 12.7% (CI 12.0–13.4) insufficient, and 6.7% (CI 6.4–7.1) recommended. Higher levels of PA were associated with significantly lower odds of PAIN, AL, and SPR and a 41–63% reduced likelihood of having a POOR disability profile even after adjusting for age, sex, race/ethnicity, education, body mass index and self-rated health status (table).

	ICF Domain Adjusted OR (95% CI)			POOR Disability Profile
	PAIN	AL	SPR	
PA level				
Insufficient vs. Inactive	0.66 (0.62–0.71)	0.84 (0.79–0.90)	0.55 (0.51–0.59)	0.59 (0.54–0.64)
Recommended vs. Inactive	0.58 (0.54–0.61)	0.64 (0.61–0.68)	0.37 (0.34–0.40)	0.37 (0.34–0.41)

Conclusions: At least 1 in 10 adults with arthritis have a poor disability profile. Increasing PA in this population may improve one's disability profile, although this needs to be tested in prospective randomized controlled trials.

The Association of Arm and Back Pain with Incidence of Slow Walking in Persons with Knee Osteoarthritis: The MOST Study. Daniel White[1], Yuqing Zhang[2], Jingbo Niu[2], Michael Nevitt[3], C. Elizabeth Lewis[4], James Torner[5] and Tuhina Neogi[2]. [1]Boston University, Boston, MA, [2]Boston University, [3]University California San Francisco, [4]University of Alabama, [5]University of Iowa

Slow walking is a marker for adverse outcomes such as persistent limitation and mortality. Due to factors such as knee pain, persons with knee osteoarthritis (OA) are already at increased risk for slow walking. However, it is not known if upper body pain, such as shoulder pain affecting arm swing during gait, or back pain that may limit activity, is associated with the development of slow walking speed. Thus, we examined the independent effects of pain in the arm and back with the incidence of slow walking speed among persons with or at risk for knee osteoarthritis (OA).

The Multicenter Osteoarthritis Study (MOST) is a NIH funded longitudinal study of persons who have or are at high risk for knee OA. Pain assessments were taken at baseline, and walking speed at baseline and 30 months. We defined incidence of slow walking as < 1.0 meter per second (m/s) at 30 months, a speed shown to be a risk factor for persistent functional limitation and death in older adults, among participants whose walking speed was ≥1m/s at baseline. We quantified pain as the number of areas subjects marked on a homunculus, counted as 0, 1, or > 2. For the arm, this included both hands, wrists, elbows and shoulders, and for the back, the lumbar, thoracic, and cervical areas. We examined the association of the number of

painful areas within arm and back areas with the incidence of slow walking using risk ratios adjusted for age, sex, BMI, race, radiographic knee OA (ROA), knee pain, and pain in the hip, ankle, or foot. We additionally adjusted for the presence of widespread pain in separate analyses.

Of the 2204 persons walking at least 1.0 m/s at baseline (mean age 62 ± 8 yrs, BMI 30 ± 6 kg/m2, female 57%) 8% had incidence of slow walking at 30 months. Arm pain was present in 0, 1, and >2 areas in 39%, 15%, and 46% of persons, and back pain in 32%, 48%, and 20%, respectively. Adjusting for potential confounders, persons with arm pain in 1 and 2 or more areas were 1.6 and 1.5 times more likely to have incidence of slow walking, respectively, compared with persons without any arm pain. No association between back pain and incident slow walking was found. (see table) We found similar results in analyses adjusted for the presence of widespread pain.

The presence of arm but not back pain was associated with the incidence of slow walking. Providers should consider that pain not only in the lower body, but also in the arms is important for future walking function.

		% (Number with incident slow walking/total number of subjects)	Adjusted Risk Ratio*	95% CI
Number of arm areas with pain	0	4 (39/882)	1.0	Ref
	1	10 (31/324)	1.6	[1.1, 2.5]
	≥2	10 (102/983)	1.5	[1.0, 2.2]
Number of back areas with pain	0	7 (50/741)	1.0	Ref
	1	7 (77/1031)	0.8	[0.6, 1.1]
	≥2	11 (45/422)	0.9	[0.6, 1.4]

*Mutually adjusted for age, sex, BMI, depressive symptoms, ROA, knee pain, and pain in the lower body apart from the knee (the hip, ankle, or foot)

The Effect of an Exercise Program in Gait Asymmetry in Patients after Total Knee Arthroplasty. Francisco J. Maia Neto[3], Gustavo J. M. Almeida[2], G. Kelley Fitzgerald[1] and Sara R. Piva[3]. [1]Univ of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, [3]University of Pittsburgh, Pittsburgh, PA

Purpose: Total knee arthroplasty (TKA) relieves pain and improves quality of life in end-stage knee osteoarthritis (OA). Unfortunately, significant functional deficits, such as gait asymmetry, often persist for years after TKA. Gait asymmetry may expose subjects to greater risk of developing OA in other weight-bearing joints. To prevent possible consequences of gait asymmetry, exercise interventions should target such impairment. We have developed and implemented an intense exercise program after TKA. The program includes balance exercises and movement control activities. The aim of this study was to determine if an intense exercise program that included balance and movement control activities decreases gait asymmetry in subjects after TKA.

Methods: Pre-test/post-test design. Subjects underwent unilateral TKA 2–6 months prior to the study. Patients completed 12 sessions of supervised exercise over 6 weeks, followed by 4 months of home exercise program (2x/week). Data were collected prior to intervention (pre) and at the end of the home exercise program (6 mo). Gait parameters were measured using the GAITRite walkway (CIR Systems Inc). Patients walked at a self-selected pace over the GAITRite. Step length was the spatial gait parameter; while the temporal parameters were loading, single support, and unloading times of the stance phase. To account for the effect of gait speed, the temporal parameters were analyzed as a percentage of the gait cycle. Spatial and temporal gait parameters between the surgical and non-surgical legs (at pre and 6mo) were analyzed using paired t-test.

Results: Twenty-five subjects participated. Mean age and BMI were 68.8±7.7 years and 29.9±4.5 respectively. Nineteen patients were females (76%), and 13 patients (52%) had surgery on the right side. At baseline, loading time was significantly longer in the surgical than the non-surgical side (15.3 ± 1.6 vs 14.7 ± 1.6 % of gait cycle, p=.02). Single support time was shorter in the surgical (34.8 ± 1.6 vs 35.4 ± 1.6 % of gait cycle, p=.02). Differences were not statistically significant for unloading time and step length. At 6 months, there were no significant differences between surgical and non-surgical sides. The Figure demonstrates that, at 6 months, the subjects decreased the time spent during loading, and increased the time spent during single support in the surgical side. Although not significant, step length became slightly larger in the surgery side compared to the non-surgical.

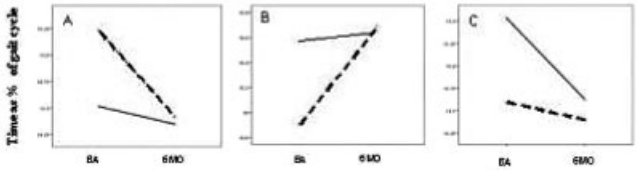

Figure. Loading (A), single support (B), and unloading (C) phases of gait from pre-intervention to the 6 months follow-up. Dashed lines represent the surgical lower extremity, whereas the solid lines represent the non-surgical side.

Conclusion: Spatial and temporal gait asymmetries after TKA were mainly during the loading and single support phases of stance. The exercise program seemed beneficial to decrease temporal gait asymmetries. If our results are confirmed in larger studies, intense exercises programs that include balance and movement control activities should be considered for subjects after TKA with asymmetrical gait.

The Effectiveness of Thoracic Spine Manipulation on Pain and Disability in Patients with Neck Pain: A Pilot Randomized Clinical Trial. Samannaaz Shamsuddin Khoja, Daniel Daliman and Piva Regina Sara. University of Pittsburgh, Pittsburgh, PA

Background: Mechanical neck pain is generally treated with a multimodal neck program (MNP) that includes electro/thermal modalities, active exercises and some form of manual therapy (commonly non thrust) directed at the cervical spine. Recent studies reported beneficial effects of using Thoracic Thrust Manipulation (TTM) to treat mechanical neck pain. The aim of this pilot study was to compare the effects of a MNP and the same MNP supplemented by TTM on neck pain and disability, and to gather preliminary data to calculate sample size for future larger studies.

Methods: Subjects were randomized to receive MNP only or MNP +TTM for a maximum of 12 sessions 2x/week. Primary outcomes were 11-point numeric pain rating scale (NPS), Neck Disability Index (NDI), and a 15-point Global Rating of Change (GRC) to measure perceived change in health status. Neck active range of motion (AROM) was secondary outcome. Outcomes were collected at baseline, 2, 4, and 6 weeks (GRC was not collected at baseline). As the goal of the study was parameter estimate, hypotheses testing were not done. We determined clinically important changes by comparing the point estimates of within-patient changes for NPS and NDI to their established minimal clinical important differences (MCIDs). MCIDs for the NPS and NDI are 2 points and 10% change respectively. We calculated the percentage of subjects in each group who reported a moderate or higher improvement in the GRC at each follow-up. For neck AROM, changes greater than the published values of minimal detectable change (MDC) were considered a noticeable change. The between-groups differences at 6 weeks in primary outcomes were used to estimate sample size.

Results: Twenty two subjects were randomized (68% female, mean age 38.2±10.7 yrs). Characteristics of both groups were similar at baseline. Both groups showed clinically important changes at 6 weeks on all primary outcome measures. Clinically important changes on the NDI were observed for the MNP+TTM group at 4 weeks as well. The only improvement in neck AROM was observed for right side rotation in the MNP+TTM group at 6 weeks. Compliance with intervention was similar in both groups. The difference between the two groups was very small for all outcomes (Figure). Results of sample size indicated that to have 80% power, α of.05, we would require over 150 subjects per group for pain and NDI, and over one thousand subjects per group for the GRC, which do not seem feasible.

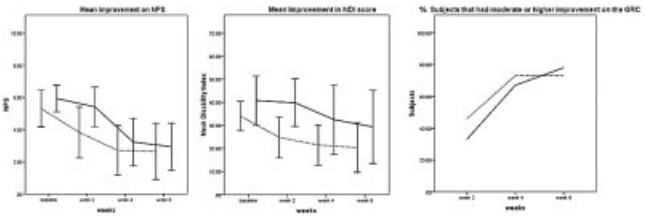

Figure. Pain, disability, and perceived change in health status across time for primary outcomes. Dashed lines represent NMP+TTM, and solid lines represent MNP group. Error bars show 95% CI around the means.

Conclusion: Adding TTM to MNP seemed to accelerate improvement on the NDI, but no additional benefits were observed on pain, perceived change in health status, or AROM at 6 weeks. It may not be beneficial to supplement MNP with TTM while treating mechanical neck pain. Results suggest it may not be worth to allocate additional resources to pursue the same research question in a larger randomized trial. Communication of these preliminary data may prevent unworthy research expenses.

Validity of Portable Devices To Assess Physical Activity in Patients with Total Knee Arthroplasty. Gustavo J. M. Almeida[1], Kelly S. Brower[2], Derya Celik[2], Hua-Chen Chang[2] and Sara R. Piva[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh

Total knee arthroplasty (TKA) is one of the most successful surgeries to reduce pain, improve function, and health-related quality of life in end-stage knee osteoarthritis. Thus, patient expectations on having a more active lifestyle after surgery are increasing, and accurate/valid measures of physical activity (PA) are needed to monitor these changes. To date, there is limited information about the validity of portable PA monitors in patients after TKA. The aim of this study was to compare measures of energy expenditure (EE) given by the SenseWear armband (SWA) (Bodymedia, Pittsburgh, PA) and the Actigraph (ACT; Pensacola, FL), against measures of EE estimated by indirect calorimetry. In addition, we aimed at characterizing PA of patients with TKA measured by the SWA and ACT in a free-living condition.

EE (kcal/min) was estimated by indirect calorimetry (MedGraphics VO2000), and by the SWA and ACT simultaneously. Patients performed several standardized activities in a laboratory setting while concurrently wearing the SWA on the arm, the ACT on the waist, and the facemask of the indirect calorimeter. Each activity was performed during 7 minutes (see table). To characterize PA in a free-living condition, patients wore the SWA and ACT over 8 consecutive days. Pearson correlation or Spearman coefficients were calculated according to data distribution.

Table. Correlation coefficients between energy expenditure measured by indirect calorimetry and the Sensewear Armband (SWA) and the Actigraph (ACT)

	Indirect Calorimetry (kcal/min)								
	Lying down	Seating Reading	Seating Typing	Standing Talking	Standing Moving Arms	Mopping	Usual walk	Slow walk	Fast walk
SWA (kcal/min)	0.80**	0.68**	0.71**	0.82§**	0.4§*	0.75**	0.31	0.40	0.52*
ACT (kcal/min)	0.63**	0.60**	0.46*	0.61**	0.33	0.17	0.76**	0.67**	0.68**

§Spearman's rho; *p ≤ .05; **p ≤ .01

21 patients, 14 females (67%), with unilateral TKA underwent one testing session. Mean age and BMI were 68±7 and 29±4 respectively; time after surgery was 3.3±0.3 years; and physical function measured by the Western Ontario and McMaster Universities Osteoarthritis Index 14.6±9.6, indicating only moderate functional limitations. During the standardized activities (Table) the correlations between EE measured by indirect calorimetry and SWA ranged from moderate to high (r=.31 to.82), and between indirect calorimetry and ACT they ranged from weak to high (r=.17 to.76). In a free-living condition, patients wore the SWA and ACT for 97% of the time each day (23:20hr/24hr). Daily values of physical activity EE (PAEE) measured by the SWA (145 [73–260]kcal/day) was lower than the one measured by the ACT (268 [222–281]kcal/day). The correlation between these two measures was weak (rho=.22, p=.37).

Results of correlations between measures from the portable PA monitors and indirect calorimetry support the validity of the SWA and the ACT to measure EE in patients with TKA in a laboratory setting. The SWA was more accurate in measuring EE during non-walking activities, whereas the ACT was more accurate in measuring EE during walking activities. Measures of PA EE given by the SWA and ACT in a free-living condition did not agree. When assessing EE in patients with TKA, it is essential to consider type of PA monitor to use according to type of activity performed. Studies comparing SWA and ACT to a reference standard measure of PA in free-living condition are warranted.

A Meta-Analytic Assessment of the Effects of Stanford's Small Group English Version of the Arthritis Self Management Program. Teresa J. Brady[1], Benita J. O'Colmain[3], Brandy S. Mobley[4], Michael C. Greenberg[4] and Louise Murphy[2]. [1]Center for Disease Control, Atlanta, GA, [2]Centers for Disease Control and Prevention, [3]ICF Macro, Calverton, MD, [4]ICF Macro

Background: Meta-analyses of arthritis self management education (SME) generally concludes it has modest, time limited effects. However, past analyses combined a variety of SME and examined only pain and disability. The purpose of this study was to examine the effects of Stanford's Arthritis Self Management Program (ASMP) using meta-analysis.

Methods: 7 Electronic databases (i.e. Medline, EMBASE) were searched using arthritis education-related keywords; reviews, reference lists, and expert recommendations guided hand searches to locate missed or gray literature.

All ASMP studies were included, regardless of language or delivery mode, if conducted in an English speaking country, containing data on at least 1 primary outcome, and reported in English. Primary outcomes: Fatigue (FAT), Self Rated Health (SRH), Pain, Self Efficacy (SE), Health Distress (HD), Physician Visits (MD-V). Secondary outcomes: Disability (DIS), Social/Role Limitations (LMTS), Anxiety (ANX), Depression (DEP), Aerobic Exercise (A.EX), Stretching/Strengthening Exercise (ST.EX), Cognitive Symptom Management (CSM), and Communication with MD (COMM).

Full random-effects meta-analysis was conducted for all available outcomes at 4–6 and 9–12 months. Heterogenity (HTG) was assessed using the Q Value (statistically significant at $a = 0.05$). Sensitivity analyses explored differences by study design (RCT vs. longitudinal [LONG]).

Results: 297 studies were identified; this report focuses on the 20 eligible studies (6 RCT, 14 LONG) of the Small Group English ASMP.

In analysis of 4–6 mo. data, there was significant HTG in 5 of 6 primary outcomes (all but SE) and 2 of 8 secondary outcomes (LMTS, CSM), indicating significant inter-study variation in effect sizes (ES) for most primary but few secondary outcomes. Only Pain and MD-V showed significant between group (RCT-LONG) HTG, indicating variation was not due to study design, and analysis of Overall effects (RCT and LONG combined) was valid.

RCT only analysis showed significant benefits in FAT (ES = −0.214), SE (0.34), ANX (−0.204), DEP (−0.201), and COMM (0.277) at 4–6 mo. At 9–12 mo. improvements in SE, ANX and DEP remained significant but slightly reduced (ES 0.21, −0.193, −0.132 respectively); no 12 mo. data were available on FAT or COMM.

In 4–6 mo. Overall analysis, all variables significant in RCT analysis were significant. HD (ES = −0.359), DIS (−0.049), A.EX (0.209), ST.EX (0.179), and CSM (0.533) were also significant with small to moderate ESs. At 9–12 mo., all variables except DIS, A-EX, and ST.EX remained significant with similar ESs. Pain and MD-V were significant in LONG 4–6 mo. analysis (ES −0.225, −0.120 respectively) but not in RCT only or Overall analyses.

Conclusions: Based on RCT analysis, the small group English ASMP has robust psychological benefits (ANX, DEP, SE) that persist at 12 mo., along with short term benefits in FAT and COMM. In Overall analysis, benefits were also seen in health behaviors and HD; most persisted at 12 mo. Consistent with previous meta-analyses, the impact of ASMP on DIS at 4–6 mo. is significant but small, and not maintained at 12 mo. The impact of ASMP on Pain and MD-V is only found in LONG studies, and should be interpreted cautiously.

2063

Development of the UK-Evaluation of Daily Activity Questionnaire (UK-EDAQ): Phase 2. Alison Hammond[3], Rachel E. Gill[3], Sarah Tyson[3], Ulla Nordenskiold[1] and Alan Tennant[2]. [1]Sahlgrenska Academy, Goteborg, Sweden, [2]University of Leeds, Leeds, Yorkshire, United Kingdom, [3]University of Salford, Salford, Greater Manchester, United Kingdom

Aims: The Swedish Evaluation of Daily Activity Questionnaire (S-EDAQ) is a comprehensive tool for reporting activity/activity limitations in Rheumatoid Arthritis (RA) [1]. It includes: 11 sub-scales of personal and instrumental activities of daily living (with 4–13 items in each; 102 in total). It is used in Occupational Therapy (OT) for clinical, audit and research purposes. We have already undertaken linguistic validation and generated potential new activity items for the UK from analysis of patient activity diaries and OT assessments (Phase 1). In Phase 2 we evaluated acceptability of wording and relevance of items for the UK.

Methods: Three stages were undertaken: (i) cognitive debriefing interviews with people with RA (n=20) who completed the prototype UK-EDAQ and then rated importance of items for inclusion on a 1=not to 5=very important scale; (ii) postal questionnaires with Rheumatology OTs (n=11) similarly rating items and (iii) 4 focus groups with RA participants (n=18) and 1 with OTs (n=7) to obtain consensus on item retention and wording. Items were considered for exclusion if RA participants and/or OTs rated these ≤3. The Project Steering Group (PSC) reviewed results from all stages to finalise the UK-EDAQ.

Results: RA participants (16 women: 4 men) were aged 61.55 (range 26–85); RA duration (16.42y SD 14.14); HAQ score 0.87 (range 0.12–1.88); 4 employed; 4 with children at home. Participants took between 25–120 minutes to complete the EDAQ. Whilst OTs rated 73/152 items with a median score ≤3, RA participants only rated 18/152 items ≤ 3; with only 15 items agreed for exclusion between groups.

Focus groups thus discussed items for modification or exclusion. From the S-EDAQ the consensus was for: 4 items to be deleted (get to toilet; get to bathroom; move round kitchen; open balcony door – as included in "move round house"); 20 S-EDAQ items merged to 10 items (eg slicing bread & slicing cheese to "slicing"). 53 new UK items were included: 26 to S-EDAQ sub-scales (eg "use a computer and mouse" "use a kettle") and 25 to 3 new scales (Hobbies; Caring; Household Maintenance). The PSC recommended 7 S-EDAQ items were slightly reworded (eg "go for a long walk" specified as 1 mile).

Many RA and OT participants expressed initial concerns on assessment length. However, once its purpose and completion at home were understood, most considered it appropriately detailed. RA participants were confident it would help an OT get a clearer picture of their abilities and difficulties in order to better help them. Comments from OTs were: "it is more patient oriented. . . It takes out the time of having to actually go through it all with them." "A lot of our patients say the time they spent with OT was very fleeting. . .filling this out would be very thorough." "You identify the talking points straight away, which helps focus it [assessment] a lot more." Both groups considered the length meant not all patients could complete it.

Conclusion: UK-EDAQ content was finalised reflecting what people with RA consider the most important daily activities to assess in the UK. We will next psychometrically test for reliability and validity.

Factors Associated with Attrition in a Longitudinal Rheumatoid Arthritis (RA) Registry. Christine K. Iannaccone[2], Anne Fossel[2], Hsun Tsao[2], Jing Cui[2], Michael E. Weinblatt[1] and Nancy A. Shadick[1]. [1]Brigham & Womens Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA

Background: Loss of participants in longitudinal data collection can affect the validity of RA registries if the characteristics of patients who drop out are systematically different from those who remain. Several studies have previously assessed factors associated with attrition with different conclusions. Some reports suggest that psychosocial and socioeconomic factors play an important role while others indicate attrition is more likely associated with population demographics. This study looks at multiple factors of attrition in a hospital-based registry over five years to identify contributors to attrition in the BRASS cohort.

Methods: The attrition patterns of RA patients enrolled in a prospective observational registry were examined. Follow-up of patients occurred every six months. Attrition rates were calculated as the proportion of patients who dropped out of the study over five years of follow-up. Demographics, clinical factors, and psychological factors were evaluated in univariate analyses to determine differences between participants who dropped out of the study and participants who completed five years of follow-up. Univariate factors with a $p<0.05$ were used in a survival analysis to determine significant factors associated with attrition.

Results: Overall, 1095 RA patients were enrolled in the registry with 461 patients completing five years of follow-up, 327 still actively enrolled and 307 having dropped out. At baseline, the mean age was 56.2(±14.1), the mean disease duration was 13.8 (±12.4) years, 93% of patients were Caucasian and 82% were female. The attrition rate for each 6 month follow-up cycle was 3.23%. Level of education, disease duration, DAS28-CRP3 score (disease severity), MDHAQ depression score, total MHAQ score (functional status) and Self-Efficacy score were associated with attrition in univariate analyses. However, in survival analyses, shorter disease duration, higher MHAQ and higher DAS28-CRP3 scores were the only factors associated with attrition this population.

Table 1. Multivariate survival analysis of factors associated with attrition

Characteristic	Hazard Ratio	95% Confidence Intervals
Disease Duration, years	0.97	0.95–0.98*
DAS28-CRP3	1.29	1.19–1.40*
MHAQ Score	1.50	1.24–1.82*

*P < 0.001

Conclusions: The attrition rate for this registry is similar to rates reported by other registries. In contrast to previous studies, worse functional status and higher disease activity were associated with attrition in this population. This suggests that in some populations, disease specific measures are major contributors to attrition. Specific population differences in each registry may play a greater role in attrition than general demographic factors indicating that each longitudinal registry may need to conduct its own analyses.

Measuring Fatigue in Patients with Inflammatory Arthritis in Clinical Practice: Single Dimension and Multidimensional Scale Comparison. Patricia Minnock[1], Barry Bresnihan[2], McKee Gabrielle[3], Oliver FitzGerald[2] and Douglas Veale[2]. [1]Rheumatology Rehabilitation, Our Lady's Hospice and Care Services, Dublin, Ireland, [2]St Vincent's University Hospital, Dublin, Ireland, [3]Trinity College Dublin, Dublin, Ireland

Background: The ease of use of a measurement instrument frequently determines instrument choice and is an important consideration for outcome assessment in routine clinical practice. The aim of this study was to compare the measurement properties of one-dimensional and multidimensional fatigue scales in patients with inflammatory arthritis.

Methods: Patients with rheumatoid arthritis (RA) and psoriatic arthritis (PsA) commencing anti-TNF therapy were clinically evaluated using the 6-core outcome measures, and fatigue at baseline, 3-months and 6-months. Fatigue was measured using 2 fatigue scales validated for use in RA 1) a one

dimensional 5 point ordinal scale (OS), and 2) a multidimensional assessment of fatigue scales (MAF). Fatigue levels were quantified and the properties of a one-dimensional scale versus a multidimensional fatigue scale were evaluated.

Results: One-hundred thirty patients were evaluated (RA, 90; PsA, 40). Mean age (SD) years, and disease duration at inclusion were 52 (13), 12 (11), respectively. Mean (SD) MAF levels (range 1–50) were 27.5 (11.1) at baseline, 18.07 (12.1) at 3-months, and 19.04 (11.8) at 6-months and demonstrated statistical difference (ANOVA $p \leq 0.001$). Change in fatigue captured by the OS were statistically significant at both 3–months and 6-months χ^2 (2) = 31.5; p= 0.000 (Friedman test). MAF and OS scores demonstrated strong and significant correlations at the 3 time points, r=0.587; r=0.689, and r=0.686 ($p \leq 0.000$), respectively, (Kendall's tau_b). Fatigue scores corresponded as follows

Fatigue Scores	None	Mild	Moderate	Severe	Very Severe
Baseline					
5-point ordinal scale (%)	10 (8)	19 (15)	47 (38)	41 (33)	7 (6)
MAF Mean (SD) (Range 1–50)	8.7 (8.4)	18. (8.2)	27 (8.1)	35 (7.1)	40 (5.1)
3-months					
5-point ordinal scale (%)	17 (16)	40 (37)	41 (38)	11 (10)	
MAF Mean (SD) (Range 1–50)	6 (11.9)	10 (10.2)	19 (10)	24 (11)	21 (11)
6-months					
5-point ordinal scale (%)	12 (14)	33 (39)	29 (34)	9 (11)	1 (1.2)
MAF Mean (SD) (Range 1–50)	6.7 (6.1)	11 (11)	19 (10)	26 (11)	24 (7)

MAF scores moderately correlated with Pain 0.423 (0.578), (0.482); GH 0.425 (0.578), (0.500) and HAQ 0.470 (0.345), (0.344) ($p \leq 0.001$) at baseline, at 3-months, and at 6-months, respectively. Similarly, OS scores correlated with Pain 0.489 (0.495), (0.456); GH 0.532 (0.536), (0.515) and HAQ 0.407; (0.346), (0.347) (p= 0.001) at baseline, at 3-months, and at 6-months, respectively. The correlations between fatigue and the core outcome measures were equivalent at all time points regardless of the scale employed. Using the standardised response mean (SRM), sensitivity to change of MAF was moderate (0.78) at 3-months and large (0.66) at 6-months. Fatigue ranked third at 3-months, next to TJC and SJC, and sixth at 6-months relative to the other measures. Noteworthy was the observation that fatigue was ranked higher than CRP at 6-months.

Conclusion: These finding support the use of a single-item ordinal fatigue scale, in the quantification of this multi-dimensional patient reported symptom, in busy routine clinical practice.

One Monthly Patient Reported Disability, Disease Activity and Fatigue Shows More Fluctuation Then Expected Based on the 3-Monthly Clinical Evaluation by DAS-28. Margot Walter, Siti Haslinda Binti Mohd Din, Mieke Hazes and Jolanda Luime. Erasmus MC

Background: In clinical practice disease activity is monitored using a physician based instrument such as DAS or SDAI. In between these clinical measurement disease activity could fluctuate which is currently missed by the clinicians. Patient Reported Outcomes (PRO) may pick these fluctuations enabling early identification of disease activity increase requiring treatment change.

Objective: i To describe the monthly change of functional status (HAQ),self-reported disease activity (RADAI) and VAS fatigue among patient diagnosed with RA ii To identify patients with DAS28 >3.2 by proposed cut off points for RADAI and HAQ.

Methods: RA patients and patients with poly arthritis using DMARD's for at least 3 months from one outpatient clinic in Rotterdam were invited to participate in this study. They were asked to complete online the HAQ, RADAI, VAS fatigue monthly during 1 year and were clinically assessed by the DAS28 3-monthly. Descriptive statistics were used to analyze the data. HAQ>1 and RADAI>2.2 for moderate to high disease activity were used to identify DAS28>3.2

Results: 159 out of 174 invited patients (53 yrs (sd 13); 76% female, median 4.5 yrs disease, median DAS28 2.66; 37% erosions) consented to the study in September-December 2008. Stratified summary of the PRO's by DAS28 categories showed the increased values when the DAS increased (table 1) which stayed stable over time (data not shown).

Table 1.

DAS28	HAQ (median; IQR)	RADAI (median; IQR)	VAS Fatigue (median; IQR)
<2.6 (n=72)	0.19 (0–0.50)	1.09 (0.6–1.82)	43 (20–66)
2.6 <=3.2 (n=29)	0.5 (0.25–1.12)	1.47 (0.92–2.20)	53 (21–79)
>3.2&<5.1 (n=39)	0.75 (0.38–1.38)	2.73 (1.46–3.61)	59 (40–70)
>5.1 (n=9)	1.25 (1.00–2.13)	4.53 (4.05–4.81)	80 (75–82)
Overall (n=159)	0.50 (0.13–1.00)	1.63 (0.84–2.99)	56 (29–70)

Between 8% and 18% of the patients had an increase of DAS28>3.2 at any of the time points. On individual level the DAS28 and the PRO's fluctuated over time (figure 1).

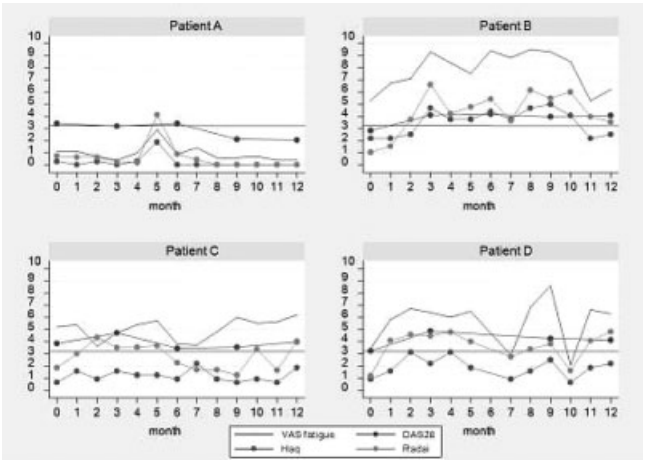

Figure 1.

Using the baseline data, the sensitivity of HAQ>1.0 to identify patients with DAS28>3.2 was 0.51 with a specificity of 0.75. For the RADAI>2.2 the sensitivity was 0.61 with a specificity of 0.83.

Conclusion: Individual patients showed fluctuating patterns of disease activity, while on group level the DAS28 and the PRO were stable over time. To identify individual patients with DAS28>3.2 the proposed cut off points for the HAQ and RADAI showed moderate sensitivity and high specificity.

Secular Trend of Adhesive Capsulitis over 13 Years: A United Kingdom General Population Cohort. Daniel K. White[1], Hyon K. Choi[4], Christine Peloquin[3], Yanyan Zhu[2] and Yuqing Zhang[2]. [1]Boston Univ School of Med, Boston, MA, [2]Boston Univ School of Medicine, Boston, MA, [3]Boston Univ School of Medicine, [4]Univ of British Columbia, Vancouver, BC, Canada

Purpose: Adhesive capsulitis (AC) is a shoulder disorder characterized by a loss in range of motion and pain, resulting in restrictions with activities of daily living. Though common, few population-based studies have investigated the epidemiology of AC. Given the recent epidemic of diabetes, a known risk factor for AC, one would expect that the incidence of AC may be rising. The purpose of this study was to estimate effect of age, sex, birth cohort (birth year) and period (year of diagnosis) on the incidence of AC in a United Kingdom (UK) general population cohort.

Methods: Incident cases of AC were identified from The Health Improvement Network (THIN), an electronic medical record database of 6.3 million patients from general practices across the UK from 1995 to 2008. General practitioners recorded diagnosis of AC. We included subjects aged 40 to 79 years and defined an incident case of AC as the first diagnosis of AC following at least one year of enrollment in the database and had no prior AC diagnosis prior to their enrollment within the practice. Crude incidence rates were calculated as number of incident AC cases divided by total person-years. We plotted age- and gender-specific incidence rates of AC, and the relative incidence rates of AC for birth cohorts and periods using an age-period-cohort spline curve based on a Poisson-type likelihood. We estimated the effects of age, sex, birth cohort (born 1920–29, 1930–39, 1940–49, 1950–59, 1960–69), and period (1995–98, 1999–2002, 2003–06, 2007–08) using a proportional hazard model.

Results: Of 2,209,672 subjects included (mean age 51.7 yrs, 50.0% women, mean follow-up 7 years), the incidence rates of AC were 2.20 and 3.15 per 1000 person-years for men and women, respectively. Incidence rate of AC increased with age in both men and women. For every 5-year age increment, AC incidence increased by 9.1% (Relative Risk [RR]=1.09, 95%CI: 1.08, 1.10). The incidence rate was higher in women than in men (RR=1.43, 95%CI: 1.40, 1.45), and was higher for more recent birth cohorts compared with later (older) cohorts (RR for each 10-year increment=1.10, 95% CI: 1.08, 1.12). We did not observe a period effect for the incidence of AC. (See figure)

Conclusion: We found that more recent birth cohorts had a higher risk of incident AC independent of age, sex, and calendar year at diagnosis within the UK general population compared with later cohorts. An increased presence of risk factors, such as diabetes, in those born more recently may account for this increase, though future research should formally identify and examine these factors.

The American Myositis Activities Profile—A Valid Disease-Specific Activity/Participation Measure. Helene Alexanderson[1], Ann M. Reed[2] and Steven R. Ytterberg[2]. [1]Department of Medicine, Karolinska Institutet, Department of Physical Therapy, Karolinska University Hospital, Solna, Stockholm, Sweden, [2]Rheumatology Division, Mayo Clinic, Rochester, MN

Background: The Myositis Activities Profile is an activity limitation measure developed and validated for patients with polymyositis and dermatomyositis in Sweden. It was recently translated into American English.

Objectives: To evaluate validity and reliability of the American version of the disease-specific 31-item Myositis Activities Profile (MAP) in patients with polymyositis (PM) and dermatomyositis (DM) in the USA.

Methods: Patients diagnosed with PM or DM seen during March-May 2007 and May-July 2008 were included. To assess content validity 30 strategically chosen patients as to gender, age, ethnicity, disease activity, disease duration and employment status were selected. They rated difficulty and importance of each activity of the American MAP on a 10-grade scale and were invited to suggest additional items. Based on the initial findings a second draft of the American MAP was developed. For construct validity purpose unselected patients with PM and DM (n=64) were included. The six-item core set for myositis disease activity, the Manual Muscle test (MMT) and measures of muscle endurance using the Functional Index 2 (FI-2) were performed. Patients filled out the second draft of the American MAP, the Health Assessment Questionnaire (HAQ) and rated disease impact on general well-being. All patients with stable disease activity and medication for three months (n=48) were given another copy of the American MAP to fill out one week later.

Results: The median value for pooled difficulty and importance of each item was 5.00 (2.10–5.95) for the 31 activities in the first draft of the American MAP. Although two activities were rated < 5.0; "Standing for a longer period" and "Using public transportation" they were still taken to the second draft of the MAP as they were considered relevant to patients living in larger cities. Five patients suggested the activity "Opening jars" which was added to the Movement subscale, giving a 32-item second draft of the American MAP. Correlations between median of subscales of the American MAP and disease impact on general well-being and the HAQ were $r_s = 0.68$ and r_s 0.70 respectively. There were lower correlations between the American MAP and MMT 8 ($r_s = -0.36$), the FI-2 (ranging between $r_s = -0.29$ to -0.44) and physician's global assessment of disease activity (r_s 0.40). Thirty-three patients sent back questionnaires to assess test-retest reliability. Weighted Kappa (K_w) ranged between 0.65 and 0.81 for the 4 subscales and between 0.52 and 0.73 for the four single items of the American MAP without systematic variations, $p>0.05$. The single item 'avoid overexertion' were excluded due to poor test-retest reliability ($K_w=0.52$) giving a 31-item final draft of the American MAP.

Conclusion: The American MAP seems to be a valid and reliable outcome measure assessing activity / participation in patients with adult PM and DM in the USA and could potentially improve clinical assessment of treatment of these patients although further studies are needed to establish sensitivity to change of the American MAP.

Arthritis Hurts . . . Your Resume: State-Specific Arthritis-Attributable Work Limitation and Employment among Working-Age (18–64) Adults. Kristina Theis[3], Jennifer M. Hootman[2] and Charles G. Helmick[1]. [1]CDC, Atlanta, GA, [2]Centers for Disease Control, Kennesaw, GA, [3]Centers for Disease Control and Prevention

Background: State-specific estimates of arthritis-attributable work limitation (AAWL) help define and raise awareness of an important consequence of arthritis, and provide state programs and policy-makers with data for planning interventions. We estimate the state-specific prevalence of AAWL and employment status among people with and without arthritis.

Methods: The Behavioral Risk Factor Surveillance System (BRFSS) survey is a state-based, random-digit-dialed telephone health survey of noninstitutionalized US civilian adults ≥18 years conducted annually in all 50 states and the District of Columbia. Data were from the 2009 BRFSS survey (n = 424,592). Arthritis was defined as 'yes' to: "Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?" AAWL was defined as 'yes' to: "In this next question, we are referring to work for pay. Do arthritis or joint symptoms now affect whether you work, the type of work you do, or the amount of work you do?" Employment rate, as defined by the Bureau of Labor Statistics, requires information on specific efforts to find employment, which is unavailable in BRFSS; so, we examined employment status by report of being: employed, out-of-work, or retired/unable to work. Students and homemakers were excluded from the analysis. Weighted point estimates and 95% confidence intervals (95% CI) were calculated for AAWL and employment, accounting for the complex survey design. Statistical significance was $p < 0.05$.

Results: Median state-specific prevalence of AAWL among all working-age adults was 6.4% (range 4.3% (NJ) to 13.2% (KY)). Among working-age adults with arthritis, median AAWL was 33.9% (range 26.2% (CT) to 44.9% (KY)) The median percent employed among people without arthritis was 81.9% (range 73.5% (NV) to 90.5% (SD)), was significantly lower in every state for those with arthritis (median 64.2%, range 50.0% (TN) to 77.3% (SD)), and lowest for adults with AAWL (median 44.5%, range 32.4% (TN) to 64.0% (IA)). There were few statistically significant differences in the prevalence of being out-of-work. With the exception of 6 states (same patterns but not significant), those with AAWL reported being retired/unable to work statistically significantly more often than those with arthritis but no AAWL (median 40.9% vs. 26.0%) In all states, those with arthritis (with or without reported AAWL) reported being retired/unable to work statistically significantly more often than those without arthritis (median 6.5%).

Conclusion: AAWL affects approximately 1-in-16 working-age adults. Working-age adults with arthritis (with and without AAWL) are more likely to report being retired/unable to work than out-of-work, suggesting that they may have given up on trying to be an active part of the labor force. These data identify higher risk states which can be targeted for expanding the reach of evidence-based programs addressing disability, as well as increasing the use of vocational rehabilitation and job retraining programs.

Disclosure: K. Theis: None; **J. M. Hootman:** None; **C. G. Helmick:** None.

2070

Assessement of Physical and Mental Health Related Quality of Life, Disease Activity and Damage, Mental Health Status, and Cognitive Impairment in Chilean Women with Systemic Lupus Erythematosus. Carla Henríquez[1], Patricia Flores[2], Babul Marcela[3], Jorge Calderón[3] and Loreto Massardo[3]. [1]Pontificia Universidad Católica de Chile, Santiago, Chile, [2]Pontificia Universidad Católica de Chile, Santiago, [3]Pontificia Universidad Católica de Chile

Background: Psychosocial factors play an important role in the course of SLE. The aim of this study is to characterize the health-related quality of life (HRQoL) in Chilean women with SLE and their relationship with disease activity, and mental health status including cognitive function.

Methods: In this cross sectional study, 52 non selected Chilean women with SLE attending out patient clinic in Santiago were recruited in an 18 months period, they pay their medications from their own pocket. Completed the following measurements (i) HRQoL using the SF-12 questionnaire (assessing general health status [GHS], physical component summary [PCS] and mental component summary [MCS], (ii) SLE disease activity (SLEDAI-2K), (iii) damage (SLICC-ACR), (iv) 26 common mental disorders (CMD), according to the DSM-IV, using the Mini-International Neuropsychiatric Interview (MINI-plus), and (v) cognitive impairment (CI) in five domains of the Cambridge neurospychological auttomated test battery (CANTAB): memory, attention, executive function, work memory, and desicion making. CI was considered one or more test with a -1SD perfomance compared to 26 Chilean healthy controls paired by sex, age, and educational level.

Results: Characteristics of participants: median age: 33 years (range= 17–64); median disease duration from diagnosis: 2 years (0.1–26); stable couple: 37%; active working/students: 65%; median years of formal education: 14 (9–19); median SLEDAI-2K: 7 (0–25); median SLICC: 0 (0–4). At least one CMD was present in 27 (53%), 14 (28%) major depressive episode (MDE), 15 (30%) at suicidal risk (29%): four were at high level, 5 at moderate and 6 at low risk.

Patients considered their GHS as poor (16%), regular (47%), good or very good (37%). PCS median was 39.1 (24.28–57.58) and MCS median was 35.8 (16.2–59.4). PCS and MCS inversely correlated with disease activity (Spearman Rho= −0.327; *P= 0.023;* R= −0.349; *P= 0.015*, respectively). Accrued disease damage inversely correlated with PCS (R= −0.347; *P=0.015*). Patients affected with MDE had lower PCS and MCS than those without MDE (*P=0.045; P=0.00*, respectively). Disease activity was similar in both groups. CI in two domains attention and executive function were found in 22 (42%) not associated with MDE (*P*=NS).

Conclusions: This survey found 53% of presence of CMD and 28% of MDE. These frequencies are considerably higher than those previously reported in the general population living in Santiago, Chile (18% and 8%, respectively), moreover the number of patients at suicidal risk is high (<0.1%). HRQoL components PCS and MCS were > 1 SD lower compared to Chilean general population (score 50 ± 10). Disease activity related to a worse HRQoL in both components while accrued damage associated only with lower PCS score. MDE affected both components of HRQoL. CI in attention and executive function is a relevant problem in this study. Overall 63% of patients considered their general health status as bad or regular implying a challenge for a the rheumatology staff to provide a better health care involving transdisciplinary teamwork.

Change in Physical Activity on Sleep Quality in Persons with Arthritis. Jennifer Lias[2], Leigh F. Callahan[1] and Jack H. Shreffler[2]. [1]Univ of North Carolina, Chapel Hill, NC, [2]University of North Carolina, Chapel Hill

Background: The role of exercise or physical activity on sleep quality in persons with arthritis has had minimal investigation, although sleep disorders are prevalent. This study examines the role of physical activity (PA) on sleep quality in older adults with arthritis who participated in an intervention trial evaluating the Active Living Everyday Program (ALED), a 20-week behavioral theory-based program designed to increase PA.

Methods: Subjects included 350 inactive persons, 18 years or older with doctor-diagnosed arthritis or joint pain/stiffness who were in either the intervention or delayed control group. Baseline and 20-week follow-up data included self report health status, physical functioning, PA and a self report assessment of sleep. Participants were asked: do you 1) Have trouble falling asleep? 2) Wake up several times per night? 3) Have trouble staying asleep, including waking up too early? 4) Wake up after your usual amount of sleep feeling tired and worn out? Responses are 0–5 with higher scores indicating more disturbances. A total sleep score summed the four responses (0–20). The Community Healthy Activities Model Program for Seniors (CHAMPS) frequency and Kcal/wk self-reports were used to measure PA level (e.g., 40 physical activities, scored by the number of times and hours per week engaged in the activity). Higher frequency and caloric expenditure indicate higher weekly PA levels. Sleep and CHAMPS baseline, post ALED and change scores were examined. Bivariate and multivariate regression analyses examined the relationship of CHAMPS change variables to sleep change variables. Age, gender, race, education, comorbidities and depression were controlled for during the analysis.

Results: Mean age of the study population was 69 years and consisted of 84% females, 79% white, and 58.1% with greater than a high school education. Baseline mean (s.d.) CHAMPS weekly energy expended and frequency for exercise were 2167 Kcal (2577) and 11.9 (10.14), respectively. The corresponding mean changes after 20 weeks were 992 (3175) Kcal and 7.39 (11.9). For the regression analyses, energy was divided by 1000 and frequency by 10 to avoid numerically small parameter estimates (β). Unadjusted analysis revealed a significant association between increased energy expenditure and improved sleep: waking up tired (β = -.095, p=.006) and sleep total score (β = −.279, p=.008). Increased frequency of activity was related to less waking up tired (β = −.211, p=.011) and improved total sleep score (β = −.549, p=.029). Adjusting for covariates, greater energy expenditure was associated with less waking up tired (β = −.102, p=.005), improved total sleep score (β = −.328, p=.003), and less waking up during the night (β = −.081, p=.019); increased frequency of activity was associated with less waking up tired (β = −.193, p=.024).

Conclusions: Sleep disturbances in people with arthritis can be significantly improved by increased weekly PA. An average increase in caloric expenditure of approximately 1000 Kcal/week produced results. These findings have important clinical implications in management of sleep disorders in older persons with arthritis, especially those that are inactive.

Disclosure: J. Lias: None; **L. F. Callahan:** None; **J. H. Shreffler:** None.

2072

Depression Rates Reported by Scleroderma (SSc) Patients Using Online Subject Recruitment and Questionnaire Completion. Feasibility of Data Collection Method and Comparison of Reported Depression Rates. Evelyn Rajan[1], Meagan Crofoot[3], Jibran Fateh[3] and Ann J. Impens[2]. [1]Briarcliff High School, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan

Objective: To evaluate the effectiveness and quality of online survey data in the assessment of depressive symptoms in SSc patients.

Methods: Data was obtained from SSc patients through a link posted on The Scleroderma Foundation website informing patient members about a study conducted by a high school student as part of the Intel Science Competition. Local IRB approval was obtained. Patients completed demographic information and the Center for Epidemiologic Studies Depression Scale (CES-D) which has been validated in SSc. CES-D is a 20-item instrument scored from 0 to 3 for a total possible score of 0 (best) to 60 (worst). Scores 16 and above indicate significant depressive symptoms.

Results: 186 completed surveys were received over a period of 2 weeks. 171 (91.9%) were female. Mean age was 49.9 ± 11yrs; 47.1 ± 10.6yrs for males and 50.2 ± 11yrs for females. Average disease duration was 8.2 ± 8.2 yrs; 7.1 ± 7.7 yrs for males and 8.3 ± 8.3yrs for females.

The mean CES-D was 18.9 ± 12.7 with 51.6% reporting a score of 16 and higher. Total CES-D score for males was 23.9 ± 14.1 and 18.6 ± 12.6 for females. This difference was not statistically significant. Mean scores on each item were compared and differences between males and females were small. Males scored significantly ($p < 0.05$) higher on 2 items: "I felt as good as other people" (1.71 vs 1.06) and "My sleep was restless" (2.29 vs 1.6). A significant, although low, negative correlation was found for females between CES-D scores and age (r = −.160), implying that with age there was less reported depression. The correlation between CES-D and years of illness was not significant (r = −.09).

Conclusion: A CES-D score of 16 or higher is commonly considered as a cut-off for significant depression. Rates of depression between 35 to 65% have been reported in studies of SSc patients. The rate of significant depression, 51.6%, found in this online sample falls within the range depression rates previously reported in clinic samples. This is also similar to depression rates reported in other chronic diseases. A recent study (Thombs, Fuss et al. 2008) compared SSc patients with online gender and age/race matched controls (no SSc). They noted that online respondents scored differently on certain items (higher on items related to appetite, sleep, effort, and bothered) suggesting qualitative differences in depressive symptom presentation between data collection methods. The item differences found in this study between males and females need to be further investigated and compared to gender item differences found in clinical and/or other community samples. The ease of administration and scoring makes the use of online questionnaires a very attractive method of data collection. The effectiveness of this method was proven by a high rate of completed surveys within a short period of time. More research is needed in comparing the composition of respondent characteristics (demographic as well as clinical) and the impact of data collection methods on results in SSc patients.

Thombs, B., S. Fuss, et al. (2008). High rates of depressive symptoms among patients with systemic sclerosis are not explained by differential reporting of somatic symptoms.Arthritis and rheumatism **59**(3): 431–7.

Effects of Tadalafil on Sexual Activity and Quality of Sexual Functioning in Female Scleroderma (SSc) Patients. Ann J. Impens[2], Elena Schiopu[2], Kristine Phillips[2] and James R. Seibold[1]. [1]University of Connecticut Health Center, Farmington, CT, [2]University of Michigan, Ann Arbor, MI

Objective: To evaluate the potential effects of Tadalafil on quality and frequency of female sexual function as assessed by Female Sexual Function Index (FSFI) and sexual activity log.

Methods: Prospective randomized, double-blinded, placebo controlled, cross-over study comparing oral Tadalafil at fixed 20 mg dose daily for 4 weeks compared to placebo in female SSC patients. FSFI assesses six domains of sexual functioning: desire, subjective arousal, lubrication, orgasm, satisfaction, and pain.

Results: 39 patients met inclusion criteria, agreed to attempt sexual activity at least once per week, and completed a series of 5 visits. Mean scores on the FSFI domains and frequency of sexual activity are as follows:

Baseline, Drug, Placebo Mean scores FSFI Domains

	Baseline (sd)	Drug (sd)	Placebo (sd)
Desire	2.77 (1.28)	3.23 (1.21)*	2.98 (1.37)
Arousal	3.38 (1.77)	3.92 (1.85)	3.64 (1.86)
Lubrication	3.60 (2.11)	3.89 (2.14)	3.77 (2.15)
Orgasm	3.54 (1.90)	4.02 (1.96)	3.73 (2.0)
Satisfaction	4.06 (1.56)	4.43 (1.50)	4.23 (1.55)
Pain	4.30 (2.43)	4.51 (2.26)	4.37 (2.37)

*p=.007, 2-tailed

Frequency sexual activity

Baseline (sd)	Drug (sd)	Placebo (sd)
5.75	7.24 (4.53)	6.12 (3.3)

*p=.021, 2-tailed

Conclusions: To our knowledge this is the first study to report on the use of PDE-5 inhibitor and its impact on sexual function in female SSc patients. Patients reported a significantly higher frequency of sexual activity on drug than placebo. Greater change from baseline was reported on all domains of FSFI on drug versus placebo but none of these were statistically significant. A statistically significant difference was found in change from baseline in the sexual desire domain for drug although this was not statistically different from the change in the placebo group.

While the majority of scleroderma patients are female most studies on sexual function have focused on male sexual dysfunction. Same holds true for the study of sexual function in the general population where many studies focus on the use of PDE-5 inhibitors in the treatment of erectile dysfunction. Few studies exist on the use of PDE-5 inhibitors in the treatment of female sexual arousal problems and their effectiveness is in question (Chivers and Rosen 2010). Chivers et al (Chivers and Rosen 2010) attribute this lack of efficacy of PDE-5 inhibitors in women to gender differences in the concordance between physiological and psychological components of sexual response. This study did not include physiological outcome measures which are likely to measure the pharmacological effects of PDE-5 inhibitors as direct vasodilators. Classification and measurement of FSD in women lacks meaningful endpoints due to the complexity of female sexual response. Research is needed for a better understanding of outcome measures (physiological and patient-reported) specifically for female sexual dysfunction.

Chivers, M. L. and R. C. Rosen (2010). Phosphodiesterase Type 5 Inhibitors and Female Sexual Response: Faulty Protocols or Paradigms? The journal of sexual medicine 7(2): 858–872.

Fibromyalgia Patients Often Visit Many Physicians before Receiving a Diagnosis. Robert S. Katz[2], Jessica L. Polyak[1] and Lauren Kwan. [1]Rheumatology Associates, [2]Rush University Medical Center, Chicago, IL

Introduction: Fibromyalgia patients see many types of medical professionals and often have difficulty obtaining a diagnosis. This study utilized on-line and written surveys to investigate the number and types of health professionals consulted before receiving a diagnosis of the fibromyalgia syndrome (FMS). To avoid confounding by gender, only female patients were included in the analyses.

Methods: 606 self-described female fibromyalgia patients responded to a survey through the community volunteer fibromyalgia organization, AFFTER (Advocates for Fibromyalgia Funding, Treatment, Education and Research). Respondents were asked about who had diagnosed their fibromyalgia and the number of physicians they had seen for fibromyalgia symptoms before reaching a diagnosis. Spearman correlations were obtained to assess linear relationships between non-categorical variables.

Results: Respondents were predominately middle-aged (58% aged 36–55) and Caucasian (91%). Fifty percent were diagnosed with fibromyalgia by rheumatologists, 13% by internists, 4% by neurologists, 26% by other physicians, and 2% by chiropractors. Only 30% of patients obtained a diagnosis after seeing 1 or 2 physicians, while 24% saw 7 or more physicians before being diagnosed, and 10% saw 11 or more physicians before being diagnosed. A statistically significant, negative correlation was found between the number of physicians seen before reaching a diagnosis and how well the respondent coped with fibromyalgia (rho = −0.14, $p = 0.001$). In addition, statistically significant, positive correlations were found between the number of physicians seen before reaching a diagnosis and the amount of pain (rho = 0.16, $p < 0.001$) and fatigue (rho = 0.16, $p < 0.001$) experienced during an average week and the total number of areas with pain or tenderness (rho = 0.17, $p < 0.001$).

Conclusions: Most fibromyalgia patients saw at least three physicians before receiving a diagnosis, and a quarter went to at least 7 doctors for fibromyalgia related symptoms before obtaining a diagnosis. Larger numbers of physicians seen before reaching the diagnosis of FMS was associated with worse symptoms and worse ability to cope with fibromyalgia. Those with more intense symptoms tended to 'doctor shop' looking for a diagnosis they could understand. Rheumatologists made the diagnosis much more often than other physicians. Better education of non-rheumatologists in the diagnosis of fibromyalgia and more acceptance of the diagnostic criteria in the general medical community would help patients with fibromyalgia receive an earlier diagnosis.

2075

Impact of Fibromyalgia (FMS) on Work. Robert S. Katz[3], Sharon M. Ferbert[1], Susan Shott[4] and Katrin F. Katz[2]. [1]Advocates for Funding Fibromyalgia Treatment, Education and Research (AFFTER), Libertyville, IL, [2]Rheumatology Associates, [3]Rush University Medical Center, Chicago, IL, [4]Rush University Medical Center

Purpose: The pain, fatigue, and cognitive difficulties associated with FMS can make it difficult for patients to perform well in most work environments. In order to investigate the extent to which FMS affects the capacity to work, we asked fibromyalgia patients about their work experiences.

Method: 115 FMS patients and 63 control patients with other rheumatic diseases answered a 2010 rheumatology clinic questionnaire that included questions about the impact of FMS and other medical problems on their ability to work and the coping mechanisms they use to deal with work. The chi-square test of association and Fisher's exact test were used to compare percentages, and the Mann-Whitney test was done to compare FMS and control patients with respect to age. A 0.05 significance level was used and all tests were two-sided.

Results: 81.7% of the FMS patients and 61.9% of the control patients were women ($p = 0.004$). The mean age was 48.1 12.3 years for FMS patients and 50.7 13.6 for control patients ($p = 0.092$). Only 42.1% of FMS respondents reported that they were working full-time, compared to 57.1% of controls, although the difference was not statistically significant ($p = 0.064$). In response to the question, If you are working part-time, why are you not working full-time?34.8% of FMS patients reported that they were unable to work full-time because of FMS. Only 30.4% of FMS respondents who worked part-time said they choose to work part-time, compared to 55.6% of controls who worked part-time, although the difference was not statistically significant ($p = 0.24$). The majority of FMS respondents who were unable to work or unable to work full-time reported that pain (80.0%), fatigue (60.0%), or concentration difficulties (73.3%) hindered their ability to work. In addition, 13.3% of FMS respondents who were unable to work or unable to work full-time reported that employers aren't sensitive to the impairments of FMS, and 46.7% reported that they were frequently late or missed work. In response to the question, If you have FMS and work full-time or part-time, what helps you cope?the most common answer was that they were taking medications that allowed them to work (66.7%). Other responses included having to work because they needed the money (56.7%), flexible work hours (26.7%), alternative treatments such as yoga and acupuncture (18.3%), and work environment changes that made work easier (13.3%).

Conclusion: FMS has a major impact on patients' ability to work. Pain, fatigue, and concentration difficulties have a strong impact on job performance among FMS patients. Medications were the most frequently reported means of coping with work, followed by the need for money.

Improvement of Hand Function in African Americans with Scleroderma: Use of a Hand Continuous Passive Motion. Paula Fenter[2], Samina Hayat[1] and Carla Saulsbury[1]. [1]Shreveport, LA, [2]Louisiana State University Health Sciences Center, Shreveport, Shreveport, LA

Introduction: Movement in the hands is essential to daily functional activities however persons with Scleroderma are at high risk for loosing this function which can lead to loss of independence. It is therefore essential that rehabilitation healthcare professionals work to maintain hand function in these individuals so that independent living can continue while living with this disease and that a good quality of life can be preserved.

Subjects: Three African American individuals who were diagnosed with Scleroderma and had hand involvement were assessed for hand function and given standard exercise program.

Methods: Active range of motion (ROM) was performed on bilateral wrists and hands and the Arthritis Hand Function Test (AHFT) was performed. Each individual was instructed to participate in a daily active motion exercise program for both hands. A continuous passive motion (CPM) machine was placed on the right hand of each individual and the left hand received no CPM intervention. The Arthritis Hand Function Test was also administered. Each individual wore the CPM at night from 2–4 hours on the right hand only. Measurements were taken after at least four weeks of CPM for comparison. The medical records of these individuals were reviewed for this study.

Results: Two of the subjects gained greater than 60 degrees of total active movement of the digits on the hand that received the CPM as compared to the hand that had only active exercise. The other subject gained more active movement in the hand that did not have CPM treatment but did have daily active exercise. All of the subjects had improvement in the AHFT.

Significance: This pilot study shows that improvement in hand function can improve with intervention addressing motion of the hands. Whether active motion alone or active motion with the addition of continuous passive motion is optimal treatment intervention is not clear. This pilot should provide a basis for further research into which is the best treatment for individuals at risk of losing hand function and independence.

The Mary Kirkland Center for Lupus Care (MKCLC): A Multi-Disciplinary Specialized Disease Center. Pretima Persad[2], Suzy Kim[2], Monica Richey[3], Jane E. Salmon[1], Doruk Erkan[2] and Kyriakos A. Kirou[2]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgery

Background: The complexity of disease in Systemic Lupus Erythematosus (SLE) and Antiphospholipid Syndrome (APS) creates management challenges that require a multi-disciplinary approach for optimal patient outcomes. Additionally, the increased interest of research in the field has generated the need for better organization in rheumatology practices and clinics in order to more efficiently recruit for research. We responded to these challenges by founding the MKCLC with the primary goal of integrating *patient care, patient/physician education, and research*.

Purpose: To report on the organization and growth of the MKCLC over the last year and show that the MKCLC is a candidate model for other multi-disciplinary specialized disease centers at our hospital.

Methods and Structure: Creation: The Center was launched by its current Co-Directors and Steering Committee with the generous support from Rheuminations, Inc.

Patient Care and Multidisciplinary Model: The Center was built around the Friday Lupus Clinic and its corresponding multi-disciplinary conference with participation of fellows, "lupus attendings" and social workers (SW). A Center Manager was given the key task to oversee the execution of the Center's goals and its growth. Additional important support roles have been the Center's Nurse Practitioner, who performs initial patient triage and the SW Manager who screens all new patients for their psychosocial needs.

Patient/Physician Education: Formal multi-disciplinary monthly conferences integrate SLE and related fields, embracing all aspects of care, with an emphasis on lupus nephritis. The Center has created a unique website within the hospital's main site, which highlights the Center's developments and provides resources for patients and staff.

Research: Patient access to research has been streamlined through the Center's Manager in order to maximize recruitment for industry or investigator-initiated research.

Results: Since April 2007, 186 SLE and/or APS clinic patients (87% female, mean age: 40, range: 18–78) have been included in the MKCLC database. Of 186 patients: a) 161 (87%) have been assessed by the SW Manager and referred to one of the five culturally relevant support and education programs offered by the Department of SW Programs; b) 99 (53%) have participated in our pre-existing Autoimmune Disease Registry and Repository; c) 88 (47%) have been referred to the Cardiovascular Disease Prevention Counseling Program and d) 42 (23%) have participated in cross sectional, observational or interventional research studies.

Conclusion: A multi-disciplinary specialized disease center dedicated to SLE and APS has been created to facilitate comprehensive care of patients, physician education, and research. Our Center provides the opportunity to examine whether: (1) specific patient-related education and support initiatives improve clinical outcomes; (2) our coordinated multi-disciplinary approach improves physician education and patient quality of care; and (3) a structured research database and patient screening improves research participation at our center.

TNF Blockage in Spondyloarthritis: Induction of Alveolar Bone Growth in Teeth with Periodontal Disease? Gisele Maria Campos Fabri[1], Cynthia Savioli[2], Carla G. S. Saad[5], Ana Luisa Garcia Calich[5], Julio Cesar Bertacilli Moraes[5], Ana Cristina Medeiros Ribeiro[5], Jozélio Freire Carvalho[5], Percival Sampaio-Barros[5], Clovis Almeida Silva[4], Rosa Maria Pereira[5], José Tadeu Tesseroli Siqueira[3] and Eloísa Bonfá[5]. [1]Dentistry and Rheumatology Division (CEDMAC), Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Dentistry and Rheumatology Division (CEDMAC), Faculdade de Medicina da Universidade de São Paulo, [3]Dentistry Division, Faculdade de Medicina da Universidade de São Paulo, [4]Paediatric Rheumatology Unit, Rheumatology Division (CEDMAC), Faculdade de Medicina da Universidade de São Paulo, [5]Rheumatology Division (CEDMAC), Faculdade de Medicina da Universidade de São Paulo

Purpose: Previous studies have shown that patients with spondyloarthritis (SpA) have a significant higher risk of periodontal disease (PD). SpA also can induce periosteal bone formation suggesting that the impact of inflammation on bone is specific to the site at which inflammation occurs. We therefore have evaluated the local effect of TNF-antagonist therapy in PD of SpA patients.

Methods: Nineteen SpA patients (ESSG criteria) were prospectively evaluated at baseline(BL) and after 6 months(6M) of anti-TNF therapy. A dentist performed systematic periodontal assessment that included: clinical measurements of periodontal disease severity [probing pocket depth(PPD), cementoenamel junction(CEJ), clinical attachment level(CAL)], gingival inflammation (gingival bleeding index), and oral hygiene (plaque index). All patients were examined by a rheumatologist, blinded to dentist assessment, in order to evaluate demographic data and outcome measures (BASDAI, BASMI, BASFI, ASQoI, CRP, ESR).

Results: Eleven patients (58%) were male, with median age 45(20–61) years and median disease duration 8(1–41) years. Infliximab was used by 12(63%) patients, adalimumab by 6, and etanercept by 1. CRP (16 vs. 4.2mg/L, p=0.003), BASDAI (5.25 vs. 2.65, p=0.001) and BASFI (5.25 vs. 1.95, p=0.017) improved significantly at 6M. No differences were observed in the median of clinical measurements of periodontal disease severity, gingival inflammation and oral hygiene 6M after TNF antagonist use in the whole group. Eight patients (42%) had PD; in these patients, the periodontal assessment of all teeth showed no differences in the median of plaque, gingival bleeding indices, PPD, CEJ, CAL at BL *versus* 6M period (p>0.05). However, the specific longitudinal analysis of teeth with periodontal disease revealed that only PPD had a significant improvement comparing BL *versus* 6M visit [3.67 (3.8–4.27) vs. 2.77mm (2.47–3.03), p=0.003] whereas CEJ [0.53 (−0.58–2.03) vs. 1.66mm (−0.74–2.04), p=1.0] and CAL [3.98 (2.83–5.93) vs. 3.54mm (2.09–4.7), p=0.130] remained stable; this isolated PPD improvement without change in other PD measurements suggests a local bone formation. Despite the PPD improvement, there was no significant resolution of the local inflammation after 6M of anti-TNF therapy, as demonstrated by the persistence of plaque [75.3 vs. 79.8%, p=0.749] and gingival bleeding index [52.4 vs. 39.6%, p=0.641].

Conclusions: This study suggests that blockade of TNF activity in SpA patients with periodontal disease may induce a local bone growth. The most likely mechanism underlying this process is a persistent periodontal inflammation disrupting local bone remodeling.

What Do We Really Know about Arthritis Impact on Employment from Prospective Studies? A Systematic Review of the Literature. Kristina A. Theis, Ross Wilkie, Lucy Busija, Gerald Elsworth and Richard Osborne. Deakin University

Background: Work disability results from many rheumatic conditions and is known to have substantial personal and societal consequences. Much of what we know about arthritis impact on employment comes from condition-specific cross-sectional studies. A comprehensive search strategy was conducted to identify prospective studies demonstrating how arthritis impacts work.

Methods: Publications were identified by an online electronic search of 6 databases (MEDLINE, JSTOR, PsychINFO, CINAL, EMBASE, and Social Science Abstracts) conducted in early 2010 together with a hand search of references in all obtained literature. Searches were performed with the following terms: "arthritis (in title or abstract) AND work (in title or abstract)" in combination (independently) with: moderate, mediat*, interaction, buffer, buffering, "path analysis", longitudinal, causal, "risk factor", mitigate, associat*, predictor, and explanatory. Inclusion criteria for review: prospective study design assessing work impact at 2 or more time points in adults (≥ 18 years) with an arthritis/rheumatic condition, published in English. Biomedical, scale/instrument development, drug trial, and intervention studies were out of scope. Compliance with the STrengthening the Reporting of OBservational studies in Epidemiology (STROBE) consensus statement was examined as a marker for study quality.

Results: Electronic searches returned 2,877 potential publications; after duplicate removal and title/abstract review 90 remained and were retrieved for complete review. An additional 110 records were identified through hand searching and assessed for eligibility. In total, 15 publications met inclusion criteria for abstraction, 10 of which concerned rheumatoid arthritis, 1 each on fibromyalgia and osteoarthritis, 2 on systemic lupus erythematosus, and 1 included multiple conditions. No study included all relevant STROBE items, with the most commonly omitted including discussion of potential biases and clear reporting of participants at each stage. Definitions of work impact varied but were most often related to work cessation; 3 studies examined more subtle impacts (i.e., productivity, sick leave, work transitions). Methodological approaches were diverse including path and survival analyses and logistic and Cox regression. Characteristics examined could be categorized into 4 general groups (demographics, arthritis-specific, general health/disability, and work-specific). Preliminary results indicated that disability/functional limitation and age were the strongest and most consistently identified predictors of work impacts with less consistent results for work-specific, arthritis-specific, and social characteristics.

Conclusion: With the exceptions of age and disability, there is little consistent evidence for predictors of arthritis impact on employment from prospective studies. Robust conclusions are limited by differences in potential predictors examined, work impact definitions, and methods. However, findings from this systematic review indicate reasonable starting places for policy and public health efforts to mitigate arthritis impact on work.

2080

Where Do Adults with Arthritis Get Information about Arthritis? Louise Murphy[3], Kristina A. Theis[3], Teresa J. Brady[2], Julie Bolen[3] and Patience White[1]. [1]Arthritis Foundation, [2]Center for Disease Control, Atlanta, GA, [3]Centers for Disease Control and Prevention

Background: Knowing what sources people with arthritis rely upon for information is important for identifying channels for disseminating arthritis information. Our study objective was to identify what existing sources adults with arthritis rely on for information about arthritis and to assess their interest in specific potential resources.

Method: We analyzed data from a national U.S. phone survey of white and black adults (n=1,002), ages 40–70 years old, who have doctor diagnosed arthritis ("Have you EVER been told by a doctor or other health professional that you have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?), and "some" or "many" limitations due to arthritis. Participants rated how much (a lot, somewhat, a little, not at all) they relied on the following sources for information about arthritis: doctor, pharmacist, family/friends, magazine/newspaper, internet, TV/radio. They also reported how likely (very or somewhat likely or very or somewhat unlikely) they would be to use a 1–800 number, arthritis expo (with exhibits and booths), and periodic 1–4 page publication for general information on arthritis. For each information source, we studied the distribution of ratings overall and by socio-demographic (S-D) variables (age, sex, race, education, income, employment status).

Results: Two thirds (68%) reported relying "a lot" on doctors for information about arthritis, with considerably less reliance on other information sources: "a lot" ratings for other sources ranged from 20% for pharmacists to 8% for TV/radio. The high reliance on doctors and substantial gap in "a lot" of reliance on other sources persisted across S-D groups. There was variation in the S-D characteristics of those reporting "a lot" of reliance on the other information sources (e.g., 28% of blacks reported "a lot" of reliance on pharmacists compared with 18% of whites). Whereas almost half of respondents reported "not at all" for reliance on TV/radio (47%) and the internet (46%), only 6% indicated no reliance on doctors for arthritis information. When asked about potential resources, 20% were "very likely" to use a 1–800 number and 24% for both an arthritis expo and the periodical. For each proposed resource, approximately a quarter indicated they would be "very unlikely" to access. Likelihood of using resources varied across S-D characteristics (e.g., 38% of blacks reported being "very likely" to use a toll-free number compared with 16% of whites).

Conclusion: Doctors were the most relied upon information source, eclipsing all other existing information sources studied; this was consistent across all S-D groups. There was some variation in the S-D characteristics of those who reported "a lot" of reliance on information sources other than doctors. This indicates that the choice of these channels should vary according to the target group. The high percent indicating no reliance on the internet or TV/radio suggests that these are less desirable channels for disseminating arthritis information to the general population of adults with arthritis.

2081

Rheuma on the Road—The Rheuma Truck Mass Communication, Educational Advertising and Creative Community Care. Matthias K. Schneider[2] and Martina Blumenroth[1]. [1]Cooperative Rheumatology Association Rhine-Ruhr MNR-Klinik, Duesseldorf, Germany, [2]MNR-Klinik, Duesseldorf, Germany

Aim: In Germany, the public is uninformed about symptoms and treatment of RA.

People are entertaining an outmoded image, e.g. that RA is an old-age disease. This has undesired consequences for early diagnosis in young RA-patients.

As the disease needs public relation in Germany, an educational advertising campaign with "The Rheuma Truck" as a mass communication medium was initiated. The truck was sent to public places to generate awareness, especially with younger people. Early diagnosis of the disease was promoted by informing the public about early symptoms of RA and to check people for RA.

Methods: The German Coop. Rheumatology Assn. Rhine-Ruhr (RZ-RR) hired a 35-ton truck, furnished with a spectacular design, slide-out extended floors on both sides, and equipped with facilities suitable for educating and screening several thousand people for rheumatic diseases. The Rheuma Truck was scientifically guided and evaluated as a screening tool for early diagnosis and mass communication.

The truck visited 22 cities during 26 days in the Rhine-Ruhr area. Participation was at no charge, there were no restrictions for participation except established diagnoses of inflammatory rheumatic disease.

Twelve medical students from the whole range of medical education accomplished the tests. Rheumatologists from RZ-RR gave advice to visitors who were assigned a consultation depending on test results.

We used the German version of the CSQ, called RheumaCheck, and also a questionnaire for ankylosing spondylitis (AS), a computer network, a rapid diagnostic bloodtest for RF and MCV-antibodies yielding qualitative results in 15 minutes, venous blood collection for quantitative results of RF and MCV-antibodies and HLA-B27, a capillary microscope and an ultrasonic device for arthrosonography.

The German patients' organization "Deutsche Rheuma-Liga" supported the crew with information leaflets and talks about early symptoms.

Results: 193 press releases with 42,728,291 contacts and 6,250 google hits were counted for the event. 3,196 visitors were tested, 2/3 female, with an average age of 54.9 years. The RheumaCheck questionnaire yielded 347 times a positive result, 65 visitors were positive for MCV-antibodies and 230 for RF, 34 were positive for RF+MCV. The AS-check was positive 711 times with 11% of those being positive for HLA-B27, too.

The costs were $ 97,000.00 ($30 for each tested person, $ 15 for each google hit and $ 0.002 for each contact).

Conclusion: The Rheuma Truck with its eye-catching design highly attracted attention. It achieved great awareness with 42,728,291 contacts for a low price of $ 0.002 each. Visitors became aware about their risk and know the symptoms of RA, in order not to lose time when they occur, and thus achieve specialized treatment within six months. It was therefore suitable for informing the public and identifying people at early stages of RA and those at risk even before symptoms occur.

A Study of Pictorial Representation (Mind Map) To Convey Health Education on Osteomalacia to People with Low Language Literacy Skills. Adewale O. Adebajo[5], David Walker[3], Sandra Robinson[4], Yogenjagat Singh[3], Philip Helliwell[2] and Anisur Rahman[1]. [1]University College London, London, United Kingdome, [2]University of Leeds, Leeds, United Kingdom, [3]University of Newcastle, Newcastle, United Kingdom, [4]University of Newcastler, Newcastle, United Kingdom, [5]University of Sheffield Medical School Sheffield United Kingdom, Sheffield, United Kingdom

Background: It is well recognised that health education needs to be provided in different ways to match different learning styles and literacy skills in order to ensure effective patient education for everyone. In order to acheive this, we have through an iterative process and in partnership with Arthritis Research UK developed a Mind Map based on pictorial representation which provides health education on the topic of osteomalacia. We were particualrly keen to ascertain whether this novel health education tool was acceptable to ethnic minorities who originate from the South Asian Sub Continent and particualrly those wih low language literacy skills. Against this background we have performed this ethnicity study using this Mind Map.

Methods: In depth studies were carried out amongst ten English speakers, six Bangali speakers, ten Gujerati speakers, ten Hindi speakers, ten Punjabi speakers and ten Urdu speakers (N=56). Participants were given sample images from the Mind Map and asked to comment on meaning to ascertain suitability, effectiveness and potential to cause inadvertant offence.

Results: Overwhelmingly, the respondents felt that the Mind Map was an effective and appropriate way of communicating health education on osteomalacia, particularly for those people with low language literacy skills. The Mind Maps were also felt to be of particular benefit to those ethnic minorities, for whom English is not their first language.

Cultural specific comments were made in relation to the depiction of food with 4/20 Gujerati and Hindu speakers saying that the picture should represent what they eat, for example depicting a vegetarian diet. Appropriateness responses divided into those which are generic and would apply to anyone, and those that were culturally specific. The general comments were that the bone metabolism depiction could be confusing (31/56), the muscle weakness could be confused with knee pain (16/56), the mending and cracking bone was confusing (22/56) and the picture of a man with bone pain could be confused with toochache (21/56). Inadvertent offence was felt to be highly unlikely and only related to the picture of an old lady in a bed (1/56) and venepuncture (2/56).

Conclusions: Our study indicates that the use of pictorial representation (Mind Maps) are an effective way of achieving patient education. Specifically our study has shown this novel health education tool to be considered appropriate and effective by participants from several ethnic minority groups arising from the South Asian Sub Continent. We recommend Mind Maps as part of the range of tools available for Health Care Professionals to provide health education about musculoskeltal conditions, espeically for people who have low language or literacy skills.

Using Social Media To Recruit for a Translational Lupus Research Study for the Millennial Generation—The SisSLE Experience. Marlene H. Kern[2], Sally Kaplan[2], Bonnie Gonzales[2], Betty Diamond[1] and Peter K. Gregersen[2]. [1]Feinstein Institute for Medical Research, Manhasset, NY, [2]The Feinstein Institute for Medical Research, Manhasset, NY

We report on our experience with a pilot registry with the goal to enroll 400 sisters, one diagnosed with lupus, along with one or more sisters without lupus to determine early risk factors of lupus. The enrollment age group is 10–35 years of age. Initially, recruitment by traditional means (i.e. newspaper articles, posters, flyers, health fair recruitment) was not effective and we moved to the use of the Internet and social media. Incorporating the use of the internet enhanced the

response rate. Most people in this age group are "connected" to the internet and we recognized we needed to utilize new methods.

We developed an interactive website that would appeal to this age group: www.SisSLE.org. The nature of the photos, graphics and presentation were intended to attract young users to the site. Study forms are available for *read only* to prepare the potential study subject for their interview. A *contact us* page allows users to email us directly from the website.

We developed standard press releases; template email letters and responses for pre-approval by the IRB. We established liaisons with lupus support organizations throughout the United States asking them to add our website link to *their* website, Facebook page, Twitter feeds, and any other social networking accounts.

As we enrolled young women into our study, we asked them to add a link to our website on their Facebook pages, Twitter feeds and any other internet interaction with lupus groups. Some study subjects took it upon themselves to *blog* about their participation in the study or add a step-by-step accounting of the process of joining the study. While HIPAA is still respected and research confidentiality has been maintained, these women have taken it upon themselves to share their lives with the world creating a ripple effect and reaching other potential study subjects. The bloggers share their written experiences with others thus becoming ambassadors for the study. Our newest recruitment addition is the use of Craigslist. Every 48 hours our posting can appear in a new city. Inquiries are directed to our email address. We have begun to receive responses at this time.

Social networking in research recruitment is new and rapidly evolving. These are new enrollment methods for many healthcare professionals and IRB's and present challenges to maintaining order and confidentiality while keeping current with trends.

Rates of Malignancy Associated with Juvenile Idiopathic Arthritis and Its Treatment: An Observational Study of National U.S. Medicaid Administrative Claims Data. Timothy Beukelman[4], Kevin Haynes[2], Jeffrey R. Curtis[3], Fenglong Xie[1], Lang Chen[1], Elizabeth Delzell[1], Hopiy Kim[2], Kenneth G. Saag[5] and James D. Lewis[2]. [1]Univ of Alabama at Birmingham, [2]Univ of Pennsylvania, [3]University of Alabama-Birmingham, Birmingham, AL, [4]University of Alabama-Birmingham, Birmingham, AL, [5]University of Alabama-Birmingham, Birmingham, AL

Background: A possible increased risk of malignancy in children with juvenile idiopathic arthritis (JIA), particularly in those receiving treatment with tumor necrosis factor alpha inhibitors (anti-TNF) has been reported. We analyzed national Medicaid administrative claims data to determine standardized rates of malignancy among children with JIA.

Methods: Using Medicaid data from all 50 U.S. states from 2000 through 2005, we identified a cohort of children with JIA based on physician diagnosis codes and dispensed medication prescriptions. We identified non-JIA control cohorts of children diagnosed with asthma and attention deficit hyperactivity disorder (ADHD). Subjects were excluded if they had any physician diagnosis code for malignancy prior to study entry. All subjects had a minimum 9 month baseline assessment period prior to study entry in which to identify prevalent malignancies. For all subjects this baseline assessment period included at least 3 months subsequent to satisfying the disease cohort definitions in order to identify potential incident cancers that were initially misdiagnosed as JIA. Exposure to methotrexate (MTX) and anti-TNF was determined based on dispensed medication prescriptions. Exposed subjects were considered forever exposed and all follow-up time was categorized into 3 groups: (1) no MTX and no anti-TNF; (2) any MTX and no anti-TNF; (3) any anti-TNF. Subjects could contribute follow-up time to more than 1 exposure category sequentially. Malignancy outcomes were defined using physician diagnosis codes, medication codes, and procedure codes using an extension of a previously validated algorithm. Follow-up was censored at loss to follow-up, malignancy outcome, and study end. We calculated crude incidence rates for all malignancies and lymphoma/leukemia for all study groups. Crude rates were standardized to the age, sex, and race distribution of the overall JIA cohort.

Results: The JIA cohort included 7,321 subjects with a median follow-up study time of 1.1 years. Among the JIA subjects, 3,194 were exposed to MTX and 1,413 were exposed to anti-TNF. The asthma (N = 623,663) and ADHD (N = 308,454) cohorts had median follow-up study times of 0.7 and 0.9 years, respectively. Malignancies were identified in 183, 63, and less than 11 patients with asthma, ADHD, and JIA respectively. Crude and standardized rates for all malignancies and for lymphoma/leukemia are shown in the Table. The standardized malignancy rates for JIA were 2 to 3-fold higher than those for ADHD and asthma. No cases of malignancy were identified in JIA subjects who had been exposed to anti-TNF.

	All Malignancy		Lymphoma & Leukemia	
Disease and Exposure Group	Crude Rate per 100K pt-years	Standardized Rate	Crude Rate per 100K pt-years	Standardized Rate
All JIA	58.6 (27.9–122.9)	58.6	25.1 (8.1–77.9)	25.1
JIA no MTX, no TNF	89.8 (37.4–215.8)	93.5	18.0 (2.5–127.5)	21.7
JIA any MTX, no TNF	54.8 (13.7–219.3)	49.3	54.8 (13.7–219.3)	49.3
JIA any TNF	(none)	(none)	(none)	(none)
Asthma	28.0 (24.3–32.4)	26.8	9.8 (7.7–12.5)	9.3
ADHD	16.8 (13.2–21.6)	22.8	7.0 (4.7–10.2)	9.4

Conclusions: Children diagnosed with JIA, irrespective of MTX use, appeared to have an increased risk of malignancy compared to children with asthma and ADHD. There were no cases of malignancy identified in more than 2,700 person-years of anti-TNF exposure in more than 1,400 subjects with JIA.

Aspreva Lupus Management Study (ALMS): Maintenance Results. Ellen M. Ginzler[4], Gerald B. Appel[1], Mary Anne Dooley[7], David A. Isenberg[5], David Jayne[3], David Wofsy[6], Neil Solomons[8], Laura Lisk[9] and David R. Close[2]. [1]Columbia University, New York, [2]MedImmune Ltd, [3]Renal Unit, Addenbrooke's Hospital, Cambridge, United Kingdom, [4]SUNY-Downstate Medical Center, Brooklyn, NY, [5]University College London, London, United Kingdom, [6]University of California, San Francisco, San Francisco, CA, [7]University of North Carolina at Chapel Hill, Chapel Hill, NC, [8]Vifor Pharma (formerly Aspreva Pharmaceuticals), BC, Canada, [9]Vifor Pharma, UK, Bagshot, Surrey, United Kingdom

Background: The 36-month, maintenance phase of the ALMS study (NCT00377637) compared the efficacy and safety of mycophenolate mofetil (MMF) with azathioprine (AZA) in patients with active lupus nephritis (LN) achieving partial or complete response during the 6-month induction phase.

Methods: Patients were re-randomized 1:1 to a double-blind comparison of either oral MMF (2 g/day) plus placebo or oral AZA (2 mg/kg/d) plus placebo. Patients were permitted to receive corticosteroids (CS; maximum dose: 10 mg/d prednisone or equivalent). The primary efficacy outcome measure was time to treatment failure (death, end-stage renal disease [ESRD], sustained doubling of serum creatinine, renal flare [proteinuric or nephritic], and/or requirement for rescue CS). Key secondary parameters included time to event for each individual component of treatment failure: complete renal remission; combined renal and extra-renal remission; major extra-renal flare (British Isles Lupus Assessment Group score category A in 1 extra-renal system or 3 systems with concurrent category B scores); and adverse events (AEs).

Results: Of 227 patients randomized (intent-to-treat population), 127 completed (MMF, 73/116 [62.9%]; AZA, 54/111 [48.6%]). Demographic and disease characteristics were similar across groups at baseline. MMF was superior (log-rank test) to AZA in time to treatment failure (primary endpoint, P=0.003). MMF was superior to AZA (log-rank test) with respect to the following components of treatment failure: time to renal flare (P=0.027) and time to rescue therapy for LN (P=0.017). All other elements of the primary efficacy parameter showed numerical benefit in favor of MMF: time to ESRD (P=0.069) and time to sustained doubling of serum creatinine (P=0.073). MMF was superior to AZA with respect to the key secondary endpoint: time to first confirmed or suspected renal flare (P=0.012). Times to combined renal and extra-renal remission, and major extra-renal flare did not differ between the 2 groups (P=0.416 and P=0.936, respectively). The superiority of MMF over AZA was consistent regardless of induction treatment (MMF or

cyclophosphamide [IVC]), race, or geographic region. The incidence of AEs was similar between MMF and AZA groups; the most common AEs in both groups were infections/infestations and gastrointestinal disorders. Numerically fewer patients treated with MMF than AZA reported at least 1 serious AE (27/115 [23.5%] vs 37/111 [33.3%]. One death (AZA group, unrelated to treatment) occurred during the study.

Conclusions: MMF was superior to AZA in maintaining renal response and preventing relapse in patients with active LN who responded to induction therapy with CS and either MMF or IVC.

Efficacy of Tadalafil in Raynaud's Phenomenon Secondary to Systemic Sclerosis: A Double Blind Randomized Placebo Controlled Parallel Group Multicentric Study. Vikas Agarwal[8], Parasar Ghosh[6], Aman Sharma[7], Darshan Singh Bhakuni[5], Sudeep Kumar[1], Upendra Narayan Singh[1], Rajesh Vijayvergiya[3], Mukesh Kumar Yadav[4], Geetabali Devi Laishram[2], Alakendu Ghosh[2], Bhuban Majhi[2], Dipankar Mukherjee, S. S. Islam and Aditya Kapoor. [1]Lucknow, India, [2]Kolkata, India, [3]Chandigarh, India, [4]Chandigarh, India, [5]Army Hospital Research & Refferal, New Delhi, India, [6]IPGMER, Kolkata, [7]PGIMER, Chandigarh, India, [8]SGPGIMS, Lucknow, UP, India

Objective: To evaluate the efficacy of Tadalafil in Raynaud's phenomenon (RP) secondary to systemic sclerosis (SSc).

Methods: Patients with scleroderma (as per ACR criteria) having ≥4 Raynaud's attacks/week were randomized to receive either placebo or Tadalafil (20 mg) on alternate days as add-on-therapy to their current vasodilators for eight weeks. Primary end points were improvement in RP parameters (daily frequency, duration and Raynaud's condition score [RCS]) and healing of existing digital ulcers (DU). Secondary outcome measures were appearance of new DU and improvement in scleroderma specific health assessment questionnaire (SHAQ) and quality of life (QoL) indices.

Results: We conducted a multicenter, randomized, placebo-controlled study with a 1-week run-in period to determine baseline severity, followed by a 8-week double-blind treatment phase. Fifty three patients (26 limited, 27 diffuse SSc, 50 females) with mean age 36.8 years and mean disease duration 62.8 months were recruited in the study. All the patients were receiving vasodilators (Calcium channel blockers n=38, angiotensin receptor blockers n=16, angiotensin converting enzyme inhibitors n=8 and a combination of two vasodilators n=13. Twenty six patients were randomized to placebo and 27 to Tadalafil arm. Baseline frequency, duration and severity of RP were not different between the two groups. Improvement in mean daily frequency, mean daily duration of RP and mean daily RCS was significant in the Tadalafil group ($p<0.001$, <0.001, <0.05, respectively), placebo ($p=0.77$, 0.821, 0.209, respectively) as compared to the baseline RP parameters. The mean change in daily frequency ($p=0.01$), duration ($p=0.063$) and severity ($p=0.039$) of RP was significantly better in the Tadalafil group as compared to placebo group. Eighteen patients in the Tadalafil group had DU as compared to 13 patients in the placebo group at baseline. Following treatment, DU healed completely in 14/18 patients in the Tadalafil group as compared to 5/13 patients in the placebo group ($p=0.026$). New DU appeared in one patient in the Tadalafil group as compared to 9 patients in the placebo group ($p=0.004$). Questions related to dyspnea (Q2), Raynaud's phenomenon (Q4) and digital ulcers (Q5) of SHAQ improved significantly in the Tadalafil group. Adverse events (AE) were similar between the two groups. No serious AE was observed.

Conclusion: Tadalafil as add-on therapy improves symptoms of RP, heals the existing DU and prevent new DU in patients with scleroderma.

Efficacy of Canakinumab (ACZ885), a Fully Human Anti-Interleukin (IL)-1beta Monoclonal Antibody, in the Prevention of Flares in Gout Patients Initiating Allopurinol Therapy. Naomi Schlesinger[8], Hsiao-Yi Lin[7], Marc De Meulemeester[6], Evgeny L. Nasonov[2], Jozef Rovensky[4], Eduardo F. Mysler[5], Udayasankar Arulmani[3], Gerhard Krammer[3], Alison Balfour[3], Dominik Richard[3], Peter Sallstig[3] and Alexander K. So[1]. [1]CHUV Vaudois, Lausanne, Switzerland, [2]Institue of Rheumatology RAMS, Moscow, Russian Federation, [3]Novartis Pharma AG, Basel, Switzerland, [4]NURCH, Piestany, Slovakia, [5]OMI Organizacion Medica de Investigacion, Buenos Aires, Argentina, [6]Private Practice, Gozée, Belgium, [7]Taipei Veterans General Hospital, Taipei, [8]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ

Background: Gout patients initiating urate lowering therapy have an increased risk of flares. Inflammation in gouty arthritis is induced by IL-1β. Canakinumab targets and inhibits IL-1β effectively in clinical studies. This study compared different doses of canakinumab vs colchicine in preventing flares in gout patients initiating allopurinol therapy.

Methods: In this 24 week double blind study, gout patients (20–79 years) initiating allopurinol were randomized (1:1:1:1:1:1:2) to canakinumab s.c. single doses of 25, 50, 100, 200, 300 mg, or 150 mg divided in doses every 4 weeks (50+50+25+25 mg [q4wk]) or colchicine 0.5 mg p.o. daily for 16 weeks. Primary outcome was to determine the canakinumab dose giving comparable efficacy to colchicine with respect to the number of gout flares occurring during first 16 weeks. Secondary outcomes included number of patients with gout flares and C-reactive protein (CRP) levels during the first 16 weeks.

Results: 432 patients were randomized and 391 (91%) completed the study. All canakinumab doses were better than colchicine in preventing flares and therefore, a canakinumab dose comparable to colchicine could not be determined. Based on a negative binomial model, all canakinumab groups, except 25 mg, reduced the flare rate ratio per patient significantly compared to colchicine group (rate ratio estimates 25 mg 0.60, 50 mg 0.34, 100 mg 0.28, 200 mg 0.37, 300 mg 0.29, q4wk 0.38; $p\leq0.05$). The percentage of patients with flares was lower for all canakinumab groups (25 mg 27.3%, 50 mg 16.7%, 100 mg 14.8%, 200 mg 18.5%, 300 mg 15.1%, q4wk 16.7%) compared to colchicine group (44.4%). All patients taking canakinumab were significantly less likely to experience at least one gout flare than patients taking colchicine (odds ratio range [0.22 – 0.47]; $p\leq0.05$ for all). The median baseline CRP levels were 2.86 mg/L for 25 mg, 3.42 mg/L for 50 mg, 1.76 mg/L for 100 mg, 3.66 mg/L for 200 mg, 3.21 mg/L for 300 mg, 3.23 mg/L for q4wk canakinumab groups and 2.69 mg/L for colchicine group. In all canakinumab groups with median CRP levels above the normal range at baseline, median levels declined within 15 days of treatment and were maintained at normal levels (ULN=3 mg/L) throughout the 16 week period. Adverse events (AEs) occurred in 52.7% (25 mg), 55.6% (50 mg), 51.9% (100 mg), 51.9% (200 mg), 54.7% (300 mg), and 58.5% (q4wk) of patients on canakinumab vs 53.7% of patients on colchicine. Serious AEs (SAE) were reported in 2 (3.6%; 25 mg), 2 (3.7%, 50 mg), 3 (5.6%, 100 mg), 3 (5.6%, 200 mg), 3 (5.7%, 300 mg) and 1 (1.9%, q4wk) patients on canakinumab and in 5 (4.6%) patients on colchicine. One fatal SAE (myocardial infarction, not related to study drug) occurred in colchicine group.

Conclusion: In this large randomized, double-blind active controlled study of flare prevention in gout patients initiating allopurinol therapy, treatment with canakinumab led to a statistically significant reduction in flares compared with colchicine (standard of care), and was well tolerated.

2088

Effects of Urate Lowering Therapy on Cardiovascular Mortality: A Taiwanese Cohort Study. Jiunn-Horng Chen[1] and Wen-Harn Pan[2]. [1]China Medical University, Taichung City, Taichung, Taiwan, [2]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, Province of China

Objective: Gout and elevated serum uric acid (sUA) level have been associated with cardiovascular disease (CVD); however, whether urate lowering therapy (ULT) is beneficial is still inconclusive. This study aimed

to clarify whether controlling sUA with ULT can improve outcomes of CVD.

Method: This prospective cohort study linked baseline clinical data of examinees from the MJ Health Clinical Center in Taiwan with drug dispensed database from the National Health Insurance, and outcome information from the National Mortality Registry for CVD death (ICD-9 code 390–459). Multivariate Cox proportional hazard model was applied to adjust for confounders including age, sex, hyperuricemia (>7.7 mg/dl for men or >6.6 mg/dl for women), overweight (BMI >24 kg/m^2), hyperglycemia (>100 mg/dl), hypertension (SBP ≥130 mmHg, or DBP ≥80 mmHg), hypercholesterolemia (>200 mg/dl), hyper-triglyceridemia (>150 mg/dl), renal insufficiency (GFR <90 ml/min per 1.73 m^2), and heart disease, kidney disease, arthritis, prior use of antihypertensive, anti-diabetic, steroid or analgesics, cigarette smoking, alcohol consumption, exercise, education, occupation, and working load.

Results: Among 45,215 participants (20,677 men and 24,538 women), 519 subjects died of CVD (308 men and 211 women) after a mean follow-up of 11.3 years. A preventive effect of ULT on CVD and stroke mortality was defined with respective hazard ratio (HR) of 0.56 (95% confidence interval, 0.46–0.70) and 0.42 (0.29–0.59) after multivariate adjustment. These effects were prominent for mortalities of hemorrhagic stroke and hypertension with corresponding HR of 0.12 (0.05–0.28) and 0.29 (0.13–0.63). Comparing with participants who did not use ULT, the users who continued treatment until outcome event or censor had better outcome (HR, 0.32; 0.21–0.49) than subjects who discontinue ULT for more than one year (HR, 0.68; 0.53–0.84). In the renal failure status (glomerular filtration rate <30 ml/min per 1.73 m^2), allopurinol usage was more beneficial (HR, 0.04; 0.01–0.25) than benzbromarone (HR, 0.60; 0.11–3.18) for CVD outcomes.

Conclusion: This study demonstrates a preventive effect of ULT for CVD mortality. Further replication studies are needed in the future.

Increased Fracture Rates among Female Osteoporosis Patients Taking Oral Bisphosphonates and Proton Pump Inhibitors Concurrently. Neetu Agashivala[1] and Wing Chan[2]. [1]Novartis Pharmaceuctical Corp, East Hanover, NJ, [2]Novartis Pharmaceuctical Corp

Background: Oral bisphosphonates can cause upset stomach and inflammation, and erosions of the esophagus. Oesophageal and stomach symptoms have been reported in patients taking oral bisphosphonates which may require proton pump inhibitor (PPI) therapy. However, PPIs may interfere with calcium absorption through induction of hypochlorhydria resulting in increased bone resorption. Recent epidemiologic studies have also found that people receiving high doses of PPIs or using them for one year or more are at an increased risk of fractures of the hip, wrist, and spine. The objective of this study was to determine the fracture rates among female osteoporosis patients taking oral bisphosphonates and PPI therapy.

Methods: A retrospective database analysis was conducted using the commercial and Medicare data from the MarketScan claims database for year 2005–06. All osteoporosis females age 50 years or above currently on oral bisphosphonates (alendronate or risedronate) for at least 90 days were included in this study. These patients were stratified into two groups based on PPI intake. The PPI group included lansoprazole, esomeprazole, omeprazaole, pantoprazole, and rabeprazole. PPI usage was defined as concurrent use of bisphosphonates and PPIs for 90 days or more. Combined fracture rates for hip, vertebral, and non-vertebral fractures were assessed among the two groups. Chi square analysis was performed by age categories using *SAS* software, version [8.2] of the *SAS* system for Windows.

Results: Of the 153,899 female osteoporosis patients age 50 and above taking oral bisphosphonates that were identified in the database, 28,304 were taking PPI concurrently. There were a total of 13,388 patients who had experienced a fracture, 3,780 in the PPI group and 9,608 in the non-PPI group. The chi square analysis showed that there was an increased fracture risk in the PPI group compared to the non-PPI group by all age groups (cmh=1.7044; p<.0001). The odds ratio were 1.8216, 1.9074, 1.6091, and 1.5166 in the >=50 and <65, >=65 and <75, >=75 and <85 and >=85 respectively (p<.0001).

Conclusion: PPIs appear to be associated with an increased fracture risk among female osteoporosis patients taking oral bisphosphonates. Further research in the area is required using case-control cohorts.

Disclosure: N. Agashivala: Novartis Pharmaceuticals Corporation, 3; **W. Chan:** Novartis Pharmaceuticals Corporation, 3.

Quality-Adjusted Life Expectancy Losses Due to Disparities in Total Knee Replacement (TKR) Offer and Acceptance Rates in African American (AA) Men and Women. Elena Losina[4], Lisa G. Suter[6], Alexander M. Weinstein[2], Ilya Golovaty[2], William M. Reichmann[3], Sara A. Burbine[2], Edward H. Yelin[5] and Jeffrey N. Katz[1]. [1]Brigham & Womens Hosp, Boston, MA, [2]Brigham and Women's Hospital, [3]Brigham and Women's Hospital, Boston University, Boston, MA, [4]Brigham and Women's Hospital, Boston University, Harvard Medical School, [5]University of California, San Francisco, CA, [6]Yale University, New Haven, CT

Background: The pathway to TKR in persons with end-stage knee OA requires both a health care provider's offer of surgery and patient's acceptance of that offer. A growing body of evidence has documented lower offer and acceptance rates of TKR in racial minorities. However, quality-adjusted life year (QALY) losses due to underutilization of TKR in racial minorities have not been described.

Methods: We defined the need for TKR as reaching Kellgren-Lawrence (K-L) grade 4 radiographic OA in persons with consistent pain. Based on published data we estimated that only about 50% of racial minorities deemed suitable for TKR are offered surgery, with immediate acceptance rates varying from 21% for African-American (AA) men to 10% for AA women for the first year followed by 7% during subsequent years. We defined index of participation (IoP) as a product of offer and acceptance rates. The base case IoP ranged from 11% for AA men to 5% for AA women. We used the Osteoarthritis Policy (OAPOL) model, a validated computer simulation model of knee OA natural history and treatment, combined with published population-based estimates of TKR outcomes and sex-race specific mortality, to determine the QALY losses due to lower IoP in AA men and women compared to White men (IoP=0.5; offer = 100%, accept = 50%). Future QALYs were discounted at 3% per year. We estimated QALYs across offer rates from 40 to 100% coupled with acceptance rates from 20% to 60% resulting in IoP varying from 8% to 60%.

Results: Estimated discounted QALYs in African American persons eligible for TKR at average age 73 years (SD 9) who did not receive TKR ranged from 6.0 QALYs for AA men to 7.1 QALYs for AA women. QALYs stratified by IoP for AA men and women are presented in the Figure. Base case IoP (11% and 5% for AA men and women respectively) resulted in estimated 6.2 QALYs for AA men and 7.2 QALYs for AA women. Compared to the IoP in White men the QALY losses were 0.62 and 0.92 QALYs for AA men and women respectively (Figure). For the same values of IoP, higher QALYs were evident in scenarios with greater acceptance (vs. offer) rates.

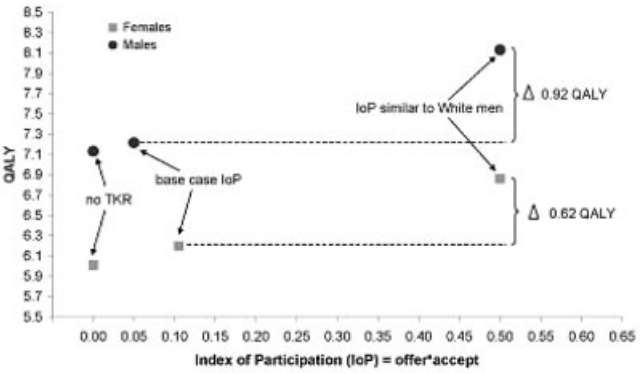

Figure. Quality-adjusted years of life losses due to lower rates of TKR offer and acceptance among African American men and women.

Conclusions: Documented underutilization of TKR in racial minorities leads to substantial losses in quality adjusted life expectancy. The same values of IoP for different offer and acceptance rates do not confer the same quality of life benefits. Interventions focused on better acceptance of TKR among those who have been offered TKR will lead to greater improvement in quality adjusted life expectancy in persons with end-stage knee OA.

Age of Symptomatic Knee OA Onset: Impact on Costs and Quality of Life. Elena Losina[5], William M. Reichmann[3], Ilya Golovaty[2], Edward H. Yelin[6], Hanna Gerlovin[2], Elizabeth A. Wright[2], David J. Hunter[7], Daniel H. Solomon[4] and Jeffrey N. Katz[1]. [1]Brigham & Womens Hosp, Boston, MA, [2]Brigham and Women's Hospital, [3]Brigham and Women's Hospital, Boston University, Boston, MA, [4]Brigham and Women's Hospital, Harvard Medical School, [5]Brigham and Womens Hospital, Boston, MA, [6]University of California, San Francisco, CA, [7]University of Sydney

Background: Symptomatic knee OA is debilitating and affects >4.5 million US adults. While traditionally viewed as a disease of the elderly, knee OA also affects younger adults, primarily due to history of sport-related injury or occupational exposure. Studies describing the age of patients with knee OA have focused on age at presentation to care or study initiation. Age of onset of symptomatic knee OA and its impact on quality of life and costs have not been described.

Methods: We used a validated computer simulation model of the natural history and management of knee OA, combined with published population-based estimates of incidence, progression, and impact on quality of life, to determine the age of onset, and the lifetime risk and costs associated with symptomatic knee OA and total knee replacement (TKR). We followed a simulated cohort representative of the US general population from age 45 to death. Knee OA treatment costs were derived from the Medicare reimbursement schedule and the Red Book, ranging from $609/yr for PT, NSAIDs, assistive devices and capsaicin to $20,456/yr for TKR. Costs related to comorbidities ranged from $557/yr for 0–1 to $3,603/yr for > 3 comorbidities. We defined TKR eligibility by Kellgren-Lawrence (K-L) grade 4 radiographic OA in persons with consistent pain. Costs (in 2008 US$) were reported as total direct medical costs and costs attributable to knee OA. Both costs and quality-adjusted life expectancy (QALE) were discounted at 3%/yr.

Results: The estimated lifetime risk of symptomatic knee OA was 15.3% with a mean age at onset of 68.7 (SD 13.6) years. Nineteen percent of those with symptomatic knee OA (2.9% of the overall population) developed it before the age of 55, 35.6% of those with symptomatic knee OA (5.4% of overall population) developed knee OA before age 65, and 62% (9.5% of overall population) developed symptomatic knee OA by 75 years of age. The discounted QALE in persons with early onset (before age 55) was 16.7 quality-adjusted life years (QALYs) compared to 17.8 for those with late onset (ages 75+). Early onset led to mean discounted lifetime costs attributable to knee OA of $14,156 per-person, compared to $1,658 for those with late onset. (Table) Among those who developed knee OA early, lifetime risk of TKR was 57.6% compared to 9.7% for those who developed knee OA late. Lifetime risk for revision TKR ranged from 12.1% for those with early onset to 0.4% for those with late onset of disease.

Age of symptomatic knee OA onset	QALE, discounted	Costs, discounted	Costs attributable to knee OA, discounted	Lifetime risk of TKR	Lifetime risk of revision TKR
45–54	16.7	$62,816	$14,156	57.6%	12.1%
55–64	17.0	$58,007	$ 9,191	46.2%	6.4%
65–74	17.5	$52,431	$ 3,714	24.6%	2.0%
75+	17.8	$50,375	$ 1,658	9.7%	0.4%

Conclusions: Early onset of symptomatic knee OA is prevalent in the general US population. It leads to substantial decrements in QALE and increases OA-associated costs. Early onset of symptomatic knee OA leads to 6- and 25-fold increases in the lifetime risk for primary and revision TKR. Injury prevention and weight management, implemented early in life, may delay the onset of symptomatic knee OA, improve quality of life and decrease the economic burden associated with knee OA.

2092

Projecting Lifetime Risk of Symptomatic Knee OA and Total Knee Replacement (TKR) in Persons Sustaining a Complete Anterior Cruciate Ligament (ACL) Tear in Early Adulthood. Elena Losina[4], Hanna Gerlovin[2], Lisa G. Suter[7], David J. Hunter[6], Sara A. Burbine[2], William M. Reichmann[5], Laurel Donnell-Fink[2], Daniel Hal Solomon[3] and Jeffrey N. Katz[1]. [1]Brigham & Womens Hosp, Boston, MA, [2]Brigham and Women's Hospital, [3]Brigham and Womens Hospital, Boston, MA, [4]Brigham and Womens Hospital, Boston, MA, [5]Brigham and Womens Hospital, Boston University, Boston, MA, [6]University of Sydney, [7]Yale University, New Haven, CT

Background: Over 175,000 persons sustain anterior cruciate ligament (ACL) tears annually in the US. ACL tears are especially common in active, younger persons. ACL tears are often accompanied by meniscal tears. We sought to forecast the lifetime risk of radiographic and symptomatic knee OA, and total knee replacement (TKR) in persons who sustain a complete ACL tear in early adulthood.

Methods: We used the Osteoarthritis Policy (OAPol) Model, a state-transition computer simulation model for the natural progression and management of knee OA, to estimate the lifetime risk of radiographic symptomatic knee OA, and TKR in persons with and without a history of a complete ACL tear by early adulthood (before age 25). Rates of OA progression in the absence of an ACL tear were estimated from the Johnston County Osteoarthritis Project. Rates of knee OA incidence in the absence of an ACL tear were derived from published literature and coupled with published estimates on the increased risk of incidence and progression of knee OA following an ACL tear, with or without a concomitant meniscal tear. Persons with symptomatic end-stage OA, defined as Kellgren-Lawrence grade 4 radiographic OA with knee pain, were considered eligible for TKA.

Results: By age 50, 43% of those who sustained a complete ACL tear in early adulthood (by age 25) developed radiographic knee OA and 19% had symptomatic knee OA, as compared with 8% and 3% respectively for those without an ACL tear. For those with a history of an ACL tear accompanied by a meniscal tear, 53% developed radiographic knee OA and 21% developed symptomatic knee OA by age 50. Among persons without an ACL tear, 0.3% were eligible for TKR by age 50, while among those sustaining an ACL tear by age 25, 2% were eligible for TKR, and for those with ACL and meniscal tears by age 25, 11% reached eligibility for TKR (Figure). By age 60, 32% of those with ACL and meniscal tears were eligible for TKR, as compared to 7% of those with an ACL tear alone and 1% of patients with neither ACL nor meniscal tears.

Conclusions: Based upon established evidence, our model-based analysis showed that sustaining an ACL tear at a young age accelerates lifetime risk of symptomatic knee OA and TKR. Subjects with an ACL tear history are likely to develop knee OA earlier than those without an ACL tear. Concomitant meniscal tears lead to even faster progression of knee OA. These findings provide a compelling rationale for developing and implementing sustainable injury prevention strategies for young adults.

2093

Validation of an Internet-Based Questionnaire for Ascertaining Cases of Hip and Knee Osteoarthritis. Charles R. Ratzlaff[2], Jacek Kopec[2] and Mieke Koehoorn[1]. [1]University of British Columbia, [2]University of British Columbia/Arthritis Research Centre of Canada

Statement of Purpose: To evaluate the validity of an internet-based questionnaire to ascertain cases of osteoarthritis (OA) of the hip and knee, in a sub-sample of a population-based study, in comparison to the American College of Rheumatology (ACR) criteria.

Methods: The validation study was nested in the Physical Activity and Joint Health (PAJH) cohort study, a population-based, 3-cycle Internet study of Canadians, which included 4,269 subjects. A sub-cohort of 100 subjects from British Columbia were recruited for interviews and clinical examination. Interviews followed a standardized questionnaire format and reporting form. Clinical exams were conducted with the examiner blinded to subject history, interview and self-report status. ACR criteria for classification of hip and knee OA were used as the reference.

Questionnaire items on hip and knee joint health included current and historic pain, aching and stiffness, previous injury, surgery and joint replacement. Separate items inquired about knee and hip-related physical function. The questions regarding a diagnosis were as follows:

'Have you ever been diagnosed by a health professional with OSTEOARTHRITIS of the knee/hip? (Please note that osteoarthritis, rheumatoid arthritis, and osteoporosis are different conditions).'

This question was asked separately for each joint, and confirmation of response required.

Results:

Table 1. Characteristics of Participants in the PAJH baseline cohort and validity study sub-cohort

Characteristics	All PAJH Subjects *(N=4,244)*	Sub-Cohort* *(N=100)*
Age, *yr*	61.5 (7.6)	63.3 (7.2)
Height, *in*	67.4 (5.0)	66.8 (3.6)
Sex, *(%)*		
Male	37%	46%
Body weight, *lbs*	177.3 (39.5)	174.8 (40.4)
BMI	27.3 (5.9)	27.4 (4.91)
Prevalence SR knee OA	19.9%	15%
Prevalence SR hip OA	9.5%	14%
Prevalence KOA-ACR criteria	—	17.5%
Prevalence HOA-ACR criteria	—	10.5%
Marital Status, %		
Married/Common-law	58.0%	64%
Widowed/Separated/Divorced	33.0%	26%
Single	4.7%	10%
Ethnic Origin, *%*		
White	93.6%	91.0%
Other	6.3%	9.0%
Level of Education, *%*		
College/Univ/Post Grad	47.7%	54.1%
Elementary/High school	33.8%	30.1%
Technical or Trade school	17.4%	15.3%

*Sub-cohort subjects are part of Physical Activity and Joint Health (PAJH) cohort and participated in interviews and clinical exams

Table 2. Sensitivity, Specificity, Predictive values and Kappa for self-report of knee or hip OA, in comparison to ACR clinical criteria

	Value	95% CI
Knee OA		
Sensitivity	0.74	(0.60, 0.89)
Specificity	0.98	(0.96, 1.00)
PPV	0.87	(0.81, 0.93)
NPV	0.95	(0.93, 0.97)
Kappa	0.76	(0.64, 0.89)
Hip OA		
Sensitivity	0.81	(0.64, 0.97)
Specificity	0.94	(0.91, 0.97)
PPV	0.61	(0.52, 0.70)
NPV	0.98	(0.97, 0.99)
Kappa	0.65	(0.49, 0.81)

Validity subjects were older, had a more equal gender distribution, less self-reported knee OA and more hip OA, but did not differ significantly across physical characteristics and demographic variables including marital status, ethnic origin and highest level of education.

Self-reported health professional diagnosis had moderate sensitivity and very good specificity, and had better measurement properties than items on pain and symptoms. Cohen's kappa was 0.76 and 0.65 for knee and hip respectively indicating substantial agreement. Consistent with previous postal questionnaires and telephone surveys, this internet-based study reports that the greatest accuracy is achieved by asking about self-report of a health-professional diagnosis.

Conclusion: An Internet-based questionnaire using self-report of a health professional diagnosis of hip or knee OA appears to be a valid measure in large epidemiological studies for assessment of OA, though some misclassification results. Self-reported diagnosis is substantially more specific than asking about pain and symptoms. Estimation of error can be used to interpret and possibly correct results derived from this case definition in analytic studies.

Prevalence of Symptomatic Knee and Hip OA: A Population-Based Survey in France. Francis Guillemin[4], Anne-Christine Rat[5], Bernard Mazières[10], Jacques Pouchot[6], Liana Euller Ziegler[8], Bruno Fautrel[11], Patrice Fardellone[3], Johanne Morvan[9], Christian H. Roux[8], Evelyne Verrouil[2], Alain Saraux[1], Joel Coste[7] and (the KHOALA Group). [1]Brest University, Brest, France, [2]C.H.U Toulouse, Toulouse, France, [3]INSERM ERI 12, C.H.U Amiens, Amiens, France, [4]INSERM, CIC-EC CIE6, Nancy-Université, Paul Verlaine Metz, Paris Descartes, EA 4360 Apemac, Vandoeuvre les Nancy, France, [5]INSERM, CIC-EC CIE6, Nancy-Université, Paul Verlaine Metz, Paris Descartes, EA 4360 Apemac, Nancy, France, [6]Nancy-Université, Paul Verlaine Metz, Paris Descartes, EA 4360 Apemac, Toulouse, France, [7]Nancy-Université, Paul Verlaine Metz, Paris Descartes, EA 4360 Apemac, Paris, France, [8]Nice-University, Nice, France, [9]Quimper Hospital, Quimper, France, [10]Toulouse-University, Toulouse, France, [11]UPMC, C.H.U Pitie Salpetriere, Paris, France

Purpose: Although osteo-arthritis (OA) is a major public health problem, there is a lack of epidemiological data in Europe. The aim of our study was to estimate the prevalence of symptomatic knee and hip OA in a multiregional representative sample in France.

Methods: A two-phase survey was designed. Using a random digit dialing phone survey, subjects 40 to 75 years old were screened with a validated questionnaire. In case of a positive screening question (presence of at least one of the listed characteristic symptoms), subjects were invited to participate to the confirmation phase including physical examination and hip or/and knee X-rays. Cases were all the subjects with symptoms suggestive of symptomatic knee or hip OA according to the clinical examination and X-Rays (Kellgren-Lawrence≥ 2). Prevalence was determined using multiple imputation to account for refusals at different phases in order to obtain more accurate estimates and to limit non-response bias. Estimates were also corrected to account for the sensitivity error of the screening questionnaire. Standardised prevalence estimates were calculated using European age and sex distribution 2006 (Eurostat).

Results: The prevalence survey, conducted in 6 regions started in April 2007. In two years, 63 232 homes answered a phone call and 27 632 had at least one subject aged between 40 and 75 years old. Among them, screening detected 9621 positive subjects, of which 3707 (39%) participated fully to the

confirmation phase. Reasons for non participation in the latter phase included 514 subjects not reached for setting visit in the clinic, 3389 refusals and 933 subjects who did not show up at the visit. Among subjects having completed the whole ascertainment procedure, 1010 had a symptomatic OA: 317 hips, 756 knees.

Participation was different according to region, age, sex, socio-professional category and the different items of the screening questionnaire. Missing data were mostly not at random. Multiple imputation of all eligible subjects accounted for these characteristics: corrected estimates of the prevalence are given by joint, sex and age.

Table. Estimates of the prevalence according to joint, age and sex.

	Men		Women	
	Knee % [IC 95%]	Hip % [IC 95%]	Knee % [IC 95%]	Hip % [IC 95%]
40–49 years	2.1 [0.9; 3.9]	1.0 [0.3; 1.9]	1.6 [0.7; 2.6]	0.8 [0.2; 1.5]
50–59 years	4.7 [3.0; 7.0]	1.6 [0.6; 2.8]	5.9 [4.3; 7.5]	2.2 [1.2; 3.2]
60–69 years	6.8 [4.5; 9.9]	3.2 [1.6; 4.9]	10.5 [8.2; 12.9]	4.2 [2.6; 5.8]
70–75 years	10.1 [6.3; 15.3]	3.9 [1.4; 6.9]	15.0 [11.4; 18.5]	5.1 [2.9; 7.5]

Prevalence increases with age and after 50 years old is more frequent among women. Standardized prevalence was 1.9% in men and 2.5% in women, and 4.7% in men and 6.6% in women for hip and knee symptomatic OA, respectively.

Conclusion: This survey is the first estimation of the prevalence of symptomatic hip and knee OA in France, increasing knowledge about population-based estimates of this condition in Europe. The use of a screening questionnaire validated during pilot studies, the application of multiple imputation to account for missing data, and the correction method to account for the sensitivity error of the screening questionnaire warrant the accuracy of the results.

This study also confirms the feasibility of using a screening questionnaire in two-phase population based surveys in this disease.

Modifiable Predictors of Racial Differences in Gait Velocity in an Elderly Urban Cohort. Irene Blanco[2], Joe Verghese[2], Richard B. Lipton[2], Chaim Putterman[1] and Carol A. Derby[2]. [1]Albert Einstein College of Med, Bronx, NY, [2]Albert Einstein College of Medicine, Bronx, NY

Background: Gait velocity (GV) is predictive of health status, hospitalizations and mortality and is used to assess functional status the elderly. In the US, elderly Blacks have higher rates of physical disability compared to Whites. Few studies have investigated modifiable risk factors predictive of GV and differences by race. Consequently, we performed a cross-sectional study within a longitudinal, elderly cohort to investigate racial differences in GV and what factors are associated with this measure.

Methods: The Einstein Aging Study (EAS) is a longitudinal study of community residing elderly. Participants are recruited using Medicare beneficiary lists and voter registration records. Demographics and medical history are collected as well as the Geriatric Depression Scale, Blessed Information Memory Concentration Test, the SF-36, and the Total Pain Index (TPI) which measures pain severity, location, duration and frequency over 3 months prior to the visit. GV is measured using the GAITrite gait mat embedded with pressure sensors (CIRsystems, Havertown, PA). Nested linear regression models, adjusted for possible confounders, were used to investigate racial differences in GV. To predict decreased GV, we fit linear regression models within each race strata.

Results: 157 Whites and 56 Blacks, recruited from 2004–2009, were included. Whites were older (median 79.9y v 75.5y, p=<0.01), more educated (median 14y v 12y, p<0.01), and had lower BMIs (mean 26.9±4.3 v 28.9±6.4, p=0.03). Blacks had higher proportions of female participants (80.4% v 59.9%, p<0.01), memory loss (7.1% v 1.0%, p=0.02) and diabetes (28.6% v 13.4%, p=0.01). There were no differences between races with regards to depression, osteoarthritis, history of heart attack, COPD, stroke, hip replacement/pinning, hip/femur/pelvis fracture, lower extremity pain or back pain. (All p-values >0.20) Blacks had higher pain levels on the TPI but the difference was not significant (median 3.2 v 2.0, p=0.09). Neither group had higher pain levels on the SF-36.

Blacks had a significantly slower GV (mean 90.19±17.87 v 99.06± 20.08cm/sec, p<0.01). This difference persists despite adjusting for: age, gender, BMI, education, the above listed comorbidities, TPI and pain as measured by SF-36.(β for racial differences: −7.80 cm/sec, p=0.01) In our predictive models, the modifiable risk factors that predicted decreased GV for Whites were: BMI(p<0.001), stroke (p=0.013), hip replacement (0.05), hip/pelvis/femur fractures (p=0.049) and lower extremity pain (p=0.011). For Blacks, lower GV was associated with back pain (p=0.007) and diabetes though not statistically significant (p=0.06)

Conclusion: Differences in GV persist between Blacks and Whites despite adjusting for many confounders like pain, depression, and comorbidities such as diabetes. When analyzed by race, both groups have modifiable risk factors for decreased GV and by extension decreased functional status. Gait velocity of less than 100cm/sec in the elderly has been associated with increased hospitalizations and mortality. Therefore using GV to screen and develop interventions may limit and reduce health disparities in functional decline in the elderly.

Physical Activity Assessed by Accelerometry in Persons with Knee OA Compared to National Guidelines: The Osteoarthritis Initiative (OAI). Dorothy D. Dunlop[6], Jing Song[5], Pamela Semanik[8], Leena Sharma[5], Rowland W. Chang[4], Joan M. Bathon[3], Charles Eaton[1], Marc C. Hochberg[11], W. Jerry Mysiw[7], Rebecca Jackson[7], C. Kent Kwoh[10], Michael C. Nevitt[9] and Jennifer M. Hootman[2]. [1]Brown University, [2]Centers for Disease Control, Kennesaw, GA, [3]Johns Hopkins Univ Ste, Baltimore, MD, [4]Northwestern Univ, Chicago, IL, [5]Northwestern University, Chicago, IL, [6]Northwestern University Medical School, Chicago, IL, [7]Ohio State University, [8]Rehabilitation Institute of Chicago, Chicago, IL, [9]UCSF, San Francisco, CA, [10]Univ of Pittsburgh, Pittsburgh, PA, [11]University of Maryland, Baltimore, MD

Purpose: Knee osteoarthritis (OA) is the most prevalent form of arthritis in the US. OA clinical practice guidelines identify a substantial therapeutic role for physical activity. However, we lack objective evidence on the physical activity experience of this population. Reports of physical activity in OA populations are largely based on self-report, which can overestimate activity time and intensity. This study uses accelerometers to objectively assess physical activity intensity and duration from a national knee OA cohort.

Methods: Physical activity was measured via accelerometers at the year 4 clinic visit on 1056 participants in the OAI with baseline radiographic knee OA (KL grade ≥2), Of these, 1021 (97%) had 4–7 valid days of accelerometer monitoring. Activity intensity was determined from accelerometer count cutpoints: light (≤2019), moderate (2020– 5998), vigorous (≥5999). Time spent in bouts lasting≥10 minutes of moderate-to-vigorous physical activity (MVPA) was determined. Gender differences in median intensity times were compared using quantile regression. Attainment of Centers for Disease Control and Prevention (CDC) guidelines for arthritis populations (≥150 bouted MVPA minutes/week) was assessed.

Results: Persons with knee OA primarily engaged in light intensity activity and no measurable activity during a large portion of the day (Table). Overall, a median of only 9.9 minutes/day was spent in moderate-to-vigorous (MVPA) activity; less than 20% (1.4 minutes) of this time was done in bouts lasting more than 10 minutes. Men with knee OA had more minutes of no activity than women. However, men also had more MVPA minutes than women. These differences persisted after controlling for age and BMI. Recommended CDC physical activity guidelines were attained by only 18% of men and 10% of women.

Table. Median daily minutes of physical activity intensity among n=1021 persons with radiographic knee OA

Unadjusted Results	n	Minutes No activity (0 counts) Median	Minutes Light PA (1-2019 counts) Median	Minutes MVPA (>=2020 counts) Median	Minutes Any activity (>0 counts) Median
Men	469	429.6	433.9	15.9	458.0
Women	552	395.0	478.0	7.3	490.3
Men vs Women	Difference (95% CI)	34.6 (22.0, 47.2)	−44.1 (−58.2, −30.1)	8.6 (6.1, 11.1)	−32.3 (−46.5, −18.1)
Adjusted for Age, BMI, Race					
Men	469	432.1	438.9	14.7	457.0
Women	552	402.4	490.7	6.9	499.4
Men vs. Women	Difference (95% CI)	32.9 (17.3, 48.5)	−42.7 (−55.3, −30.1)	5.4 (3.3, 7.5)	−36.9 (−51.6, −22.1)

Conclusion: Despite substantial health benefits from physical activity, persons with knee OA were particularly inactive. Physical activity guideline attainment among persons with knee OA based on accelerometry was under half the proportion previously reported based on self-reported activity, underscoring the importance of objective measures for accurate assessments. Although men were more likely than women to meet recommended physical activity guidelines they were also more likely to be inactive. These findings point to the importance of public health efforts to increase physical activity among persons with knee OA.

Brain Activity in Patients with Chronic Knee Pain Due to Osteoarthritis: Dissociating Evoked from Spontaneous Pain. Elle L. Parks[2], Marwan N. Baliki[2], Paul Y. Geha[3], Thomas J. Schnitzer[1] and Apkar V. Apkarian[2]. [1]Northwestern University, Chicago, IL, [2]Northwestern University, [3]Yale University

Background: Although chronic pain is a primary manifestation of osteoarthritis (OA), its properties and representation in the brain have not been fully explored. Prior work from our group indicated that brain activity for spontaneous pain and evoked pain in people suffering chronic pain activate brain areas distinct from that observed for acute pain in healthy subjects[1,2] but this has not been studied in people with OA.

Objectives: To define: 1) Psychophysical differences in knee joint pressure-induced pain between OA and healthy subjects, and between OA patients' reported better and worse knees; 2) brain activity differences for knee joint pressure-induced pain in these groups; 3) brain activity differences for evoked and spontaneous pain in OA; 4) the representation of clinical OA pain characteristics in the brain and their relationship with spontaneous and evoked pain-related activity;

Methods: Fourteen OA patients (10 males; age 56.1 ± 2.09 years) and nine healthy controls (6 males; age 46.55 ± 2.6 years) were recruited for this study. Subjects rated pain using a finger-span device in response to pressure applied by means of a custom-made apparatus to the most sensitive part of each knee for patients, and at the center of the knee joint in healthy controls. During each scan run subjects were presented with up to nine stimuli distributed in time in a pseudo-random design of variable intensities and durations. The pressure signal and finger-spanning device were synchronized and time locked with the fMRI acquisition sequence.

Results: Psychophysical properties and brain activation patterns of evoked pain were similar between OA patients and healthy controls, and between worse and better OA knees. In OA patients, stimulus-related brain activity could be distinguished from brain activity associated with ongoing pain. The former activated brain regions (bilateral insula, SII, ACc, SMA, inferior and posterior parietal cortices) commonly observed for acute painful stimuli in healthy subjects, while the spontaneous pain of OA engaged prefrontal-limbic regions closely corresponding to areas observed for spontaneous pain in other chronic pain conditions, such as chronic back pain and post-herpetic neuralgia. We also identified, for the first time, arthritis and chronic pain-related clinical characteristics in the brain, which mapped to distinctive but overlapping prefrontal-limbic regions similar to those involved in spontaneous OA pain.

Conclusion: This study demonstrates the existence of two distinct pain states in knee OA patients. Knee pressure-evoked pain activates brain regions commonly observed for acute pain in healthy subjects for the same stimulus while ongoing spontaneous OA pain activates mainly medial prefrontal-limbic cortical areas, corresponding closely to brain areas activated for spontaneous pain in chronic back pain patients[1,2].

Central Sensitization and Knee Pain in Osteoarthritis: Preliminary Results from the MOST Study. Tuhina Neogi[3], Jingbo Niu[4], Lars Arendt-Nielsen[1], Joachim Scholz[2], Laura Frey-Law[9], Clifford Woolf[2], Yuqing Zhang[4], Larry Bradley[8], Irina Tolstykh[7], Michael C. Nevitt[6] and David T. Felson[5]. [1]Aalborg University, Denmark, [2]Boston Childrens Hospital, [3]Boston Univ Schl of Med, Boston, MA, [4]Boston Univ School of Medicine, Boston, MA, [5]Boston University School of Medicine, Boston, MA, [6]UCSF, San Francisco, CA, [7]UCSF, [8]University of Alabama at Birmingham, [9]University of Iowa

Purpose: Mechanisms contributing to knee pain in osteoarthritis (OA) are not well understood. Sustained mechanical and inflammatory stimuli in the joint may lead both to changes in the peripheral threshold of nociceptors (peripheral sensitization) and a central amplification of signals in the CNS (central sensitization), resulting in heightened pain sensitivity. We hypothesized findings of central sensitization may be associated with symptomatic knee OA (SxOA).

Methods: The Multicenter Osteoarthritis (MOST) Study is cohort study of persons with or at high risk of knee OA. At the 60-month clinic visit, participants underwent knee radiography, answered pain questionnaires, and had an assessment of temporal summation (TS). TS is an augmented pain response to repetitive mechanical stimuli associated with central sensitization. A 60g monofilament was applied repeatedly over the skin of each patella at a frequency of 1 Hz for 30 seconds. TS was defined as being present when the subject reported an increase in pain following the mechanical stimulation at the site being tested. Knees were categorized according to presence of SxOA based on KL≥2 and presence of consistent frequent knee pain (answering yes to a question about frequent knee pain at a telephone screen and a subsequent clinic visit within 30 days). Pain severity was dichotomized as moderate or greater pain on any of the 5 knee-specific WOMAC pain questions versus none/mild. We used a within-person knee-matched approach to explore the relationships of interest while eliminating between-person confounding using matched conditional logistic regression. In the first matched analyses, we examined the relation of TS with presence of SxOA among persons with knees discordant for SxOA. In the second matched analyses, we examined the relation of TS with pain severity among persons with knees discordant for pain severity, adjusting for radiographic severity.

Results: To date, data on 920 participants' 60-month clinic visit are available (mean age 68.0, mean BMI 30.8, 67.3% female). Among persons with no SxOA, unilateral SxOA, and bilateral SxOA, the age- and sex-adjusted prevalences of TS at the patella were: 59%, 60%, and 61%, respectively. In the within-person knee-matched analyses for SxOA (N=135 that met criteria), radiographic knee OA without regards to knee pain symptoms was associated with 2.3 times higher odds of TS than no OA (95% CI 1.1–4.8, p=0.03), but SxOA itself was not significantly associated with TS once radiographic severity was accounted for (crude OR 1.7, 95% CI 0.7–3.8, adjusted OR 1.1, 95% CI 0.3–3.4). For the knee-matched analyses regarding pain severity (N=152 that met criteria), TS was associated with WOMAC pain severity (OR 3.3, 95% CI 1.3–8.3), but this was attenuated when adjusting for radiographic severity (OR 2.6, 95% CI 0.7–9.5).

Conclusions: In these preliminary results from a large cohort, TS was associated with the presence of radiographic knee OA and knee pain severity in the same knee, but not significantly with SxOA. Such findings suggest that the pathology of OA may be the source of prolonged sensory input required for central sensitization, and in turn, central sensitization may be related to pain severity.

Gait Adaptation after 6 Months of Specialized Shoes in Knee Osteoarthritis. Najia Shakoor[3], Roy H. Lidtke[4], Markus A. Wimmer[2], Kharma C. Foucher[2], Rachel A. Mikolaitis[2], Louis F. Fogg[2], Alan J. Shoelson[2] and Joel A. Block[1]. [1]Rush University Medical Center, Chicago, IL, [2]Rush University Medical Center, [3]Rush-University Medical Center, Chicago, IL, [4]University of Iowa

Purpose: Biomechanical interventions for knee osteoarthritis (OA) aim to improve pain and retard disease progression by decreasing knee loading. These interventions require chronic use to achieve maximum efficacy and may have a delayed response. Chronic load alterations may also result in neuromuscular gait adaptations that persist even after the intervention is removed. Here, we evaluate the effects of 6 months' use of a "mobility shoe", intended to replicate the advantages of barefoot gait, on knee loading in symptomatic knee OA.

Methods: Subjects with radiographic (KL grades ≥ 2) and symptomatic (at least 30mm pain of 100mm scale while walking) medial compartment knee OA were recruited. Baseline gait analyses were performed using an optoelectronic camera system and multi-component force plate in subjects' "own shoes", "mobility shoes", and barefoot. Subjects were instructed to wear the mobility shoes at least 6 hours/day for 6 days/week. Gait analysis was then repeated at 6, 12, and 24 weeks. The peak knee adduction moment (PAddM), a validated marker of medial compartment loading, represented the primary endpoint. An intent to treat analysis (ITT) was performed using repeated measures analyses of variance and simple main effects were used to further evaluate differences between shoes at various time points.

Results: Complete data are available for 16 subjects. Three terminated early: two due to lack of efficacy (6 and 12 weeks), and one was unable to return for study visits after 8 weeks. All data were carried forward for the ITT analysis. Mean PAddMs during all footwear conditions are represented over time in Figure 1. Overall, in comparison to conventional shoes, the "mobility" shoes were associated with significantly decreased loads during gait ($p=0.001$)(Figure 1). Whereas at baseline the reduction in load with the mobility shoe compared to conventional shoes was only 3.7% ($p=0.081$), this increased to 9.4% ($p<0.001$) after 6 weeks of use, and reached an overall reduction of 18% at 6 months compared to conventional shoes at baseline ($p<0.001$). Interestingly, by 24 weeks, a gait adaptation was evident yielding an 11% ($p<0.001$) reduction in PAddM from baseline even when tested in conventional shoes (Figure 1).

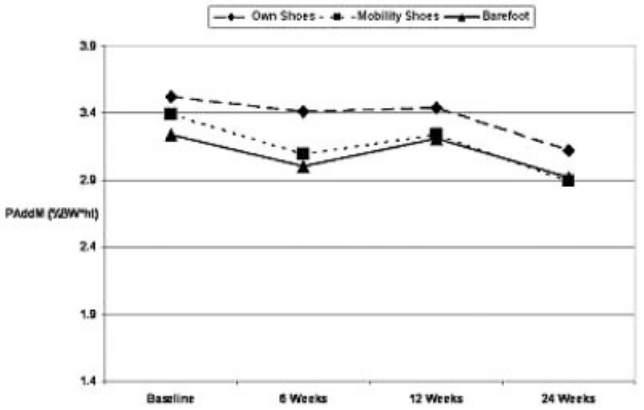

Figure 1.

Discussion: This study suggests that 6 months' use of mobility shoes results in significant reductions in knee loading in subjects with knee OA. This effect is delayed, taking 6 weeks to achieve significant reductions, and it is associated with a gait adaptation by 24 weeks that maintains load reduction even when the mobility shoes are removed. This gait adaptation, likely resulting from beneficial neuromuscular and behavioral changes, may be especially important in OA, which progresses slowly and for which subtle alterations may have profound long-term consequences. The durability of these adaptations will need to be evaluated in longer term studies.

The Role of Varus and Valgus Alignment in the Initial Development of Cartilage Damage at the Knee: The MOST Study. Leena Sharma[3], Orit Almagor[4], Joan S. Chmiel[4], David T. Felson[1], Ali Guermazi[2], Frank Roemer[2], James Torner[9], Cora E. Lewis[6], Neil Segal[9], John A. Lynch[8], Derek Cooke[5], Jean Hietpas[8] and Michael C. Nevitt[7]. [1]Boston University, Boston, MA, [2]Boston University, [3]Northwestern University, Chicago, IL, [4]Northwestern University, [5]Queens University, [6]UAB, [7]UCSF, San Francisco, CA, [8]UCSF, [9]University of Iowa

Purpose: Varus and valgus alignment are each associated with subsequent progression of knee OA but their role in incident disease is less certain. Radiographic measures of incident OA cannot capture cartilage tissue change directly or reveal the compartment of initial disease. We identified knees with normal cartilage morphology by MRI in all tibial and femoral subregions at baseline to test the hypothesis: varus alignment is associated with incident medial cartilage damage and valgus alignment is associated with incident lateral cartilage damage.

Methods: MOST includes persons at risk for or with knee OA. In all participants, full-limb x-rays were acquired at baseline, and MRI (1.0T extremity system) at baseline and 30 months later. Varus malalignment was defined as ≤ 178° (hip-knee-ankle angle) and valgus as ≥ 182°. Cartilage and menisci were assessed using WORMS. In knees with normal baseline cartilage morphology (WORMS score 0 in all subregions), we used logistic regression with GEE to examine the association between baseline alignment and incident cartilage damage (WORMS score ≥ 2 at 30 months in ≥ 1 subregion) adjusting for age, gender, BMI, laxity, and meniscal tear and extrusion.

Results: Of 1881 knees, 293 knees (110 varus, 55 valgus, 128 neutral) from 256 persons (mean age 60 years, BMI 28.6, 67% women) had normal cartilage morphology in all subregions at baseline. At 30 months, 34 had incident medial and 15 had incident lateral cartilage damage. As shown in Table 1, varus alignment was associated with a significantly increased risk of new medial cartilage damage vs. either reference group (non-varus or neutral) and when analyzed as a continuous variable. This relationship held even when knees with medial meniscal tear or extrusion were excluded (adjusted OR 1.37/1° varus, 95% CI 1.11, 1.68). Significant relationships were not detected for valgus and incident lateral disease (Table 2), possibly due in part to the low frequency of this outcome. In addition, varus was protective against incident lateral damage [adjusted OR 0.75/1°, 95% CI 0.59, 0.95] and valgus against incident medial damage [adjusted OR 0.72/1°, 95% CI 0.63, 0.83].

Table. Median daily minutes of physical activity intensity among n=1021 persons with radiographic knee OA

Unadjusted Results	n	Minutes No activity (0 counts)	Minutes Light PA (1–2019 counts)	Minutes MVPA (≥2020 counts)	Minutes Any activity (>0 counts)
		Median	Median	Median	Median
Men	469	429.6	433.9	15.9	458.0
Women	552	395.0	478.0	7.3	490.3
Men vs Women	Difference (95% CI)	34.6 22.0, 47.2)	−44.1 −58.2, −30.1)	8.6 (6.1, 11.1)	−32.3 −46.5, −18.1)
Adjusted for Age, BMI, Race					
Men	469	432.1	438.9	14.7	457.0
Women	552	402.4	490.7	6.9	499.4
Men vs. Women	Difference (95% CI)	32.9 17.3, 48.5)	−42.7 −55.3, −30.1)	5.4 3.3, 7.5)	−36.9 −51.6, −22.1)

Table 2. Valgus Alignment (Baseline) and Incident Lateral Cartilage Defect (Outcome Variable) between Baseline and 30 Month Follow-up (n=293 knees with normal cartilage morphology at baseline)

Alignment	OR (95% CI) adjusted for age, gender, BMI, medial laxity	OR (95% CI) adjusted for age, gender, BMI, medial laxity, lateral meniscal tear, lateral meniscal extrusion
Non-valgus (reference)	reference	reference
Valgus	1.49 (0.40, 5.50)	0.97 (0.26, 3.70)
Neutral (reference)	reference	reference
Valgus	0.97 (0.25, 3.83)	0.62 (0.14, 2.77)
Valgus (continuous), OR per 1*	1.31 (1.04, 1.66)	1.18 (0.94, 1.48)

Conclusion: In knees with normal cartilage morphology, varus alignment was associated with the initial development of cartilage damage in the more loaded compartment, and both varus and valgus were associated with a reduced risk of incident damage in the less loaded compartment. These results

suggest that varus alignment is a risk factor for incident cartilage damage in knees without OA and provide further evidence that varus alignment increases the risk of incident knee OA.

2101

Varus Thrust Is Associated with Worse Physical Function. William F. Harvey[3], Grace H. Lo[1], Erica McAdams[4], Melanie A. Ripley[4], Melynn Nuite[3] and Timothy E. McAlindon[2]. [1]Tufts Medical Center, Houston, TX, [2]Tufts Medical Center Box 406, Boston, MA, [3]Tufts Medical Ctr, Boston, MA, [4]Tufts Medical Ctr

Purpose: Varus Thrust (VT) is rapid lateral bowing of the knee during ambulation and represents a combination of malalignment and instability. VT has been associated with knee cartilage loss, medial joint space narrowing and knee pain. It is unknown how presence of VT affects function in knee osteoarthritis (KOA). We hypothesize that presence of VT would be associated with worse functional outcomes in persons with KOA.

Method: This is a cross-sectional study of a convenience sample selected from participants of a randomized controlled trial of vitamin D for symptomatic radiographic KOA. All those in the RCT were eligible to participate in this study except participants who used ambulatory devices. Participants were video recorded in the frontal plane using a standard digital video camera (60 Hz) walking at a self-selected speed. These videos were viewed at separate reading sessions by two rheumatologists trained to evaluate VT. Participants were classified as VT present vs. absent. Disagreements were adjudicated by consensus of both (achieved in all cases). The functional outcomes were WOMAC function subscale and SF-36 function subscale. We also examined the standard functional performance measures chair stand (total time for 5 sequential sit-to-stand movements) and timed 20 meter walk. We used linear regression to model the association of these functional outcomes and presence of VT. As a 'control' we examined a variable we hypothesized should not be associated with VT, the SF-36 Mental Health Subscale.

Results: Participants (N=82) had a mean age 63.0 (±8.5), BMI 30.2 (±5.4), 60% female, 49% with varus alignment, 23% with valgus alignment, and 31% with definite VT. Those with VT and without VT were not different in mean age or height, but were more likely to be male (68% vs. 29% male, $p<0.01$). Although not reaching statistical significance, those with VT were somewhat heavier (Mean weight 87 ± 16 kg vs. 81 ± 15 kg $p=0.35$). Results did not change when adjusting for age, BMI or sex. Table 1 shows the results of the linear regression of functional outcomes. For WOMAC function, chair stand and walk time (for all higher number = more functional impairment), the presence of VT was associated with worse function. VT was also associated with worse functional status by SF-36 (lower number = more functional impairment).

Table 1. Linear Regression of Functional outcomes.

Functional Outcome	VT Absent (n = 57)	VT Present (n = 25)	p-value
WOMAC function (Mean (SD))*	12.4 (9.4)	21.4 (13.5)	<0.01
SF-36 Physical Function Subscale (Mean (SD))**	44.6 (8.7)	38.2 (12.3)	<0.01
SF 36 Mental Health Subscale (Mean (SD))**	51.5 (8.7)	49.9 (8.5)	0.43
Walk Time (Mean (SD)) seconds*	15.3 (2.7)	17.4 (3.9)	<0.01
Chair Stand Time (Mean (SD)) seconds*	14.8 (2.0)	17.0 (3.4)	<0.01

*Lower = better function
**Lower = worse function

Conclusion: VT is associated with worse physical function, as measured by WOMAC function and SF-36 and worse performance in the functional performance measures of chair stand and timed walk. The mental health component score was not associated with VT. The interpretation of the results is limited by the cross-sectional nature of the analysis and should be confirmed prospectively. The results also raise the question of whether a modification of VT (i.e. through bracing, shoe modification, gait modification, etc) may lead to improved physical function.

Pediatric Rheumatic Disease in the Intensive Care Unit: Lessons Learned from 15 Years Experience in a Tertiary Care Pediatric Hospital. Suhas M. Radhakrishna[2], Bracha Shaham[2], Katherine A. B. Marzan[2], Diane E. Brown[3] and Andreas O. Reiff[1]. [1]Childrens Hosp LA MS60, Los Angeles, CA, [2]Childrens Hospital of Los Angeles, Los Angeles, CA, [3]Childrens Hospital of Los Angeles

Purpose: Pediatric rheumatic diseases and their treatment can cause significant morbidity requiring admission and treatment in the pediatric intensive care unit (PICU). No studies describe the reasons for PICU admission and outcomes of pediatric rheumatology patients. This study describes a large urban single center experience for critically ill patients with rheumatic disease requiring PICU admission. Understanding these data may aid in decreasing morbidity and improving survival.

Methods: The PICU internal database at this tertiary care pediatric hospital was searched for patients with rheumatic disease admitted between January 1, 1995 and July 30, 2009. Medical records were reviewed for demographics, diagnosis, comorbidities, and prior treatments, reason for admission, types of organ dysfunction, supportive care needs, infections, and outcomes. PRISM III (Pediatric Risk of Mortality III) was calculated from the PICU database. Area under receiver operative characteristic curve (AUR) for PRISMIII was calculated. Standard mortality ratio (SMR) was calculated based on PRISMIII estimated mortality with mid-P exact 95% CI. Fisher's exact test was used to determine risk factors for patient mortality.

Results: 90 patients with 122 total admissions were identified. Female: male ratio was 7:3. Mean age at first PICU admission was 14.2 ± 4.3 years. 63% were Hispanic, 20% African American, 12% Caucasian, and 5% Asian. Rheumatic diagnoses included SLE (n=57), systemic vasculitides (n =13), JIA (n=12, 8 with systemic JIA), and dermatomyositis (n=8). Cause of admission was related to rheumatic disease in 61 (50%), infection in 26 (21%), both infection and rheumatic disease in 18 (15%), iatrogenic causes in 5 (4%), and other causes in 12 (10%). Multi-organ dysfunction was present in 39 (32%) and single organ dysfunction occurred as follows: pulmonary in 23 (19%), CNS in 13(10%), GI and renal each in 11 (9%), cardiac in 8(7%), and other in 17 (14%). In 30 admissions (24.6%) a new rheumatologic diagnosis was made. Median length of PICU stay was 3.1 (0–55) days. In 105 (86%) admissions, the patient was discharged from PICU. There were 18 deaths (20%): 9 from combined infection and active rheumatic disease, 4 from infection only, 2 from rheumatic disease only, and 3 from other causes. There were a higher proportion of SLE patients (83% vs 58%, $p=0.06$) and patients on hemodialysis (33% vs 13%, $p=0.07$) in the non-survivor group compared to survivors. AUR for PRISMIII was 0.84 (SE 0.06). SMR based on PRISMIII was 0.72 (95% CI 0.38 – 1.25) for pediatric rheumatology patients and 0.87 (95% CI 0.79–0.96) for all PICU patients.

Conclusions: Rheumatic disease related illness accounted for the majority of PICU admissions, most often with multi-organ dysfunction. Deaths occurred most often from severe infections in patients receiving multiple immunosuppressive medications for active rheumatic disease. Non-statistically significant risk factors for mortality included a diagnosis of SLE and concurrent hemodialysis. Observed mortality in pediatric rheumatology patients correlated well with PRISMIII and SMR was similar to the general PICU population at this institution.

Rates of Hospitalized Bacterial Infection in Juvenile Idiopathic Arthritis and Its Treatment: An Observational Study of National U.S. Medicaid Administrative Claims Data. Timothy Beukelman[2], Fenglong Xie[2], Lang Chen[2], John W. Baddley[2], Elizabeth Delzell[2], Carlos G. Grijalva[3], Nivedita M. Patkar[2], Kenneth G. Saag[2], Kevin L. Winthrop[1] and Jeffrey R. Curtis[2]. [1]Oregon Health and Science University, [2]Univ of Alabama at Birmingham, Birmingham, AL, [3]Vanderbilt University

Purpose: We analyzed national Medicaid administrative claims data to examine incidence rates of hospitalized bacterial infection among children with juvenile idiopathic arthritis (JIA) in clinical practice.

Methods: Using Medicaid administrative claims data from all 50 U.S. states from 2000 through 2005, we identified a cohort of children with JIA based on physician diagnosis codes and dispensed medication prescriptions. We defined a control cohort of children diagnosed with attention deficit hyperactivity disorder (ADHD). All subjects had a 6 month baseline period for assessment of covariates prior to study entry. Exposures to MTX and anti-TNF were based on dispensed prescriptions and were classified as current use (within 30 days of a missed prescription refill) or recent use (current use within past 6 months). New and prevalent medication exposures were included. All anti-TNF agents were grouped together. Hospitalized bacterial infection outcomes were defined using inpatient discharge diagnosis codes in any position. Follow-up was censored at loss to follow-up, first hospitalized infection outcome, and study end. We calculated crude infection rates for children with JIA with various drug exposures and for children with ADHD. Using Cox proportional hazard models, we calculated hazard ratios (HR) for infection while adjusting for age, sex, race, baseline oral glucocortiocid (GC) use, time-varying current oral GC use, and hospitalized bacterial infection during the baseline period. A secondary analysis of JIA subjects restricted to new-users of MTX and anti-TNF was performed.

Results: The JIA cohort included 8,348 subjects with mean follow-up of 1.6 years. 3,482 JIA subjects were MTX users and 1,477 were anti-TNF users (89% etanercept). The ADHD cohort included 358,534 subjects with mean follow-up of 1.3 years. Crude rates of hospitalized bacterial infection are shown in Table. The crude rate for current oral GC users was 2 to 3-fold higher in all JIA drug exposure groups. The adjusted HR for JIA subjects without any MTX or anti-TNF use was 1.25 (1.07–1.47) compared to ADHD subjects. The adjusted HR for current and recent anti-TNF use was 1.2 (0.9–1.6) compared to JIA subjects without any MTX or anti-TNF use and was 1.3 (1.0–1.8) compared to current and recent MTX users without any anti-TNF use. The analysis of new-users produced an adjusted HR of 1.6 (0.8–3.1) for new anti-TNF compared to new MTX without any anti-TNF.

	No Oral Glucocorticoids		Current Oral Glucocorticoids	
Disease and Exposure Group	Person-years of observation	Infection Rate per 100 person-years (95% CI)	Person-years of observation	Infection Rate per 100 person-years (95% CI)
JIA MTX none, anti-TNF none	6148.4	2.4 (2.1–2.9)	326.0	9.8 (6.9–13.9)
JIA current or recent MTX, anti-TNF none	2824.7	2.3 (1.8–2.9)	640.0	7.2 (5.3–9.9)
JIA current or recent anti-TNF	1776.9	3.1 (2.4–4.0)	478.2	6.1 (4.2–8.7)
ADHD	446, 345	1.01 (0.98–1.04)	5100	5.3 (4.7–6.0)

Conclusion: Children with JIA appeared to have an increased risk of hospitalized bacterial infection compared to control children with ADHD. Current oral CG use was associated with a substantially increased rate of infection in all groups and overshadowed the rate differences associated with MTX and anti-TNF. The additional risk of hospitalized infection associated with anti-TNF use appeared relatively small, with a number needed to harm of 125 compared to non-users of anti-TNF.

Outcomes of End-Stage Renal Disease Due to Lupus Nephritis among Children in the U.S., 1995–2006. Linda T. Hiraki[6], Bing Lu[3], M. Alan Brookhart[8], Tamara Shaykevich[4], Graciela S. Alarcon[1], Daniel Hal Solomon[5], Wolfgang Winkelmayer[7] and Karen H. Costenbader[2]. [1]Oakland, CA, [2]Brigham & Women, Boston, MA, [3]Brigham and Women's Hospital, Foxboro, MA, [4]Brigham and Women's Hospital, [5]Brigham and Womens Hospital, Boston, MA, [6]Harvard School of Public Health, Boston, MA, [7]Stanford University School of Medicine, [8]University of North Carolina, Chapel Hill

Purpose: Little information is available on kidney transplantation and overall survival among children with end-stage renal disease (ESRD) due to lupus nephritis in the U.S. We examined rates and predictors of kidney transplantation and overall survival among children with ESRD due to lupus nephritis from 1995–2006.

Methods: We identified children ages 5–19 years with new onset ESRD due to lupus nephritis from 1995–2006, as defined by Medicare eligibility and entry into the U.S. Renal Data System, which includes data on approximately 94% of all U.S. ESRD patients. Lupus was identified as the cause of ESRD on medical evidence forms. We investigated baseline demographic and clinical characteristics of patients at ESRD onset, rates of kidney transplantation and overall survival, and causes of death. Predictors of these outcomes in the first five years of ESRD were identified using Cox proportional hazards models, adjusting for sociodemographic and clinical factors.

Results: We identified 583 children in the U.S. who had incident ESRD due to lupus nephritis. Mean age at ESRD onset was 16.2 (SD 2.4) years. Sex, race, ethnicity, region of residence and medical insurance type at ESRD are shown in Table 1. Within 5 years after onset of ESRD, 193 (33% overall) received a kidney transplantation and 131 (22%) died. Mean age at kidney transplantation was 18.2 (SD 3.4) years and at death was 19.5 (SD 3.5) years. Causes of death were cardiorespiratory (39%), infectious (19%), hemorrhagic (10%), neurologic (9%) and other (19%). In multivariable models, residence in the U.S. Northeast, compared to the South, was associated with increased rates of kidney transplantation. Five year rates of both kidney transplantation and overall survival were less than half among Black compared to white children. Sex, ethnicity, medical insurance and clinical factors were not independent predictors of outcomes in these children.

Table 1. Multivariable-adjusted* Five Year Hazard Ratios (HRs) according to Sociodemographic Factors for Children ages 5–19 years with End-Stage Renal Disease (ESRD) due to Lupus Nephritis in the U.S., 1995–2006

Sociodemographic factor (n)	Renal Transplantation** (95% CI***)	Survival** (95% CI***)
Sex		
Female (442)	1.0 (ref.)	1.0 (ref.)
Male (141)	0.99 (0.68, 1.43)	0.68 (0.45, 1.03)
Race		
White (219)	1.0 (ref.)	1.0 (ref.)
Black (287)	0.48 (0.32, 0.71)	0.44 (0.24, 0.80)
Asian (46)	0.85 (0.49, 1.48)	1.01 (0.36, 2.86)
Other (14)	0.66 (0.20, 2.17)	0.39 (0.13, 1.2)
Ethnicity		
Non-Hispanic (441)	1.0 (ref.)	1.0 (ref.)
Hispanic (142)	0.65 (0.41, 1.01)	1.1 (0.55, 2.22)
Region		
South (247)	1.0 (ref.)	1.0 (ref.)
Northeast (82)	1.84 (1.21, 2.80)	1.56 (0.53, 2.94)
MidWest (97)	1.04 (0.66, 1.64)	1.56 (0.9, 2.78)
West (146)	1.2 (0.80, 1.81)	1.12 (0.66, 1.92)
Medical Insurance		
Private (224)	1.0 (ref.)	1.0 (ref.)
Medicaid (285)	0.79 (0.57, 1.09)	1.01 (0.66, 1.52)
None (52)	0.71 (0.38, 1.32)	0.78 (0.41, 1.45)
Other (14)	1.33 (0.47, 3.75)	0.78 (0.18, 3.33)

*Multivariable model: Age, sex, race, ethnicity, medical insurance, region, diabetes mellitus, hypertension, erythropoietin use, body mass index (kg/m^2), and initial ESRD therapy (hemodialysis, peritoneal dialysis or pre-emptive transplant)
**Renal transplantation among all incident *dialysis* patients (n = 579) and survival among all incident ESRD patients (including pre-emptively transplanted, n = 583)
***95% Confidence Interval by Wald method

Conclusions: Among children with ESRD due to lupus nephritis in the U.S., geographic region and race were the most important predictors of five year kidney transplantation and survival rates. Although these analyses do not account for WHO class of nephritis or lupus disease activity, the results suggest that important disparities in access to care and outcomes exist by region and race in the U.S.

2105

The Clinical Significance of a Single *MVK* Mutation in HIDS. Karyl S. Barron[2], Amanda K. Ombrello[4], Donald P. Goldsmith[1], Ivona Aksentijevich[4], Anne Jones[5], Beverly K. Barham[6] and Daniel L. Kastner[3]. [1]Drexel Univ College Med, Philadelphia, PA, [2]NIAID/NIH, Bethesda, MD, [3]NIAMS, NIH, Bethesda, MD, [4]NIAMS/NIH, [5]NIH, NIAMS, Damascus, MD, [6]Ntl Inst of Arthritis & MSK SD, Bethesda, MD

Background: HyperIgD syndrome (HIDS) is an autoinflammatory disorder caused by mutations in the *MVK* gene that encodes mevalonate kinase. Traditionally it is considered to be transmitted as an autosomal recessive disorder. As a large referral center for children with periodic fever syndromes, we have seen a cohort of symptomatic patients with only 1 mutation in the *MVK* gene. Since there are no defined diagnostic criteria for HIDS, we compared these patients with our cohort of HIDS patients with 2 *MVK* mutations.

Methods: Patients were evaluated in the Periodic Fever Clinic at the National Institutes of Health. Clinical and laboratory information were collected at each visit. CHI square and Mann-Whitney U tests were performed to compare patients with 2 *MVK* mutations and those with only 1 *MVK* mutation.

Summary: 22 patients with mutations in *MVK* were evaluated in our clinic; 15 patients were found to have 2 mutations (V377I and 1 other mutation). 7 patients were found to have only 1 mutation, V377I. All *MVK* coding regions were screened in these patients and we were unable to identify a second mutation. The carrier frequency of V377I in our control Caucasian population was 0.3% (2/739). In contrast, in 344 independent cases of recurrent fever submitted for *MVK* testing, 8 bore a single copy of V377I for a frequency of 2.3%.

Clinical presentation at the time of a flare was compared between the 2 groups:

	2 mutations	1 mutation
Age of onset (mo)	5.4	5.9
Duration (d)	5.1	5.3
Frequency (wks)	3.6	4.5
T max	104.8	105.1
	n (%)	n (%)
Flare with immunizations	12/13 (92.3)	5/7 (71.4)
Abdominal pain	15/15 (100)	6/7 (85.7)
Diarrhea	14/15 (93.3)	6/7 (85.7)
Oral ulcers	11/15 (73.3)	4/7 (57.1)
Sore throat	13/15 (86.7)	5/7 (71.4)
Arthralgia	13/15 (86.7)	5/7 (71.4)
Arthritis	4/15 (26.7)	2/7 (28.6)
Myalgia	8/15 (53.3)	5/7 (71.4)
Rash	11/15 (73.3)	5/7 (71.4)
Cervical adenopathy	15/15 (100)	6/7 (85.7)
Conjunctivitis	7/15 (46.7)	1/7 (14.3)
Headache	11/14 (78.6)	4/6 (66.7)
Developmental delay	4/15 (26.7)	2/7 (28.6)

There was no significant difference in clinical presentation between the 2 groups of patients.

The two groups were similar in percentage with documented elevations of acute phase reactants with flares and mild elevations of IgA. Mean serum IgD levels for those with 2 *MVK* mutations was 103 mg/dl vs. 31 mg/dl for those with 1 mutation ($p=0.03$).

Conclusions: Aside from the higher IgD levels in those children with 2 *MVK* mutations, there does not appear to be any significant clinical differences between these 2 groups. Prior studies in children with 2 mutations have not correlated IgD levels with disease severity. The relatively small number of children with 1 mutation in our cohort may influence the analyses, but thus far there are no clear trends to offer the clinician in the identification or predictability of the disease course in children with either 1 or 2 mutations. Given the higher frequency of V377I heterozygotes in our patient cohort as opposed to the general population, our data suggests that under some circumstances this could be associated with clinical HIDS, although clearly other factors must play a role given the 0.3% frequency in the general population.

Biomarkers for Global and Renal Disease Activity in Juvenile Systemic Lupus Erythematosus (jSLE). Rina Mina[4], Michael Bennett[3], Joseph M. Ahearn[1], Joshua Pendl[3], Jamie Eaton[3], Nicole Wilson[5], Prasad Devarajan[3] and Hermine Brunner[2]. [1]Wexford, PA, [2]Cincinnati Child Hosp Med Ctr, Cincinnati, OH, [3]Cincinnati Children's Hospital Medical Center, [4]Cincinnati Children's Med Ctr, Cincinnati, OH, [5]Univerisity of Pittsburgh

Background: Preliminary data suggest that the Lupus Nephritis Renal Panel (LNRP), composed of transferrin, ceruloplasmin, acid-1-glycoprotein, neutrophil gelatinase-associated lipocalin, prostaglandin-D synthethase and monocyte chemotactic protein1, is associated with worsening lupus nephritis in jSLE. Cell-bound complement activated products (CB-CAP) which consist of erythrocyte, reticulocyte and platelet-bound complement components (E-C4d, E-C3d E-fBb, E-CR1, R-C4d, R-C3d, R-fBb and P-C4d) have been shown to reflect ongoing global disease activity in studies limited to adults with SLE.

Objectives: Evaluate the association of the LNRP and CB-CAP with global and renal disease activity in jSLE.

Methods: Clinical, laboratory and biomarker data were collected from 12 jSLE patients during initial and follow-up visits. Levels of LNRP standardized to urine creatinine and CB-CAP were measured by enzyme-linked immunosorbent assay and flow cytometry respectively. Physician-rated change in patient's disease course between visits (global/renal disease worsening: yes/no) served as the criterion standard.

Results: Using Wilcoxon Rank Sum Test and Spearman's correlation, statistically significant association was seen between levels of specific urine biomarkers and the renal domains of disease activity indices and the criterion standard *(see Table 1)*. Levels of urine biomarkers were seen to be elevated three months prior to renal worsening with the change in the biomarker level associated with the change in the renal disease activity scores. No significant correlation between extra-renal disease activity and urine biomarkers was seen. Of the CB-CAP, E-CR1, P-C4d and R-C4d were associated with current global/extra-renal disease activity. Traditional biomarkers for global and renal worsening correlated poorly with disease course and activity.

Correlation of Biomarkers with Disease Variables¶

		Concurrent validity			Predictive validity	
Biomarker¶¶	Disease variable	ρ	p-value	Disease variable	ρ	p-value
Ceruloplasmin	Renal BILAG	0.61	0.02	Renal SLAM	0.70	0.02
	Renal SLEDAI	0.60	0.01	Renal BILAG	0.69	0.02

Childhood Primary Angiitis of the CNS: Identifying Disease Trajectories and Early Risk Factors for Persistently Higher Disease Activity. Tania Cellucci, Pascal N. Tyrrell, Suzanne Laughlin, Derek Armstrong, William Halliday, Shehla Sheikh and Susanne M. Benseler. The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada

Purpose: Childhood Primary Angiitis of the CNS (cPACNS) is a devastating inflammatory brain disease. cPACNS comprises of distinct clinical subtypes at presentation. Disease courses of cPACNS have never been systematically studied. The aim of the study was to characterize and compare distinct disease activity trajectories in cPACNS and to identify early risk factors for persistently higher disease activity over time.

Methods: A single centre cohort study was performed including consecutive children diagnosed with cPACNS based on Calabrese criteria between December 1998 and June 2010. Patients had to be <18 years of age at diagnosis and have serial measures of disease activity as defined by physician global assessment (10 cm Visual Analogue Scale). Standardized clinical assessments, Pediatric Stroke Outcome Measures, inflammatory markers, and

neuroimaging characteristics were collected serially. Longitudinal data were analyzed using mixed effects models accounting for repeated measures and linear regression of slope parameter estimates over time.

Results: The study cohort consisted of 45 children: 21 males, 24 females, median age at diagnosis 9.8 years, and median follow-up 21 months. Diagnoses: 26 (57%) had angiography-negative cPACNS, and 19 (43%) had angiography-positive cPACNS. At diagnosis, children with angiography-negative cPACNS were more likely to be female (81% vs. 16%, $p<0.001$), present with seizures (85% vs. 10%, $p<0.001$), and have elevated levels of ESR ($p=0.036$) and CRP ($p=0.046$). Disease activity decreased significantly over time in all cPACNS patients ($p<0.001$). Distinct trajectories of disease activity over time were identified for each cPACNS subtype. Children with angiography-negative cPACNS had persistently higher disease activity and required a longer time to remission ($p=0.046$). Female sex and elevated inflammatory markers at diagnosis were not predictive of delayed remission. Seizures at diagnosis of cPACNS were found to be an early risk factor for persistently higher disease activity over time ($p=0.016$).

Conclusions: Distinct subtypes of cPACNS were found to have unique disease activity trajectories. In all children, disease activity improved significantly over time. However, children diagnosed with angiography-negative cPACNS and those presenting with seizures were at the highest risk for persistently higher disease activity. Early recognition of this high-risk cohort may enable physician to initiate targeted therapies and prevent long-term brain injury in children with cPACNS.

2108

Predictive Validity of the New Preliminary ACR/EULAR Definitions for Remission in Rheumatoid Arthritis. David T. Felson[2], Josef S. Smolen[3], George A. Wells[5], Bin Zhang[1], Lilian H. D. van Tuyl[7], Julia Funovits[4], Maarten Boers[6] and for the ACR/EULAR Commission To Redefine Remission in Rheumatoid Arthritis. [1]Boston Univ Schl of Medicine, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Krankenhaus Lainz, Vienna, Austria, [4]Medical University of Vienna, [5]Univ of Ottawa Faculty of Med, Ottawa, ON, Canada, [6]VU University Medical Center, Amsterdam, The Netherlands, [7]VU University Medical Center, Amsterdam

Background: With remission in rheumatoid arthritis (RA) an increasingly attainable goal, there is no widely used definition of remission that is stringent but achievable and could be applied uniformly as an outcome in clinical trials.

Methods: A committee constituted from members of the American College of Rheumatology, the European League Against Rheumatism and the Outcome Measures in Rheumatology (OMERACT) Initiative guided the process and reviewed prespecified analyses from clinical trials of patients with RA. A stringent definition was requested including at least joint counts and an acute phase reactant, but excluding duration of state. As part of the search for a remission definition, trial data were analyzed to examine the ability of candidate measures to predict later good x-ray and functional outcomes (defined as change ≤0 in van der Heijde/Sharp scores and Health Assessment Questionnaire (HAQ) change ≤0 and HAQ score consistently ≤0.5 both during the 2nd year of respective trials). Likelihood ratios compared the proportion of patients in remission having the good outcome to the proportion of patients *not* in remission having the good outcome. To rank candidate definitions of remission, the *p* value from the logistic regression chi square test were used.

Candidate definitions of remission were downgraded when they led to values of core set measures which suggested disease activity incompatible with remission.

Results: Patients in a state of remission by several of the Boolean candidate definitions, as well as by traditional SDAI (≤3.3) and CDAI (≤2.8) definitions had an increased likelihood of both x-ray and HAQ stability (see Table 1).

Table 1. Predictive validity of candidate remission definitions for a good outcome in both x-ray and health assessment questionnaire

Candidate remission definition	Prevalence of good outcome in patients: *in* remission	*not in* remission	LR(+)	P
TJC28, SJC28, CRP ≤1	46%	17%	3.2	***
TJC28, SJC28, CRP, PhGA ≤1	55%	17%	4.5	***
TJC28, SJC28, CRP, PtGA ≤1§	66%	17%	7.2	***
TJC28, SJC28, CRP, Pain ≤1	60%	17%	5.7	***
TJC28, SJC28, CRP, PhGA, PtGA ≤1	68%	17%	8.0	***
TJC28, SJC28, CRP, PhGA, Pain ≤1	64%	18%	6.7	***
TJC28, SJC28, CRP, PtGA, Pain ≤1	64%	17%	6.8	***
TJC28, SJC28, CRP, PhGA, PtGA, Pain ≤1	67%	18%	7.5	***
SDAI ≤3.3§	56%	17%	4.8	***
DAS28 <2.6	38%	18%	2.2	**
DAS28 <2.0	56%	20%	4.5	*
Definitions without CRP (for clinical practice)				
TJC28, SJC28, PhGA, PtGA ≤1	68%	17%	7.9	***
TJC28, SJC28, PtGA ≤1	66%	16%	7.2	***
CDAI ≤2.8	63%	16%	6.4	***

*P-value < 0.02; **P-value ≤ 0.01; ***P-value < 0.001
§New preliminary ACR/EULAR definitions for remission in RA

However, reaching remission according to DAS28, both at the traditional (<2.6) and a more stringent cut point (<2.0), was associated only with the likelihood of HAQ stability but not x-ray stability. Additional definitions were tested, including definitions that incorporated pain or patient global at remission levels and other variations, and results were similar. Apart from the DAS28 result, the analyses did not help to distinguish between definitions.

Conclusion: Based on these and other considerations, we propose that a patient be defined as in remission based on one of two definitions of remission: 1: When their scores on the following measures are all ≤1: tender joint count, swollen joint count, CRP (in mg/dL) and patient global assessment (0–10 scale), OR 2: when their score on the SDAI ≤3.3.

These new definitions can be uniformly applied and widely used in RA clinical trials. We recommend that one of these be prespecified in each trial as an outcome and that the results of both be reported. These definitions are currently 'preliminary' and are pending approval from the ACR and EULAR boards.

Acknowledgements: Some of the results were generated using clinical trial data provided by Abbott, Amgen, and Wyeth-Pfizer.

Three Physician-Assigned Global Estimates for Inflammation, Damage and Non-Inflammatory Symptoms/Fibromyalgia Help To Clarify Overall Physician Global Estimates of Status in Patients with Different Rheumatic Diseases. Martin J. Bergman[1] and Theodore Pincus[2]. [1]Arthritis and Rheumatology, Ridley Park, PA, [2]New York University Hospital for Joint Disease, Hastings-on-Hudson, NY

Purpose: To analyze the capacity of three physician-assigned global estimates for inflammation, damage and non-inflammatory symptoms/fibromyalgia to clarify the overall physician global estimate of status in patients with various rheumatic diseases, and for these global estimates to serve as surrogates for a quantitative physical examination.

Methods: All consecutive patients in a rheumatology setting in Pennsylvania, with any diagnosis, were assigned four global estimates by a rheumatologist, including overall global status, and 3 additional global estimates for inflammation, damage to any organ (e.g., joint, kidney) and non-inflammatory/fibromyalgia symptoms. The overall estimate was on a scale of 0–10, while the other 3 scales were scored 0–3, which were recoded to 0–10 for comparison with the overall global score. Consecutive patients were classified at first visit in 7 categories: rheumatoid arthritis (RA) (n=40), osteoarthritis (OA) (n=56), fibromyalgia (FM) (n=14), systemic lupus erythematosus (SLE) (n=9), spondyloarthropathy (n=21), gout (n=26) and other (n=64). Mean scores were compiled in the 6 specific disease categories; the "other" patients were not analyzed.

Results: The overall physician global estimate ranged from 2.00 to 4.36, highest for patients with FM (4.36), followed by RA, spondyloarthropathy, OA, gout, and SLE. Physician global estimates for **inflammation** ranged from 0.50 to 4.53, highest for RA, followed by spondyloarthropathy, gout, SLE, and <1.0 (on the recoded 0–10 scale) for OA and FM. Physician global estimates for joint **damage** ranged from 0.37 to 3.83, highest for OA, followed by RA, spondyloarthropathy, and <1.0 for gout, SLE and FM. Physician global estimates for **non-inflammatory/fibromyalgia symptoms** ranged from 0.37 to 5.13, highest for FM (5.13), followed by spondyloarthropathy and RA, and <1.0 for OA, gout, and SLE. One of the 3 more-detailed global estimates was within 1 unit of the overall global estimate for all 6 diseases studied: for **inflammation** in RA, SLE, spondyloarthropathy, and gout; for **damage** in OA; and for **non-inflammatory symptoms/ fibromyalgia** in FM.

Mean physician-estimated scores for overall global status, inflammation, damage, and non-inflammatory symptoms/fibromyalgia at first visit, in consecutive patients in 6 diagnostic categories

Variable	RA	OA	Fibromyalgia	SLE	Spondyloarthropathy	Gout
Number of patients	40	56	14	9	21	26
Overall Physician global (0–10)	4.03	3.25	4.36	2.00	3.33	2.23
Inflammation (0–10)	**4.53**	0.57	0.50	**2.23**	**4.17**	**2.27**
Damage (0–10)	2.40	**3.83**	0.77	0.37	1.58	0.43
Non-inflammatory/fibromyalgia symptoms (0–10)	1.03	0.83	**5.13**	0.37	1.17	0.43

Conclusion: Physician global estimate scales for inflammation, joint/organ damage and non-inflammatory symptoms/fibromyalgia can clarify an overall physician global estimate. These detailed physician global estimates may be regarded as a quantitative summary of the physical examination. Limitations include the absence of longitudinal data, including disease flares. Nonetheless, in view of the importance of physical examination in clinical decisions in rheumatic diseases, these scales may supplement laboratory tests, which often are the only quantitative data in patient records, to assess and monitor patients with rheumatic diseases over long periods.

Rheumatologists on the Road: A Subspecialist's Role in Caring for the Homebound. Ruchi Jain[1], Suma Dasari[2], Theresa Soriano[2], Linda DeCherrie[2] and Leslie Dubin Kerr[2]. [1]Mount Sinai Medical Center, New York, NY, [2]Mount Sinai Medical Center

Background: In the next 20 years, the number of permanently homebound individuals in the United States will increase by 50% to reach 2 million. To address this problem, the Mount Sinai Visiting Doctors Program has proven to be a successful model as the largest primary care academic home visit program in the nation, serving over 1000 patients in New York City. Currently, there are no medicine subspecialty consult services in place for this rising subset of the population.

Our purpose in establishing a Rheumatology consult service within the Mount Sinai Visiting Doctors program was to provide a remedy to the unmet need for homebound patients with Rheumatologic diseases, and also to provide an educational opportunity for Residents and Fellows in community Rheumatology. Many of these patients were homebound by the very nature of their disease and social environment, and many had no care under a Rheumatologist.

Methods: Through electronic medical record, home-based primary care physicians sent consult requests to the Rheumatology Division. Initial assessments were made through the Routine Assessment of Patient Index Data 3 (RAPID 3) questionnaire.

Results: Over 6 months, 33 home visits were made; 25 as new consults and 8 as follow up visits. Reasons for referral included: medical management of a known connective tissue disease; a question of inflammatory arthritis; procedures including intra-articular injections, arthrocentesis and bursa drainage.

Demographics of patients (as of June 2010): 100% of consults were women, 40% of patients were Hispanic and 76% of patients were between the ages of 60–101. Twenty patients lived alone or with a home health aide, 5 patients lived with other family members. Fifty percent of patients had rheumatoid arthritis (RA). Osteoarthritis comprised 30% of patients seen. Treatment interventions included the following: addition of a disease modifying anti-rheumatic drug (DMARD) in 10 patients, 8 procedures, counseling in 7 patients and a change in the dose of existing medication in 4 patients. At initial evaluation, the average RAPID 3 score for patients with RA was 22.4, reflecting high severity of disease. One patient with psoriatic arthritis (PsA) on initial evaluation had a RAPID 3 score of 21 (high severity); after intervention the RAPID 3 score was 11 (moderate severity). One patient with diffuse scleroderma had a RAPID 3 score of 20.3 (high severity).

Conclusions: The ongoing, increasing number of consults and extent of disease on initial evaluation of these homebound individuals highlights the importance of a Rheumatologist's role in the community. This initiative underscores a hidden, but growing population with current unmet needs. It also defines our role in patient advocacy consistent with our goals and beliefs as Rheumatologists, and as physicians.

Validation of Electronic Audiovisual Media Assessments of Patients with Rheumatic Diseases. Sarah McNamara[1], Lorraine O' Neill[3], John J. Carey[2] and Robert J. Coughlan[1]. [1]N.U.I Galway University Hospitals, Galway, Ireland, [2]N.U.I Galway University Hospitals, Galway, Ireland, [3]N.U.I. Galway University Hospitals, Galway, Ireland

Purpose: Rheumatology centres often service remote or geographically dispersed areas where patients have significant access issues because of poor transport service or inclement climate. Our centre services such an area including inhabitants of several islands. The extensive availability of audiovisual communication via the Internet has introduced the possibility of 'virtual' assessment of patients living remote from their rheumatology centre. Studies in other diseases show such technology offers promise with obvious advantages for the patient such as saved travel time and cost. There are no published studies comparing the quality of information gained through remote contact to that gained in conventional face to face clinical encounters for patients with rheumatic diseases. The purpose of this study was to assess the validity of the information collected from a virtual patient visit (e-clinic) using "off the shelf" web based technology.

Methods: This study was approved by the local I.R.B. We planned to evaluate 20 patients referred to our centre with 'possible early arthritis' from different primary care centres (PCC) in our region for this pilot programme. An initial assessment using 'Skype®' or 'iChat®' was performed using 'laptop' computers by an experienced rheumatologist (RJC). A follow-up assessment was scheduled within 2 weeks for a face to face encounter in the rheumatology clinic by the same rheumatologist (RJC). Clinical features and diagnosis were compared using both methods.

Results: 5 PCC agreed to participate. 19 (95%) of subjects completed both assessments. Diagnostic agreement was 100% for both assessments (Rheumatoid Arthritis, Osteoarthritis, Tendonitis, Carpal Tunnel Syndrome). Agreement was ≥90% between both assessments for the following clinical features: joint swelling, restricted motion, Heberden's nodes, tendonitis.

Conclusion: Web-based "off the shelf" technology can be used to accurately assess patients referred with 'possible arthritis' to rheumatologists. Support for further studies and development of audiovisual media for assessment of patients with rheumatic complaints is warranted.

Quality of Care in Patients with Systemic Lupus Erythematosus.
Jinoos Yazdany[4], Laura Trupin[5], Chris Tonner[5], Gabriela Schmajuk[3], Joann Z. Gillis[2], Pantelis Panopalis[1], Laura J. Julian[5], Lindsey A. Criswell[5], Patricia Katz[5] and Edward Yelin[5]. [1]McGill University, [2]National Jewish Medical Center, [3]Stanford University, [4]UCSF, San Francisco, CA, [5]UCSF

Objective: We applied newly developed quality indicators (Qis) for systemic lupus erythematosus (SLE) to a large, community-based cohort of individuals to detect areas where health care quality is suboptimal and to identify groups at risk for lower quality care.

Methods: Data derive from a prospective study of individuals with SLE, the Lupus Outcomes Study (LOS). In 2009, 814 individuals participated in the eighth annual survey. Respondents were queried by telephone regarding receipt of care recommended in 13 (of 20) SLE Qis amenable to self-report, as well as their sociodemographic characteristics, health care utilization, disease activity and medication use. For each QI, we calculated the proportion of eligible participants who received recommended care. In addition, we conducted multivariate analyses in which the primary outcome was a global pass rate, defined as the percentage of times recommended care was received among all eligible individuals. In these analyses, respondents contributed one observation for each eligible service, and thus there were between two and twelve observations per respondent. We accounted for these repeated measures in our regression models through generalized estimating equations, adjusting for age, sex, race/ethnicity, education, and poverty status. After eliminating observations with missing data, a total of 794 (98%) participants remained.

Results: The 794 LOS participants were mostly women (92%); 48% were <55 years old; 36% were non-white; 14% had poverty level incomes; 42% had college degrees. They were eligible for 4,054 quality indicators (mean 5 ± 2 Qis/person, range 2–12 Qis). Qis with the highest rates of receipt included counseling regarding sun avoidance (90%), influenza vaccination in those receiving immunosuppressant medications (80%), and calcium and vitamin D supplementation in those taking glucocorticoids (84%) [Table]. Participants were less likely to report receiving care consistent with other Qis, including assessment of traditional cardiovascular risk factors (smoking, lipids, body-mass index, blood pressure, diabetes; 29%), and counseling regarding medication risks and contraception in women at risk for pregnancy initiating potentially teratogenic medications (40%). The global pass rate was 65%; younger age, nonwhite race/ethnicity, and low income were associated with lower global pass rates. In multivariate analysis, only younger age remained statistically significant.

Discussion: In this community-based cohort of individuals with SLE, receipt of recommended care varied significantly depending on the QI assessed. For some Qis, rates of receipt of recommended care were low, suggesting the need for targeted quality improvement. Younger individuals appear to be at risk for lower quality care.

Quality Indicator summary[1], time frame (*in last year unless noted*)	Number Eligible	% Rec'd
Sun avoidance counseling, ever	814	90%
Influenza vaccination if taking immunosuppressive medications	508	80%
Pneumococcal vaccination if taking immunosuppressive medications, ever	508	69%
Bone mineral density testing if receiving prednisone ≥7.5 mg/day	145	56%
Calcium and vitamin D if receiving prednisone ≥7.5 mg/day	145	83%
Antiresorptive or anabolic agent in patients with osteoporosis receiving prednisone ≥7.5 mg/day	98	61%
Counseling regarding risks if initiating new medication	148	68%
Appropriate drug monitoring for NSAID, DMARD or glucocorticoid, varies	683	69%
Glucocorticoid management plan if receiving prednisone ≥10 mg/day for ≥3 months	51	65%
Management of hypertension if renal disease and consecutively elevated blood pressures	26	54%
ACE inhibitor or ARB if renal disease	180	49%
Assessment of traditional cardiovascular risk factors	814	29%
Counseling regarding risks and contraception if reproductive age woman initiating potentially teratogenic medication	25	40%

NSAID = non-steroidal anti-inflammatory drug. DMARD = disease-modifying anti-rheumatic drug.
ACE = angiotensin-converting enzyme. ARB = angiotensin receptor blocker.

The Gene-Environment Interaction between HLA-SE and Smoking Plays an Important Role in Shaping the Reactivity of the ACPA Response to Several Citrullinated Antigens.
Annemiek Willemze[2], Diane van der Woude[3], Wendim Ghidey Alemayehu[1], René R. P de Vries[4], Tom W. J. Huizinga[3], Leendert A. Trouw[3] and René E. M Toes[3]. [1]Leiden University Medical Center, Department of Medical Statistics, [2]Leiden University Medical Center, Department of Rheumatology, Leiden, The Netherlands, [3]Leiden University Medical Center, Department of Rheumatology, [4]Leiden University Medical Center. Department of Immunohematology and Blood Transfusion

Objective: Rheumatoid arthritis is a complex genetic disorder. Human leucocyte antigen shared epitope (HLA SE) alleles are the strongest genetic risk factor for anti-citrullinated protein antibodies (ACPA) positive rheumatoid arthritis (RA). It has recently been postulated that a specific interaction exists between genotype, smoking and autoimmunity to a peptide from enolase. We showed recently that this is not specific for citrullinated α-enolase, but also for a peptide derived from citrullinated vimentin. The aim of this study was to further expand these findings by investigating if gene-environment interactions affect the reactivity pattern to other citrullinated antigens as well.

Methods: The reactivity of 766 RA patients to cyclic citrullinated peptide (CCP) and to four citrullinated peptides derived from vimentin (cVim), fibrinogen (cFib), linear Enolase (cEnolase=C6lin) and Myelin Basic Protein (cMBP=anti-SA) was determined by enzyme-linked immunosorbent assay (ELISA). The separate effects of the HLA SE alleles and smoking were assessed by logistic regression analysis. Biologic interaction was analyzed by investigating if the effects of the risk factors combined exhibited departure from additivity.

Results: The ACPA reactivity profile was affected by a significant biological interaction between the HLA SE alleles and smoking. Both the separate effects of HLA SE alleles and smoking, as well as their combined effects were present for anti-cVim, anti-cEnolase, anti-cMBP and anti-cFib. This effect was strongest for anti-cVim with an odds ratio (OR) of 41 (95% CI 14.7–118.5) in the anti-cVim-positive subset for smokers who were homozygous for the HLA SE alleles, compared to an OR of 6.2 (95% CI 2.4–16.1) in the anti-cVim-negative subset. For anti-enolase, this resulted in an OR of 40.0 (95% CI 11.4–135.2) in the positive subset and an OR of 10.1 (95% CI 4.2–24.2) in the negative group. Anti-MBP and Anti-cFib resulted in a more modest effect in interaction for smokers who were homozygous for SE (see table 1). Combining anti-cVim positive and anti-cEnolase positive patients that were homozygous for HLA SE and smokers, resulted in an even higher OR of 160.0 (95% CI 18.6–1373.0) compared to the anti-cVim negative and anti-cEnolase negative subset with an OR of 5.4 (95% CI 1.9–15.3).

Table 1. Interaction between HLA SE alleles, smoking and autoimmunity to various citrullinated peptides in RA patients

	HLA SE positive and smoker		HLA SE homozygous and smoker	
	OR	(95% CI)	OR	(95% CI)
CCP2−	1.0	(ref)	1.0	(ref)
CCP2+	7.7	(4.7–12.4)	14.5	(6.4–33.0)
CCP2+cVim+	18.0	(8.2–39.7)	41.7	(14.7–118.5)
CCP2+cVim−	4.5	(2.6–7.8)	6.2	(2.4–16.1)
CCP2+cEnolase+	20.6	(7.9–54.1)	40.0	(11.8–135.2)
CCP2+cEnolase−	5.4	(3.2–9.1)	10.1	(4.2–24.2)
CCP2+cMBP+	11.7	(6.4–21.5)	23.3	(9.3–58.3)
CCP2+cMBP−	4.1	(2.2–7.7)	6.7	(2.3–19.0)
CCP2+cFib+	8.4	(4.8–14.7)	17.6	(7.3–42.7)
CCP2+cFib−	6.0	(3.0–12.0)	9.2	(3.1–27.2)
CCP2+cVim+cEnolase+	73.1	(9.8–544.8)	160.0	(18.6–1373.0)
CCP2+cVim−cEnolase−	3.9	(2.2–7.1)	5.5	(1.9–15.3)

Conclusion: The gene-environment interaction between the HLA SE alleles and smoking is not specific for citrullinated α-enolase or citrullinated vimentin, but rather extends to other citrullinated antigens as well. These findings indicate that gene-environment interactions play an important role in shaping the reactivity of the ACPA response by broadening the ACPA-recognition profile.

Antibodies of IgG, IgA and IgM Isotypes Against Cyclic Citrullinated Peptide Precede the Development of Rheumatoid Arthritis. Heidi Kokkonen[2], Mohammed Mullazehi[4], Ewa Berglin[2], Göran Hallmans[1], Göran Wadell[3], Johan Rönnelid[4] and Solbritt Rantapää-Dahlqvist[2]. [1]Department of Nutritional Research, Umeå University, Umeå, [2]Department of Public Health and Clinical Medicine/Rheumatology, Umeå University, Umeå, [3]Department of Virology, Umeå University, Umeå, [4]Division of Clinical Immunology, Uppsala University, Uppsala

Background and Statement of Purpose: We have previously shown that the presence of anti-cyclic citrullinated peptide (CCP) antibodies precedes the development of rheumatoid arthritis (RA) by several years. In a recent study we also showed that individuals who later developed RA had significantly increased levels of several cytokines, cytokine-related factors, and chemokines. In this study we aimed firstly to investigate the presence and predictive value of isotypes, IgG, IgA and IgM, of anti-CCP antibodies in individuals before onset of symptoms of RA and to assess their relation to rheumatoid factors (RF), cytokines and chemokines, genetic factors, and smoking habits, and secondly to evaluate the predictive effect of these predating antibodies for radiological score after disease onset.

Methods: A case-control study was nested within the Medical Biobank and the Maternity cohorts of Northern Sweden. Patients with RA were identified amongst blood donors antedating onset of their disease by years by co-analyzing the registers of the patients and for the biobanks. Controls, matched for age, sex, date of sampling and residential area, were selected randomly from the same cohorts. Anti-CCP antibody isotypes were determined using EliA anti-CCP assay on ImmunoCAP 250 (Phadia AB, Uppsala, Sweden)

Results: Eighty-six individuals with RA were identified as being blood donors prior to onset of symptoms of joint disease, median (IQR), 2.5 (1.1–5.9) years before onset, with 71 available samples. The prevalence of anti-CCP antibodies in the pre-patient samples was 35.2% of IgG, 23.9% of IgA, and 11.8% of IgM with a specificity of 98.9%, 97.1% and 93.9%, respectively. IgG- and IgA anti-CCP antibodies were highly significant compared with controls, whereas the IgM isotype did not reach statistical significance compared with controls. Anti-CCP antibody of the IgG and IgA isotype predicted RA significantly in conditional logistic regression models (OR=98.1, 95% CI (13.3–723.8) and OR=13.3, 95% CI (4.9–36.0), respectively), whereas the IgM isotype showed borderline significance (OR=2.5 95% CI (0.9–6.3)). The mean antedating time was longest for IgA isotype, 2.2 years, followed by IgG, 2.1 years and for IgM, shortest, 1.4 years. The concentrations of the antibodies increased significantly and the frequencies of the isotypes increased significantly until disease onset and where at diagnosis of RA 70%, 40% and 30%, respectively. IgA antibodies but not IgG were significantly associated with up-regulated chemokines. In smokers IgA anti-CCP antibodies appeared much earlier before onset of symptoms of RA vs. in non-smokers. Patients positive for all three anti-CCP antibody isotypes already before onset of symptoms had a higher radiographic score both at baseline and after 24 months of disease compared with pre-RA individuals with fewer or no anti-CCP2 isotypes before onset.

Conclusions: Anti-CCP antibodies of both the IgG and IgA isotypes pre-dated the onset of RA by several years, also, anti-CCP antibodies of both IgG and IgA isotypes predicted the development of RA, with the highest predictive value for IgG antibodies.

Epitope Spreading of the Autoantibody Response in the Pre-Clinical Phase Predicts Progression to Rheumatoid Arthritis (RA). Jeremy Sokolove[2], Reuven Bromberg[3], Kevin D. Deane[5], Piyanka Chandra[3], Leslie Derber[6], Jess D. Edison[7], William R. Gilliland[8], Jill Norris[5], V. Michael Holers[4] and William Robinson[1]. [1]Stanford Univ School of Med, Stanford, CA, [2]Stanford University, Mountain View, CA, [3]Stanford University, [4]Univ of Colorado School of Med, Aurora, CO, [5]University of Colorado Denver, Aurora, CO, [6]University of Colorado Denver, [7]Walter Reed Army Med Ctr, Washington, DC, [8]Walter Reed Army Med Ctr, Potomac, MD

Purpose: Anti-CCP antibodies have been demonstrated in the preclinical phase of RA, however, the fine specificity of antigens targeted by these anti-citrullinated protein antibodies (ACPA) has not been well defined. Similarly, elevations in serum cytokines have been demonstrated in the preclinical phase of RA. We sought to determine the fine specificity of the ACPA response in the preclinical phase of RA, to demonstrate a pattern of epitope spreading, to correlate this spreading with the development of cytokine elevations, and to a derive profile of ACPA fine specificity which can predict the imminent onset of clinical RA.

Methods: We performed multiplex bead arrays using the Bio-Plex system to evaluate a panel of 36 putative RA associated autoantibodies and 48 cytokines/chemokines in serial serum samples collected prior to the development of clinical RA. Serum collected prior to clinical diagnosis of RA was obtained from the US Department of Defense Serum Repository. 81 subjects and matched controls were evaluated. Average number of specimens was 2.9 (range 1–4) with first sample obtained an average of 6.6 yrs before diagnosis (range 0.1–13.7 yrs). Results for antibodies or cytokines with a value 3 SD above the median value of matched controls controls were considered positive. Kaplan-Meier survival analysis was performed based on time to first positive test for each subject and hazard ratios calculated compared to controls. Significance Analysis of Microarrays was applied to compare paired samples pre- and post-anti-CCP seroconversion (CCP2 ELISA) and to compare all samples at the earliest and later timepoints. We evaluated the accumulation of ACPA subtypes over time and correlate this accumulation with (i) anti-CCP titer and (ii) cytokine elevations. We performed logistic regression analysis to identify markers which could predict imminent onset of clinical RA (defined as within 2 years of testing).

Results: Pre-clinical RA subjects displayed a time-dependent expansion of ACPA fine specificity. The timing of appearance of ACPA subtypes was similar to that of anti-CCP antibodies and there was a parallel rise in anti-CCP titer and number of ACPA subtypes during the preclinical period. A rise in several RA-related inflammatory cytokines was strongly associated with the expansion of the ACPA response. Finally, we identify a panel of markers

consisting of autoantibodies alone, or autoantibodies in combination with serum cytokines, which is able to identify those subjects most proximate to onset of clinical RA.

Conclusion: The preclinical phase of RA is characterized by an accumulation of multiple autoantibody specificities targeting a variety of citrullinated epitopes. The pattern of accumulation likely reflects epitope spreading and is correlated with rise in anti-CCP titer and ultimately, preclinical inflammation as reflected by rise in RA-associated cytokines. Characterization of the breadth and fine specificity of ACPA enabled identification of individuals within 2 years of RA diagnosis. Identification of such individuals may provide the opportunity for preclinical interventions in imminent RA not previously possible with use of anti-CCP testing alone.

Citrullinated Epitopes within the Atherosclerotic Plaque: A Target for Anti-Citrulline Protein Antibodies? Jeremy Sokolove[2], Orr Sharpe[3], Matthew Brennan[3], Andrew J. Connolly[3] and William Robinson[1]. [1]Stanford Univ School of Med, Stanford, CA, [2]Stanford University, Mountain View, CA, [3]Stanford University

Purpose: Patients with rheumatoid arthritis have a significantly increased risk for cardiovascular disease (CVD) due to accelerated atherosclerosis. Atherosclerosis is an inflammatory process similar to that observed within the RA synovium. Notably, elevated risk of CVD is mainly limited to anti-citrullinated protein antibody (ACPA) positive patients. Given our recent observation that citrullinated fibrinogen (cFb) immune complexes co-stimulate macrophage TNF production we sought to determine if citrullinated epitopes, specifically cFb, are present in the atherosclerotic plaque where they could be targeted to form immune complexes thus inducing inflammation and accelerating atherosclerosis.

Methods: We performed a series of proteomic and immunohistochemical studies of atherosclerotic lesions obtained from non-RA patients at time of autopsy to evaluate for the presence and identification of citrullinated proteins. Lysates were prepared from atherosclerotic segments of human aortic arch and subjected to 1 and 2-D polyacrylamide gel electrophoresis (PAGE). Parallel gels were transferred to nitrocellulose and probed for the presence of citrulline modified proteins using an anti-modified citrulline antibody (Millipore) and fibrinogen. Spots from 2D gel corresponding to citrullinated peptides were identified by mass spectroscopy. Atherosclerotic plaque and pulmonary artery lysates were immunoprecipitated with anti-fibrinogen antibody and subjected to immunoblot with IgG purified purified from anti-cFb RA patients. Paraffin sections of human coronary plaque were examined by immunohistochemistry for the presence of citrullinated proteins, fibrinogen, human PAD4, and fibrinogen.

Results: Western analysis of 1 and 2-D PAGE demonstrated several citrulline modified proteins within atherosclerotic plaque lysate. Mass spectroscopy as well as re-probing of the western blot membrane for fibrinogen confirmed the presence of cFb. Fibrinogen immunoprecipitated from atherosclerotic plaque lysate, but not pulmonary artery lysate, stained strongly with IgG purified from anti-cFb positive RA patients. Interestingly, several additional ACPA targets were identified from pre-cleared atherosclerotic lysates probed with ACPA+ IgG. Finally, immunohistochemistry demonstrated co-localization of (i) citrullinated proteins, (ii) PAD4, and (iii) fibrinogen within the coronary artery atherosclerotic plaque.

Conclusion: Citrulline modified proteins are prevalent within the atherosclerotic plaque. Specifically, the presence of citrullinated fibrinogen is confirmed to be present and targeted by RA patient derived IgG. This observation suggests that humeral targeting of citrullinated epitopes, specifically cFb, by ACPA within the atherosclerotic plaque could provide a mechanism for accelerated atherosclerosis observed in ACPA+ RA.

Risk Factors in Different Subsets of Rheumatoid Arthritis. Karin Lundberg[3], Camilla Bengtsson[1], Lena Israelsson[4], Iskra Pollak-Dorocic[4], Leonid Padyukov[4], Lars Alfredsson[1], Vivianne Malmström[4] and Lars Klareskog[2]. [1]Institute for Environmental Medicine, Karolinska Institutet, [2]Karolinska University Hospital, Stockholm, Sweden, [3]Reumatology Unit, Karolinska Institutet, Stockholm, Sweden, [4]Reumatology Unit, Karolinska Institutet

Background: Risk factors for rheumatoid arthritis (RA), such as *HLA-DRB1* 'shared epitope' (SE) alleles, *PTPN22* and cigarette smoking, associate with anti-CCP positive disease. By subdividing CCP positive patients based on reactivity to CEP-1, the immunodominant B cell epitope on citrullinated alpha-enolase, we have previously shown that SE, *PTPN22* and smoking mainly constitute risk factors for CEP-1 positive, rather than CCP positive RA. Here, we investigate 5 RA subsets, grouped based on reactivity to CCP, CEP-1 and a citrullinated vimentin peptide (CitVim), representing another anti-citrullinated protein/peptide antibody (ACPA)-specificity.

Methods: Antibodies were analysed in serum from 1027 RA patients from the Epidemiological Investigation of RA (EIRA), a Swedish population-based case-control study. An ELISA was set up for detection of anti-CitVim antibodies, using a biotinylated CitVim peptide (amino acid 60–75). One hundred and fifty healthy controls were used to determine the 95th percentile cut-off. A positive and a negative control and a standard of pooled anti-CitVim positive serum were included on each plate. Anti-CCP was measured using the Immunoscan CCPlus kit (Euro-Diagnostica) and anti-CEP-1, using an in-house ELISA previously described (Mahdi et al, Nature Genetics, 2009). Different RA subsets were compared with regard to risk factors by calculating odds ratios (OR) with 95% confidence interval by means of logistic regression.

Results: Patients were divided into 5 subsets: CEP-1+/CitVim+ (41%); CEP-1+/CitVim− (15%); CEP-1−/CitVim+ (11%) (the majority of patients in these subsets were anti-CCP positive and not divided further based on CCP status); CEP-1−/CitVim−/CCP+ (18%) and CEP-1−/CitVim−/CCP− (15%). SE, *PTPN22* and smoking each showed strongest association in the CEP-1+/CitVim+ subset, intermediate association in the single positive subsets and low association in the ACPA negative subset. The combined effect of risk factors showed a similar pattern, with an OR of 52 in the double positive subset, 16 in the CEP-1 single positive, 5 in the CitVim single positive, 6 in the CCP single positive, and 2 in the triple negative. Additionally, antibody levels were higher in CEP-1+/CitVim+ patients compared to single positive patients.

Conclusion: Our data show that the anti-CEP-1 and the anti-CitVim antibody response only partly overlap, and that SE, *PTPN22* and smoking predispose to the development of ACPA with multiple reactivities, rather than one single specificity. Interestingly, the CEP-1-/CitVim-/CCP+ subset still showed a strong association with SE (OR: 12), suggesting that other ACPA fine-specificities, for example citrullinated fibrinogen or collagen type II, could be found in this subset.

Anti-CCP Positivity in Patients with Lung Disease but No Apparent Articular RA: A Pre-RA State? Joshua J. Solomon[1], Allen Stevens[1], Mary Gill[1], Jennifer Brandorff[1], Jeffrey J. Swigris[1], Kevin Deane[2], Richard Martin[1], Roland M. du Bois[1] and Aryeh Fischer[1]. [1]National Jewish Health, [2]University of Colorado

Background and Objectives: Anti-CCP positivity is highly specific for RA, and can be identified in patients prior to the development of articular manifestations of RA. Also, lung disease may be the initial clinical manifestation of RA, and as such patients with lung disease but no articular RA may have anti-CCP positivity, reflecting early RA-related immune dysregulation. For this study, we sought to identify and describe a patient cohort characterized by lung disease, with moderate-to-high anti-CCP positivity, in the absence of articular manifestations of RA.

Methods: Between January 2008 and January 2010, 2393 patients had an anti-CCP antibody test at our center using the INOVA CCP3.1 IgG/IgA ELISA kit. 312 patients had a positive anti-CCP (≥ 20 IU). Of these, we excluded those with a low-titer positive anti-CCP (20 IU–39 IU) (n=63), patients in whom the anti-CCP was assessed due to joint disease (either with a pre-existing diagnosis of RA, or due to presence of joint symptoms of inflammation or synovitis on examination as determined by the treating physician) (n=214), patients younger than 18 (n=1), those without lung disease (n=2) and all patients with other defined connective tissue diseases (CTD) (n=8). Thus, the study cohort was comprised of 52 patients with a positive anti-CCP of at least moderate titer (≥ 40 IU) along with symptoms of respiratory impairment—without a prior diagnosis of RA, any other CTD, or presence of joint inflammation at initial testing for anti-CCP. All data were extracted by retrospective chart review.

Results:

Clinical characteristics of anti-CCP positive subjects with lung disease	
Number of patients	52
Median follow-up duration (d)	458 (114–755)
Median age (y)	68 (36–84)
Male gender	22 (42%)
Smokers-Past	29 (57%)
Smokers-Current	0 (0)
First degree relative with RA	7 (17.5%)
Dyspnea/cough at presentation	52 (100%)
Synovitis by history or exam at presentation	0 (0%)
Median anti-CCP (IU)	86.5 (40–235)
RF positivity	18 (37%)
Median RF (IU)	148 (20–3650)
Development of articular RA during follow-up	1 (2%)
High-Resolution Computed Tomographic Findings	
Airways disease	17 (33%)
Parenchymal lung disease	18 (35%)
Airways + Parenchymal disease	13 (24%)
*Miscellaneous patterns	4 (8%)

*Includes one each of emphysema, vasculitis, sarcoidosis, and non-tuberculous mycobacterial infection

Conclusions: We have identified a cohort of patients, predominately former smokers, with lung disease, a moderate-to-high positive anti-CCP and no articular manifestations of RA. Within a median follow-up of 15 months, 2% of this cohort has already developed inflammatory arthritis. These findings suggest i) the lung is the site of initial RA-related immune dysregulation, and that such patients represent a 'pre-articular RA' phenotype, ii) the lung in some cases is a pre-articular target of RA-related autoimmunity, or iii) in cases who never develop articular RA, anti-CCP generation may be a non-RA specific immune response, or that some factor prevents these patients from later developing RA-related articular disease. Prospective assessments of this unique cohort should help further our understanding of the etio-pathogenesis of RA.

Background: Patients with SLE have an increased risk for cardiovascular disease (CVD).Traditional assessment of CVD risk profile is measured using Framingham Risk Score (FRS), but this may not capture all CVD risk factors in patients with SLE. An alternative tool to assess CVD risk is the Flow Mediated Dilation (FMD)

Objective: 1) To perform CVD risk assessment using FRS and endothelial flow mediated dilatation (FMD) using high-resolution brachial artery ultrasound and 2) To determine association between endothelial function and FRS in women with SLE.

Methods: Our cohort consists of 173 females, ≥4 ACR criteria for SLE in whom the FRS and FMD were assessed as part of a study. Ten-year FRS was calculated on the basis of patients: age, smoking, systolic blood pressure (SBP), total cholesterol (TC) and HDL-cholesterol. Smoking, family history, SBP>130mmHg, serum TC>5.5 mmol/l and HDL<1.3mmol/l, were considered as risk factors for CVD. Normal FMD was defined as a 6% to 15% increase in the post-cuff inflation diameter change of the artery. Abnormal FMD was defined as <6% increase in the post-cuff inflation diameter. Associations between FMD and FRS were assessed using linear regression analysis.

Results: The mean (SD) age was 43.6 (12.7) years, SLE duration was 8.9 (2.4, 18.6) and 23% (n=77) were smokers. The mean SBP was at 121.9 mmHg (14.7) and. 22.5% had elevated SBP. The mean (SD) serum profile were as follows; triglycerides: 1.2 (0.6) mmol/l, total cholesterol: 4.7 (1.1) mmol/l, LDL-cholesterol 2.6 (0.8) mmol/L, HDL-cholesterol: 1.7 (0.6) mmol/L, TC/HDL ratio: 3.0(1.0), homocysteine:10.7 (4.3) μmol/L and CRP: 3.2 (6.2) mg/l. Abnormal serum levels were seen in 14.2 % for TG, 21.2% for TC, 50.8% for LDL, 18.4% for HDL,16.7% for homocysteine and 62.7% for CRP. The distribution of total CVD risk factors were as follows: 31% had 1, 44 % had 2 – 4 and 25 % had ≥5 risk factors. 44% (n=76) were at low risk (FRS=1–5 %), 24% (n=42) intermediate risk (FRS=6–10%), 20% (n=35) at high risk (FRS=11–20%) and 12% (n=20) at very high risk (FRS> 20%). For each FRS risk the equivalent % FMD change and proportion of patients with abnormal FMD are reported in Table 1. Adjusted linear regression showed that for each increase of 1% in FRS one observes an average 0.24% decrease in FMD cuff change.

Table 1. FRS, FMD cuff change (%) and proportion of abnormal FMD.

Framingham Risk Score	Mean %FMD +/− SD (cuff change)	No of abnormal FMD/No of patients
<5%	10.1 +/− 8.2	30/76 (40%)
6–10%	9.4 +/− 6.7	14/42 (33%)
11–20%	8.8 +/− 8.9	17/35 (49%)
>20%	7.0 +/− 5.7	10/20 (50%)

Conclusion: FRS explains only a subgroup of patients with abnormal FMD, with approximately 40% of SLE patients with low FRS having abnormal FMD. Assessment of FMD in SLE may identify a subgroup of patients with endothelial dysfunction not identified by FRS. Following these patients prospectively may help to determine their actual CVS risk.

Protection from Cardiovascular Events and Nephritis in SLE Correlates with Levels of IgM Natural Autoantibodies to Different Apoptosis-Associated Antigens. Caroline Gronwall[3], Ehtisham Akhter[2], Michelle A. Petri[1] and Gregg J. Silverman[3]. [1]Johns Hopkins University School of Medicine, Timonium, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Univ of California San Diego, La Jolla, CA

Background: In murine models, we have reported that induction of high levels of IgM antibodies to phosphorylcholine (PC), a phospholipid neo-determinant on apoptotic cells but not healthy cells, halts the progression of atherosclerosis in hypercholesterolemic mice (1), and can block in vivo and in vivo inflammatory responses to diverse agonists to TLR 3, 4, 7 and 9 (2) that is linked to the inhibition of central inflammatory signaling pathways.

Methods: To investigate for relationships between IgM antibodies to PC and other apoptosis-associated antigens with the clinical and laboratory features of SLE disease, we used standard ELISA to perform

serologic surveys to PC, malondialdehyde (MDA) as well as cardiolipin (CL) and β2 glycoprotein I (β2 gp I) in 95 SLE patients from the well characterized Hopkins Lupus cohort.

Results: In a pre-set series of analyses, for overall disease activity we found only modest inverse correlations with levels of IgM anti-MDA antibodies and the SLEDAI clinical disease activity index and Physicians global estimate (Pearson, P=0.01), but not with other IgM antibodies. Yet, patients without a history of past atherosclerotic cardiovascular (ASCVD) events (i.e., MI, CVA or TIA) had significantly higher IgM anti-PC levels (P= 0.00024, two-tailed t test) compared with those with past events, while there was no relationship with a history of documented lupus nephritis. In contrast, patients without lupus nephritis had higher levels of IgM anti-β2 gp I (P=0.003) and IgM anti-CL (P=0.0001) than in those with lupus nephritis, while there was no association between levels of IgM anti-β2 gp I with history of ASCVD events (P=0.46) and only a trend for IgM anti-CL (P=0.051). IgM anti-β2 gp I levels by themselves did not correlate with other thrombotic events (P=0.3). Patients with higher levels of IgM anti-MDA had modest associations with the absence of past ASCVD events (P=0.04) and the absence of lupus nephritis (P=0.04). Higher IgM anti-β2 gp I levels also correlated with lower C4 levels (Pearson, P=0.006), and a trend toward lower C3 levels (P=0.057). Otherwise there were no other significant associations with IgG anti-dsDNA or anti-C1q, or with C3 or C4, or ESR.

Conclusions: These findings support our hypothesis, based on murine studies and multiplex autoantibody microarray surveys of lupus twins (3), that some IgM autoantibodies are part of an evolutionarily conserved immune repertoire that provide homeostatic functions, which may protect from certain clinical features of autoimmune disease. Future studies will need to address whether these differences in antibody levels are present at earlier stages of disease development, which could provide valuable prognostic tools.

Non-Calcified Coronary Plaque (NCP) in Systemic Lupus Erythematosus (SLE): Quantitative Analysis. Adnan N. Kiani[2], Jens Vogel-Claussen[2], Margaret Yew[2], Laurence S. Magder[3] and Michelle A. Petri[1]. [1]Timonium, MD, [2]Johns Hopkins University, School of Medicine, Baltimore, MD, [3]University of Maryland, School of Medicine

Purpose: Coronary calcium (CC) is increased in SLE. New technology (CTA) can measure non-calcified plaque (NCP). Noncalcified plaque is less stable and more prone to rupture. We report on the largest study of quantified non-calcified coronary plaque in SLE.

Methods: 64 slice coronary multidetector computed tomography (MDCT) was performed in 106 patients with SLE. The MDCT scans were evaluated quantitatively by a radiologist, using dedicated software.

Results: The 106 SLE pts were 88% female, 67% Caucasian, 29% African-American, 4% other; mean age 51±11yrs. Significant results are shown in Table 1. Obesity was the major traditional CVRF associated with NCP. NCP did increase with age. NCP was increased with low complement, particularly with low C3. Anticardiolipin (but not lupus anticoagulant) was associated with increased NCP. Prednisone and Plaquenil therapy had no effect, but methotrexate use had increased NCP (table 1). In the best multivariate model (table 2) age, obesity, and MTX remained significant.

Table 1.

	Group	Mean NCP Score	p-value	p-value for trend, controlling for age
Age			0.011	
	<45 (n = 30)	0.16		
	45–55 (n = 39)	0.21		
	55+ (n = 36)	0.33		
Body Mass Index (BMI)			0.20	0.015
	<25 (n = 34)	0.18		
	25–29 (n = 36)	0.21		
Anticardiolipin antibodies (aCL)			0.027	0.048
	No (n = 37)	0.17		
	Yes (n = 69)	0.28		
Low C3			0.29	0.068
	No (n = 51)	0.21		
	Yes (n = 55)	0.26		
Low C4			0.58	0.090
	No (n = 63)	0.23		
	Yes (n = 43)	0.25		
Current Prednisone			0.24	0.92
	No (n = 69)	0.25		
	Yes (n = 36)	0.22		
Current Plaquenol			0.54	0.91
	No (n = 21)	0.21		
	Yes (n = 84)	0.25		
Current Imuran			0.16	0.29
	No (n = 98)	0.25		
	Yes (n = 8)	0.12		
Current Methotrexate (MTX)			0.011	0.0029
	No (n = 101)	0.22		
	Yes (n = 5)	0.51		
Current Cellcept			0.24	0.58
	No (n = 96)	0.24		
	Yes (n = 10)	0.20		
Current Non-steroidal anti-inflammatory drugs (NSAIDS)			0.95	0.74
	No (n = 62)	0.24		
	Yes (n = 43)	0.24		

Table 2. Multivariable regression model to assess the joint association of predictors and the mean level of NCP

Variable	Effect on mean NCP score (95% CI)	p-value
Age (per 10 years)	0.08 (0.05, 0.12)	<.0001
BMI (per 5 unit change)	0.03 (0.00, 0.07)	.049
History of Anticardiolipin	0.089 (−0.01, 0.17)	.097
Hypertension	0.03 (−0.07, 0.13)	.54
MTX ever	0.27 (0.07, 0.47)	.0076

Conclusion: NCP is a better marker of immediate atherosclerotic risk than is calcified plaque. In our univariate analysis, low complement was associated with NCP. This is the only association with a marker of active lupus. Of the traditional CVRF- obesity- rather than hypertension- is strongly associated with NCP. Our results suggest that both active SLE (serologically) and traditional CVRF (obesity) contribute to NCP in SLE. The association with MTX is of concern, but should be replicated in larger studies and in multiple centers.

Aspirin Response Is Impaired in Patients with Systemic Lupus Erythematosus. Vivian K. Kawai[1], Ingrid B. Avalos[2], Annette M. Oeser[5], John Oates[4], Ginger Milne[4], Cecilia P. Chung[3] and C. Michael Stein[1]. [1]Vanderbilt University, Nashville, TN, [2]Vanderbilt University, Brookline, MA, [3]Vanderbilt University, Baltimore, MD, [4]Vanderbilt University, [5]VUMC 23rd Ave South Pierce, Nashville, TN

Background: Patients with systemic lupus erythematosus (SLE) have an increased risk of myocardial infarction, stroke and other thrombotic events. Low-dose aspirin, used to prevent thrombotic events, irreversibly acetylates the platelet cyclooxygenase-1 (COX-1) enzyme and thus inhibits thromboxane A_2 (TxA_2) formation and platelet aggregation. However, some individuals do not respond adequately to aspirin—sometimes termed "aspirin resistance". Although many lupus patients receive aspirin to prevent thrombosis, there is no information about platelet responses in this population. We examined the hypothesis that response to aspirin is impaired in SLE.

Material and Methods: We prospectively studied 34 patients with SLE and 36 age and sex-matched controls who received immediate-release aspirin 81 mg /day for 7 days with monitoring of adherence. Subjects did not take NSAIDs for 7 days before the study. As a measure of aspirin's effect on its pharmacologic target, platelet COX-1, we measured concentrations of serum TxB_2, the stable metabolite of TxA_2, by mass spectrometry in whole blood allowed to clot at 37°C, before and after 7 days of aspirin treatment. We compared concentrations of serum TxB_2 in patients and controls who were not receiving aspirin therapy at baseline, and after a week of aspirin therapy. Failure to suppress serumTxB_2 below 10 ng/ml is widely reported as a threshold for defining aspirin resistance; we compared the proportion of patients and controls with aspirin resistance. Continuous variables were expressed as median and interquartile range [IQR]. McNemar and Wilcoxon rank sum tests were used to compare categorical and continuous data.

Results: The demographic characteristics of patients with SLE (n = 34, 82% female, age 41 [29–47 years] and controls (n = 36, 72% female, age 45 [33–50 years]) were similar. At baseline, median serum TxB_2 was similar in SLE (76.8 [39.0–134.8 ng/ml]) and controls (103.3, [30.6–130.3 ng/ml]) (P=0.84). Aspirin suppressed serum TxB_2 production almost completely in controls to 1.5 [0.8–2.7 ng/ml] but had significantly less effect in SLE (3.1 [2.2–5.3 ng/ml]) (P=0.002) (Figure). Aspirin resistance was present in 5/34 (15%) SLE patients and 0/36 controls (P<0.001). Compared to those that were aspirin sensitive, the 5 aspirin resistant patients were more likely to have diabetes (P=0.034), hypertension (P=0.007), a history of smoking (P=0.056), and a higher BMI (p=0.055), but measures of disease activity (SLEDAI) (P=0.96) and damage (SLICC) (P=0.43) did not differ.

Conclusions: Patients with SLE are less responsive to aspirin than controls and resistance to the effect of aspirin on platelet COX-1 occurs. Obesity, diabetes, hypertension and a history of smoking were more common among lupus patients with aspirin resistance.

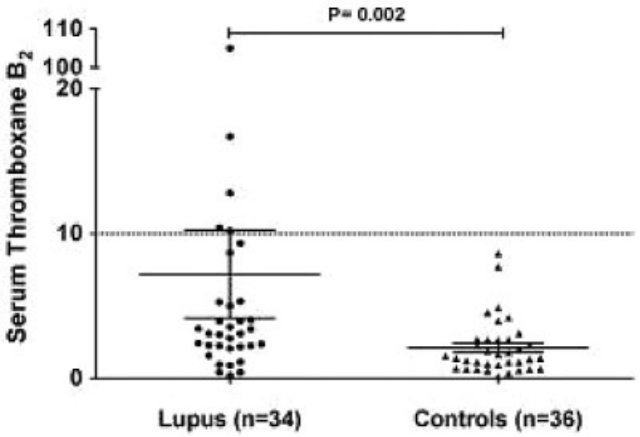

Figure. Serum Thromboxane B_2 in patients with lupus and controls after aspirin treatment.

Rates of Adverse Cardiovascular Events among SLE Patients Are Higher during Episodes of Disease Activity. Laurence S. Magder[2] and Michelle A. Petri[1]. [1]Timonium, MD, [2]Department of Epidemiology and Preventive Medicine, University of Maryland, School of Medicine, Baltimore, MD

Background: SLE patients are at higher risk of cardiovascular events (CVE) than non-SLE patients, even after accounting for traditional cardiovascular risk factors. We investigated whether CVE risk was associated with SLE disease activity, and whether past history of activity or current activity incurred a greater risk.

Methods: The CVE experience of patients in a large clinical cohort was analyzed. CVE was defined as myocardial infarction (MI), stroke, coronary procedure, incident angina, or claudication. SLE disease activity was defined using SLEDAI, the Physicians Global Assessment (PGA), and various disease components. The analysis was based on a data set with one record per patient-month of cohort participation. Each record contained data regarding the patient's clinical history up until that time, the most recently measured levels of disease activity, medications taken at that time, and whether a CVE occurred during that month. This file was analyzed using pooled logistic regression.

Results: 134 CVE events were observed from among 1874 patients who were followed for 9485 person-years. Events included 65 strokes, 27 MI, 29 cases of angina or coronary procedures, and 13 cases of claudication. The table shows rates of CVE in subgroups.

Table. CVE rates, in subgroups defined by SLE clinical characteristics

Subgroup	# CVE	Rate per 1000 person-yrs	Age-adjusted Rate Ratios (95% CI)	P-value
Duration of SLE				
0–6 years	43	11.4	1.0 (Ref. Group)	
6+ 10 years	29	13.4	1.5 (0.7, 1.7)	.83
10–15 years	24	13.9	1.0 (0.6, 1.7)	.97
15+	38	21.0	1.3 (0.8, 2.0)	.28
Recent SLEDAI				
0	36	9.5	1.0 (Ref. Group)	
1 or 2	30	12.4	1.4 (0.9, 2.4)	.14
3 or 4	31	17.3	2.1 (1.3, 3.4)	.0027
5+	37	24.9	3.4 (2.1, 5.3)	<.0001
Mean SLEDAI in cohort				
0–1	23	10.8	1.0 (Ref. Group)	
1–2.5	35	12.2	1.2 (0.7, 2.1)	.44
2.5–5	49	15.9	1.8 (1.1, 2.9)	.023
5+	27	19.4	2.8 (1.6, 4.9)	.0004
Recent PGA (3 point scale)				
0	36	11.2	1.0 (Ref. Group)	
0.1 to 0.9	29	10.6	1.0 (0.6, 1.6)	.89
1.0 to 1.4	30	14.8	1.4 (0.9, 2.3)	.17
1.5+	39	25.7	2.6 (1.7, 4.1)	<.0001
Mean PGA in cohort				
0–.9	97	12.9	1.0 (Ref. Group)	
1+	37	18.6	1.8 (1.2, 2.6)	.0040
Recent low C3				
No	34	19.3	1.0 (Ref Group)	
Yes	99	12.8	0.5 (0.4, 0.8)	.0019
History of low C3				
No	47	12.3	1.0 (Ref Group)	
Yes	87	15.4	1.6 (1.1, 2.3)	.0082
Recent anti-dsDNA				
No	83	11.9	1.0 (Ref. Group)	
Yes	50	20.1	2.1 (1.5, 3.1)	<.0001
History of anti-dsDNA				
No	48	13.4	1.0 (Ref Group)	
Yes	96	14.6	1.3 (0.9, 2.0)	.15

CVE were not associated with duration of SLE, after age-adjustment. In general, CVE were more strongly related to recent disease activity than to past or average disease activity. A moderate association between recent disease activity (SLEDAI) and CVE persisted after adjustment for cortico-steroids and other risk factors (RR=1.8, p=.054 comparing those with SLEDAI of 5 or more to those with SLEDAI of 0).

Conclusion: CVE rates are elevated during episodes of SLE activity, both in terms of clinical activity (SLEDAI) and serologic activity (low C3, anti-dsDNA). This might be explained by the acute effects of SLE activity on the endothelium, or conditions that cause both SLE activity and CVE.

Atherosclerosis Is Associated with Low 25(OH) Vitamin D Levels, Lack of Angiotensin Converting Enzyme Inhibitor Use, and Hyperlipidemia in African-American Lupus Patients. Roneka L. Ravenell[3], Diane L. Kamen[4], Spence David[5], Hollis Bruce[2], Almeida Jonas[1] and Jim C. Oates[3]. [1]Department of Bioinformatics and Computational Biology, The University of Texas M. D. Anderson Cancer Center, Houston, TX, [2]Department of Pediatrics, Medical University of South Carolina, Charleston, SC, [3]MUSC, Charleston, SC, [4]MUSC PO Box 250637, Charleston, SC, [5]Robarts Research Stroke Prevention and Atherosclerosis Research Centre, London, ON, Canada

Purpose: Patients with systemic lupus erythematosus (SLE) have a greater prevalence of atherosclerosis than the general population. This study was designed to identify risk factors for preclinical atherosclerosis in a predominantly African-American group of SLE patients.

Methods: Subjects with SLE but without a history of clinical cardiovascular events were enrolled. At entry, a Framingham risk factor history and medication list were recorded. Sera and plasma samples were analyzed for lipids, lupus activity markers, and total 25(OH) vitamin D (25(OH)D) levels. SLE Disease Activity Index (SLEDAI) and SLICC Damage Index scores were calculated. Carotid ultrasound measurements were performed to determine total plaque area (TPA) in both carotids as a validated measure of preclinical atherosclerosis that associates longitudinally with major cardiovascular events. Cases were defined as those with TPA values above that of age-matched controls from a population of 4272 patients in stroke and hypertension clinic. Descriptive analysis was performed on all variables between cases and controls. Associations between TPA and continuous variables were determined by correlation. Chi-square analysis was performed for ordinal variables against case or control status. Logistic regression analysis was performed to explore predictive modeling. P values < 0.05 were considered significant. A nearest related neighbor machine learning model (NRN) to explore variables associating with elevated TPA in a nonlinear or collinear fashion.

Results: Fourteen of 51 subjects (27%) enrolled had elevated TPA compared to age-matched controls. 25(OH)D levels (16.6 ± 3.2 vs. 22.6 ± 1.8 ng/dl), SLEDAI scores (2.3 ± 0.5 vs. 4.3 ± 0.5), and anti-dsDNA antibody levels (34 ± 18 vs. 136 ± 59 IU) were significantly lower, while SLE disease duration (11.9 ± 1.6 vs. 8.7 ± 13 years) was significantly higher in cases. Age ($r=0.58$), C4 ($r=0.36$), and SLE disease duration ($r=0.37$) significantly correlated with TPA, while 25(OH)D levels significantly inversely correlated with age-adjusted TPA ($r=-0.33$). ACE-inhibitor use and a history of hypercholesterolemia were significantly associated with case status. Logistic regression models containing ACE-inhibitor use, 25(OH)D levels, and LDL levels had a diagnostic accuracy of 84%. Season of enrollment was not significant in the model. An NRN model was trained. Variables retained in the model as associating with abnormal TPA were hydroxychloroquine, ACE-inhibitor, and statin use as well as 25(OH)D levels. This model resulted in a receiver operating characteristics area under the curve of 0.75 for discriminating cases.

Conclusions: This study demonstrates in SLE patients novel and previously described associations between lower atherosclerotic burden and factors that are known to restore endothelial function and reduce plaque in non-SLE populations. These associations provide a rational basis for studying the effect of these therapies on endothelial function and vascular outcomes in patients with SLE.

Dipyridamole Inhibits SLE T Cell Activation and Alleviates Nephritis in Lupus-Prone Mice. Vasileios C. Kyttaris, Zheng Zhang, Ourania Kampagianni and George C. Tsokos. Beth Israel Deaconess Medical Center

Background: SLE T cells provide help to B cells to produce autoantibodies and infiltrate tissues orchestrating local inflammatory responses. We have previously shown that SLE T cells are characterized by a robust calcineurin-mediated dephosphorylation of the transcription factor NFAT. Dephosphorylated (activated) NFAT tranlsocates to the nucleus and activates a host of genes, including the co-stimulatory molecule CD154 that enhances antibody production by B cells, and several pro-inflammatory cytokines.

NFAT/calcineurin inhibition represents an attractive option for the treatment of various inflammatory diseases. Yet calcineurin inhibitors (cyclosporine A, tacrolimus) have significant side effects including nephrotoxicity. It was shown recently that dipyridamole inhibits the activation of NFAT without affecting total calcineurin phosphatase activity, potentially causing fewer side effects.

Methods: T and B cells were isolated from the peripheral blood of patients with SLE and healthy individuals. The cells were incubated in the presence of dipyridamole (20μM or 50μM), or tartaric acid as control. T cells were activated with anti-CD3 and anti-CD28 antibodies. MRL/lpr lupus-prone mice were injected intraperitoneally with dipyridamole 50 mg/kg three times a week for 4 weeks. CD154 and cytokine production was measured with flowcytometry.

Results: Dipyridamole treatment of SLE T cells inhibited NFAT activation and decreased the expression of CD154 by $66\pm21\%$ ($p<0.0001$, $N=9$). The production of IFN-γ decreased by $96\pm3\%$ ($p<0.0001$, $N=9$), that of IL-17 by $74\pm29\%$ ($p<0.0001$, $N=9$), and of IL-6 by $57\pm22\%$ ($p<0.0001$, $N=9$). Moreover, dipyridamole inhibited the T cell directed production of immunoglobulin, including anti-dsDNA antibodies, in T:B cell mixed cultures. Activation of isolated B cells by anti-IgM was not affected by dipyridamole. Dipyridamole decreased significantly the expansion of T cells in vitro as assessed by CFSE staining.

Next, we treated MRL/lpr mice with dipyridamole. MRL/lpr mice have a very large number of CD3+CD4-CD8- T cells (double negative T cells, DNT) that express high levels of NFAT. Treatment of these mice with dipyridamole decreased proteinuria by 33% and prevented the emergence of pyuria. The dipyridamole treated mice did not develop skin lesions and were protected from early death (3/5 control-treated mice died by the fourth week of the trial as opposed to 0/5 in the dipyridamole treated group).

Dipyridamole treatment decreased the concentration of IL-6 in the serum (dipyridamole vs. control treated mice$=364\pm52$ vs. $5{,}280\pm206$ pg/mL, $p<0.0001$). The percentage of CD3+ cells in the spleen decreased in the dipyridamole treated animals, primarily due to a decrease in DNT subpopulation (splenic DNT cells in dipyridamole vs. control treated mice$=47\pm2\%$ vs. $67\pm4\%$, $p=0.0045$).

Conclusions: Inhibition of NFAT with dipyridamole results in decreased activation and expansion of lupus T cells, blocking at the same time T cell directed autoantibody production. Dipyridamole alleviates nephritis and prolongs survival of lupus-prone mice. Therefore we propose that dipyridamole is an attractive NFAT inhibitor that can be used in the treatment of SLE.

Defective T Cell Tolerance in Rheumatoid Arthritis Due to Increased B-Raf and K-Ras Expression. Pratima Deshpande[2], Karnail Singh[1], Mingcan Yu[2], Guangjin Li[2], Cornelia M. Weyand[3] and Jorg J. Goronzy[3]. [1]Emory University, Atlanta, GA, [2]Stanford University, Stanford, CA, [3]Stanford University School of Medicine, Stanford, CA

Background/Purpose: Autoantibodies to common auto- and neoantigens such as IgG Fc and citrullinated peptides are immunological hallmarks of rheumatoid arthritis (RA). Identified disease risk genes suggest that signaling pathways abnormalities are involved in RA pathogenesis. We have examined the hypothesis that defects in T cell receptor (TCR) signaling lower the activation threshold of RA T cells predisposing for a failure in maintaining tolerance.

Methods: TCR-induced signaling was compared in 65 patients with seropositive RA and 54 healthy controls by phosphoepitope flow cytometry. The MAP Kinase Signaling Pathway PCR Array was used to screen for differentially expressed genes. SOS1, RasGRP1, DUSP5, DUSP6, K-Ras and B-Raf transcription was quantified by qPCR. Protein expression of B-Raf, C-Raf, K-Ras and N-Ras were compared by Western blotting and by flow cytometry. siRNA for K-Ras and B-Raf from Qiagen was used in silencing experiments. Co-localization of B-Raf or C-Raf with K-Ras or N-Ras in T cells from control and RA patients was examined by confocal microscopy. CD4 T cells from healthy HLA-DR4+ individuals were transfected with K-Ras or B-Raf cloned into the pIRES2-AcGFP1 vector. Cells were stimulated with 1 μM aa 65–77 native or R70Cit vimentin peptides.

Summary of Results: RA T cells responded to TCR stimulation with increased ERK phosphorylation compared to healthy controls of the same age

($p<0.0001$). Increased ERK responsiveness was a feature of all functional T cell subsets including naive T cells and did not correlate with disease activity. Increased expression of K-Ras and B-Raf in RA T cells, first identified in gene expression arrays of ERK pathway members, was confirmed by qPCR, Western blotting and flow cytometry ($p<0.01$). None of the RA-implicated cytokines TNF-α, IL-1, IL-6, IL-15 or IL-21 induced B-Raf or K-Ras gene expression in vitro. Partial silencing of K-Ras and B-Raf significantly lowered activation-induced p-ERK levels ($p<0.01$). In individual cells, B-Raf and K-Ras baseline levels correlated with activation-induced ERK phosphorylation ($p<0.001$) confirming that B-Raf and K-Ras are rate-limiting in T cells and concentration differences of these signaling molecules in RA are functionally important. In confocal studies, B-Raf/K-Ras clustering was significantly increased in RA T cells two minutes after TCR stimulation ($p<0.001$). Increased ERK activity was sustained by activation of a positive feedback loop involving p-ERK dependent RKIP phosphorylation and release of sequestered C-Raf. Overexpression of transfected B-Raf or K-Ras lowered the TCR threshold and enabled responses to citrullinated vimentin in healthy HLA-DR4+ individuals.

Conclusions: Restricting ERK activity, in part by Rap-1 mediated inactivation of C-Raf is an important mechanism to maintain anergy to self-antigens or in the absence of costimulation. Expression of B-Raf that can bypass this pathway is low in T cells from healthy individuals. Naive and memory T cells from RA patients have increased B-Raf and K-Ras expressions that enable T cell responses to low affinity and autoantigens. Our data suggest that B-Raf and K-Ras are promising targets to treat autoimmunity.

SLAP Deficiency Enhances Both Number and Function of FoxP3$^+$ Regulatory T Cells and Inhibits Chronic Arthritis in SKG Mice. Lisa K. Peterson[2], Laura A. Shaw[2], Anthony Joetham[3], Shimon Sakaguchi[1], Erwin W. Gelfand[5] and Leonard Dragone[4]. [1]Kyoto University; Osaka University, [2]National Jewish Health, Denver, CO, [3]National Jewish Health, [4]National Jewish Health; University of Colorado Denver; The Children's Hospital, Denver, CO, [5]National Jewish Health; University of Colorado Denver; The Children's Hospital

Background: Intrinsic defects in lymphocyte signaling have been implicated in the pathogenesis of rheumatoid arthritis. Manipulation of T cell function by altering TCR complex-mediated signaling could be a viable strategy to treat autoimmune disease. However, the signaling networks initiated or regulated by the TCR signaling complex that are required to eliminate or modulate the function of autoreactive T cells are not known, which is an obstacle in our capacity to manipulate autoreactive T cells. SKG mice have a point mutation in zeta-associated protein of 70kDa (ZAP-70) rendering it hypomorphic. Decreased signaling through the TCR complex in developing thymocytes results in selection of highly autoreactive Th17 cells and autoimmune arthritis upon exposure to inflammatory triggers. We hypothesized that increasing signal strength through the TCR complex in SKG mice will prevent autoimmunity. To enhance TCR signal strength, we crossed SKG mice with Src-like adaptor protein (SLAP)-deficient mice. SLAP targets the zeta chain of the TCR (TCRz) for degradation. The same signaling chain of the TCR complex to which ZAP-70 binds. Thus, we specifically chose to create the Double SKG SLAP KnockOut (DSSKO) model because ZAP-70 and SLAP have opposing functions on the regulation of TCR complex mediated signaling. The combination of these two mutations provides a unique opportunity to determine how alterations in TCR complex-mediated signaling can modulate autoimmune disease in the context of a defined genetic background, uniform environmental conditions, and a well-characterized signaling disruption.

Methods: SKG mice were crossed with SLAP-deficient mice to generate Double SKG SLAP KnockOut (DSSKO) mice.

Results: DSSKO mice do not develop zymosan-induced chronic autoimmune arthritis. This prevention of arthritis development is not due to significant alteration in thymocyte development or repertoire selection. Instead, regulatory T cells (Tregs), known to be critical in suppression of autoreactive T cells and prevention of autoimmunity, are increased in both the thymus and spleen of DSSKO mice. This was accompanied by inhibition of differentiation and/or expansion of Th17 cells, upon zymosan exposure, and suppression of chronic arthritis. Treg depletion and/or functional blockade unleashed the autoreactive Th17 cells and arthritis developed in DSSKO mice. *In vitro* suppression of effector T cell proliferation was also enhanced which demonstrated that DSSKO mice have increased numbers of Tregs with improved function.

Conclusions: These data show that DSSKO mice have enhanced development and function of Tregs, preventing the development of arthritis. Understanding how TCR complex-mediated signals influence Treg development, expansion, and function will advance our capacity to manipulate Treg biology. The long-term goal of these studies is to apply our findings to patients in a way that enhances Treg number and/or function to treat autoimmune disease.

2129

The Role of BAFF in Promoting the Development of IL-17-Producing Cells and Th17-Mediated Disease. Xiaohui Zhou[2], Julie Wang[4], Zhongmin Liu[1], William Stohl[3] and Song Guo Zheng[4]. [1]Tongji University Medical School, [2]Univ S Calif Keek Schl of Med, Los Angeles, CA, [3]Univ Southern California, Los Angeles, CA, [4]USC Keck School of Medicine, Los Angeles, CA

Background: B cell-activating factor belonging to the TNF family (BAFF; BLyS) plays a critical role in promoting B cell maturation and survival and the development of autoimmune disorders. BAFF also affects T cell function through binding to one of the BAFF receptors, BAFF-R. BAFF arguments the Th1- but suppresses Th2-mediated inflammatory responses. It is less clear whether BAFF affects the development and Th17 cells-mediated autoimmune diseases.

Methods, Materials: Freshly isolated splenocytes and lymph node cells in BAFF knock out (KO), BAFF transgenic and wild type mice were analyzed ex vivo for the surface staining of CD19, CD4, CD8, CD69, CD44, CD62L, CCR-6, CD25 and intracellular staining of ROR-γt, IL-17, IFN-γ, IL-4 and Foxp3. IL-17A and IL-17F mRNA was determined by qPCR. The effect of BAFF on in vitro differentiation of naïve CD4+ T cells into Th17 cells was assessed through stimulation with soluble anti-CD3/CD28 in the presence of IL-6 and TGF-β plus irradiated APC. We further detected the frequencies of Th1, Th2 and Treg cells in these mice. In addition, we evaluated the role of BAFF in the Th17 development in vivo using a Th17-mediated disease model, EAE.

Results: In comparison to WT mice, the frequencies and total numbers of Th1 and Th17 cells in BAFF KO mice decreased, while that of these cells increased significantly in BAFF Tg mice. IL-17A and IL-17F mRNA in BAFF KO mice decreased compared to WT and Tg mice. In vitro induction of Th17 cells was also down regulated significantly in BAFF KO T cells. In addition, different origins of APC do not affect the induction of Th17 cells. There is no significant difference of Treg induction in these mice. Lack of BAFF delayed the appearance and attenuated the severity of Th17-mediated EAE symptoms. Conversely, the excessive expression of BAFF promoted Th17 cell development and persistent EAE symptoms. Increased IL-6R expression and function by CD4+ cells in BAFF Tg may be responsible for the increased Th17 cell production.

Conclusions: This study suggests that BAFF may promote the development of autoimmune diseases through Th17 cell development and function in addition to its direct effect on B cell maturation and survival. These results implicate that manipulation of BAFF pathways has a beneficial role in treating Th17- and/or Th1-mediated inflammatory diseases.

Activated Th17 Cells Drive Rheumatoid Inflammation and Are Resistant to Inhibition by Natural Antagonists of Their Development. Jan Leipe[2], Mathias Grunke[2], Claudia Dechant[2], Christiane Reindl[2], Hendrik Schulze-Koops[1] and Alla Skapenko[2]. [1]University of Munich, Munich, Germany, [2]University of Munich, Germany

Background: IL-17 has been identified as a new pro-inflammatory cytokine contributing to autoimmune inflammation in several animal models. Since the major source of IL-17 in human autoimmune diseases

is still elusive, we analyzed Th17 cells, defined as a cell type producing IL-17, but not IFN-γ or IL-4, in patients with the prototypic autoimmune diseases, rheumatoid arthritis (RA) and psoriatic arthritis (PsA).

Methods: Th17 cells were analyzed *ex vivo* and *in vitro* by various methods e.g. multi-color flow cytometry, enzyme-linked immunosorbent assay (ELISA) and real-time PCR in well-defined cohorts of patients: active treatment-naive RA (n = 36) and PsA (n = 20) with very early disease (disease duration < 3 months), and patients with established RA (n = 21; mean disease duration 68 months) responding or not responding to therapy. For control, patients with osteoarthritis (n=20) and age-matched healthy individuals (n=25) were analyzed.

Summary of the Results: Th17 cell frequencies and IL-17 production of CD4 T cells from the peripheral blood of RA and PsA patients were significantly increased compared to controls. Importantly, Th17 cells frequencies strongly correlated with systemic disease activity in early ($r = 0.91$, $p < 0.0001$) and established ($r = 0.72$, $p < 0.001$) RA, and were reduced to control levels in response to clinically effective treatment. Th17 cells were specifically enriched in the inflamed joints of RA and PsA patients, and increased frequencies of synovial Th17 cells expressed the chemokine receptors CCR4 and CCR6 required for selective migration of Th17 cells into the joints. As molecular mechanisms underlying the pathophysiological Th17 cell activity in autoimmune arthritis, we identified an intrinsically elevated expression of the master transcription factor for Th17 cells, RORC, accompanied by increased Th17 cell differentiation, and a resistance of Th17 cells from the RA and PsA patients to the natural antagonists of their development, e.g. IL-4 and IFN-γ.

Conclusion: Together the data indicate an important role of Th17 cells and their effector functions in the pathogenesis of autoimmune arthritides and provide the scientific basis for treatment approaches targeting Th17 cell functions.

Regulatory T Cell Recovery in HCV-Related Autoimmunity through IL-2 Treatment. David Saadoun[2], Michelle Rosenzwajg[1], Lucile Musset[1], Fabrice Carrat[1], David Klatzmann[1] and Patrice Cacoub[1]. [1]Internal Medicine Department, [2]Internal Medicine Department and Immunology Laboratory Pitie Salpetriere Hospital

Background: Twenty to 30% of hepatitis C virus (HCV)-related vasculitis patients are resistant to conventional therapy (i.e. antiviral therapy and/or immunosppressors) and still have an active disease. We recently described a $CD4^+$ $CD25^{++}$ regulatory T cell (Treg) deficiency in HCV-related vasculitis patients. Immunomodulatory effects of interleukin-2 (IL-2) are well established, notably the preferential expansion of Treg able to suppress inflammatory responses mediated by $CD4^+$ and $CD8^+$ T cells.

Objective: To evaluate the cellular immune response after IL-2 therapy in HCV-MC Vasculitis patients, resistant to conventional therapy.

Patients: HCV+ patients with cryoglobulinemia vasculitis (n=10), resistant to conventional therapy (i.e. antiviral therapy and/or immunosppressors). Vasculitis was defined according to international criteria: chronic HCV infection (HCV RNA+), serum cryoglobulin ≥ 0.05g/l in at least two determinations, presence of the triad purpura-arthralgia-asthenia and/or biopsy proven vasculitis (kidney, nerve or skin).

Methods: This is an open prospective phase I/II trial. Four cycle of subcutaneous IL-2 therapy (3 millions IU/day from day 1 to 5 every 21 days were carried out at W1, W3, W6, and W9). All patients were followed after IL-2 therapy (W11 to W37). The end points were the immunologic follow-up of Treg and of HCV cellular immune response before, during and after IL-2 therapy and the clinical tolerance.

Results: The percentage of Tregs (CD4+CD25hiCD127-FoxP3+) dramatically increased following IL-2 therapy (3.5 ± 0.25% to 14.5 ± 2.89%, $p<0.001$) with a similar trend between naïve and memory Tregs. This was associated with an increased expression of molecules associated with suppression of Tregs (i.e. GITR, CD152 and LAP). Suppressive function of Tregs was confirmed by suppression tests. At a 1/1 and 1/8 ratio (between effector and tregs cells) the suppression was 97±1% and 66 ± 7%, respectively. A decrease in CD4+CD25+ effector Tcells (41.4 ± 4% to 24 ± 4%, $p<0.01$) and in CD27+IgM+ marginal zone B cells (11 ± 2% to 4.5 ± 0.6%, $p<0.01$) was observed following IL-2 therapy. After IL-2 therapy serum level of IL-2 and IL-2RA were still higher than before therapy. IL-2 therapy was safe with no vasculitis flare.

Conclusion: This is the first study to report the use of IL-2 in human autoimmune disease to modulate the homeostasis of Tregs. IL-2 therapy dramatically increase the percentage of Treg in HCV-vasculitis and was well tolerated.

Progressive Resistance Exercise in Women with Knee Osteoarthritis. Renata Jorge[1], Marcelo Souza[2], Aline Chiari[2], Anamaria Jones[2], Império Lombardi, Jr[2], Artur Fernandes[2] and Jamil Natour[2]. [1]UNIFESP, Sao Paulo, SP, Brazil, [2]UNIFESP

Background: Knee osteoarthritis (OA) is a common musculoskeletal disorder. Recent guidelines for the management of knee OA emphasize the role of strengthening exercises. While most studies focus on the benefits of quadriceps strengthening, little is known about hip strengthening exercises in knee OA and also, about prescription in terms of intensity, duration, frequency and load.

Objectives: To assess pain, function, quality of life, walking endurance and muscular strength in women with knee OA who participated in a progressive resistance exercise program (PREP).

Methods: Eligible patients included women, age 40–70 years old with pain between 3 and 8 on a 10-cm pain scale. Of the 144 patients screened, 60 met the eligibility criteria and were randomized to the Experimental Group (EG) or Control Group (CG). Patients in EG participated in a 12-week PREP twice a week and CG remained on a waiting list for physiotherapy. The PREP consisted of strengthening exercises for knee extensors, knee flexors, hip abductors and hip adductors, all performed with 50% and 70% of the maximum amount of weight that can be tolerated for a given exercise (1 repetition maximum-1RM) using machines with free weights. The resistance was reevaluated every 2 weeks. Assessment for pain (VAS), muscle strength (RM), walking endurance (6MWT), function (WOMAC) and quality of life (SF-36) were done at baseline, 6 weeks and 12 weeks by a blinded assessor.

Results: 29 female patients were randomly assigned to the EG and 31 to the CG. In the comparison between groups using ANOVA for repeated measures, we found better results for the EG with statistical difference for VAS ($p<0.001$), WOMAC (pain: $p < 0{,}001$; function: $p < 0{,}001$ and aggregate score: $p<0.001$), some domains of SF-36 (physical function: $p=0.002$; physical role limitation: $p=0.002$ and pain: $p = 0{,}044$) and on muscular strength (extensors: $p<0.001$; flexors: $p=0{,}002$ and abductors muscles: $p<0.001$). At 6 weeks, there was a significant statistical difference in the pain VAS (EG: 5.9; CG:7.0; $p=0.022$); the WOMAC (EG: 30.9; CG:39.1; $p=0.017$); SF-36 physical component summary (EG:39.1; CG: 30.3; $p=0.045$) as well on muscular strength of knee extensors (EG:10.4; CG:5.7; $p<0.001$); knee flexors (EG:7.4; CG:5.2; $p=0.003$) and hip abductors (EG:29.2; CG:21.0; $p<0.001$). At 12 weeks, there was a statistically significant difference in the pain VAS (EG: 4.3; CG: 6.6; $p<0.001$); the WOMAC (EG:24.1; CG: 38.3; $p<0.001$); SF-36 physical component summary (EG: 49.8; CG: 30.8; $p=0.000$); physical role limitation (EG: 48.3; CG: 16.9; $p=0.001$) and pain (EG: 58.6; CG: 41.7; 0,006); as well on muscular strength of knee extensors (EG: 11.8; CG: 5.7; $p=0.000$), knee flexors (EG: 8.6; CG: 5.3; $p=0{,}000$) and hip abductors (EG: 32.7; CG: 19.5; $p=0.000$).

Conclusion: A progressive resistance exercise program was effective in reducing pain and improving function, some domains of quality of life and strength in women with knee osteoarthritis at 6 weeks and 12 weeks after the intervention.

2133

Reasons for Decline in Walking Despite Improvements in Knee Pain: The MOST Study. Daniel K. White[2], David T. Felson[4], Jingbo Niu[3], Michael C. Nevitt[5], C. Elizabeth Lewis[6], James Torner[7] and Tuhina Neogi[1]. [1]Boston Univ Schl of Med, Boston, MA, [2]Boston Univ School of Med, Boston, MA, [3]Boston University, Boston, MA, [4]Boston University School of Medicine, Boston, MA, [5]UCSF, San Francisco, CA, [6]University of Alabama, [7]University of Iowa

Purpose: Reducing knee pain in persons with knee osteoarthritis (OA) is a key therapeutic goal of rehabilitation. However, recent studies have shown that improvements in pain do not necessarily result in improvements in function, and it's not clear as to why this might be. We therefore evaluated factors associated with substantial declines in walking speed among persons who had meaningful improvements in knee pain.

Methods: The Multicenter Osteoarthritis Study (MOST) is a NIH funded longitudinal study of people who have or are at high risk for knee osteoarthritis. We included subjects who had meaningful improvement over 30 months in pain in either knee, defined as a 41% decrease in VAS pain with an absolute change of 20/100. We defined meaningful decline in walking speed as a decrease of 0.1 meters per second (m/s) during a 20 meter walk. Both values are based on previously published sources. We assessed changes in radiographic OA, comorbidities, widespread pain, and depressive symptoms over 30 months, and baseline knee strength as risk factors for decline in walking speed. To examine the association of risk factors with meaningful decline in walking speed we calculated risk ratios adjusted for age, sex, BMI, race, and baseline knee pain.

Results: Of the 465 persons with meaningful improvement in knee pain (mean (sd) age=63.3 (7.8), 67% female, BMI= 31.3 (6.3), 82% White), 20% (91/465) had a meaningful decline in walking speed. More persons with a new onset of comorbidity had a decline in walking speed (32% (15/47)) compared with those with no comorbidity at baseline or follow up (17% (46/267)). Similarly, more persons with widespread pain at baseline and follow up had a decline in walking speed (24% (40 /165) compared with those with no widespread pain at baseline or follow up (16% (22/139)). Adjusting for confounders, persons with new comorbidities and those with widespread pain had 1.8 and 1.7 times the risk of decline compared with those without comorbidities and widespread pain, respectively (RR 1.8 95% CI [1.1,2.9], 1.7 [1.0,2.9], respectively).

Conclusions: Improvements in knee pain do not guarantee positive changes in walking speed. Health providers should consider that onset of new comorbidities and pain in areas other than knee pain may increase risk of decline in walking speed despite improvement of pain in one or both knees.

Reduction of the Foot Plantar Maximum Vertical Force Using Medial-Wedge Insoles in Valgus Knee Osteoarthritis. Priscilla Teixeira Rodrigues[2], Rosa M. R. Pereira[2], Julia M. D. Greve[1] and Ricardo Fuller[2]. [1]Rheabilitation Division, Faculdade de Medicina da Universidade de São Paulo, [2]Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo

Introduction: The use of medial-wedge insole associated with ankle support produces a clinical improvement in osteoarthritis of the knee valgus, as described in our previously study [Arthritis Rheum 59(5): 603–608]. However, there are no data regarding the biomechanics effect of these orthoses.

Objective: To evaluate the foot plantar maximum vertical force in patients with OA in the lateral compartment of the valgus knee using medial-wedge insole associated with ankle support.

Method: A total of 42 feet of 21 women with bilateral knee osteoarthritis (ACR criteria), with valgus deformity ≥ 8 degrees were evaluated regarding clinical and biometrics data. Patients were assessed with: 1. standard shoes without the insoles (control); 2. with the medial-wedge insoles (with 8 mm medial elevation at rearfoot) and 3. with these insoles and neoprene ankle support. The system FSCANR 3.816 version, with flexible soles and 960 load sensors on the surface, was used to obtain the foot plantar vertical force. The acquisition of the measures took 8 seconds and the data was collected between seconds 2 and 6. The values were given in Newtons (N).

Results: The patients were 65.14 +10.24 years old; the mean disease duration was 9.3 years, the body mass index was 29.4 ± 4.1. The pain at rest was 5.57 ± 2.18 (range 2–8) by visual analogue scale, the degree of radiographic OA (Kellgren-Lawrence) was 2.62 ± 0.82, WOMAC index was 70.8 ± 11.2 and Lequesne 14.55 ± 3.19. The femorotibial angle was 169.38 ± 4.32 degrees. The maximum vertical force was significantly lower in in the patients with the use of medial-wedge insoles compared to control (287.30 ± 89.28 vs. 347.42 ± 87.14 N, p= 0.003). Likewise, patients with the use of medial-wedge insoles and ankle support had a diminished vertical force compared to control (248.15 ± 99.77 vs. 347.42 ± 87.14 N, p<0.0001). The support promoted a further reduction in strength compared to the isolated use of the insole (248.15 ± 99.77 vs. 287.30 ± 89.28 N, p=0.03).

Conclusion: The use of medial-wedges insoles promotes a reduction in the maximum vertical force in osteoarthritis of valgus knee. This finding may explain the clinical improvement observed in our previous study probably by a more homogenous load distribution in the involved ankle and knee.

Functional Benefits Following Dynamic Exercise in Patients with RA Taking Anti-TNFα Therapy Reflected in Lower Limb Function Tests but Not the HAQ. Angela Reid[1], Audrey Brady[2], Tara Cusack[5], Catherine Blake[5], Anne Barbara Mongey[3], Douglas J. Veale[4] and Oliver FitzGerald[3]. [1]Our Lady's Hospice, Dublin, Ireland, [2]Our Lady's Hospice, [3]St. Vincent's University Hospital, [4]St. Vincent's University Hospital, [5]University College Dublin, Ireland

Background: The medical management of rheumatoid arthritis (RA) has advanced with the introduction of biologic drugs including anti-TNFα therapy medication. Dynamic exercise is an important non-pharmacological therapy in RA and has been shown to improve function. The effect of dynamic exercise on function for people with RA on anti-TNFα medication has not yet been described. The purpose of this study was to investigate the effect of dynamic exercise, either on land or in water, on function in people with RA taking anti-TNFα medication.

Methods: A convenience sample of people with RA on anti-TNFα medication was recruited. Participants were randomised into one of 3 groups: a gym, a hydrotherapy or a control group. The gym and hydrotherapy interventions consisted of flexibility, strengthening and aerobic exercises. Exercise classes were undertaken for 1 hour, twice weekly for 8 weeks. The control group received no intervention. Participants were assessed by a blind assessor at baseline, 8 and 24 weeks. The primary outcome measure used was the HAQ. Secondary measures of outcome included the 50ft Walk Test (50ftWT) and the Timed Chair Stand Test (TCST). Semi-structured interviews were conducted at 24 weeks to ascertain the exercise participation levels of individuals following completion of the study.

Results: Fifty one people (12 male / 39 female) with a mean age of 56 (± 10) years were recruited. The mean length of diagnosis was 14.1 (± 10.5) years and the mean length of time taking anti-TNFa medication was 2.9 (± 2.1) years. The 50ftWT improved significantly in both the gym and hydrotherapy groups at 8 weeks compared to the control group (gym p=0.02, hydrotherapy p=0.01). The TCST significantly improved in the gym group (p=0.02) when compared to the control group at 8 weeks. These improvements were not maintained at 24 weeks. No significant change was noted in HAQ scores. Of the 17 exercise group participants interviewed post-study, 3 had continued the exercise programmes between the eight and 24 week time-points. Reasons identified for failing to continue to exercise included lack of access to facilities and reduced motivation.

Table 1. Results

	Group (n = 17)*	Baseline	8 weeks	24 weeks
HAQ (0–3) mean ± SD	Gym	0.79 (0.51)	0.63 (0.48)	0.79 (0.61)
	Hydro	1.07 (0.85)	0.99 (0.85)	1.03 (0.85)
	Control	0.83 (0.55)	0.83 (0.59)	0.79 (0.56)
50ft Walk test (s) mean ± SD	Gym	9.35 (1.97)	8.21 (1.86)†	8.6 (2.62)
	Hydro	11.53 (3.87)	10.07 (2.05)†	10.24 (2.17)
	Control	10.10 (3.36)	10.56 (3.34)	10.35 (2.60)
Timed Chair Stand Test (reps) median (range)	Gym	13 (5–19)	16 (10–32)‡	16 (6–32)
	Hydro	9 (6–23)	12 (8–23)	12 (8–29)
	Control	11 (5–20)	13 (6–22)	13 (0–22)

*Hydro Group n = 16 at 24 weeks. †p ≤ 0.05 one-way Anova, ‡p ≤ 0.05 Mann-Whitney U Test.

Conclusion: Participating in 8 weeks of dynamic exercise, either on land or in a hydrotherapy pool, improved function in this sample of people with RA on anti-TNFα medication as evidenced by the significant improvements in lower limb function tests at 8 weeks. This was not reflected by changes in HAQ scores. Access to facilities and support in terms of organised, suitable, supervised exercise classes may be necessary to enable this population to continue to engage in long term exercise.

Co-Morbid Pain in Hips, Low Back, and Non-Operative Knee Associated with Physical Function before and after TKR. Patricia D. Franklin[2], Wenjun Li[2], David C. Ayers[2] and Carol A. Oatis[1]. [1]Arcadia University, Glenside, PA, [2]Univ of MA Med Schl, Worcester, MA

Introduction: Older age, female gender, obesity, and poor emotional health are associated with poorer function before and after total knee replacement (TKR). In addition, medical co-morbidities are related to peri-operative adverse events. However, no research has documented the role of co-morbid pain in the low back, hips, and the non-operative knee on physical function before and after TKR. We evaluated the association of co-morbid low back, hip, and bi-lateral knee pain with function in TKR patients.

Methods: A prospective cohort of 130 consecutive, primary, unilateral TKR patients enrolled in a clinical trial reported demographic, pain, and function data before and at 6 months after TKR. Descriptive and multivariate analyses evaluated the associations among age, gender, BMI, emotional health (SF36, MCS), WOMAC pain score in both hips and both knees, and Oswestry low back pain and associations with (1) pre-op function (SF36, PCS) and (2) pre-post functional gain.

Results: Patients were 60% women with mean age=65, BMI=32.6, pre-TKR PCS=32.7. Before TKR, 52% reported mild or no pain in the non-operative knee, hips, and low back. Twenty (20) percent reported moderate/severe pain in one other joint or back, 13% in two locations, and 10% in 3 or 4 locations. Women reported moderate/severe pain more than men in the non-operative knee (34.5% vs. 11%); ipsilateral hip (28% vs. 15%); and low back (33% vs. 20%). After adjusting for age, gender, BMI, and MCS, greater pain in the surgical knee ($p < 0.000$), contralateral hip ($p < 0.074$), and low back ($p < 0.028$) was associated with poorer function in TKR patients (r2=.39).

Conclusion: In addition to pain in the surgical knee, co-morbid pain in the non-operative knee, hips, and low back explain much variation in peri-TKR function. Women report more non-operative joint pain than men at the time of TKR. These data suggest a need for a musculoskeletal co-morbidity score to assess total pain burden when evaluating TKR patient function before and after surgery.

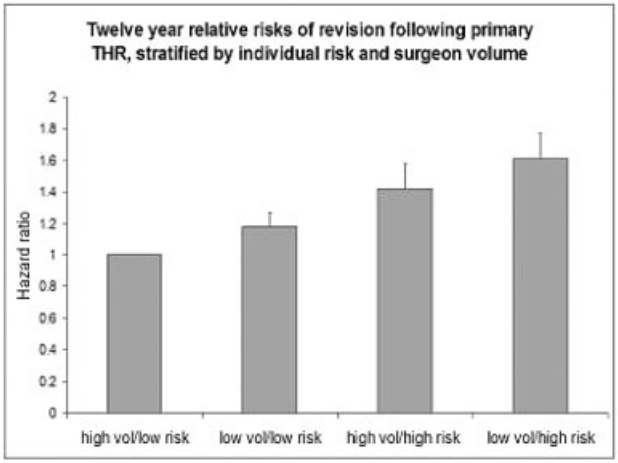
Predictors of 12 Year Revision Risk Following Primary THR for Osteoarthritis in the US Medicare Population. Jeffrey N. Katz[1], Elizabeth A. Wright[1], Akosua A. Nti[1], John Wright[2], Henrik Malchau[5], John A. Baron[4] and Elena Losina[3]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, [3]Brigham and Womens Hospital, Boston, MA, [4]Dartmouth Medical School, [5]Massachusetts General Hospital

Introduction: There have been no prior US national population-based studies of the risk of revision following primary total hip replacement (THR) for osteoarthritis (OA) with 12 year follow up and complete ascertainment of revision and mortality.

Methods: We used Medicare claims data to assemble a cohort of 51,347 patients ≥65 years old who had primary THR for OA in 1995–96. We followed this cohort in claims through 2008 and identified patients who had claims with ICD-9 codes indicating revision THR. We used Cox proportional hazard models to examine the association of age, sex, race, Medicaid eligibility (proxy for low income), comorbidity, surgeon and hospital Medicare THR volume on the risk of revision. We aggregated individual risk factors into a risk score and examined the effects of high individual risk score and THR volume in a Cox model.

Results: At the time of primary THR, the cohort had mean age 74, 63% were female, and 53% were operated upon by surgeons who performed fewer than 12 THRs per year in the Medicare population. Over 12 year follow-up, 27,955 patients died and 4,185 underwent revision THR. Factors independently associated with risk of revision THR included younger patient age (65–75 versus > 75; HR 1.47, 95% CI 1.37, 1.57), male sex (HR 1.23, 95% CI 1.16, 1.31) and low annual surgeon THR volume (< 12 cases/year; HR 1.23, 95% CI 1.13, 1.34). After adjusting for these factors, comorbidity, race, Medicaid eligibility and hospital volume were not associated with revision risk. We designated patients with both individual risk factors (male, younger age) as high risk, and those with 0 or 1 of these factors as lower risk. In a Cox regression model, low surgeon volume and high individual risk contributed independently to revision risk (Figure). We found no evidence for an interaction between individual risk and surgeon volume.



Conclusions: These first national, population based estimates of the 12-year risk of revision following primary THR confirm the risk associated with younger age and male sex and demonstrate that low surgeon volume is associated with revision risk in both high- and low-risk patients. The analyses are limited by our inability to adjust for patient weight or activity level with claims data. As THR is performed in increasingly younger patients, these findings underscore the need for further research on the risk of revision in patients < 65 undergoing primary THR.

Keep Working with Arthritis
Wednesday, November 10, 2010, 2:30 PM–4:00 PM

2138

Too Young? Arthritis Is "Main Cause" of Disability for Millions of Working-Age U.S. Adults. Kristina Theis[3], Charles G. Helmick[1], Jennifer M. Hootman[2] and Matthew Brault. [1]CDC, Atlanta, GA, [2]Centers for Disease Control, Kennesaw, GA, [3]Centers for Disease Control and Prevention

Background: Arthritis is well-established as a cause of disability, particularly among older adults. However, much less is known about its impact on working-age (18–64 years) adults. Using the most recent Survey of

Income and Program Participation (SIPP) data, we describe the prevalence and specific impacts of disability due to arthritis/rheumatism among working-age US adults.

Methods: SIPP is a longitudinal panel survey fielded by the US Census Bureau representing the civilian, non-institutionalized US population. Panel members undergo in-person interviews at 4-month intervals for a period of 2.5–4 years. Data presented here are cross-sectional findings from a disability topic module (fielded June–September 2005) of the 2004 SIPP panel. The disability module was administered to panel adults to identify self-reported disability (difficulty with ≥1 specified functional activities, activities of daily living (ADL), instrumental activities of daily living (IADL), selected impairments, use of an assistive aid, or limitation in ability to work around the house or at a job or business) and ascertain its "main cause." Analyses weighted to population controls and incorporating sampling weights produced estimates and 95% confidence intervals (95% CI) of disability prevalence overall and by specific disability subcomponents for working-age adults overall and by age group (18–44 or 45–64 years) and sex for respondents identifying arthritis as the main cause of their disability. Statistical comparisons by age group and sex were considered significant at the 95% confidence level.

Results: At least 3.6 million working-age adults report arthritis as the main cause of their disability. Of these, 22.4% (95%CI 19.7–25.1) receive federal work disability benefits, 21.0% (95%CI 18.2–23.8) use assistive aids (e.g., cane), 17.7% (95%CI 15.4–20.0) have difficulties with ADLs, 20.9% (95%CI 18.3–23.5) with IADLs, 40.5% (95%CI 37.4–43.6) and 37.8% (95%CI 34.7–40.9) are limited in their ability to work around the house or at a job or business, respectively, and 89.9% (95%CI 88.1–90.7) have difficulty with specified functional activities, e.g., walking 3 city blocks (51.1%), lifting/carrying 10 pounds (32.9%). In absolute numbers, ~1.4 million report limitation in their ability to work at a job, 808,000 receive federal work disability benefits, and 740,000 require the use of cane, crutches, or a walker. The absolute number and % having difficulties with selected specified activities are significantly higher in those 45–64 compared with 18–44 year olds; yet, 743,000 younger adults report that arthritis disables them. Women comprise ¾ of the 3.6 million and ½ to ¾ of those in all specific disability subcomponents.

Conclusion: Respondents in vulnerable pre-retirement years (45–64) and women at all ages, bear a substantial portion of arthritis disability and may be well-served by increasing reach of evidence-based programs that improve pain and physical function. Occupational and physical therapy and increased use of appropriate assistive devices may help mitigate current disability among adults with arthritis.

Arthritis and Labor Force Attachment among Working-Age Australians. Kristina A. Theis, Lucy Busija, Ross Wilkie, Gerald Elsworth and Richard H. Osborne. Deakin University

Background: The impact of arthritis on employment is well-documented in many countries; however, little is known about its extent in working-age (18–64 years) adults in Australia. The aim of this study is to estimate the prevalence of arthritis and explore its links with age, gender, and labor force attachment in working-age Australians.

Methods: Data were obtained from the Household, Income, and Labour Dynamics in Australia (HILDA), a nationally representative survey of community-dwelling adults, with data collected by in-person interview and supplemented by a self-complete questionnaire. Data presented here are cross-sectional findings from HILDA 2007, the most recent time period in which arthritis status was ascertained. Participants reported an arthritis diagnosis by identifying arthritis from a list of conditions following: "Have you ever been told by a doctor or nurse that you have any of the long-term health conditions listed below?" Analysis was restricted to those with known arthritis status (n = 10,940) to estimate arthritis prevalence and the links with age, gender, and labor force attachment (categorized as employed, unemployed (actively seeking employment), or not in the labor force (all other dispositions, including discouraged job seekers). Weighted point estimates and 95% confidence intervals [95% CI], accounting for the complex survey design, were calculated for working-age adults overall and by age group (18–44 or 45–64 years) and sex.

Results: Arthritis affects 14.9% [95% CI 13.8–15.9] of working-age adults in Australia (1.6 million people) and was significantly greater in women (17.5% [16.1–19.0]) compared with men (12.1% [10.8–13.3]. Overall, employment was statistically significantly lower in those with arthritis compared to those without arthritis (57.7% [53.8–61.5] vs. 80.2% [78.9–81.5]). The same pattern of statistically significantly lower employment for those with arthritis vs. no arthritis holds for men (59.8% [53.9–65.8] vs. 86.8% [85.3–88.2]), women (56.2% [51.6–60.8] vs. 73.5% [71.6–75.3]), and both age groups. But the arthritis vs. no arthritis employment gap was much narrower for younger adults (70.9% vs. 81.6%) than for those in the older age group (54.5% vs. 77.5%). More than twice the prevalence of working-age adults with arthritis were not in the labor force compared to those without arthritis (40.6% [36.7–44.5] vs. 17.0% [15.9–18.2]). Unemployment was low and not significantly different between working-age Australians with and without arthritis.

Conclusion: Arthritis is common among working-age Australians, affecting approximately 1 in 7 potential workers. Employment is substantially lower among those with arthritis compared to those without for men and women and across age groups; however, the increase in employment gap between the older versus younger age group suggests that employment is a greater challenge for individuals in middle age. Also, despite lower arthritis prevalence overall, men with arthritis appear to be more affected than women by low employment participation. The application of policy and public health interventions in combination may be needed to reduce the impact of arthritis on employment.

Association of Depressive Symptoms and Helplessness with Socioeconomic Status in People with Knee Osteoarthritis. Leigh F. Callahan[2], Jack H. Shreffler[4], Kathryn Remmes Martin[3], Britta Schoster[4], Jordan Renner[4] and Joanne M. Jordan[1]. [1]Chapel Hill, NC, [2]Univ of North Carolina, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]University of North Carolina, Chapel HIll

Purpose: Individual and community socioeconomic status (SES) variables have been demonstrated to be associated with psychosocial outcomes in self-report and other types of arthritis, but these associations have not been examined in knee osteoarthritis to date. The purpose of this study is to evaluate associations between educational attainment, occupational status, and community poverty rate with depressive symptoms and perceived helplessness in people with knee OA.

Methods: A cross-sectional analysis was performed using data from 3085 people in the first follow-up evaluation (2000–2003) of the Johnston County Osteoarthritis Project. Depressive symptoms were measured with the 20-item Center for Epidemiologic Studies Depression (CES-D) on a scale of 0–60. Perceived helplessness was measured with the 5-item Rheumatology Attitudes Index (RAI) on a scale of 1–5. Educational attainment was dichotomized as less than high school (HS) diploma or at least a HS diploma. Occupational status was dichotomized as high (e.g. professional, managerial, technical, sales) versus low (labor, service, farm, manufacturing) based on U.S. Census 2000 categories for self-reported occupation. Community poverty was defined from the U.S. Census household poverty rate for the block group in which the participant resided. Poverty rate was trichotomized as <12% (reference), 12–25%, and >25%. Separate analyses were performed for those people having knee radiographic OA (rOA), defined as KL grade>=2 in one or both knees, and for those with symptomatic knee OA (sOA) defined as KL grade >=2 and with symptoms (pain or stiffness) in the same knee. Regression analyses were used to relate CES-D and RAI outcomes to all SES variables while controlling for age, gender, race, and BMI.

Results: Of the sample, 750 people had rOA. The average age was 67 years (45–94), 36% were African American, 58% had BMI ≥ 30, and 64% were female. 37% of the population had less than HS diploma, and 60% were in non-managerial occupations. The average CES-D was 6.9 (8.1), and the average RAI was 2.55 (0.71). Of those with rOA, 488 also met the definition of sOA. For people with knee rOA, CES-D scores were significantly higher for those with low educational attainment (β=2.04, C.I.= [0.77, 3.3]) and, independently, low occupational status (β=1.58 [0.33, 2.8]). RAI scores were significantly associated only with educational attainment (β=0.31 [0.19, 0.43]). Important covariates for CES-D were age ≥ 65 (β=-4.8 [−6.5, −3.2]) and being female (β=3.3 [2.1, 4.4]). Important covariates for RAI are being female (β=0.16 [0.05, 0.27]) and having BMI≥30 (β=0.25 [0.14,

0.37]). For people with knee sOA, results generally paralleled those for rOA, except that CES-D was not independently associated with occupational status. Community poverty was not significantly associated with CES-D or RAI in bivariate or multivariable analyses.

Conclusions: Low educational attainment is associated with higher levels of depression and feelings of helplessness in people with knee OA. Low occupational status may also play an independent role.

The Effect of a 6 Week Walking Program on Work Activity Limitations in Adults with Arthritis. Brian L. Charnock[3], Kathryn Remmes Martin[2], Jack Shreffler[3], Mary Altpeter[3] and Leigh F. Callahan[1]. [1]Univ of North Carolina, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill

Purpose: To evaluate the effect of a revised 6 week walking intervention program, Walk With Ease (WWE), on work limitations among people with self-report arthritis.

Methods: While conducting an evaluation of the Arthritis Foundation's (AF) Walk With Ease (WWE) community based walking program, pretest-posttest physical evaluations and self-report surveys were administered to 462 individuals. Of these, 94 were employed and answered a series of questions using the Workplace Activity Limitation Scale (WALS). This 12-item scale gauges physical activity limitations in working adults with arthritis. Participants answered individual WALS items by marking 0 (no difficulty), 1 (some difficulty), 2 (a lot of difficulty), and 3 (unable to do). Individual item scores were then summed and averaged to yield an overall WALS score which ranged from 0 (good) to 3 (bad) for each participant. At the 1 year WWE follow-up, 67 participants were still employed and retook the WALS. Pre-post t-tests were conducted for each individual WALS item and the overall WALS to determine whether participants significantly improved work limitations. Post-1yr t-tests were also conducted to determine if any improvements were maintained at 1 year.

Results: Employed WWE participants were on average 56 years old, 88% female and 61% Caucasian. Mean Body Mass Index was 32 and 81% had more than a high school education. Overall, 59% of participants improved their WALS during the 6 week program. In pre-post comparisons, the overall WALS significantly improved from a mean of 0.57 (SD $\pm$0.34) to a mean of 0.47 (SD $\pm$0.36), $p<0.001$. Individual WALS items with significant improvement were: "Lifting/Carrying objects" (0.96 ($\pm$0.72) to 0.71 ($\pm$0.78), $p<0.001$), "standing for long periods of time" (0.85 ($\pm$0.77) to 0.6 ($\pm$0.73), $p<0.01$)," maintaining concentration" (0.34 ($\pm$0.50) to 0.19 ($\pm$0.40), $p<0.01$), as well as "using hands" and "reaching" (both $p<0.05$). Improvements shown at 6 weeks were maintained at one year in both the overall WALS (0.45 ($\pm$0.31) to 0.43 ($\pm$0.33)) and the 5 individual WALS items listed above.

Conclusion: After a 6 week walking program, working adults with arthritis showed significant improvement in overall work limitations. Improvements were primarily in lifting/carrying, standing for long periods of time and maintaining concentration while at work. One year after the walking program, work limitation improvements were maintained. Walking intervention programs, such as WWE, should be considered by employers to improve the health and productivity of employees in both the short and long term.

The Effect of Structural Deformities on Typing Styles of Touch Typists with Rheumatoid Arthritis. Nancy A. Baker[2], Norman P. Gustafson[2], Hyekyoung Shin[3] and Joan C. Rogers[1]. [1]Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh

Purpose: Rheumatoid arthritis (RA) may lead to severe fixed structural deformities of the hand and wrist that may change postures/motions during touch typing. Understanding the mechanism of hand motions during touch typing may provide insight into how people with RA can use their computer safely. This cross-sectional study examined the effect of structural deformities on the postures/motions of the hand/wrist during touch typing. We hypothesized that touch typists with RA with structural deformities would have significantly different typing postures/motions and speeds than those without structural deformities.

Method: A total of 33 subjects with RA were recruited from the University of Pittsburgh Medical Center (UPMC). Subjects were adults with RA, aged from 18 to 65 years, who self-reported being touch typists. Subjects' posture/motions during typing were videotaped and rated for visual structural deformities (VSD) by a certified hand therapist. Typing postures/motions were rated by two trained raters using the Keyboard-Personal Computer Style Instrument (K-PeCS). Typing speed was calculated in words per minute. Based on the presence of any VSD, subjects were divided into two groups: 22 subjects with VSD and 11 subjects without VSD. Chi Square statistics and independent t-test were used to compare the K-PeCS items and typing speed between the two groups.

Results: The subjects were primarily female (88%), a mean age of 56.3 $\pm$ 8.8, and white (91%). Touch typists with VSD showed more fixed hand/wrist motions than those without VSD (Figure 1). Significantly more subjects with VSD showed whole hand motions to activate the keys rather than individual finger motions (i.e., no ulna deviation, no MCP hyperextension, straight finger joints, and use of 2 or less fingers). Significantly fewer subjects with VSD also used a wrist support. There was no significant difference for typing speed between the subjects with VSD (25.9 $\pm$ 13.0 wpm) and without VSD (27.7 $\pm$ 11.4 wpm) (p =.70).

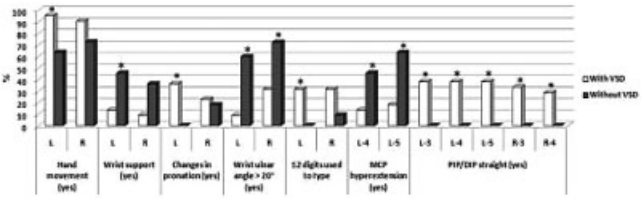

Figure 1. Significantly different postures/motions during touch typing (* $p<.05$).

Conclusion: Structural deformities can affect the typing styles of touch typists with RA. To compensate for inflexible hand movements, touch typists with VSD showed alternative typing strategies, such as "hunt and peck" style: moving whole hands rather than individual joints, floating the wrists, using fewer fingers, and keeping their fingers straight rather than curved. However these strategies may exacerbate existing problems by putting additional stress on already affected joints. Further evaluation by age should be considered.

Possible suggestions to ensure proper working posture include ergonomic keyboard, moveable wrist support, or redesign of computer workstation.

Formation of Solutions for Rheumatic Condition-Related Work Barriers by Occupational and Physical Therapists (OTs/PTs). Saralynn H. Allaire[2], Julie J. Keysor[1], Nancy A. Baker[5], Jingbo Niu[3] and Michael P. LaValley[4]. [1]Boston Univ Sargent College, Boston, MA, [2]Boston Univ School of Medicine, Boston, MA, [3]Boston University, Boston, MA, [4]BU School of Public Health, Boston, MA, [5]University of Pittsburgh, Pittsburgh, PA

Purpose: Identification of patients' rheumatic condition work barriers along with generation of solutions for barriers can reduce work disability. We have been exploring whether this type of intervention could be effectively provided by OTs/PTs. In a previous study 10 OTs/PTs had difficulty generating solutions for patients' work barriers. To address this finding we used literature and expert opinion to develop an informational booklet containing possible solutions for a wide variety of barriers. In this study, we examined solution generation quality in a large sample of OTs/PTs and tested the effect of providing the solution booklet on quality of solutions generated.

Methods: Subjects were recruited from OT/PT professional associations. We developed and pre-tested 3 patient cases. Case information included a patient's 3 most bothersome barriers. and subjects were asked to provide $\geq$ 1 solution for these 3 barriers. OT and PT subjects were each randomized to either receive (experimental=EXPM) or not receive (control=CTRL) the solution booklet to use as a resource. Three reviewers, blinded on subjects' EXPM/CTRL and OT/PT status, rated the helpfulness of the solutions generated by each subject using a 5-point ordinal scale. Proportions of EXPM

and CTRL subjects giving solutions rated as probably or very likely helpful were calculated. Wilcoxon rank tests were conducted to examine differences in the solution helpfulness scores between the two groups.

Results: 113 subjects provided data, 55 OTs (26 EXPM/ 29 CTRL) and 58 PTs (24 EXPM/ 34 CTRL). To date we have evaluated data from 2 cases. The quality of solutions generated by CTRL subjects was good for 2 physical activity type of work barriers, with ≥ 75% giving probably/very likely helpful solutions. The helpfulness scores of solutions from EXPM subjects for these 2 barriers were not significantly better. For a work/home life barrier the quality of CTRL subject solutions was poor, with only 22% providing helpful solutions. The EXPM subject solution score for this barrier was significantly better (p=.04), but quality was modest with 40% of solutions helpful. The quality of CTRL subject solutions for the remaining 3 barriers was modest with 45% giving helpful solutions for a cognitive barrier, 56% for a company policy barrier and 35% for a vocational direction barrier. However, the quality of solutions given by EXPM subjects for these barriers was good with 86%, 76% and 82% respectively giving helpful solutions (p<.001 for all).

Table. Helpfulness of Solutions Formed by Subjects Who Did and Did Not Receive Information about Possible Solutions

Work barrier	Subjects Who Did Not Receive information (CTRL)* n = 63	Subjects Who Did Receive information (EXPM)* n = 50	p value for comparison of CTRL/EXPM solution quality scores†
Physical job activity barrier: prolonged standing			
Proportion giving helpful solutions‡	75%†	76%	
Median (interquartile range) score§	3.0 (2–4)‡	3.5 (3–4)	0.08
Physical job activity barrier: carrying suit cases			
Proportion giving helpful solutions	87%	90%	
Median (interquartile range) score	4.0 (3–4)	3.5 (3–4)	0.75
Work/home life barrier: attending children's recreational events			
Proportion giving helpful solutions	22%	40%	
Median (interquartile range) score	2.0 (1–2)	2.0 (1–3)	0.04
Cognitive work barrier: concentrating on work activities			
Proportion giving helpful solutions	45%	86%	
Median (interquartile range) score	2.0 (0–3)	4.0 (3–4)	<.0001
Company policy barrier: completing required overtime hours			
Proportion giving helpful solutions	56%	76%	
Median (interquartile range) score	3.0 (0–3)	3.0 (3–4)	0.0002
Vocational direction barrier: change job/career			
Proportion giving helpful solutions	35%	82%	
Median (interquartile range) score	2.0 (1–3)	4.0 (3–4)	<.0001

*CTRL = control group; EXPM = experimental group
†From 0–4 rating of quality (helpfulness) of proposed solutions; 0 = unlikely to be helpful, 4 = very likely to be helpful
‡Subjects giving responses rated as probably (3) or very likely (4) to be helpful
§Wilcoxon rank statistical analyses

Conclusions: OTs/PTs not receiving supplemental information about potential solutions had only a modest ability to form helpful solutions for work barriers not related to physical job activities. However, providing information on ideas for solutions greatly enhanced the quality of solutions for other types of work barriers.

ACR Concurrent Abstract Sessions
Genetics, Genomics and Proteomics: SLE
Wednesday, November 10, 2010, 4:30 PM–6:00 PM

2144

Exome Resequencing in a Densely Affected Multigenerational SLE Pedigree. Graham Wiley[2], Chee Paul Lin[2], Indra Adrianto[3], Jennifer A. Kelly[3], Kathy L. Moser[2], Kenneth M. Kaufman[3], John B. Harley[4], Courtney Gray-McGuire[2] and Patrick M. Gaffney[1]. [1]Oklahoma Med Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Oklahoma Medical Research Foundation, [4]Univ of OK Hlth Sci Ctr, Oklahoma City, OK

Background: Systemic lupus erythematosus (SLE) is a complex autoimmune disease that has heretofore been the subject of intense genetic scrutiny. While genome-wide association studies in SLE have successfully identified approximately 30 new risk loci the low odds ratios of associated loci leave a substantial portion of the estimated heritability of SLE unexplained. By comparison, the high odds ratios of highly penetrant rare polymorphisms (e.g. *TREX1*, OR=25) suggest the possibility that some of the missing heritability of SLE may exist in the form of rare variants.

Methods: To begin to explore the role of rare variants in SLE susceptibility we resequenced the exome in a unique, densely affected multigenerational SLE pedigree with 7 affected individuals. A densely affected pedigree was specifically chosen with the assumption that rare variations conferring higher SLE risk are more likely to be represented within such a family as opposed to the general population. The entire exonic region for the individuals within this family were captured through the use of the Agilent SureSelect sequence capture system and sequenced to 15x coverage using an Illumina GAIIx second-generation sequencer. Assembly of sequence to reference, variant calling, and other analysis were carried out using the CLC Genomics Workbench bioinformatics suite. Variants were verified with Illumina Omni1 Quad genotyping assays. Identified variants were screened using effect on protein function as determined by the SIFT algorithm.

Summary: Over 1700 coding variations were identified as shared between all case subjects within the family with approximately 40% encoding a nonsynonymous amino acid change. Of these amino acid changes approximately 7% are predicted to be damaging to the encoded protein. We have identified several nonsynonymous changes in proteins previously associated with SLE (*TNIP1*) as well as in loci not previously implicated in SLE including *NFKBIL1* and *NOTCH1*.

Conclusions: We have identified a number of potentially rare variants that appear to preferentially segregate with case samples within a densely affected SLE pedigree. These variants, in some cases, are predicted to cause a nonsynonymous amino acid change which will damage the affected protein. Several of these damaging variants are within genes which have been previously associated with SLE while others are within associated pathways. We believe the identification of these variants may assist in the identification of causal variants as well as shed some light on missing heritability within recent GWAS studies.

Large-Scale Mapping of Systemic Lupus Erythematosus (SLE) Variants across Different Ethnicities Reveals That the IRF5-TNPO3 Region Is the Strongest Common Risk Factor. Timothy J. Vyse[8], Paula S. Ramos[3], Kenneth M. Kaufman[2], Jennifer A. Kelly[2], Caroline Gallant[7], Angelica Delgado[6], Sharon A. Chung[10], Lindsey A. Criswell[12], Robert P. Kimberly[4], Mary E. Comeau[3], Adrienne H. Williams[3], Laurie P. Russell[3], Chaim O. Jacob[9], Betty P. Tsao[11], Marta E. Alarcon-Riquelme[5], Kathy L. Moser[1], Patrick M. Gaffney[1], John B. Harley[13], Carl D. Langefeld[3] and SLEGEN Consortium. Genome-wide association studies (GWAS) have been extremely successful at identifying important SLE risk factors. Nevertheless, in spite of being more prevalent in African Americans, Hispanics and Asians, the majority of GWAS have been performed in Caucasians. Recent GWAS in Asians have been reported, but there is still a paucity of large-scale data on the genetics of SLE in non-European populations. As such, the specific genetic variants predisposing to SLE and their overlap with European ancestry risk factors are largely unknown. This study is aimed at elucidating the patterns of disease association across different ethnicities. We conducted a trans-ethnic study called Lupus Large Association Study 2 (LLAS2) consisting of 8436 SLE cases and 7554 controls of European (3977 cases and 3538 controls), African American (1679 cases and 1934 controls), Asian (1272 cases and 1270 controls) and Hispanic and Native American ancestries (1508 cases 812 controls). We selected 7069 candidate SNPs from the SLEGEN European

ancestry genome-wide association study (GWAS)(Harley et al, 2008) and genotyped them on an Illumina custom array; approximately 400 ancestry informative markers were included and principal components analysis and admixture estimates were computed. We computed ethnic-specific case-control association analyses adjusting for admixture and trans-ethnic meta-analysis using the weighted inverse normal approach. Analyses were repeated adjusting for ethnic-specific tags for HLA-DR2 and –DR3, and the results were comparable in non-HLA regions. Strongest associated SNP in the region is reported. The most significant trans-ethnic variation is located in the IRF5-TNPO3 region (rs4728142, P=4.77×10–60), followed by STAT4 (rs11889341, P=4.66×10–53), HLA (rs3131379 in MSH5, P=1.17×10–52), ITGAM (rs9888739, P=5.38×10–31), BLK (rs13277113, P=4.79×10–29), PTTG1 (rs2431697, P=6.55×10–24), TNIP1 (rs960709, P=7.22×10–21), UBE2L3 (rs2298429, P=1.98×10–15), NMNAT2 (rs12146097, P=9.64×10–14), and TNFSF4 (rs10798269, P=5.69×10–12). Some regions are dominated by the European association (HLA, ITGAM, PTTG1 and NMNAT2), others by two or more ethnicities (IRF5-TNOP3, STAT4, BLK, TNIP1, UBE2L3, TNFSF4). Some regions share a similar pattern of association between two (IRF5-TNOP3, ITGAM) or more (STAT4, BLK, PTTG1, TNIP1, UBE2L3, NMNAT2) ethnic groups, while in others it is apparently discordant (HLA, TNFSF4). This is the first report of large-scale trans-ethnic mapping in SLE. This study shows that the IRF5-TNPO3 region is the strongest SLE trans-ethnic risk factor, and helps elucidate common versus ethnic-specific risk factors for SLE.

Targeted Resequencing in Systemic Lupus Erythematosus Genetic Risk Loci: Initial Results from the REVEAL (Resequencing Variants Enhancing Autoimmunity and Lupus) Resource. Patrick M. Gaffney[1], Graham Wiley[2], Jennifer A. Kelly[2], Kenneth M. Kaufman[2], John B. Harley[3], Ekta Rai[4] and Edward K. Wakeland[4]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Univ of OK Hlth Sci Ctr, Oklahoma City, OK, [4]University of Texas Southwestern Medical Center, Dallas, TX

Background: Genetic predisposition is a potent element in susceptibility to SLE. Previous studies by the International Consortium for Systemic Lupus Erythematosus (SLEGEN) and others have associated more than 20 genomic segments with SLE susceptibility. These studies have localized causative genes into small genomic segments, but have not identified the precise genetic variations responsible for the functional changes that cause SLE. To elucidate the genetic lesions that are causative for SLE susceptibility, we have initiated deep sequencing studies of all of the genomic segments exhibiting suggestive or significant association with susceptibility to SLE.

Methods: DNA samples for sequencing were obtained from the Lupus Family Registry and Repository (LFRR) at the Oklahoma Medical Research Foundation. Samples were ranked based on their content of SLE associated SNP haplotypes at defined susceptibility alleles and samples with the highest content of SLE-associated SNP haplotypes were prioritized for sequencing. Isolation of 86 SLE associated genomic segments was performed using either solid-phase microarray capture (Nimblegen) or solution-based capture (Agilent SureSelect) followed by sequencing on the Illumina GAIIx platform. Custom software scripts were used to de-convolute multiplexed samples, eliminate redundant reads and assess for overall sequence coverage. Polished reads were aligned to the human genome reference (hg18) and variants (SNPs and deletion/insertion polymorphisms (DIPs)) were called using CLC Genomics Workbench Software (v4.0).

Results: We have completed sequencing of more than 100 SLE cases. Of the over 40 gigabases of total sequence reads aligning to the human genome in this study, 60–80% mapped to the targeted regions, yielding 35–45-fold average coverage. A comparison of 50 SNP genotypes previously determined in 5 samples with these sequences revealed concordance > 0.95. Further analysis of data from the first 32 European-American samples has revealed more than 2000 novel SNPs or DIPs in 2.9 megabases derived from 25 genomic segments showing significant associations with SLE. Our ongoing analysis of the organization of these polymorphisms, utilizing phylogenetic algorithms to network the SNP haplotypes formed in strong linkage disequilibrium with SNPs associated with SLE, has delineated multiple allele lineages with novel variants in haplotypes that are associated with susceptibility to SLE. These preliminary results suggest that identification of novel, potentially functional variants, in SLE-associated risk haplotypes will significantly improve our understanding of the functional changes that mediate disease susceptibility and ultimately lead to identification the precise causal variants.

Conclusion: We have initiated a large-scale, targeted resequencing resource (REVEAL) to identify and disseminate novel functional variants in 86 regions of SLE susceptibility. Production sequencing is currently underway with a goal of completing 600 subjects (1200 chromosomes) by the end of 2011. Public access to the REVEAL data will parallel policies similar to the ENCODE project.

Background: SLE is a chronic, heterogeneous autoimmune disorder characterized by inflammation, loss of tolerance to self-antigens and dysregulated interferon responses. In this study, we sought to replicate a putative association at 11p13 from a genome-wide association (GWA) study not yet exceeding the stringent threshold for genome-wide significance (typically P<5×10−8).

Methods: Genotyping was performed using Illumina iSelect technology. Stringent quality control measures were applied for Hardy-Weinberg proportions, proportion of missing genotypes and missingness between cases and controls. After quality control filtering, 3562 SLE cases and 3491 controls of European ancestry, 1527 cases and 1811 controls of African-American (AA) descent and 1265 cases and 1260 controls of Asian origin were included in the replication analysis. Logistic regression was implemented using PLINK under dominant, recessive and additive genetic models. Covariates for gender and population admixture were included. Stouffer's weighted Ztrend scores were calculated for a meta-analysis between the GWA and replication results.

Results: Our GWA scan identified two SNPs in strong linkage disequilibrium (LD, r2=0.94) located ~74kb telomeric to CD44 showing suggestive evidence of association with SLE in cases of European descent (rs2732552, P=0.004, OR=0.78, 95%CI=0.690–0.9334; rs387619, P=0.003, OR=0.78, 95%CI=0.675–0.9141). We observed independent replication at both rs2732552 (P=9.03×10−8, OR=0.83, 95%CI =0.77–0.88) and rs387619 (P=7.7×10−7, OR=0.83, 95%CI=0.77–0.90) in the European samples with a Pmeta=1.82×10−9 for rs2732552. The AA and Asian SLE cases also

demonstrated association at rs2732552 (P=5×10−3, OR=0.81, 95%CI=0.70–0.94 and P=4.3×10−4, OR=0.80, 95%CI=0.70–0.91, respectively). The Asian SLE cases were associated with rs387619 (P=0.001, OR=0.8 95%CI=0.70–0.91), but not the AA SLE cases, consistent with differences in the haplotype patterns between racial groups. The meta-analysis at rs2732552 for all 4 ethnic groups produced Pmeta=3.00×10–13.

Conclusion: We have established genetic association with SLE to a haplotype near CD44. Imputation and trans-ethnic mapping focus the effect on a ~14kb haplotype in a region of strong regulatory potential that may influence expression of the centromeric gene CD44. This locus contains multiple regulatory sites that could potentially affect expression and functions of CD44, a cell-surface glycoprotein influencing immunologic, inflammatory and oncologic phenotypes. Further functional studies of this complex locus will be required to determine the precise variant(s) influencing SLE risk and to characterize the contribution to disease.

Background: Genome-wide association studies (GWAS) have proven highly effective for identifying hundreds of associations across numerous complex diseases. Four GWAS for systemic lupus erythematosus (SLE) in European populations and two in Asian populations have identified more than 20 robustly associated susceptibility genes. Differences in the prevalence and severity of SLE between various ethnicities are well documented, showing the need for further genetics studies in non-European populations.

Objective: The aim of this study was to evaluate and replicate all genes previously associated with SLE with p values <0.05 in the SLEGEN1 study through fine mapping in Hispanic SLE cases and controls.

Material and Methods: Here we evaluated 7069 single nucleotide polymorphisms (SNPs) in a set of 1510 Hispanic SLE patients and 825 Hispanic healthy controls. Tests of association were under a logistic regression model (SNPGWA), adjusting for ancestry proportions (ADMIXMAP) as covariates.

Results: We confirmed 17 previously reported loci in European and Asian populations (BLK, IRF5, TNPO3, STAT4, ITGAM, ITGAX, 1q25, TNIP1, MSH5, HLA-DRA, XKR6, CFB, C2, MICB, PRDM1, ATG5 and LYN). In addition, we identified six new susceptibility loci in Hispanic SLE with a P< 0.0001 (C6orf10, MSRA, SLC44A4, ZBTB12, EHMT2 and CLIC1).

Conclusion: While we replicated the majority of the previous GWAS genes, new candidate genes have been discovered. These findings support the need to perform GWAS and additional fine mapping in Hispanics to locate additional susceptibility loci.

Peripheral Blood Expression Signatures Reflect Current Lupus Activity and Likelihood of Future Flare. Carolyn Meyer[4], Jason W. Bauer[4], Thearith Koeuth[4], Joseph Wilson[4], Michelle A. Petri[1], Peter K. Gregersen[3], Timothy W. Behrens[2] and Emily C. Baechler[4]. [1]Timonium, MD, [2]Genentech Inc, South San Francisco, CA, [3]The Feinstein Institute for Medical Research, Manhasset, Manhasset, NY, [4]University of Minnesota Department of Medicine, Minneapolis, MN

Background: Clinical management of patients with systemic lupus erythematosus (SLE) is complicated by the lack of biomarkers for evaluation of current disease activity and prediction of future flares. Type I interferon (IFN)-regulated genes and proteins are promising biomarkers for disease activity in lupus. However, many other pathways are likely to influence clinical activity. Here we used comprehensive gene expression profiling in blood cells to identify molecular signatures associated with current lupus activity and risk for future flare.

Methods: Illumina WG-6 BeadChips were used to compare expression profiles in blood cells of active SLE (SLEDAI ≥6, n=36) vs. inactive SLE (SLEDAI≤2 and physician's global assessment=0, n=96). Genes with t-test p<0.01 and average difference ≥25 were identified as differentially expressed. Hierarchical clustering was used to identify 10 molecular signatures of activity. Three genes from each signature, plus 16 other genes of interest, were then measured by TaqMan low density arrays (LDA) in longitudinally collected blood samples from additional SLE patients (Phase I, 443 visits from 100 patients). A subset of 23 genes selected from the Phase I study were then measured in 2 additional groups (Phase II, 816 visits from 194 patients; Phase III, single visits from 379 patients). GAPDH was used as a housekeeping control in relative quantification. Wilcoxon's rank sum test identified transcripts that changed in paired visits before and during flare (increase in SLEDAI of ≥3 points; n=62 patients), or before and during attenuation of activity (decrease in SLEDAI of ≥3 points; n=73 patients). Logistic regression analysis identified transcripts associated with future flare (≤1 year).

Results: Among the activity signatures were clusters of translation-related genes, genes encoding MHC proteins, erythrocyte-related genes, granulocyte-related genes, and interferon (IFN)-regulated genes. Of the 23 genes selected for further study, 13 transcripts were differentially expressed between active and inactive SLE in both Caucasians (56% of subjects) and non-Caucasians (44%). However, 7 transcripts were markers for activity only in Caucasians, and 3 transcripts were significant only in non-Caucasians. In longitudinal analyses, 3 genes showed significant changes in expression from pre-flare to flare (CD93, ICAM3, and CXCR3), while HINT1 changed significantly with attenuation of activity. In Phase II, multivariate regression analysis of baseline transcript levels in 139 patients with a year of clinical follow-up (41 patients with flare, 98 with no flare), 3 transcripts showed significant ability to predict future flare: PECAM1 (p=0.0008), MX1 (p=0.01), and GPR183 (0.03) (model p<0.0001). We then tested the same genes in the Phase III validation samples. While GPR183 was not a significant predictor of flare in the Phase III data, both MX1 (p=0.001) and PECAM1 (p=0.07) were significant (model p=0.0008).

Conclusions: These results suggest that gene expression profiles in peripheral blood reflect changes in lupus disease activity and may have utility in predicting future lupus flares.

The NALP3 Inflammasome Is Activated by Sodium Overload and Water Influx in Gouty Arthritis. Christine Schorn[1], Benjamin Frey[2], Christina Janko[1], Georg Schett[3] and Martin Herrmann[1]. [1]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Department of Radiation Oncology, Friedrich-Alexander University of Erlangen-Nuremberg, Erlangen, Germany, [3]Friedrich Alexander Univ, Erlangen, Germany

Background: One of the endogenous danger molecules of dying cells generated during apoptosis is monosodium urate (MSU). Precipitated MSU crystals in tissues and joints induce an inflammatory process with IL-1β induction after NALP3 inflammasome activation resulting in gouty arthritis. However, the exact mechanism of NALP3 activation is still elusive.

Purpose: Identification of the mechanism of NALP3 inflammasome dependent IL-1β production induced by MSU crystals.

Methods: The uptake of MSU was analysed by time lapse microscopy and cytofluorometry. The plasma membrane integrity after ingestion of MSU was investigated by propidium iodide staining. Via REM-EDX the morphological and chemical structure of urate crystals was identified. The relative intracellular sodium concentration was analysed by Sodium Green fluorescence. The human IL-1β induction in presence of inhibitors of lysosomal acidification and of aquaporins in culture supernatants was quantified by simplex bead technology. Additionally, in an *in vivo* mice experiment animals were treated i.p. with chloroquine following injection of MSU in generated air pouches. The IL-1β production in the pouch fluid was quantified by ELISA.

Results: Blood borne phagocytes ingest MSU crystals and substantially increase their side scatter (SSc) reflecting increased "granularity". After the uptake of the crystals the cells swell shown by augmented forward scatter (FSc) and time lapse microscopy. Most of the phagocytes show an intact plasma membrane after ingestion of crystals. The treatment of phagocytes with MSU results in an induction of IL-1β production. Needle-shaped MSU crystals release sodium after treatment with acidic milieu and switch into barrel-shaped crystals. In swollen cells the intracellular sodium concentration of phagocytes after the uptake of MSU displays a markedly increased intracellular sodium concentration. Furthermore, the inhibition of lysosomal acidification and of aquaporins results in reduction of IL-1β production in *in vitro* and *in vivo*.

Conclusion(s): We suggest a novel model of NALP3 inflammasome activation after phagocytosis of MSU crystals: the phagocytes ingest crystals into endosomes resulting in fusion with acidic lysosomes. That induces a massive release of sodium from the MSU crystal and enhances the intracellular osmolarity. The hyperosmolarity of the cell is compensated by passive water influx through aquaporins following cell swelling. The latter reduces the intracellular potassium concentration below the threshold of NALP3 inflammasome activation. Finally, the decreased IL-1β production by treatment with inhibitors of lysosomal acidification or inhibitors of aquaporins supports our new model of inflammasome activation by MSU.

Octacalcium Phosphate (OCP) Crystals Induce Synovial Inflammation and Cartilage. Nathalie Busso[1], Véronique Chobaz[3], Nathaliane Bagnoud[3], Peter Van Lent[5], Christelle Nguyen[4], Frédéric Lioté[4], Alexander So[2] and Hang-Korng Ea[4]. [1]Department of Rheumatology, DAL CHUV, Lausanne, Switzerland, [2]Department of Rheumatology, DAL, CHUV, Lausanne, Switzerland, [3]Department of Rheumatology, DAL, CHUV, Lausanne, Switzerland, [4]INSERM U606, Hospital Lariboisière, University Paris VII, Paris, France, [5]Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands

Introduction: The presence of intra-articular basic calcium phosphate (BCP) crystals, including OCP, carbonated-apatite, hydroxyapatite and tricalcium phosphate crystals, is associated with severe osteoarthritis and destructive arthropathies such as Milwaukee shoulder. Although BCP crystals displayed, in vitro, mitogenic, anabolic and catabolic responses, their intra-articular effect was never assessed.

Objective: To determine the effects of OCP crystals in joints in vivo.

Methods: OCP crystals (200 ug in 20 μl PBS) were injected into the right knee joint (the contra-lateral knee joint injected with 20 ul of PBS serving as a control) of wild-type mice treated or not by the IL1R antagonist Anakinra or mice deficient for the inflammasome proteins ASC and NALP3. 4 days and 17 days after crystal injection, mice were sacrificed and knee joints dissected. Histological scoring for synovial inflammation and characterisation of macrophages, neutrophils and T cells were performed. Technetium (Tc) uptake was measured at 6h, 1 and 4 days after OCP injection. Cartilage degradation was evaluated by Safranin O staining and VDIPEN immunohistochemistry. Intra-articular localisation of injected OCP crystals was evidenced by Von Kossa staining.

Results: The intra-articular localisation of injected OCP crystals was evidenced by Von Kossa staining performed on non-decalcified samples embedded in methyl-metacrylate. Injection of OCP crystals into knee joints led at day 4 to an inflammatory response with intense macrophage staining and also some neutrophil recruitment in the synovial membrane. This synovitis was not accompanied by increased Tc uptake into the knee joint, Tc uptake being similar in OCP crystal injected knee or control knee at all time points investigated (6h, 1 day, 4 days). The histological modifications persisted over 17 days, with an additional fibrosis evidenced at this later time-point. The OCP crystal-induced synovitis was totally IL-1α and IL-1 independent as shown by the absence of inhibitory effects of anakinra injected into wild-type mice. Accordingly, OCP crystal-induced synovitis was similar in ASC$-/-$ and NALP3$-/-$ mice as no alterations of inflammation were demonstrated between these mice groups. Concerning cartilage matrix degradation, OCP crystals induced a strong breakdown of proteoglycans 4 and 17 days after injection, as measured by loss of red staining from Safranin O-stained sections of cartilage surfaces. In addition, we also measured advanced cartilage matrix destruction mediated by MMPs, as evidenced by VDIPEN staining of cartilage. OCP-mediated cartilage degradation was similar in all experimental conditions tested (WT+Anakinra, or ASC or NALP3 deficient mice).

Conclusion: These data indicate in vivo that the intra-articular presence of OCP crystals is associated with cartilage destruction along with synovial inflammation. This is an interesting and new model of destructive arthropathy related to BCP crystals which will allow to assess new therapies in this disease.

Quantitative Documentation of Tophus Volume Change Using Dual Energy Computed Tomography Scans. Mohammed Abufayyah[3], Savvas Nicolaou[3], Arash Eftekhari[3], Graham Reid[3], Kamran Shojania[2], Steven Co[3] and Hyon K. Choi[1]. [1]Boston University School of Medicine, Vancouver, BC, Canada, [2]Univ of British Columbia, Vancouver, BC, Canada, [3]University of British Columbia, Vancouver, BC, Canada

Objectives: Dual Energy Computed Tomography (DECT) scans produce obvious color displays for urate deposits and allow quantitative volumetric measurement of urate deposits in the articular and extra-articular structures. This report describes our recent experience on the potential utility of DECT scans to document changes in tophus volume in patients with tophaceous gout receiving urate lowering therapy.

Methods: This study included 12 consecutive patients with tophaceous gout who received urate-lowering therapy agents at our rheumatology clinic and underwent initial and follow-up DECT scans on at least one of the following four peripheral articular regions - elbows, wrists/hands, knees, and ankles/feet. The average interval between the two scans was 19 months (range, 11 – 29 months). Using a computer automated procedure to measure the apparent color-coded information of the urate deposits on DECT scans, we measured volumes of uric acid deposition in cm^3 in initial and follow-up scans. The Wilcoxon rank-sum test was used to compare changes in tophus volume.

Results: All 12 patients (mean age, 67 yrs) with tophaceous gout showed color-coded urate deposits. Ten patients showed clinical improvement due to urate lowering therapy, with lowering serum urate levels (mean follow-up level, 5.9mg/dl) and lower frequency of gout attacks (mean, 1.4/yr), whereas two patients showed clinical deterioration during the follow-up (mean serum uric acid levels=9.1 mg/dl and mean gout attacks 7.5/year). All ten responders showed reduction in tophus volume with a median reduction of 64% (p =

0.002) (See Table and Figure below). Total volumes from 10 patients reduced from 322.1 cm^3 to 107.35 cm^3 (67% reduction). Improvement of individual articular regions in these 10 patients ranged from 41% to 83% (all p-values <0.05). In contrast, the two non-responders showed 36% increase in total tophus volume (total volumes from 157.74 cm^3 to 246.19 cm^3) with similarly increasing volumes in individual articular regions (range, 31% to 38% increase).

Table. Changes in DECT Urate Volume after Urate-Lowering Therapies among Ten Responders*

		Regions of Urate Deposition				
No	Age/Sex	Hands & Wrists	Elbows	Knees	Feet & Ankies	Total Volume (Reduction %)
		Initial Scan → Follow-Up Scan (Volume by DECT, cm^3)

Total		48.04→8.09	20.57→12	130.46→58.73	124.54→28.75	322.10→107.35 (67%)
P-values		0.008	0.03	0.008	0.03	0.002

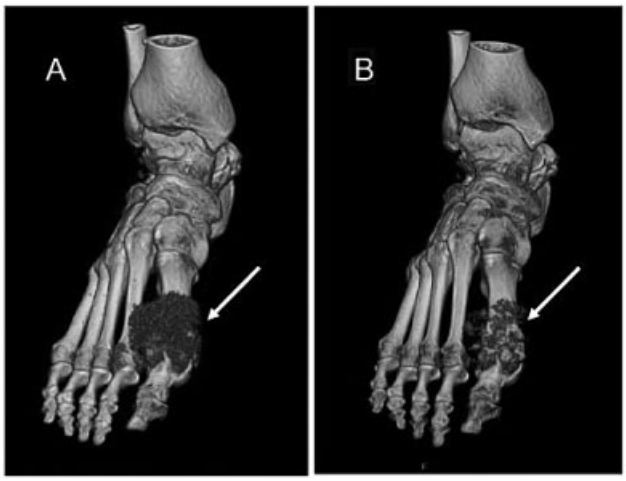

Figure. A. The initial 30-DECT scan image of patient #4 (see Table) showing extensive urate deposits at the first metacarpophalangeal joint. **B.** The follow-up scan showing reduced MSU deposits on after urate-lowering therapy (Arrows denote tophi that appear in red in color display and appear in gray in black/white display).

Conclusion: This study provides a proof of concept for the ability of DECT scan as a potentially sensitive, quantitative imaging tool in assessing urate volume changes in patients with tophaceous gout. These data provide support for further prospective studies to examine the utility of DECT as a reliable imaging tool in following the response to urate-lowering therapy, through measurement of individual tophus volumes and total tophus burden in clinical care and trials.

Lead and Gout—Going, Going . . . Not Gone! Eswar Krishnan[2], Bharathi Lingala[3], James F. Fries[1] and Vivek Bhalla[3]. [1]Stanford Univ Medical Ctr, Palo Alto, CA, [2]Stanford University, Palo Alto, CA, [3]Stanford University

Background: Saturnine gout, which characteristically follows the onset of chronic kidney disease and hyperuricemia is associated with whole blood lead levels>80microgram (mcg)/dL, and has become rare over time. A whole blood lead level (BLL) ≤25 mcg/dL in adults or ≤10 mcg/dl for children has been considered "not elevated" by several authorities including the Centers for Disease Control. However, it is not known whether such "non-elevated" BLL can still cause hyperuricemia and gout.

Methods: We analyzed data BLL from the NHANES 2005–2007, a series of nationally representative surveys of the US population. We correlated BLL with serum uric acid (SUA) concentration and gout using appropriate sampling weights (SURVEYREG; SAS®). Participants with renal dysfunction were excluded. Geometric means were used to assess BLL due to skewed distribution. Gout was defined as self-reported physician diagnosis and/or use of gout medications (allopurinol and colchicine). Hyperuricemia was defined as SUA≥7.0 mg/dl for men and ≥6.0 mg/dl for women.

Results: Prevalence of gout was 8-fold higher in the highest quartile of blood lead level compared to the lowest.The mean concentration of SUA was 5-fold higher with the highest quartile of lead (3.06 vs 0.57 mcg/dL $p<0.001$). After adjusting for the effects of age, gender, BMI, and ethnicity (variables that emerged statistically significant in bivariate regressions), the highest quartile of lead was associated with a ~2 fold increase in risk for hyperuricemia and gout.

Conclusions: In the era of decreased overt lead intoxication, "non-elevated" BLL remains a significant risk factor for hyperuricemia and gout. Further studies are needed to determine the utility of BLL for evaluating gout in clinical settings.

Table 1.

		Quartile 1	Quartile 2	Quartile 3	Quartile 4

Increasing Gout Prevalence in the US over the Last Two Decades: The National Health and Nutrition Examination Survey (NHANES). Yanyan Zhu[1], Bhavik Pandya[2] and Hyon Choi[1]. [1]Boston University of School of Medicine, Boston, MA, [2]Takeda Pharmaceuticals International, Inc, Deerfield, IL

Objective: The prevalence of gout in the US more than doubled between the 1960s and 1990s, but it is unknown whether the increasing trend continued over the past 2 decades. To address this issue, we compared the prevalence of gout between National Health and Nutrition Examination Survey (NHANES) III (1988–1994) and NHANES 2007–2008. We also compared the prevalence of hyperuricemia and mean serum urate (sUA) levels between the same time periods.

Methods: Using data from 5,707 participants (2,797 men and 2,910 women) aged 20 years and older in NHANES 2007–2008, we estimated overall, gender-specific, and age-specific prevalence of gout and compared it with data from 18,825 participants (8,816 men and 10,009 women) aged 20 years and older in NHANES III (1988–1994). Using the same data, we compared sUA levels between NHANES III and NHANES 2007–2008. The NHANES definition of hyperuricemia was sUA level >7.0 mg/dL in men and >5.7 mg/dL in women. During the NHANES survey, all participants were asked about a history of health-professional–diagnosed gout.

Results: The overall prevalence of gout among US adults was 3.9% (8.3 million adults) in 2007–2008 (Table). This gout prevalence was significantly higher than that in NHANES III (2.7%), with a difference of 1.2% (95% confidence interval [CI], 0.6 to 1.9). The difference was primarily due to increased prevalence among men and the elderly. Correspondingly, the

prevalence of hyperuricemia in 2007–2008 (21.4%) was significantly higher than that in NHANES III (18.2%), with a difference of 3.2% (95% CI, 1.2% to 5.2%). The mean sUA level significantly increased over the same time period (difference 0.15 mg/dL; 95% CI, 0.07 to 0.24 mg/dL).

Table. Overall, Gender-Specific, and Age-Specific Prevalence of Gout, NHANES III and 2007–2008

	NHANES 2007–2008	NHANES III (1988–1994)	Difference (95% CI)
Overall*	3.9 (3.3 to 4.4)	2.7 (2.3 to 3.0)	**1.2 (0.6 to 1.9)****
Gender			
Male	5.9 (4.7 to 7.1)	3.8 (3.2 to 4.4)	**2.1 (0.8 to 3.4)****
Female	2.0 (1.5 to 2.5)	1.6 (1.3 to 2.0)	0.4 (−0.2 to 0.9)
Age Category (Yrs)			
20–39	0.8 (0.4 to 1.3)	0.7 (0.3 to 1.2)	0.1 (−0.5 to 0.7)
40–59	3.5 (2.5 to 4.5)	2.6 (1.9 to 3.2)	0.9 (−0.2 to 2.1)
60–79	8.5 (6.4 to 10.6)	6.8 (5.8 to 7.9)	1.7 (−0.7 to 4.0)
80+	12.6 (10.1 to 15.1)	5.9 (4.7 to 7.2)	**6.7 (3.9 to 9.4)****

*Adults aged 20 years and above. **$p < 0.05$; bold face type indicates significance.

Conclusions: These findings from 2 separate nationally representative samples of US adults suggest that the prevalence of gout remains substantial and may have increased over the last 2 decades, particularly among men and the elderly. Correspondingly, the prevalence of hyperuricemia increased during the same period.

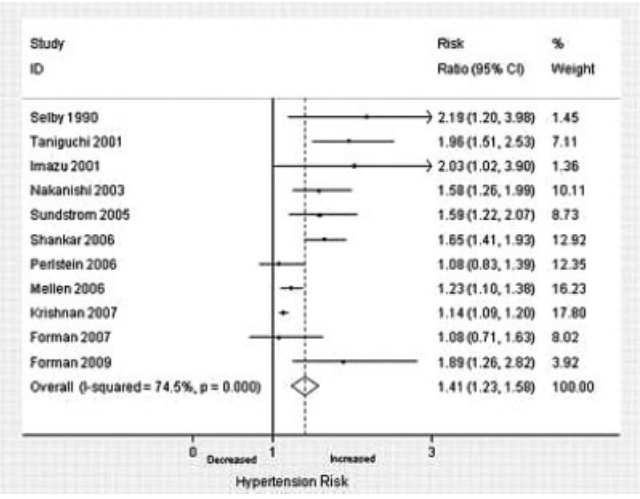
Independent Impact of Hyperuricemia on the Future Risk of Hypertension: A Systematic Review and Meta-Analysis. Peter C. Grayson[1], Seo Young Kim[3], Michael P. LaValley[2] and Hyon K. Choi[4]. [1]Boston University School of Medicine, [2]Boston University School of Public Health, Boston, MA, [3]Brigham & Women's Hospital, Boston, MA, [4]Univ of British Columbia, Vancouver, BC, Canada

Purpose: A novel rodent model and a recent randomized trial of hyperuricemic adolescents with hypertension suggest a pathogenetic role of uric acid in hypertension, but it remains unknown whether these findings apply to adult populations where the larger disease burden exists. We conducted a systematic review and meta-analysis to determine if hyperuricemia was associated with incident hypertension, particularly in demographic subgroups.

Methods: We searched major electronic databases using Medical Subject Headings and keywords without language restrictions (through April 2010). Studies with data on incident hypertension related to serum uric acid levels were eligible for inclusion. We only included (1) prospective cohort studies without age restrictions; (2) at least 1 year of follow-up; (3) sample sizes of at least 100 subjects; and (4) inception cohorts free of hypertension. Hyperuricemia was analyzed both as a categorical and continuous variable, and pooled estimates of both unadjusted and adjusted risk ratios (RRs) for incident hypertension were calculated using a random-effects model. The I^2 - value was calculated to evaluate between-study heterogeneity. We analyzed age, gender, and race subgroups and performed meta-regression to explore any detected heterogeneity.



Results: A total of 18 prospective cohort studies representing data from 55,607 participants and 13,025 incident hypertension cases were included. Hyperuricemia was associated with an increased risk of incident hypertension (unadjusted risk ratio (RR) 1.81, 95% confidence interval (CI): 1.55–2.07). When using adjusted values, the pooled RR was 1.41 (95% CI: 1.23–1.58) and there was high heterogeneity among included studies ($I^2 = 0.75$, $p<0.01$).

For a 1 mg/dl increase in uric acid level, the pooled adjusted RR for incident hypertension was 1.13 (95% CI, 1.06–1.20). These RRs were significantly larger in younger study populations ($p=0.02$) and tended to be larger in women ($p=0.06$). Two studies suggested that the RR may also be larger among black individuals. Furthermore, later publication year and US-based studies were significantly associated with lower RR estimates (p-values <0.02).

Conclusion: Hyperuricemia is associated with an increased risk for incident hypertension, independent of traditional hypertension risk factors. Risk for future hypertension appears more pronounced in hyperuricemic younger individuals and women and appears diminished in US-based studies and studies conducted more recently.

Effectiveness of Zoledronic Acid in the Prevention and Treatment of Glucocorticoid-Induced Osteoporosis in Men and Premenopausal Women. K. Saag[5], C. Roux[2], J.-P. Devogelaer[3], C.-S. Lau[6], J.-Y. Reginster[7], C. Bucci-Rechtweg[1], G. Su[1], P. N. Sambrook[8] and D. M. Reid[4]. [1]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [2]Paris-Descartes University, Paris, France, [3]Universite Catholique de Louvain, Brussels, Belgium, [4]University of Aberdeen, Aberdeen, UK, [5]University of Alabama at Birmingham, Birmingham, AL, [6]University of Dundee, Dundee, UK, [7]University of Liege, Liege, Belgium, [8]University of Sydney, Sydney, NSW, Australia

Background: Bisphosphonates are effective in increasing bone mineral density (BMD) and reducing vertebral fracture risk in patients beginning or continuing glucocorticoid (GC) treatment. However, there are limited data available on the effect of bisphosphonates in men and premenopausal women receiving GC therapy. We studied 265 men, (mean age 56.4 years, mean femoral neck BMD T-score −0.8) and 195 premenopausal women (mean age 38.1 years, mean femoral neck BMD T-score −0.7) among patients enrolled in two arms of a double-blind, double dummy, 1-year study comparing the effects of zoledronic acid (ZOL) *vs.* risedronate (RIS) in patients either commencing GC treatment at a dose of at least 7.5 mg/day of prednisone or equivalent (prevention arm) or continuing long-term treatment of GC at that dose (treatment arm).

Methods: Patients received either ZOL 5 mg infusion at study entry or RIS 5 mg daily, along with calcium and vitamin D supplementation (1000 mg and 400–1200 IU, respectively). The primary endpoint was difference in BMD at the lumbar spine at 12 months. Secondary endpoints included changes in BMD at other sites (total hip and femoral neck), changes in bone turnover markers (BTM) (β-C-terminal telopeptides of type 1 collagen [β-CTx] and procollagen type 1 aminoterminal propeptide [PINP]), and overall safety.

Results: The percentage change in BMD is listed in Table.

Table. Between-treatment comparison of percentage change from baseline in bone mineral density (BMD) for men and premenopausal women at 12 months (modified ITT population)

Men

	Prevention arm				Treatment arm			
Variable	Zoledronic LS Mean (SE)	Risedronate LS Mean (SE)	Treatment difference (CI)	*p*-value	Zoledronic LS Mean (SE)	Risedronate LS Mean (SE)	Treatment difference [CI]	*p*-value
Lumbar spine BMD	2.46 (0.64) n = 38	−0.24 (0.90) n = 40	2.70 (0.99, 4.42)	0.0024	4.69 (0.52) n = 75	3.27 (0.52) n = 77	1.42 (0.20, 2.64)	0.0232
Total Hip BMD	1.10 (0.64) n = 35	−0.39 (0.66) n = 40	1.49 (0.21, 2.77)	0.0230	1.82 (0.39) n = 74	0.18 (0.38) n = 75	1.60 (0.75, 2.54)	0.0004

Premenopausal women

	Prevention arm				Treatment arm			
Variable	Zoledronic LS Mean (SE)	Risedronate LS Mean (SE)	Treatment difference (CI)	*p*-value	Zoledronic LS Mean (SE)	Risedronate LS Mean (SE)	Treatment difference (CI)	*p*-value
Lumbar spine BMD	1.76 (0.75) n = 28	0.72 (0.72) n = 29	1.04 (−0.85, 2.92)	0.2746	3.12 (0.56) n = 63	1.74 (0.54) n = 60	1.38 (−0.08, 2.85)	0.0636
Total Hip BMD	0.93 (0.57) n = 28	−0.52 (0.55) n = 29	1.45 (0.01, 2.88)	0.0487	1.41 (0.44) n = 62	0.07 (0.44) n = 57	1.34 (0.17, 2.51)	0.0249
Femoral neck BMD	0.86 (0.72) n = 28	−0.34 (0.70) n = 29	1.20 (−0.62, 3.02)	0.1901	0.96 (0.50) n = 62	−0.40 (0.49) n = 57	1.36 (0.06, 2.67)	0.0411

In the treatment subgroup, ZOL demonstrated a significantly greater reduction in serum β-CTx and PINP relative to RIS at all time-points for men and premenopausal women. In the prevention subgroup, ZOL demonstrated a significantly greater reduction in β-CTx at all time-points for men and premenopausal women, and in PINP at Month 3 ($p=0.0297$) for men and at Month 3 ($p=0.0207$) and Month 12 ($p=0.0160$) for premenopausal women. Both treatments were well tolerated in men and premenopausal women, albeit with a higher incidence of influenza-like illness and pyrexia events post-infusion with ZOL.

Conclusion: In men receiving GC therapy, once-yearly ZOL infusion preserves or increases lumbar spine and total hip BMD within 1 year to a greater extent than daily oral RIS and shows a similar trend for femoral neck BMD compared with RIS in both treatment and prevention arms. In premenopausal women receiving GC therapy, once yearly ZOL or daily oral RIS preserves or increases BMD within 1 year with a significant increase in total hip BMD for ZOL compared with RIS in both treatment and prevention arms.

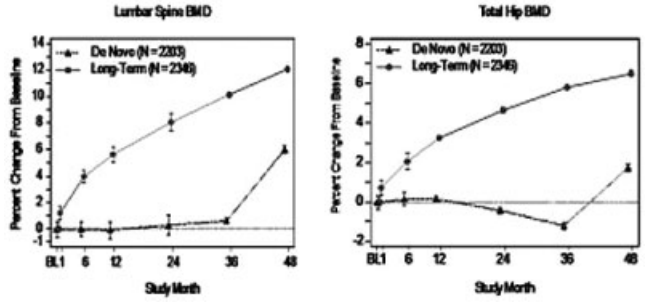
Background: FREEDOM was the pivotal 3-year Phase 3 study to establish the efficacy and safety of denosumab for the treatment of osteoporosis in postmenopausal women. The open-label extension of FREEDOM will evaluate the long-term (up to 10 years) efficacy and safety of denosumab. We report here first year results of this extension study, representing up to 48 continuous months of denosumab exposure.

Methods: Subjects enrolled in the extension study previously completed the FREEDOM trial. All subjects received subcutaneous denosumab (60 mg) injection every 6 months during the extension study and continued to take daily calcium (1 g) and vitamin D (≥400 IU) supplements. For those randomized to the denosumab arm in FREEDOM (long-term group), the data reported here reflect a total of up to 8 injections of denosumab. For those previously assigned to placebo (de novo group), the data are from exposure of up to 2 doses of denosumab for 12 months. Changes in bone mineral density (BMD) and bone turnover markers (BTM) over 12 and 48 months are reported for subjects enrolled in the extension. No formal statistical testing was planned for this interim report. *P*-values are descriptive.

Results: A total of 4550 (70.2%) subjects from FREEDOM were enrolled in the extension study: 2343 in the long-term and 2207 in the de novo group. The long-term group had a further 2.0% and 0.8% increase in lumbar spine and total hip BMD, respectively, during the 4th year of denosumab administration ($P<0.0001$ compared to baseline BMD of the extension study; see Figure). The total increase over the 48 months treatment with denosumab in lumbar spine and total hip BMD was 12.1% and a 6.5%, respectively. The de novo group had a 6.0% and 1.7% increase in lumbar spine and total hip BMD, respectively, during their 1st year of treatment with denosumab in the extension study ($P<0.0001$ compared to baseline BMD). The serum C-telopeptide (CTX) reduction profiles after denosumab initiation, and the increase in CTX levels at the end of the dosing period, were similar for the long-term and de novo groups. Adverse events (AEs) were reported by 70.4% and 67.9% of subjects in the long-term and de novo groups, respectively. Serious AEs were reported by 9.8% and 11.2% of subjects in the long-term and de novo group, respectively.



Percentage Change in BMD With Denosumab Treatment for 4 Years (Long-term) or 1 Year (De Novo)

Conclusion: These results suggest that treating postmenopausal women with osteoporosis with denosumab for 48 months continues to significantly reduce bone resorption and further increase BMD. Long-term treatment decreases BTM with a similar pattern and to a similar degree as observed in the first year of treatment.

IL-3 Inhibits Osteoclast Differentiation by Inducing of ID Expression. Chang Hoon Lee[5], Myeung Su Lee[6], Yun Kyung Hong[3], Jin-Jeong Choi[2], Min-Ho Whang[4], Han-Bok Kwak[1] and Jae Min Oh[1]. [1]Anatomy, Wonkwang University, Iksan, Korea, Republic of, [2]Rheumatology, Cha University Hospital, Sungnam, [3]Rheumatology, Chonbuk University Hospital, [4]Rheumatology, Presbyterian Medical Center, Chonju, [5]Rheumatology, Wonkwang University Hospital, Iksan, Jeollabukdo, Republic of Korea, [6]Rheumatology, Wonkwang University Hospital

Purpose: Interleukin-3 (IL-3) is produced in various pathological conditions and is thought to induce diseases, but it is unclear about its function under normal and disease conditions associated with bone homeostasis. Here we examined the effect of IL-3 on osteoclast differentiation from mouse and human bone marrow macrophages (BMMs).

Methods: Human bone marrow cells were obtained from iliac crest marrow aspirates from healthy donors and multiple myeloma patients. BMMs were used as precursors for RANKL-induced osteoclast differentiation. RT-PCR and Western blotting were used to detect mRNA and protein expression.

Results: Although IL-3 can induce osteoclast differentiation from multiple myeloma bone marrow cells, IL-3 greatly inhibited osteoclast differentiation of mouse BMMs and human BMMs obtained from healthy donors. These effects of IL-3 were determined by treating at early time points (days 0 and 1). IL-3 inhibited the expression of c-Fos and NFATc1, the master transcription factor for osteoclast differentiation, as well as osteoclast-specific genes in BMMs treated with RANKL, but IL-3-mediated inhibition of osteoclast differentiation was partially reversed by ectopic expression of c-Fos and NFATc1. Importantly, IL-3 induced inhibitor of DNA binding/differentiation (Id) 1, Id2, and Id3 expression and Id2 was sustained during course of osteoclast differentiation. Ectopic expression of NFATc1 in Id2-deficient BMMs completely reversed the negative effect of IL-3 on osteoclast differentiation.

Conclusion: We provide evidence that IL-3 inhibited osteoclast differentiation of hBMMs and mBMMs partly by inhibiting c-Fos and NFATc1 expression. Also, IL-3 can induce Ids expressions, which are involved in the inhibitory effect exerted by IL-3.

Raloxifene for Prevention of Glucocorticoid-Induced Bone Loss: A 12-Month Randomized Double-Placebo-Controlled Trial. Chi Chiu Mok, Chi Hung To, Ling Yin Ho, Ka Lung Yu and Kwok Man Ma. Tuen Mun Hospital

Objectives: To study the efficacy of raloxifene in preventing bone loss in women receiving long-term glucocorticoids.

Methods: Postmenopausal women receiving glucocorticoids were randomized in a double-blind manner to receive either raloxifene (60mg/day) or placebo (one tablet/day) on top of calcium (1000mg/day) and calcitriol (0.25ug/day). Bone mineral density (BMD) and bone turnover markers (urine DPD/Cr, serum osteocalcin, P1NP and CTX) were assessed at baseline, month 6 and 12. New radiological fracture of the spine was assessed at month 12.

Results: 114 patients were recruited (age 55.3±7.7 years; 29% patients naive to calcium and 75% patients naive to calcitriol). The underlying medical diseases were: SLE(51%), rheumatoid arthritis(33%), inflammatory myopathies(4%) and systemic vasculitides(4%). The duration and dose of prednisolone received by the participants was 62.2±64 months and 6.7±5.9mg/day, respectively. The mean duration of menopause was 8.5±7.7 years and the body mass index (BMI) was 23.7±3.5kg/m^2. Pre-existing vertebral fracture was present in 6(5%) patients. Fifty-seven patients were assigned to receive raloxifene whereas the other 57 patients were assigned to receive placebo treatment. Demographic data, osteoporotic risk factors, and BMD at various sites were similar between the two groups of patients. At month 12, a significant gain in the lumbar spine (+1.3±0.4%;p=0.004) and total hip BMD (+1.0±0.4%;p=0.01) was observed in raloxifene-treated patients (N=57). Conversely, BMD of the spine (−0.9±0.4%;p=0.045) and hip (−0.8±0.3%;p=0.01) dropped significantly in the placebo group (N=57). Three new fractures developed exclusively in the placebo-treated patients. All the bone formation and resorption markers dropped significantly in the raloxifene group but did not change significantly in placebo-treated patients. Leg cramps were numerically more frequent in the raloxifene group but none of the participants developed arterial or venous thromboembolism. Other adverse events were not significantly different between the two treatment groups. Nine patients withdrew from the study because non-compliance to treatment (N=5) and adverse events (skin rash N=2, leg cramp N=1 and generalized aching N=1).

Conclusions: In postmenopausal women receiving long-term glucocorticoids, raloxifene is well tolerated and significantly increases spinal and hip BMD after 12 months' treatment.

Unsuppressed Parathyroid Hormone in Patients with Autoimmune Rheumatic Diseases: Implications for Vitamin D Supplementation. Pier Paolo Sainaghi[1], Mattia Bellan[2], Giuseppina Antonini[3], Giorgio Bellomo[3] and Mario Pirisi[1]. [1]Immuno-Rheumatology Outpatient Unit, DMCS, "A. Avogadro" University and IRCAD (Interdisciplinary Reseach Center of Autoimmune Diseases), Novara, Novara, Italy, [2]Immuno-Rheumatology Outpatient Unit, DMCS, "A. Avogadro" University, Novara, Italy, [3]Laboratory of Chemistry and Clinical Research, DSM, "A. Avogadro" University and "Maggiore della Carità" Hospital, Novara, Italy

Background: Conflicting data have been reported concerning the relationship between vitamin D deficit and autoimmune rheumatic diseases (ARD), but desirable vitamin D concentrations in ARD patients have not been defined taking into consideration calcium homeostasis. In fact, a plasma 25(OH)vitamin D (VITD) concentration should be considered optimal when able to suppress parathyroid hormone (PTH). Therefore, our aim was to verify the hypothesis that ARD patients may be more refractory to PTH suppression by VITD.

Methods: Data from 105 consecutive ARD patients (including rheumatoid arthritis, polymyalgia rheumatica, spondyloarthritis and other connective tissue diseases) attending a tertiary level immuno-rheumatology clinic, and 1542 consecutive adult patients tested at our central laboratory from 2008 to 2010 (controls) were collected. After exclusion of patients with renal failure, known primary hyperparathyroidism, and hypercalcemia (N.=522), plasma VITD, PTH, calcium and phosphorus concentrations were compared between these two groups.

Results: Plasma VITD concentrations were <25 nmol/L in 257 patients (severe deficit, 22.8%), ≥25 but <75 in 661 (mild deficit, 58.8%) and ≥75 in 207 (normal, 18.4%). Despite similar mean age, plasma VITD, calcium and phosphate values (p=n.s.), PTH was higher in ARD (74.8±25.5 pg/ml) than in controls (65.1±24.2, p<0.001). Moreover, mean PTH was always higher in ARD vs controls in all above defined VITD categories.

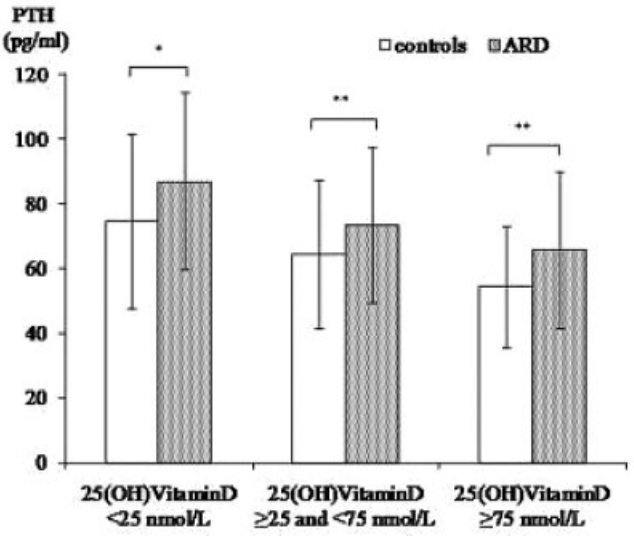

Figure 1.

As expected, the proportion of patients with increased PTH (≥73 pg/ml) was inversely related to VITD; suppressed PTH was observed in 96.9 % [95.8–98.0; 95%CI] of controls with VITD ≥75 nmol/L. However, PTH was increased more frequently in ARD vs controls.

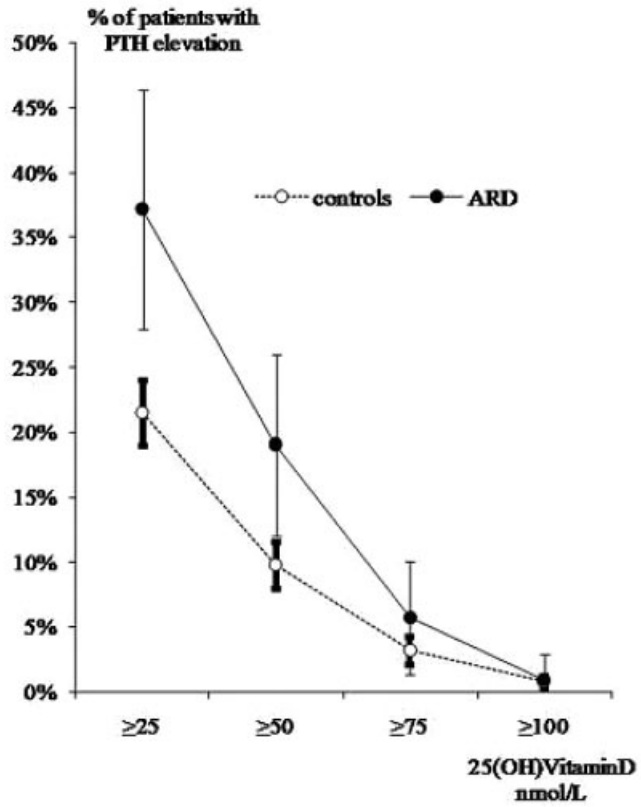

Figure 2.

At multivariate analysis, low VITD values (F: 59.3, $p<0.001$) and the presence of an ARD (14.4, $p<0.0003$) were independent predictors for an increased PTH.

Conclusions: Patients with ARD have an impaired vitamin D metabolism evidenced by an increased PTH concentration for any plasma VITD range. Therefore, vitamin D supplementation to ARD patients should be targeted to reach full PTH suppression and not simply to obtain VITD concentrations considered optimal in other categories of patients.

Bone Remodeling in Postmenopausal Women Who Discontinued Denosumab Treatment. Rachel B. Wagman[1], Jaques Brown[4], David W. Dempster[2], Beiying Ding[1], Ricardo Dent[1], Javier San Martin[1], Andreas Grauer[1] and Jose R. Zanchetta[3]. [1]Amgen Inc., Thousand Oaks, CA, [2]Helen Hayes Hospital, West Haverstraw, NY, [3]Instituto de Ivestigaciones Metabolicas, Buenos Aires, Argentina, [4]Laval University Department of Medicine, Quebec, QC, Canada

Background: Denosumab is a fully human monoclonal antibody to RANKL which increases bone mineral density (BMD), reduces bone resorption, and decreases risk for vertebral, nonvertebral, and hip fractures in postmenopausal women with osteoporosis (Cummings et al. NEJM 2009). Transiliac crest bone biopsies from subjects with osteoporosis treated with denosumab for 1 to 3 years demonstrate low bone remodeling. The effects of denosumab on biochemical bone-turnover markers (BTM) and BMD are reversible upon treatment discontinuation. However, the effects of denosumab discontinuation on bone histology and histomorphometry are not known. This study was designed to characterize the effects of denosumab therapy discontinuation on variables of bone histology and histomorphometry in postmenopausal women with low bone mass or osteoporosis. We report here interim bone remodeling results from a subset of subjects.

Methods: Subjects included in this study completed all denosumab doses in the phase 3 trial they were previously enrolled in, after which they received not more than 1 month of treatment for their osteoporosis. Transiliac crest bone biopsies were obtained for histology and histomorphometry evaluation ≥ 12 and < 36 months after subjects completed the original trial. Fasting serum samples were collected to assess BTM levels at the time of tetracycline (TC) labeling. This study is ongoing with an expected enrollment of approximately 15 subjects. Data from 5 subjects are available and are reported here.

Results: Mean (SD) age for the 5 subjects at enrollment in the biopsy study was 59.6 (4.3) years. The first set of TC labeling occurred after a mean (SD) of 23.4 (2.7) months from denosumab discontinuation. All biopsies showed normal histology without evidence of pathology. Double TC labels were present in all biopsies, suggesting active remodeling. While osteoclast numbers increased, the other bone remodeling parameters were within the reference range. Both bone resorption and formation markers were similar to the subjects' pretreatment baseline BTM levels.

Conclusions: These data demonstrate that bone remodeling returned to pre-treatment levels when postmenopausal women discontinued denosumab treatment. These results confirm that the effects of denosumab on reduction in bone turnover are reversible when therapy is discontinued.

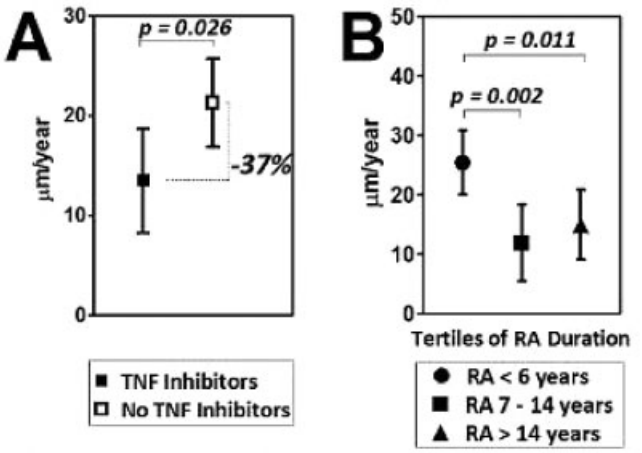
Longitudinal Predictors of Progression of Subclinical Carotid Atherosclerosis in Rheumatoid Arthritis. Jon T. Giles[3], Wendy Post[5], Roger S. Blumenthal[5], Joseph Polak[6], Michelle A. Petri[1], Allan C. Gelber[2], Moyses Szklo[5] and Joan M. Bathon[4]. [1]Timonium, MD, [2]Baltimore, MD, [3]Johns Hopkins Univ, Baltimore, MD, [4]Johns Hopkins University, Baltimore, MD, [5]Johns Hopkins University, [6]Tufts-New England Medical Center

Background: Coronary and extra-coronary atherosclerosis are increased in rheumatoid arthritis (RA) relative to controls; however, few longitudinal studies have explored predictors of change in atherosclerosis in RA patients.

Methods: Men and women with RA enrolled in ESCAPE RA, a cohort study of subclinical cardiovascular (CV) disease in RA, underwent bilateral B-mode ultrasonography of the common (CCA) and internal (ICA) carotid arteries at the first and third study visits, separated by an average of 3.2 ± 0.3 years. Multivariate linear or Poisson regression, as appropriate to the outcome, were used to explore the associations of baseline and cumulative demographic, lifestyle, and RA disease and treatment characteristics with the average yearly change in maximal intima-medial thickness (IMT) of the CCA and ICA, and incident or progressive carotid plaque (defined as newly identified plaque or progression in plaque stenosis). Baseline scans were reanalyzed concurrent with follow-up scans, to control for interpretive drift.

Results: A total of 158 RA patients [36% male; mean baseline age $= 59 \pm 8$ years; median baseline RA duration $= 8.5$ years; median baseline DAS28 $= 3.6$] underwent carotid scanning at both time points. CCA-IMT increased over time in 82% of patients (median yearly increase $= 16$ μm; $p<0.001$) and ICA-IMT increased in 70% of patients (median yearly increase $= 25$ μm; $p<0.001$). After adjusting for demographics, CV risk factors, and baseline IMT, baseline TNF inhibitor use was associated with a 37% lower rate of CCA-IMT progression vs.

non-users (14 vs. 22 μm/year; p=0.026: Figure, Panel A). The adjusted average yearly change in CCA-IMT was significantly higher for patients with earlier RA compared with those with longer duration disease (Figure, Panel B).



Adjusted for age, gender, ethnicity, hypertension, diabetes, hyperlipidemia, exercise, smoking, body surface area, baseline maximum CCA-IMT, RA duration (where appropriate), and TNF inhibitor use (where appropriate).

Figure. Adjusted yearly rate of change in CCA-IMT according to (A) baseline TNF inhibitor use and (B) RA duration.

For ICA-IMT, cumulative prednisone exposure was the only RA feature associated with progression [1.2 μm per year per gram increase in cumulative dose (95% CI 0.1, 2.4)] after adjustment. This rate was significantly lower in patients prescribed statins at baseline. Any plaque was identified in 104 patients (68%), with 13 of these (12%) demonstrating new or progressive plaque during follow-up. After demographic and CV risk factor adjustment, higher average swollen joint count (SJC) and higher average CRP were significantly and independently associated with incident or progressive plaque. Cumulative CRP and SJC were both more strongly associated with plaque progression than cross-sectional levels obtained at the time of scanning. Other RA disease and treatment characteristics were not associated with plaque progression.

Conclusions: These prospective data provide evidence for systemic inflammation and RA disease activity as a contributor to progression of atherosclerosis in RA patients. Further, they suggest that atherosclerosis progression in RA may be modified favorably by TNF inhibitors and detrimentally by glucocorticoids.

At What Age Is Carotid Ultrasound Most Effective in Predicting Cardiovascular Events and Mortality in Rheumatoid Arthritis? Inmaculada Del Rincon[3], Mrisa Sahai[4], Daniel H. O'Leary[2], Daniel F. Battafarano[1] and Agustin Escalante[3]. [1]Brooke Army Medical Ctr, San Antonio, TX, [2]Tufts School of Medicine, [3]UTHSCSA, San Antonio, TX, [4]UTHSCSA

Introduction: Established cardiovascular (CV) risk factors are limited in their ability to predict CV events and mortality in RA. Carotid ultrasound may improve upon the CV risk factors as a tool to predict CV events in RA. However, because of the strong effect of age on CV disease, the predictive ability of ultrasound may be blunted if it is applied to all age groups. We examined the ability of carotid ultrasound to predict acute coronary syndromes (ACS) and CV mortality in different age groups in an RA cohort.

Patients and Methods: We studied patients with RA who were free of CV disease. We imaged the carotid arteries for plaque and intima-media thickness (IMT) using high-resolution ultrasound and then followed patients prospectively until they either developed an acute coronary syndrome (ACS), died from CV causes, or reached a censoring date. ACS were defined as unstable angina, myocardial infarction, cardiac arrest, or death due to ischemic heart disease. CV death was defined by mention of a CV cause in the death certificate. We used logistic regression to examine the association of carotid ultrasound with ACS or CV death in tertiles of the cohort's age distribution, adjusting for gender, CV risk factors and the erythrocyte sedimentation rate (ESR).

Results: We followed 599 RA patients for 3,085 person-years for ACS, and 6,525 person-years for CV mortality. We observed 66 new ACS, for an incidence of 2.1 per 100 person-years (95% CI 1.7, 2.7) and 120 CV deaths, for a CV mortality rate of 1.8 per 100 person-years (1.5, 2.1). The strength of association between plaque and ACS or CV death varied between cohort's age strata (Table). These findings did not change appreciably with adjustment for gender, CV risk factors or the ESR. Similar results were obtained with the IMT.

		Events		Plaque odds ratio (95% CI)	
Age	Patients	ACS	CV death	For ACS	For CV Death
18 to 53	282	14	8	4.13 (1.72, 9.88)	3.87 (1.32, 11.31)
54 to 64	202	23	28	3.12 (1.02, 9.48)	2.36 (0.91, 6.07)
65 to 91	115	29	84	1.46 (0.38, 5.53)	1.41 (0.44, 4.49)

Conclusion: The ability of carotid ultrasound to predict CV events in RA varies with age. Plaque and IMT are most strongly associated with CV outcomes in younger RA patients. These findings may have implications for the early identification of patients at risk for CV events in RA.

Higher Prevalence, Extent and Severity of "Vulnerable" Coronary Plaque in Asymptomatic Patients with Rheumatoid Arthritis (RA). George A. Karpouzas[1], Naser Ahmadi[2], Tae-Young Choi[2], Fereshteh Hajsadeghi[2], Silvia Munoz[2] and Mathew Budoff[2]. [1]Harbor-UCLA, Long Beach, CA, [2]Harbor-UCLA

Background: Higher incidence of myocardial infarctions (MI), sudden cardiac death, and worse survival after MI have all been reported in patients with RA. This risk exceeds traditional risk factors (RF) and insinuates accelerated atherogenesis in RA. We prospectively evaluated the presence, extent, total burden, and differences in the quality of coronary plaque in asymptomatic pts with RA compared to matched controls.

Methods: We report on the first 74 of 150 recruited pts with RA from a single center. Demographic, serologic, metabolic, Disease Activity Score (DAS28-3v-ESR), radiographic parameters and treatments are quarterly recorded. Pts underwent 64+ slice cardiac Computed Tomography Angiography (CTA); this non-invasive modality includes an initial non-contrast phase assessing coronary calcium, followed by a contrast scan that detects plaque with equal accuracy to conventional angiography, and is superior in the assessment of non-calcified, lipid-rich, non-obstructive or "vulnerable" plaque. RA pts were matched for age, gender, hypertension, diabetes, smoking, dyslipidemia and family history with controls undergoing CTA for evaluation of coronary arteriosclerosis. Individual coronary trees were evaluated for plaque volume and composition by standard methods (American Heart Association). Non-parametric tests were used for data analysis; regression models for plaque prevalence ratios (PR) and relative risk for plaque burden in RA vs. controls, adjusted for conventional risk factors were developed.

Results: Asymptomatic RA pts have higher prevalence and more extensive total coronary plaque (table); higher numbers have 2 or 3-vessel disease (p=0.04 for both), and total plaque burden in RA is greater than controls (p=0.01). More importantly, RA pts have higher prevalence, extent and severity of "vulnerable" plaque; 54% of diseased arterial segments in RA pts vs. 21% in controls harbor NC plaque (p=0.0001), and NC plaque burden score is superior in RA (p=0.0001). RA pts have 6-fold the risk and 87% higher burden risk of NC plaque vs. controls adjusted for age, sex and Framingham RF.

Variables	RA=74	Controls=74	p-value
n (%) with plaque	62.2	51.4	0.18
n (%) with Normal atreries	28 (37.8)	36 (48.6)	0.2
1-vessel dz	28 (37.8)	30 (40.5)	0.62
2-vessel dz	14 (18.9)	6 (8.1)	***0.04***
3-vessel dz	4 (5.4)	2 (2.7)	***0.04***
n (%) diseased segments (296)	67 (22.6)	48 (16.2)	0.11
Non-calcified	36 (53.7)	10 (20.8)	***0.0001***
Mixed	15 (22.4)	7 (14.6)	0.06
Calcified	16 (23.9)	31 (64.6)	***0.001***
Total plaque burden score	6.4 ± 4.8	4.3 ± 4.1	***0.01***
Non-calcified	3.2 ± 4.3	1 ± 2.9	***0.0001***
Mixed	1.7 ± 2.9	0.9 ± 2	***0.01***
Calcified	1.5 ± 3.4	2.4 ± 3.3	0.19
Non-calcified	6.06	1 (ref)	***0.0001***
Mixed	2.4	1 (ref)	***0.002***
Calcified	0.38	1 (ref)	***0.009***
Relative Risk-total burden score*	1.38	1 (ref)	***0.02***
Non-calcified	1.87	1 (ref)	***0.001***
Mixed	1.43	1 (ref)	***0.01***
Calcified	0.73	1 (ref)	***0.05***

* Relative risk regression analysis: per standard deviation increase in burden

Conclusion: Asymptomatic RA pts have greater extent, severity and risk of coronary plaque compared to controls matched for all traditional risk factors. More importantly, they have higher prevalence, severity, burden and risk of "vulnerable", rupture-prone plaque that might account for the higher incidence of future MIs.

Anti-b2-Glycoprotein-1 (b2GP1) IgA Ab Are Highly Prevalent and Predict "Vulnerable" Coronary Plaque in Asymptomatic Patients with Rheumatoid Arthritis (RA). George A. Karpouzas[1], Naser Ahmadi[2], Tae-Young Choi[2], Fereshteh Hajsadeghi[2], Silvia Munoz[2] and Mathew Budoff[2]. [1]Harbor-UCLA, Long Beach, CA, [2]Harbor-UCLA

Background: B2GP1 is present in atherosclerotic plaque and b2GP1 IgA Ab have been associated with documented atherosclerosis, including myocardial infarction (MI). RA pts have higher risk of MI; however, the prevalence of b2GP1 IgA Ab in RA and their relevance to plaque characteristics are unknown. We evaluated prospectively the presence of b2GP1 IgA and its associations with coronary plaque prevalence, burden and consistency in asymptomatic pts with RA.

Methods: We report on the first 74 of 150 recruited pts from a single center (table 1). Lupus Anticoagulant (LA), Anticardiolipin (ACL), and b2GP1 IgG, IgM and IgA were assessed by standard methods (DRVVT, Varelisa, and Bindazyme Elisa respectively). Positive (+) tests were confirmed 3 months later. Pts underwent coronary plaque evaluation with 64+ slice cardiac Computed Tomography Angiography (CTA); this non-invasive modality includes an initial non-contrast phase assessing coronary calcium, followed by a contrast scan that detects plaque with equal accuracy to conventional angiography, and is superior in the assessment of non-calcified, lipid-rich, non-obstructive or "vulnerable" plaque. Coronary trees were graded in a standard fashion according to AHA. Non-parametric tests were used for data analysis; linear regressions between disease parameters and plaque, as well as relative risk regression models for plaque burden and consistency were constructed after adjustments for age, sex, classic coronary risk (CRF), RA duration and severity.

Results: B2GP1 IgA was highly prevalent in asymptomatic RA pts, by contrast to all other Ab classes and isotypes ($p<0.0001$). No differences in age, disease duration, or laboratory parameters were seen in (+) vs. negative (−) pts.The number of diseased arterial segments was not different in (+) vs. (−) pts; however, the total plaque burden, and more importantly the NC/mixed plaque was significantly higher in the affected arteries of the b2GP1 IgA (+) ones ($p=0.0001$). In fact, b2GP1 IgA had the strongest correlation with NC/ mixed plaque burden than any other factors tested ($p=0.003$). After adjustments for all CRF, RA duration and severity (DAS28-3v), b2GP1 IgA (+) pts had a 47% higher plaque burden risk for total and 52% higher risk for "vulnerable" plaque ($p=0.01$ and 0.004 respectively).

Conclusions: B2GP1 IgA Ab previously reported in symptomatic pts with documented atherosclerosis, are highly prevalent in asymptomatic RA pts. They independently predict higher total, but more importantly higher vulnerable, NC plaque burden more robustly than the composite of classic CRF. As such, they may represent a useful screening test for "high-risk" plaque in asymptomatic pts with RA.

Table 1. Patient Characteristics

Positive test	X1	X2 (≥3 months later)
Any ACL (%)	1.6	0
LA (%)	7.7	4.6
Any a-b2GP1 (%)	39***	29***
a-b2GP1-IgA (%)	39†	29†

Increased Epicardial and Thoracic Pre-Aortic Fat Depots Predict "Vulnerable" Coronary Plaque in Asymptomatic Patients with Rheumatoid Arthritis (RA). George A. Karpouzas[1], Naser Ahmadi[2], Fereshteh Hajsadeghi[2], Tae-Young Choi[2], Silvia Munoz[2] and Mathew Budoff[2]. [1]Harbor-UCLA, Long Beach, CA, [2]Harbor-UCLA

Background: There is increasing evidence of an association between volume of visceral adipose tissue (VAT) and clinical or subclinical atherosclerosis. Perivascular AT including epicardial (EAT), pericardial (PAT), thoracic pre-aortic (TAT) and subcutaneous (SAT) is metabolically active and a source of pro-inflammatory as well as anti-inflammatory cytokines with both paracrine and systemic effects. VAT volume and associations with coronary plaque burden and features in RA are unknown. We assessed the volume of these AT depots in asymptomatic patients (pts) with RA compared to non-RA matched controls for age, gender and all traditional risk factors undergoing evaluation for coronary artery disease. Additionally, we explored the ability of these diverse AT depots to predict non-calcified (NC), lipid-rich, "vulnerable" coronary plaque burden in RA.

Methods: We report on 74 recruited RA pts from a single center. Pts underwent VAT evaluation with 64+ slice multidetector Computed Tomography Angiography (MDCTA), with advantages of submillimeter collimation, high temporal and spatial resolution, and 3-dimensional

views of the heart and its epicardial surface. Additionally, MDCTA detects coronary plaque with equal accuracy to conventional angiography, and is superior in assessing "vulnerable" plaque. Coronary trees were graded in a standard fashion according to Americn Heart Association (AHA). Non-parametric tests were used for data analysis; linear regressions between different AT depot volumes and vulnerable plaque, as well as relative risk regression models for AT volume risk and prediction of vulnerable plaque burden in RA pts were constructed after adjustments for age, sex, classic coronary risk (CRF), RA duration, and disease activity.

Results: Patients with RA had significantly higher volumes of EAT, PAT, TAT and SAT compared to non-RA matched controls ($p<0.05$ for all, table 1). RA subjects had 44% higher EAT and 49% higher TAT volume risk than non-RA controls after adjustments for age, sex, all CRF, and body mass Index ($p=0.001$ and 0.005 respectively). Additionally, RA pts had significantly higher total coronary plaque burden ($p=0.01$), predominantly accounted for by "vulnerable" NC plaque ($p=0.0001$). EAT and TAT where the strongest predictors of "vulnerable" plaque ($p=0.001$ for both) in asymptomatic RA pts. EAT volume change was the strongest predictor of presence and extent of such friable, high-risk coronary plaque after adjustments for age, sex, all CRF, body mass Index, DAS28-3v and disease duration ($p=0.009$), followed by TAT ($p=0.01$).

Conclusions: VAT tissue depots- especially EAT and TAT- are significantly expanded in asymptomatic RA pts compared to matched controls. They significantly predict the presence of "vulnerable" coronary plaque and remain its strongest determinants after adjustments for traditional CRF, anthropometric, and RA-specific features.

Citrullination Is Present in the Perivascular Interstitium of the Myocardium and Is Increased in Rheumatoid Arthritis Compared to Controls.

Jon T. Giles[1], Marc K. Halushka[4], Fox-Talbot K. Mary[4], Clifton O. Bingham[2], Felipe Andrade[5], Jin Kyun Park[3], Antony Rosen[2], Justyna Fert-Bober[4], Jennifer van Eyk[4] and Joan M. Bathon[2]. [1]Johns Hopkins Univ, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD, [4]Johns Hopkins University, [5]Johns Hopkins University School of Medicine, Baltimore, MD

Background: Myocardial dysfunction is increased among rheumatoid arthritis (RA) patients relative to controls. Autoimmunity against post-translationally modified (citrullinated) myocardial proteins may represent a pathophysiological link to both myocardial structural and functional abnormalities in RA patients.

Methods: Archived myocardial samples obtained during autopsy between 1995 and 2009 were assembled into four groups: RA; scleroderma; fatal myocarditis with no underlying rheumatic disease; and non-rheumatic disease controls. Records were adjudicated to confirm diagnosis. Samples were examined by immunohistochemistry for the presence and localization of citrullination using a commercial anti-modified citrulline antibody. A blinded cardiovascular pathologist graded average citrullination intensity, peak intensity, and average fibrosis for each case on a 0–3 scale. RA and control samples were further examined for the presence of peptidyl argenine deiminase enzymes (PADs 2 and 4) by immunohistochemistry.

Results: Myocardial samples from 17 RA patients were compared to those from 14 controls, 5 fatal myocarditis patients, and 9 scleroderma patients. The RA and control groups did not significantly differ by age, gender, race, or post-mortem interval. Citrullination was detected in the perivascular myocardial interstitium in each of the groups. Citrullination was not detected in the cardiomyocytes or endothelium. Average and peak citrullination were significantly higher in the RA group compared to the other groups, among which citrullination was equivalent (Figure, panels A and B). Myocardial fibrosis did not differ between the groups (Figure, panel C).

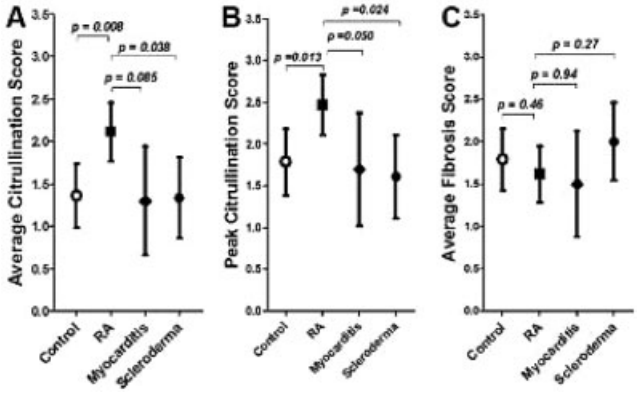

Figure. Average semiquantitative scores for immunohistochemical assessments of average citrullination (A), peak citrullination (B), and average myocardial fibrosis (C), according to group. Means and 95% confidence intervals are depicted. *P*-values were calculated using the Kruskal-Wallis test.

Myocarditis did not differ between the RA and control groups, and did not co-localize with citrullination. Rare, scattered PAD2 and PAD4 staining leukocytes were observed in both the RA and control samples. PAD2 and PAD4 staining was negligible within the cardiomyocytes and endothelium in both groups.

Conclusions: These data provided evidence for the first time that: 1) Citrullinated proteins are present in the myocardium, in general, 2) Higher levels of myocardial interstitial citrullination appear to be specific to RA, 3) differences in demographics, post-mortem interval, and histologic features did not account for higher citrullination in RA, and 4) While myocardial leukocytes were potential sources of PAD2 and PAD4 within the myocardial interstitium, these cells were not increased in RA at the time of death. Further investigation is centered on identifying the specific myocardial proteins that are targets for citrullination, determining whether citrullinated myocardial proteins are recognized by RA sera, and elucidating the consequences of interstitial citrullination on myocardial structure and function in RA patients.

ALD518 (BMS945429), a High Affinity Monoclonal Antibody Directed Against Interleukin-6, Reduces Disease Activity and Achieves Remission in Patients with Rheumatoid Arthritis and Inadequate Response to Methotrexate. Philip Mease[5], Vibeke Strand[4], Levan Shalamberidze[6], Aleksandar Dimic[3], Richard Aranda[2] and Jeff Smith[1]. [1]Alder Biopharmaceuticals Inc., Bothell, WA, [2]Bristol-Myers Squibb, Princeton, NJ, [3]Institute of Rehabilitation and Treatment, Niska Banja, Serbia, [4]Stanford University, Palo Alto, CA, [5]Swedish Medical Center and University of Washington, Seattle, WA, [6]V. Tsitlanadze Scientific Practical Centre of Rheumatology, Tbilisi, Georgia

Background: Interleukin-6 (IL-6) plays a key role in the inflammatory cascade in rheumatoid arthritis (RA). ALD518 (BMS945429) is an asialated, humanized, anti-IL-6 monoclonal antibody with a half-life of ~30 days. ALD518 binds to IL-6 with high affinity, preventing interaction and signaling mediated via soluble and membrane-bound IL-6R. Here, we report the impact of ALD518 on disease activity and DAS28 remission over 16 weeks.

Methods: Patients with active RA and an inadequate response to MTX were randomized 1:1:1:1 to intravenous ALD518 80, 160 or 320 mg or placebo during this 16-week, double-blind, placebo-controlled Phase II study. Patients received two IV infusions of ALD518 (Day 1 and Week 8), while continuing on stable doses of MTX. The primary efficacy endpoint was ACR 20 responders at Week 12. Disease activity was assessed via DAS28 (CRP) as a secondary endpoint, including mean change from baseline and DAS28-defined remission (score <2.6). Efficacy data were assessed for the modified intent-to-treat population. Safety was monitored throughout. P values for ACR responses are based on Fisher's exact test and for DAS28 classes are based on chi-square tests.

Results: Of 127 randomized and treated patients, 116 completed the trial. At baseline, mean age was 52.3 years and RA duration was 6.8 years. Mean baseline DAS28 (CRP) scores were 6.3, 6.2, 6.2 and 6.1 in the ALD518 80, 160, 320 mg and placebo groups, respectively. Reductions in DAS28 score and the proportion of patients achieving Low Disease Activity State (LDAS; DAS28 [CRP] ≤3.2), remission and ACR 20, 50 and 70 responses were rapidly achieved and greater than placebo for all ALD518 doses at each time point (Table). For all assessments, there was a trend toward greater responses with higher ALD518 doses.

	Time point	ALD518 80 mg (N=32)	ALD518 160 mg (N=34)	ALD518 320 mg (N=28)	Placebo (N=33)

ACR 50 (%)	Week 4	9.4	14.7	28.6*	3.0
	Week 12	34.4*	26.5*	50.0*	9.1
	Week 16	40.6*	41.2*	50.0*	15.2
ACR 70 (%)	Week 4	6.3	0	10.7	0
	Week 12	12.5	11.8	25.0*	3.0
	Week 16	21.9	17.6	42.9*	6.1

* $p<0.05$ vs placebo.

Through 16 weeks, serious AEs were reported in two ALD518 patients (both had significant increases in liver enzymes, and discontinued treatment). Increases in ALT >3x upper limit of normal occurred in 12, 6 and 29% of patients in the ALD518 80, 160 and 320 mg groups, respectively. Modest increases in total cholesterol were observed; mean levels at Week 16 were 6.5, 6.4 and 6.0 mmol/L in the ALD518 80, 160 and 320 mg groups, versus 5.4 mmol/L in the placebo group. Nine ALD518 patients had transient Grade II (five in the ALD518 80 mg group and four in the 160 mg group) and two had transient Grade III neutropenia (both in the 80 mg group). There were no serious infections or infusion reactions in any treatment group, and no evident immunogenicity.

Conclusions: In this Phase II study, the IL-6 inhibitor ALD518 resulted in rapid and significant improvements in disease activity sustained over 16 weeks of assessment in patients with RA and an inadequate response to MTX. ALD518 was well tolerated, with a safety profile consistent with the biology of IL-6 blockade.

Efficacy and Safety of Ocrelizumab in Patients with Active Rheumatoid Arthritis Who Have an Inadequate Response to at Least One TNF Inhibitor: Results from the Phase III SCRIPT Trial. Paul P. Tak[1], Philip J. Mease[7], Mark C. Genovese[8], Joel M. Kremer[9], Boulos Haraoui[4], Yoshiya Tanaka[10], Clifton O. Bingham[5], Ali Ashrafzadeh[2], Helen Travers[6], Simon Safa-Leathers[6], Sanjeev Kumar[6] and Wolfgang Dummer[3]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Genentech, San Francisco, CA, [3]Genentech, [4]Institut de Rhumatologie, Montreal, QC, Canada, [5]Johns Hopkins University, Baltimore, MD, [6]Roche, [7]Seattle Rheumatology Associate, Seattle, WA, [8]Stanford Univ, Sunnyvale, CA, [9]The Center for Rheumatology, Albany, NY, [10]U Occupa & Environ Hlth, Kitakyushu, Japan

Purpose: Treatment with rituximab has demonstrated clinical benefit in patients (pts) with rheumatoid arthritis (RA). This phase III study evaluated efficacy and safety of Ocrelizumab (OCR, a humanized anti-CD20 antibody) plus methotrexate (MTX) or leflunomide (LEF), in pts with active RA who had an inadequate response to ≥1 TNF inhibitor.

Methods: SCRIPT was a randomized, double-blind and placebo (PBO)-controlled (DBPC) study. 840 pts with active RA (1987 ACR criteria; SJC ≥4, TJC ≥4, CRP ≥0.6 mg/dL and RF+ and/or anti-CCP+) and on stable MTX (7.5–25 mg/wk) or LEF (10–20 mg/day), were randomized (1:1:1; 277 PBO, 278 OCR 2 × 200 mg, 285 OCR 2 × 500 mg). Pt baseline (BL) characteristics were well balanced between treatment groups (mean: age ~54 yrs, SJC ~17, TJC ~26, CRP ~2.8, DAS28 ~6.5 and RA duration 11.8 to 12.7 yrs). The DBPC period (48 wks) was comprised of 2 courses of 2 treatments each (Days 1, 15 and Wks 24, 26). All pts received 100 mg IV methylprednisolone premedication. Co-primary endpoints were ACR20 responses at Wks 24 and 48. Secondary endpoints included the change from BL in the total modified (van der Heijde) Sharp score (mTSS) at 48 wks and ACR50/70 responses at 24 and 48 wks.

Results: Key efficacy and safety data are shown in Table 1. Both OCR doses showed statistically significant ($p<0.0001$) improvements (vs PBO) in ACR20/50/70 at Wks 24 and 48. At Wk 48, statistically significant slowing of progression of joint damage (PJD) (change from BL in mTSS) was seen in OCR 500 mg dose group (62% inhibition, $p=0.0020$) but not in OCR 200 mg dose group (30% inhibition, $p= 0.2153$) vs PBO. Frequencies of AEs, SAEs, and overall infections were comparable among the 3 treatment arms. Serious infections (SIEs) were observed more

frequently in OCR dose groups (5.1% and 4.3%) compared to PBO (2.5%). SIE rates were similar in both OCR and PBO groups outside Japan. Most common SIEs included pneumonias, cellulitis and urinary tract infections. Opportunistic infections in OCR-treated groups included 1 suspected Pneumocystis jiroveci, 2 de novo pulmonary tuberculosis, and 1 hepatitis B reactivation and none in PBO. There were no fatal infections during the DBPC period in any treatment groups.

Background: Osteopontin (OPN) is an extracellular matrix protein that is constitutively expressed in bone and epithelial tissues and upregulated in activated T cells, macrophages, synoviocytes and chondrocytes. OPN has diverse functions including chemotaxis, immunomodulation and activation of osteoclasts. High levels of OPN in serum, synovial fluid and tissue have been reported in rheumatoid arthritis (RA) patients. OPN-blockade improves arthritis in animal models of RA. In this study we assessed the safety, tolerability, pharmacokinetics, pharmacodynamics and initial efficacy of the humanized monoclonal antibody ASK8007 which binds to the SVVYGRL epitope of OPN in patients with active RA receiving methotrexate (MTX), leflunomide (LEF) or sulfasalazine (SSZ).

Methods: In this combined first-in-man single dose escalation study (part A) and multiple dose proof-of-concept study (part B), patients meeting the American College of Rheumatology (ACR) criteria for RA who had been taking MTX, LEF or SSZ for 4 months with active disease were randomly assigned to receive either ASK8007 or matching placebo intravenously while continuing to receive MTX, LEF or SSZ. In Part A, patients were treated with a single dose of 0.3, 1.25, 5 or 20 mg/kg ASK8007 intravenously in four consecutive dose cohorts of 8 patients each. In part B, patients received 3 consecutive infusions of 20 mg/kg ASK8007 or matching placebo on day 1, day 8 and day 29. Safety monitoring, pharmacokinetic and pharmacodynamic analyses and clinical assessments were performed throughout the study. Synovial tissue was obtained at baseline and after 43 days of treatment, and was analyzed by immunohistochemistry and digital image analysis. The two co-primary efficacy endpoints were the change from baseline in the disease activity score evaluated in 28 joints (DAS28) and the change from baseline in the number of CD68 positive sublining macrophages in the synovium as assessed on day 43.

Results: ASK8007 was well tolerated up to the highest studied dose of 20 mg/kg in both parts of the study. No anti-ASK8007 antibodies were detected and no renal clearance of ASK8007 was observed. In part B, in the intention-to-treat population, no difference was observed in the delta DAS28 between the ASK8007 treated patients (n=33) and the placebo-treated patients (n=16, $P = 0.95$). Results were similar for the per protocol population. In addition, no difference was observed in the delta CD68 positive sublining macrophages between the ASK8007-treated patients (n=9) and the placebo-treated patients (n=4, $P = 0.61$). Paired analysis also did not show a clear cut decrease in sublining macrophages within the ASK8007 treatment group. Although quantifiable ASK8007 concentrations were obtained in synovial fluid samples which indicates that it reaches the target site, there was also no effect of multiple doses of ASK8007 on the biomarkers for bone and cartilage metabolism and for inflammation in any of the matrices tested (blood, urine, synovial fluid and synovial tissue).

Conclusion: The results of this trial consistently show that blocking the extracellular matrix protein osteopontin is unlikely to be a feasible strategy for the treatment of RA.

Tasocitinib (CP-690,550) Appears To Be Effective and Tolerated When Administered Either as Long-Term Monotherapy or on Background Methotrexate in Patients with Rheumatoid Arthritis. Carol A. Connell[1], Richard Riese[2], Susan Wood[2], John Bradley[2] and Samuel H. Zwillich[2]. [1]Pfizer Inc, New London, CT, [2]Pfizer Inc

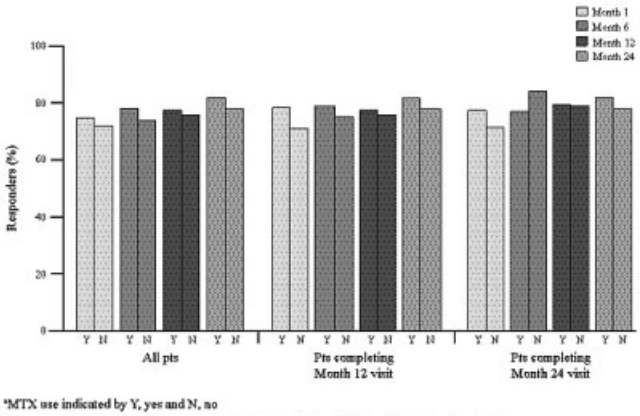
Background: Tasocitinib (CP-690,550) is an oral, selective Janus kinase inhibitor that has previously demonstrated efficacy in treating rheumatoid arthritis (RA) and a manageable safety profile in randomized studies. Patients were enrolled in this long-term follow-up study upon completion of participation in a prior randomized study of tasocitinib (PRST). Here safety and efficacy is compared between patients who received tasocitinib monotherapy and those on background methotrexate (MTX).

Methods: In this Phase 2/3 open label study of 1070 patients who had participated in a PRST, treatment was initiated with either 5 or 10 mg tasocitinib twice daily. Key outcome measures included safety and ACR20 response rates. Results are presented for all patients (ALL, n=1070), patients who completed Month 12 (M12, n=648), and patients who completed Month 24 (M24, n=207) visits. The baseline is that of the PRST for patients who enrolled within 14 days of PRST participation; if enrollment was >14 days after PRST participation, baseline was the start of this study. Some PRSTs required background MTX; others were conducted as monotherapy.

Results: Background MTX use was reported in 422/1070 (39.4%, ALL MTX), 332/648 (51.2%, M12 MTX), and 162/207 (78.3%, M24 MTX). Treatment-related adverse events (TRAEs) were generally manageable and infrequently led to discontinuation (70/1070). The most frequently reported TRAEs were infections and infestations for both MTX and non-MTX treatment groups. The most common TRAEs reported by MTX patients were urinary tract infection (4.7%), bronchitis (4.0%), and sinusitis (3.6%); in non-MTX patients, the most common TRAEs were upper respiratory tract infection (2.5%), bronchitis (2.3%), and herpes zoster (2.2%). These TRAEs and TRAEs of abnormal liver laboratory tests are presented by treatment group in the table below.

	Tasocitinib monotherapy (n=639)			Tasocitinib + MTX (n=422)		
Treatment-related AEs, n	**Mild**	**Mod**	**Severe**	**Mild**	**Mod**	**Severe**
Infections and Infestations, n (%)	**49 (7.7%)**	**38 (6.0%)**	**4 (0.6%)**	**47 (11.1%)**	**45 (10.7%)**	**14 (3.3%)**
Bronchitis	9	6	0	6	11	0
Herpes zoster	7	6	1	6	5	2
Nasopharyngitis	6	5	0	9	1	0
Sinusitis	2	1	0	7	8	0
Upper respiratory tract infection	13	3	0	8	5	0
Urinary tract infection	4	3	1	10	8	2
Liver Laboratory Test AEs, n (%)	**3 (0.5%)**	**5 (0.8%)**	**0**	**15 (3.6%)**	**11 (2.6%)**	**0**
Alanine aminotransferase increased	0	1	0	6	3	0
Aspartate aminotransferase increased	0	1	0	5	2	0
Gamma-glutamyl transferase increased	0	0	0	1	2	0
Hepatic enzyme increased	3	2	0	1	3	0
Liver function test abnormal	0	1	0	2	1	0

ACR20 response rates demonstrated similar efficacy of tasocitinib between ALL MTX and non-MTX patients, as well as M12 and M24 patients (Figure 1). ACR20 response rates at Month 24 were 81.8% and 77.8% for M24 MTX and non-MTX patients, respectively.



[a]MTX use indicated by Y, yes and N, no

ACR, American College of Rheumatology; BID, twice daily; MTX, methotrexate; pts, patients

Figure 1. % responders for ACR20[a] by MTX use for pts initially treated with tasocitinib 5 or 10 mg BID.

Conclusion: The safety profile of tasocitinib, regardless of background MTX use, was generally tolerable and manageable. Tasocitinib demonstrated sustained efficacy over 24 months in the treatment of RA. ACR response rates were similar in patients receiving tasocitinib monotherapy compared with patients on background MTX therapy.

A Randomized Dose-Ranging, Placebo-Controlled Study of INCB028050, a Selective JAK1 and JAK2 Inhibitor in Subjects with Active Rheumatoid Arthritis. Maria W. Greenwald[1], Rosanne Fidelus-Gort[4], Rich Levy[4], Jinjin Liang[4], Kris Vaddi[4], William V. Williams[3], Robert Newton[4], Swamy Yeleswaram[4], Robert Flores[4], Edward McKeever[4], James Rodgers[4], Stacey Shepard[4], Pierre-Yves Berclaz[2], Chin Hyok Lee[2] and Monica E. Luchi[3]. [1]Desert Medical, Palm Desert, CA, [2]Eli Lilly & Company, [3]Incyte Corporation, Wilmington, DE, [4]Incyte Corporation

Purpose: To characterize safety and efficacy of INCB028050 (050) in RA in subjects who have had an inadequate response to any DMARD therapy including biologics.

Methods: Subjects with active RA(≥6 tender>/4 swollen joints of 28), ESR≥28mm or CRP ≥ 7mg/L) despite DMARD therapy were randomized to placebo (PBO)or 050 at once daily oral doses of 4mg, 7 mg or 10 mg with background DMARDs (excluding biologics). After 12 weeks subjects randomized to placebo were re-randomized to 7mg or 10mg for an additional 12 weeks (wks). The primary analysis was at the end of the 12-week PBO-controlled period. Subjects remained blinded to treatment assignment during the 24-wk treatment period. Subjects could be on stable doses of methotrexate (MTX), hydroxychloroquine, leflunomide, corticosteroids (<10 mg/day) and/or sulfasalazine. Results below are at Wk 12. The study was not designed to test for statistically significant differences between individual dose groups and placebo; p-values and significance levels are not displayed.

Results: The study enrolled 127 subjects, eighty percent women. Two subjects were randomized but not treated. One subject had no post-baseline assessments. Mean ages across treatment groups 54–58yrs. Mean disease duration ranged from 7–9 yrs. The proportion of subjects on background MTX ranged from 72–77%. The proportion of subjects who failed biologics in the past was 13%, 38%, 6% and 20% for the PBO, 4mg, 7mg and 10mg groups respectively. Of the subjects who had failed biologics, 30% failed multiple biologics.

Response rates are expressed as mean % (also percent change from baseline for DAS28).

Wk 12 results	PBO n=31	4 mg 050 n=31	7 mg 050 N=32	10 mg 050 N=30
ACR20 (%)	32	52	59	53
ACR50 (%)	13	35	31	30
ACR70 (%)	3	16	9	10
DAS28 CRP Mean (%change)	5 (−19)	4 (−34)	4 (−32)	4 (−33)
DAS28 <=2.6 (%)	16	23	25	17

Responses were observed as early as the first assessment (Wk2), demonstrating a rapid onset of action. Similar ACR responses were achieved with 050 regardless of background therapy or previous biologic experience. ACR20 responses for biologic experienced subjects was 33% for PBO and 53%, 73% and 43% for 4mg, 7mg and 10mg, respectively. ACR50 responses for biologic experienced subjects was 11% for PBO and 33%, 45% and 29% for 4mg, 7mg and 10mg, respectively.

The nature of treatment-emergent adverse events (TEAEs) was similar across groups. The frequency of TEAEs in PBO, 4mg, 7 mg and 10 mg 050 groups was 61.3%, 48.4%, 59.4% and 74.2%, respectively. One subject reported an unrelated serious AE (GI bleed). The most frequently reported TEAEs were headache (active 10.6% vs. 6.5% PBO), URI (active 5.3% vs. 9.7% for PBO) and diarrhea (active 5.3% vs. 6.5% PBO). At Wk 12, two cases of herpes zoster were reported (2.1% active vs. 0% PBO). Increases were observed in HDL and LDL, and HDL:LDL ratios tended to increase with therapy (active 10.06% vs. 0.41% PBO).

Conclusion: In this study, INCB028050 given once a day over 12 weeks was well tolerated and demonstrated clinically meaningful responses in subjects with inadequate response to DMARDs including biologics over 12 wks of treatment. All three doses tested were effective.

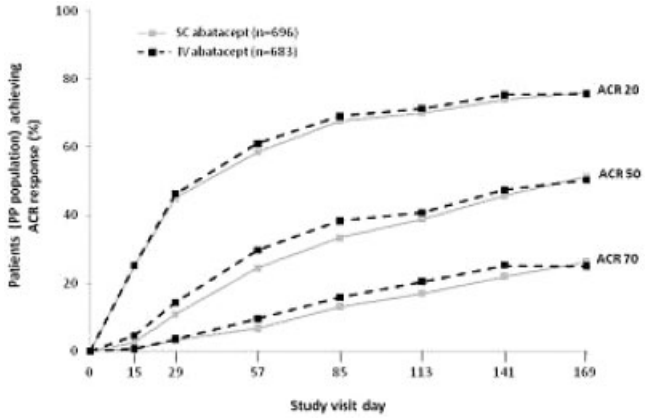
A Large, Phase IIIb Non-Inferiority Trial of Subcutaneous (SC) Abatacept Compared with Intravenous (IV) Abatacept, in Patients with Rheumatoid Arthritis (RA). Mark C. Genovese[13], Jose Arturo Covarrubias[3], Gustavo Leon[5], Eduardo F. Mysler[8], Mauro W. Keiserman[10], Robert M. Valente[9], Peter Nash[15], J. Abraham Simon[2], Wieslawa Porawska[11], Jane H. Box[14], Clarence W. Legerton[6], Evgeny Nasonov[7], Patrick Durez[4], Richard Aranda[1], Ramesh Pappu[1], Ingrid Delaet[1], Julie Teng[1] and Rieke Alten[12]. [1]Bristol-Myers Squibb Co, Princeton, NJ, [2]Centro de Especialidades Médicas, Merida, Mexico, [3]Centro Medico de Las Americas, Merida, Yucatan, Mexico, [4]Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Brussels, Belgium, [5]De Ginecologia Y Reproduccion, Lima, Peru, [6]Department of Medicine, Medical University of South Carolina, Charleston, SC, [7]Institute of Rheumatology, Moscow, Russia, [8]Organización Médica de Investigación, Buenos Aires, Argentina, [9]Physician Research Collaboration, Lincoln, Lincoln, NE, [10]Pontificial Catholic University, School of Medicine, Porto Alegre, Brazil, [11]Poznanski Osrodek Medyczny Novamed, Ponzan, Poland, [12]Schlosspark-Klinik, Charité, University Medicine Berlin, Department of Internal Medicine II Rheumatology, Berlin, Germany, [13]Stanford University, Palo Alto, Sunnyvale, CA, [14]The Arthritis Clinic & Carolina Bone & Joint, Charlotte, NC, [15]University of Queensland, Brisbane, Australia

Background: The efficacy and safety of IV abatacept has been well established in patients with RA;[1,2] an SC abatacept formulation will provide additional treatment options. Here we compare the efficacy and safety of SC and IV abatacept.

Methods: This was a Phase IIIb, double-blind, double dummy study of patients with active RA (≥10 swollen and ≥12 tender joints, CRP ≥0.8 mg/dL) and inadequate response to MTX. Patients were randomized to weekly SC abatacept (125 mg) injections with added IV loading (~10 mg/kg) on Day 1, or IV abatacept (~10 mg/kg) on Days 1, 15, 29 and every 4 weeks thereafter, plus MTX (≤15 mg/week), for 6 months. The primary objective was to determine non-inferiority of SC to IV abatacept, by difference in ACR 20 response at Month 6. Secondary endpoints included ACR 50 and 70 responses, physical function (HAQ-DI response; improvement from baseline of ≥0.3) and immunogenicity (ELISA). Efficacy was assessed for both per protocol (PP) and intent to treat (ITT) populations. Patients who received ≥1 dose of abatacept were monitored for safety.

Results: Of 1457 randomized and treated patients, 693/736 (94.2%) SC and 676/721 (93.8%) IV patients remained on treatment at Month 6; 78 patients deviated protocol. Mean baseline characteristics were similar between groups (PP population): RA duration was 7.7 years; tender and swollen joint counts were 29.6 and 20.0; HAQ-DI was 1.7. At Month 6, 76.1% (95% CI: 73.0, 79.3) of SC vs 75.7% (72.5, 78.9) of IV patients achieved ACR 20, with an estimated difference (95% CI) of 0.3 (–4.2, 4.8) confirming non-inferiority of SC abatacept to IV abatacept. ACR responses over time were comparable (Figure). At Month 6, similar proportions of SC and IV patients achieved HAQ-DI response; 69.8 (66.4, 73.2) and 65.0% (61.4, 68.6), respectively. Results were consistent for PP and ITT populations. Frequencies of AEs and serious AEs over 6 months were comparable for SC versus IV (67.0 vs 65.2% and 4.2 vs 4.9%, respectively). Events of interest were comparable in the SC versus IV groups, respectively (serious infections in 5 [0.7%] vs 10 [1.4%], most common being pneumonia [1 vs 3]; malignancies in 3 [0.4%] vs 5 [0.7%], most common being basal cell carcinoma [2 vs 1]; pre-specified autoimmune events in 7 [1.0%] vs 6 [0.8%], most common being psoriasis [2 vs 4]). Local injection site reactions occurred in 19 (2.6%) SC and 18 (2.5%) IV patients; most were mild. Abatacept-induced antibodies were observed in 1.1 and 2.3% of SC and IV patients, respectively, and did not affect safety, efficacy or pharmacokinetics.



Conclusions: Consistent with the established IV abatacept profile, SC abatacept provides comparable efficacy and safety, with low immunogenicity and high retention rates; injection site reactions were few and mild. SC abatacept will provide additional treatment options for RA patients.

Receptor-Mediated Small Interfering RNA Delivery in Sjögren's Syndrome. Kaleb M. Pauley, Adrienne E. Gauna and Seunghee Cha. University of Florida, Gainesville, FL

Background: Sjögren's syndrome (SjS) is characterized by xerophthalmia and xerostomia resulting from loss of secretory function due to immune cell infiltration in lacrimal and salivary glands. Current SjS therapeutic strategies employ secretagogues to induce secretion via muscarinic receptor stimulation. Based on our expertise on muscarinic type-3-receptor (M3R), we are utilizing ligands specific for MR to deliver siRNA into cells via receptor-mediated endocytosis, thereby altering epithelial cell responses to external cues such as pro-inflammatory or death signals while simultaneously stimulating secretion.

Methods: MR agonist carbachol was conjugated with siRNA targeting caspase-3. To test siRNA efficacy after conjugation, HSG cells were transfected with conjugate. To test conjugate efficacy, conjugate was added to HSG cells in culture. Quantitative RT-PCR and immunofluorescence were used to detect caspase-3 gene and protein expression, respectively. Carbachol functionality was assessed using intracellular calcium release assays. A FAM-labeled DNA probe was designed to target the antisense strand of caspase-3 siRNA and in situ hybridization was utilized to detect conjugate entry into cells.

Results: Transfection of conjugate into cells resulted in 80%-reduction in caspase-3 gene expression, confirming retained function of siRNA after conjugation. External conjugate treatment of HSG cells resulted in similar intracellular calcium release and induction of endocytosis as carbachol stimulation indicating that the carbachol portion of conjugate also retained function after conjugation. Using the FAM-labeled probe, conjugate uptake was visualized in HSG cells, indicating that the conjugate binds M3R and is taken into cells via receptor-mediated endocytosis as expected. In conjugate-treated HSG cells caspase-3 mRNA and protein expression was reduced 50% demonstrating the efficacy of our conjugate in siRNA delivery.

Conclusion: Both siRNA and carbachol portions of the conjugate were shown to retain function after conjugation, and external treatment of HSG cells with conjugate shows promising results. Further in vitro/in vivo studies are needed to optimize conjugate entry and test efficacy of conjugate in the prevention of cytokine-induced apoptosis. This therapeutic strategy can easily be manipulated to target different genes of interest while maintaining cell-type specificity, and has many potential clinical applications in the treatment of SjS. Structure and Antigenicity of the Ro/La RNP Particle. hY1 RNA Differentiates the Recognition of Epitopes in Systemic Lupus Erythematosus and Sjogren's Syndrome. John G. Routsias[1], Nikos C. Kyriakidis[1], Stathis Kotsakis[1] and Athanasios G. Tzioufas[2]. [1]Department of Pathophysiology, Medical School, University of Athens, Athens, Greece, [2]Medical School-Univ of Athens, Athens, Greece

Background: Ro/La RNP particle is targeted by autoantibodies in patients with Sjögren's syndrome (SS) and systemic lupus erythematosus (SLE). Although the antigenicity of the components of the complex has been extensively studied, its overall 3D structure remains unknown. In contrast to Xenopus laevis, human Ro60 structure has not been solved. Two parts of the human La structure have been solved till now, one comprising the conserved La motif and its adjacent RNA recognition motif (RRM1) and another holding the C-terminal RNA recognition motif (RRM2), followed by a C-terminal nuclear retention element (NRE). For hY1 RNA, only its secondary structure has been experimentally defined. The aim of this study was to determine the 3D structure of Ro/La RNP complex, evaluate the modeled structure experimentally and define its antigenicity

Methods: Human Ro60 protein model was built by homology modelling from Xenopus Ro. 81% of human La was constructed by the assembly of its 3 parts: (i) 5–202 aa (La motif +RRM1), (ii) 203–224aa (linker region), (iii) 225–334 aa (RRM2 + NRE). hY1 RNA was built on the basis of its known secondary structure by a stepwise fashion. The whole Ro/La RNP complex was assembled and the structure was refined using extensive molecular dynamics. EMSA was performed using synthetic hY1RNA and recombinant Ro60 and La antigens. ELISA experiments were performed using immobilized biotinylated synthetic hY1RNA analogue, recombinant Ro60 and La antigens and purified antibodies against specific epitopes or Ro60 and La autoantigens.

Results: Electrostatic analysis of the Ro/La RNP complex revealed that adjacent Ro and La autoantigens form a consecutive positively charged patch, interacting with the negatively charged hY1 RNA molecule. More specifically, hY1 RNA binds to conserved amino acid residues located on the outside domain of the Ro60 doughnut and within the cleft formed between the La motif and an edge of the adjacent RRM1 of La. At this orientation, hY1-RNA completely masks epitopes 169–190aa of Ro60 and 145–164aa of La that were previously associated with SLE but not the SS related epitopes 211–232aa of Ro60 and 349–364aa of La. EMSA experiments demonstrated that the synthetic hY1-RNA analogue could form a complex with Ro60 and La autoantigens. In this regard, an ELISA assay was carried out, based on competition between synthetic-hY1 RNA and purified antibodies against specific epitopes on Ro and La autoantigens. It was found that Ro60 – hY1-RNA interaction was inhibited by anti-443–454, anti anti-211–232 and anti 169–190 antibodies by 13%, 45% and 76%, respectively while La-hY1-RNA interaction was inhibited by purified anti-349–364, anti-301–320 and anti-145–164 antibodies by 10%, 43% and 97%, respectively. Moreover, EMSA experiments demonstrated that Ro60 and La interactions with hY1 RNA can also be inhibited by peptides corresponding to regions 169–190aa and 145–164aa of Ro60 and La autoantigens.

Conclusions: Our study demonstrates that the SLE related epitopes on Ro and La autoantigens are actually cryptotopes in Ro/La RNP three-dimentional structure masked by hY1 RNA. On the other hand, SS related epitopes are directly accessible by autoantibodies in Ro/La RNP structure.

A Role of Autoimmune Response to M3 Muscarinic Acethylcholine Receptor in the Pathogenesis of Sjogren's Syndrome Like Autoimmune Sialoadenitis. Mana Iizuka[2], Hiroto Tsuboi[2], Yumi Nakamura[2], Naomi Matsuo[2], Isao Matsumoto[2] and Takayuki Sumida[1]. [1]Univ of Tsukuba/Inst Clin Med, Tsukuba City, Japan, [2]Univ of Tsukuba/Inst Clin Med

Objective: Sjögren's syndrome (SS) is a chronic autoimmune disease characterized by lymphocytic infiltration of salivary glands, in which $CD4^+$ T cells are predominant. These infiltrating T cells play a crucial role in the generation of SS. Previous studies showed that autoantibodies and autoreactive T cells against M3 muscarinic acethylcholine receptor (M3R) were detected in patients with SS. In this study, to reveal the pathological role of M3R immune response in SS, we tried to induce SS like sialoadenitis by autoimmune response to M3R.

Methods: (1) C57BL/6J ($M3R^{+/+}$) mice and M3R knockout ($M3R^{-/-}$) mice were immunized intradermaly with synthesized peptides encoding the extracellular domains of murine M3R (N-terminus, 1st, 2nd, and 3rd extracellular loops) in CFA. On day 10, these mice were boosted with intradermal injection. Ten days after booster immunization, spleens were isolated, the immune response to M3R was examined in vitro, and then the splenocytes were transferred to Rag1 knockout mice ($Rag1^{-/-}$) ($M3R^{-/-} \rightarrow Rag1^{-/-}$). (2) Anti-M3R antibodies and the amount of saliva flow $M3R^{-/-} \rightarrow Rag1^{-/-}$ were measured on day 0, 15, 45. (3) In $M3R^{-/-} \rightarrow Rag1^{-/-}$ mice, salivary glands were investigated histologically by H&E staining and evaluated immunohistochemically using anti-Thy1, anti-B220, anti-CD4 and anti-CD8 antibodies. Infiltrating lymphocytes derived from salivary glands were cocultured with M3R peptides in vitro and cytokine (IFN-g, IL-17, IL-4) in the supernatant was measured by ELISA. (4) $CD3^+$ T cells purified from $M3R^{-/-}$ mice immunized with M3R were transferred to $Rag1^{-/-}$ mice ($M3R^{-/-}CD3^+ \rightarrow Rag1^{-/-}$) and salivary glands were examined by histological analysis. (5) The splenocytes from IFN- $g^{-/-}/M3R^{-/-}$ mice immunized with M3R were transferred to $Rag1^{-/-}$ mice (IFN- $g^{-/-}/M3R^{-/-} \rightarrow Rag1^{-/-}$).

Results: (1) IL-17 and IFN- g were highly produced in splenocytes of immunized $M3R^{-/-}$ mice compared with $M3R^{+/+}$ mice. (2) In $M3R^{-/-} \rightarrow Rag1^{-/-}$ mice, anti-M3R antibodies was significantly increased and saliva flow were decreased. (3) On day 45, the sialoadenitis with remarkable mononuclear infiltration was observed and $Thy1^+CD4^+$ cells predominantly infiltrated in salivary glands of $M3R^{-/-} \rightarrow Rag1^{-/-}$ mice. IL-17 was preferentially produced from M3R reactive infiltrated T cells. (4) The moderate sialoadenitis with T cell infiltration was also detected in $M3R^{-/-}CD3^+ \rightarrow Rag1^{-/-}$ mice. (5) The obvious sialoadenitis was also observed in IFN- $g^{-/-}/M3R^{-/-} \rightarrow Rag1^{-/-}$ mice as well as $M3R^{-/-} \rightarrow Rag1^{-/-}$ mice.

Conclusion: These findings support the notion that M3R reactive Th17 cells might play a crucial role in the generation of autoimmune sialoadenitis such as SS.

Δ4BAFF, an Alternate-Splice Isoform That Acts as a Transcription Factor To Enhance BAFF Production in Primary Sjögren's Syndrome. Jacques-Olivier Pers, Gabriel J. Tobon, Laëtitia Le Pottier and Pierre Youinou. Brest University, Brest, France

Background: Elevated expression of 'B cell activating factor belonging to the tumor necrosis factor family' (BAFF), a potent B cell survival factor contributes to the expansion of low-affinity self-reactive B cells during the establishment of tolerance. However, mechanisms leading to BAFF overexpression in autoimmune settings, such as primary Sjögren's syndrome (SS) or rheumatoid arthritis (RA) and in lymphoproliferation such as chronic lymphocytic leukemia (CLL) are not understood. To date, 3 transcriptional variants of the BAFF gene have been described, including Δ3BAFF, a truncated form that negatively regulates BAFF, by forming non-functional heterotrimers with full-length (FL) BAFF. Herein, we report the discovery and the role of a new transcript for BAFF due to the fact that exon 4 is spliced out.

Methods and Results: A 3' RACE-PCR was performed in B cells from SS patients and revealed another transcript with deletion of nucleotides 749 to 861 encoding the predicted exon 4. A new in-frame stop codon was artificially generated resulting in a truncated protein. A same alternate splice isoform was detected in mice. To assess the biochemical properties of the new variant of BAFF, RAMOS B cells were transiently transfected with pIRES2-EGFP-Δ4BAFF. Two bands at 21 and 17-kD prove to belong to Δ4BAFF, which is very telling of a post-translational modification. Incubation with PNGase F showed that Δ4BAFF was glycosylated and led to the predicted mobility of Δ4BAFF at 17kD. Interestingly, Δ4BAFF was located in the nucleus and, contrary to FL BAFF, absent from the cytoplasm. Because BAFF was up-regulated after Δ4BAFF transfection in RAMOS cells, we asked the question as to whether Δ4BAFF might function as a transcriptional regulator of BAFF. A ChIP analysis revealed that the Δ4BAFF protein bound to the BAFF promoter. To confirm the role of Δ4BAFF as a transcription factor that activates its own gene to increase BAFF production, we synthesized a digoxigenin-labeled consensus NFkB binding probe within the BAFF promoter and performed an EMSA. When nuclear extracts from Δ4BAFF transfected RAMOS B cells were incubated with this probe, a protein/DNA complex was seen. A supershift was only detected when the anti-BAFF mAb was added. Finally, we observed the presence of the Δ4BAFF protein in B

cells from patients with CLL, in synoviocytes from patients with RA or in epithelial cells from patients with SS.

Conclusion: We thus expand the view of BAFF gene regulation, which should contribute a better understanding of complex physiologic mechanisms involved in normal B cell survival, as well as in pathophysiology of autoreactive B cells. Our work introduces for the first time an entirely novel concept in biology suggesting that a human cytokine gene can be transcriptionally regulated by the activity of one of its own splice variants.

Local TACI-Ig Gene Therapy of the Salivary Gland of NOD Mice Reduces Auto-Immune Inflammation by Affecting the B Cell Compartment. Nienke Roescher[2], Jelle L. Vosters[2], Marco Guadagnoli[2], Jan P. Medema[2], Gabor G. Illei[4], John A. Chiorini[3] and Paul P. Tak[1]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Academic Medical Center-University of Amsterdam, [3]National Insitutes of Health-National Institute of Dental and Craniofacial Research, [4]NIDCR, NIH #10 1N114, Bethesda, MD

Background: Sjögren's syndrome (SjS) is characterized by inflammatory autoimmune exocrinopathy in which B cells and B cell-related factors are important. Some patients have benefited from the use of the pan B cell depleting agent rituximab, validating the B cell compartment as a therapeutic target. An alternative therapeutic approach could be to use the soluble receptor TACI, which binds BAFF and APRIL, factors important in B cell survival and activation. Overexpression of BAFF in mice leads to a SjS-like syndrome and BAFF and APRIL are aberrantly expressed in salivary glands (SG) of patients with SjS. Therefore, we evaluated the effect of blockade of APRIL and BAFF using local gene transfer of a gene encoding for a TACI-Ig fusion protein in the SG of Non-Obese Diabetic (NOD) mice that spontaneously develop a SjS-like disease.

Material and Methods: An adeno-associated virus serotype 2 (AAV2) vector encoding the TACI fusion protein was constructed by cloning of the extra-cellular domain of mouse TACI coupled to the Fc-part of mouse immunoglobulin (Ig) G1. Expression of this gene was driven by the CMV promoter. The TACI-Ig vector or a control vector expressing beta galactosidase (LacZ) was administered once locally into the SG of NOD mice at the age of 10 weeks. Stimulated saliva flow was determined 10 weeks post-vector delivery. Gene transfer was measured by QPCR and protein analysis of the transduced SG. Inflammation was assessed by quantitative immunohistochemisty as well as by analysis of Ig and cytokine levels in the SG and in serum.

Results: TACI-Ig was highly expressed following transduction of 293T cells, and media from transduced cells could block BAFF induced B cell proliferation in vitro. In vivo, retrograde canulation of mouse SG also resulted in stable transduction and expression of TACI-Ig as determined by QPCR and ELISA. No change in stimulated saliva flow was observed between TACI treated and control mice. However, TACI-Ig treated mice had reduced SG inflammation as determined by the number of inflammatory foci per cross sectional surface area of the SG (LacZ 3.8 vs TACI-Ig 2.6, $p < 0.01$) and pro-inflammatory cytokines levels (IL-2, IL1β, IFN gamma) in the SG tended to be lower compared with control mice. Moreover, the numbers of B and plasma cells, were significantly lower ($p<0.05$) in the SG of treated mice, as well as IgG and IgM levels (50% and 41% reduction respectively, $p<0.05$). IgA levels did not change resulting in a significant improvement of the IgG/IgA ratio for the treated mice. Systemically, no significant changes in Ig-subtypes or cytokine levels were observed.

Discussion: The results presented here suggest that local B-cell targeted therapies may be beneficial in the treatment of SjS. The expression of a soluble TACI-Ig fusion protein in SG of NOD mice decreased autoimmune inflammation by reducing the number of B and plasma cells locally. The observed changes in IgG and IgM and the reduced IgG/IgA ratio levels suggest restoration of the balance of the mucosal immune system. When tested in patients with SjS, the timing of administration of the gene construct in the disease process may be critical in determining the outcome for salivary flow.

EBV-mir-Bart13 Downregulates Stim1, a Protein Involved in Calcium Signaling, in Human Salivary Gland Cells and May Contribute to the Pathogenesis of Sjogren's Syndrome. Alessia Gallo[1], Mayank Tandon[1], Gabor G. Illei[2] and Ilias Alevizos[1]. [1]National Insitutes of Health-National Institute of Dental and Craniofacial Research, [2]NIDCR, NIH #10 1N114, Bethesda, MD

Background: Loss of secretory function of salivary glands is one of the most important functional effects of Sjogren's syndrome (SS), a chronic systemic autoimmune disease. Previous studies have reported the presence of Epstein Barr Virus (EBV) DNA in salivary glands of SS patients. MicroRNA profiling studies in our laboratory have identified an EBV microRNA (ebv-mir-BART13) as significantly over-expressed in minor salivary gland biopsies of SS patients, when compared to the expression in minor salivary glands from non-Sjogren's controls.

Methods: Using the RNA22 target prediction algorithm, we identified STIM1 3'UTR as a target of ebv-mir-BART13. Store-operated calcium entry (SOCE) and calcium release-activated calcium current (CRAC) are critical events for the replenishment of intracellular calcium stores and have indispensable roles in various cellular functions, including salivary secretion. SOCE is activated by the depletion of calcium in the endoplasmic reticulum (ER). STIM1, is a protein that has recently been identified as a critical molecular component of CRAC channels. STIM1, is suggested to be the ER-Ca2+ sensor protein regulating SOCE in a number of different cell types. Attenuation of SOCE current underlies salivary gland dysfunction in mice lacking transient receptor potential 1 (TRPC1). We hypothesized that ebv-miR-BART13 may contribute to the salivary gland dysfunction by down-regulating STIM-1 and decreasing cacium influx in salivary gland epithelial cells.

Summary of the Results: To test this hypothesis, an expression plasmid was generated containing the 3'UTR of STIM1 downstream of the firefly luciferase coding sequence. The plasmid was co-transfected with ebv-mir-BART13 analogues and antagonists in HSG cells (human submandibular salivary gland cells). A 40% decrease in the intensity of the luciferase activity was observed 48 hrs after transfections, compared to controls, suggesting that ebv-mir-BART13 binds directly to the 3'UTR of STIM1.

HSG cells were transfected for 24 and 48hrs, with ebv-miR-BART13 analog and the mRNA and protein levels of STIM1 were measured. The mRNA level was not affected by the presence of this viral miRNA. However, the protein level was dramatically decreased (over 70% decrease) both 24 and 48hrs after transfection, suggesting that the ebv-mir-Bart13 exerts its effects on STIM1 not by degrading its transcript, but by repressing STIM1 translation. Functional Ca2+ assays through Thapsigargin-mediated depletion of the ER calcium in the ebv-mir-BART13 transfected cells showed a significant delay in the influx of calcium in the cytosol compared to controls.

Conclusions: Together, these functional measurements suggest that the presence of ebv-miR-BART13 in the salivary glands of SS patients might be, at least partially, responsible for the salivary gland dysfunction in those patients, by reducing the expression of STIM1, a critical member of the saliva secretion mechanism.

Striking Prevalence of Axial Spondyloarthritis in Primary Care Patients with Chronic Low Back Pain; a Cross-Sectional Study. Lonneke van Hoeven[3], Jolanda Luime[1], Huub Han[2] and Angelique Weel[4]. [1]Erasmus Medical Centre, [2]Maasstadziekenhuis, [3]Maasstadziekenhuis/Erasmus Medical Centre, Rotterdam, The Netherlands, [4]Maasstadziekenhuis Rotterdam, Rotterdam, The Netherlands

Background: Chronic low back pain (CLBP) is one of the most common pain syndromes with unknown cause. Few studies however report that 5–7 % is caused by Ankylosing Spondylitis (AS), a disease that until recently could be diagnosed 7–10 years after first presentation of symptoms. Since treatment of AS is most successfully in an early stage of the disease, the ASAS group[1]

developed new criteria to diagnose axial Spondyloarthritis (aSpA) early. Early treatment requires early recognition and should therfore be done in primary care. Until now however, prevalences of aSpA in primary care patients with CLBP are missing.

Purpose: To determine the prevalence of aSpA in primary care patients with CLPB classified by ASAS criteria. To assess the diagnostic value of clinical tests commonly available to GPs and inflammatory back pain (IBP) questionnaires completed by patients themselves.

Method: In this cross-sectional study primary care patients with CLBP aged 19–45 years were identified from GP records by the International Classification of Primary Care code L03. All patients completed IBP questionnaires, (ASAS, Calin and Berlin) and underwent a complete history and physical examination by rheumatologist. Blood was drawn to assess HLAB27 and CRP. Sacroiliac joints (SIJ) were imaged by conventional radiography and MRI (Siemens Essenza). All images were scored by two experienced MSD radiologist, without any clinical information. Radiographic sacroiliitis was defined by Modified New York criteria and MRI (T1, T2 and fat suppression series) evaluation followed ASAS recommendations.[1] Definite aSpA was defined by the ASAS criteria of aSpA.[1] Statistics were performed by using chi-square and logistic regression analysis.

Results: 364 patients (43% male, 36.3 yrs(sd 6.8), 9 yrs (sd 7.44) of symptoms) were evaluated. The overall point prevalence of aSpA was 21.5 % (n= 77;) using the ASAS criteria, n=52 were diagnosed by the MRI criteria with one other SpA feature and n=12 were diagnosed by a positive HLA B 27 and two other SpA features. Based on the modified New York criteria we identified 6.6% (n = 24) of which 75% also fulfilled the ASAS criteria. Figure 1 shows the diagnostic value of characteristics available to GPs and IBP questionnaires. Highest post probability test were achieved for the diagnostic test HLA-B27 and X-SIJ with respectively 68.3% and 75%.

Berlin	**79.2**	**34.1**	**24.4**

** **Post test probability;** probability of having the disease after a positive test. This could be compared to the pre test probability to assess information gain by the test.

Conclusion: In this cross-sectional study of primary care patients with CLBP the prevalence of aSpA based on the ASAS criteria is strikingly high. Additional 'red flag' symptoms determined by medical history and IBP questionnaires have modest diagnostic value. However, determine HLA-B27 and X-ray of SIJ could help physicians in primary care identifying patients that should have accelerated referral to rheumatologist to start accurate treatment as early as possible.

Screening for Axial Spondyloarthritis in a Primary Care: Comparison of Two Strategies in a Multicenter Prospective Study. Denis Poddubnyy[1], Janis Vahldiek[1], Inge Spiller[1], Beate Buss[1], Martin Rudwaleit[1] and Joachim Sieper[2]. [1]Charité - Campus Benjamin Franklin, Berlin, Germany, [2]Charite Campus Benjamin Frankl, Berlin, Germany

Background: The delay between first symptoms of axial spondyloarthritis (SpA) and the final diagnosis has been reported in different surveys to be still between 5 and 10 years. A major reason for such a delay in the diagnosis is the difficulty in identifying axial SpA patients among the large group of patients with chronic back pain in primary care. The current prospective randomized study was designed 1) to confirm the applicability of the established referral strategy [1, 2] in a multicenter study with rheumatologists not specialized in SpA and with primary care physicians, 2) to investigate whether this strategy can be improved by comparing it with a second strategy including additional screening parameters and asking for at least two parameters to be positive in case of referral.

Methods: Primary care physicians (n=259) were randomly assigned either to strategy 1 or strategy 2 for referral of patients with chronic back pain (duration of more than 3 months), age of back pain onset <45 years and no diagnosis of axial SpA to a cooperating rheumatologist (n=43) for further diagnostic workup. According to strategy 1 suitable patients were referred if at least one of the following 3 screening parameters was present: HLA-B27, inflammatory back pain (IBP), or sacroiliitis detected by imaging. According to strategy 2, patients were referred if 2 out of 5 parameters were positive: the same 3 parameters from strategy 1 and additionally a positive family history of ankylosing spondylitis (AS) or a good treatment response to non-steroidal anti-inflammatory drugs. The final diagnosis of the rheumatologist was used as the gold standard.

Results: 560 consecutively referred patients were included in this analysis. Among 318 patients referred via the 1st strategy 41.8% (n=133) were diagnosed with definite axial SpA: AS in 61.7% (n=82) and non-radiographic axial SpA in 38.3% (n=51) of all axial SpA cases. Among 242 patients referred via the 2nd strategy, 36.8% (n=89, p>0.05 vs strategy 1) were diagnosed with definite axial SpA: similarly, AS in 61.8% (n=55) and non-radiographic axial SpA in 38.2% (n=34) of the SpA cases. The probability of the axial SpA diagnosis was clearly increased with the increase of the number of positive referral parameters. The most common referral parameter in both strategies was IBP but the best performance demonstrated HLA-B27 in strategy 1 (with 57.7% of the referred with this parameter patients diagnosed as axial SpA) and sacroiliitis by imaging in strategy 2 (axial SpA was diagnosed in 53.3% of the patients). The best combination of two referral parameters in both strategies was the combination of HLA-B27 with sacroiliitis by imaging with about 70% of the patients diagnosed as axial SpA.

Conclusion: The simpler referral strategy 1 confirmed it's applicability in a multicenter study and demonstrated a slightly better performance in comparison to strategy 2. Therefore, strategy 1 can be recommended as an easy and reliable screening method for axial SpA on the primary care level.

Do the New EULAR/ACR Rheumatoid Arthritis Classification Criteria Identify Early Psoriatic Arthritis Patients? Laura C. Coates[2], Philip G. Conaghan[2], Paul Emery[2], Michael J. Green[3], Gamal Ibrahim[1], Helen MakIver[1] and Philip S. Helliwell[2]. [1]Bradford Hospitals NHS Trust, UK, Bradford, United Kingdom, [2]LIMM, Section of Musculoskeletal Disease, University of Leeds, Leeds, UK, [3]York Hospitals NHS Trust, York, UK

Background: The new ACR-EULAR classification criteria for rheumatoid arthritis (RA) have been developed to enable an early identification of patients with RA. They were tested during development in undifferentiated arthritis populations. The aim of this study was to investigate whether the new ACR/EULAR criteria for early RA are robust in excluding PsA and whether any patients would meet both these criteria and PsA classification criteria.

Methods: The new ACR/EULAR criteria for early RA and the Moll&Wright and CASPAR criteria for PsA were applied to cases of early PsA (less than 24 months symptom duration) early RA and other forms of

early inflammatory arthritis who were all disease-modifying anti-rheumatic drug naive. Gold standard diagnosis was confirmed by a consultant rheumatologist. All joints required for the ACR/EULAR criteria were assessed.

Results: 111 early PsA cases, 82 early RA cases and 29 other early arthritis controls (undifferentiated arthritis n=13, spondyloarthritis n=9, inflamm OA n=4, crystal arthritis n=3) were recruited. The sensitivity of the ACR/EULAR criteria (score ≥6) in classifying early RA was 91%. The specificity for the criteria when considering all other diagnoses was 53%. When considering the specificity only for PsA, it was lower at 48%. When comparing classification criteria for RA and PsA, none of the RA patients met the PsA criteria (either Moll&Wright or CASPAR), and only 1 of the other inflammatory arthritis patients fulfilled these criteria. The majority of PsA patients who met the RA classification criteria also met a PsA classification criteria.

ACR/EULAR criteria components (%)	Early PsA (n=111)	Early RA (n=82)	Other controls (n=29)
Synovitis of at least 1 joint	92	96	83
1 large joint only	46	50	45
2–10 large joints	53	46	59
1–3 small joints	23	11	28
4–10 small joints	41	37	35
>10 joints including 1 small	30	60	7
Neg RF and ACPA	94	20	79
Low positive RF or ACPA	4	10	14
High positive RF or ACPA	3	71	7
Duration ≥6 weeks	99	98	83
Raised CRP or ESR	48	77	63
	Early PsA (n=111)	**Early RA (n=82)**	**Other controls (n=29)**
Met ACR/EULAR criteria	52	92	28
Met CASPAR criteria	87	0	3
Met Moll&Wright criteria	80	0	3
Met ACR/EULAR criteria AND Moll&Wright criteria	39	0	0
Met ACR/EULAR criteria AND CASPAR criteria	43	0	0

Conclusion: The new ACR/EULAR criteria are sensitive at identifying early RA but are not specific when considering psoriatic arthritis. The majority of PsA patients met the criteria due to high joint counts despite having negative immunology. The ACR/EULAR criteria must be used with caution in an early arthritis population particularly when patients have evidence of skin or nail psoriasis.

Disclosure: L. C. Coates: None; **P. G. Conaghan:** None; **P. Emery:** None; **M. J. Green:** None; **G. Ibrahim:** None; **H. MakIver:** None; **P. S. Helliwell:** None.

2183

The CASPAR Criteria Can Be Used To Identify Early Psoriatic Arthritis. Laura C. Coates[2], Philip G. Conaghan[3], Paul Emery[3], Michael J. Green[4], Gamal Ibrahim[1], Helen MakIver[1] and Philip S. Helliwell[3]. [1]Bradford Hospitals NHS Trust, UK, Bradford, United Kingdom, [2]LIMM, Section of Musculoskeletal Disease, University of Leeds, Leeds, United Kingdom, [3]LIMM, Section of Musculoskeletal Disease, University of Leeds, UK, [4]York Hospital NHS Trust, York, UK

Background: The classification of psoriatic arthritis (CASPAR) criteria were derived from a large patient dataset and have been shown to be valid in classifying established PsA (sensitivity 91.4%, specificity 98.7%). However in the original study, only 5% of the cohort had early disease (less than 12 months disease duration). The aim of this study was to assess the sensitivity and specificity of the CASPAR criteria in classifying early psoriatic arthritis and to compare the results to that of the Moll & Wright criteria.

Methods: The CASPAR criteria were applied to cases of early PsA (less than 24 months symptom duration) and controls with other forms of early inflammatory arthritis who were all disease-modifying anti-rheumatic drug naive. Gold standard diagnosis was confirmed by a consultant rheumatologist. Proportions of cases and controls meeting the criteria were compared using McNemars test. Receiver operator characteristic (ROC) curve analysis was performed to identify the area under the curve (AUC) and optimal cut point in the CASPAR criteria for a diagnosis of early PsA. Logistic regression was performed to identify which features were associated with PsA.

Results: 111 early PsA cases and 111 early arthritis controls (RA n=82, undifferentiated arthritis n=13, spondyloarthritis n=9, inflamm OA n=4, crystal arthritis n=3) were recruited. The sensitivity of the CASPAR criteria (score ≥3) in classifying early PsA was 87.4% compared to 80.2% for the Moll and Wright criteria. The specificity for both criteria was 99.1%, with only 1 control patient fulfilling both criteria for PsA. The AUC for the CASPAR criteria was 0.991 compared to 0.896 for the Moll & Wright criteria. When considering different cut-points for the CASPAR criteria, the best cut-point for classification remained a score of ≥3 as in the original CASPAR analysis. Considering a score of ≥2 gave a higher sensitivity of 99.1% but resulted in a drop in specificity to 94.6%.

When considering the individual components of the CASPAR criteria, 96.4% of cases had current, previous or a family history of psoriasis with 84% having current psoriasis. Dactylitis and nail psoriasis were highly discriminatory as only 1 control patient each had these features. Regression analysis identified that psoriasis and a negative RF were the most important features to differentiate PsA, followed by nail psoriasis and the presence of dactylitis.

CASPAR Features of PsA	Cases (n=111)	Controls (n=111)
Current psoriasis (%)	84	4
Previous psoriasis (%)	6	1
Family history of psoriasis (%)	18	8
Nail psoriasis (%)	38	1
Negative Rheumatoid factor (%)	96	47
Dactylitis (%)	28	1
New bone formation (%)	2	0

Conclusion: The CASPAR criteria are more sensitive than the Moll & Wright criteria in classifying early PsA. Although the sensitivity is slightly lower than that in established disease, the CASPAR criteria are valid for use as inclusion criteria for early psoriatic arthritis trials.

Disclosure: L. C. Coates: None; **P. G. Conaghan:** None; **P. Emery:** None; **M. J. Green:** None; **G. Ibrahim:** None; **H. MakIver:** None; **P. S. Helliwell:** None.

Supppression of Both DKK-1 and SOST in a Mouse Model of Ankylosing Spondylitis Implicates the WNT-Signalling Pathway in the Linkage of Inflammation and Bony Ankylosis in Spondyloarthritis. Gethin P. Thomas[2], Ran Duan[3], Allison Pettit[4], Tibor Glant[1] and Matthew A. Brown[2]. [1]Rush University Medical Center, [2]The University of Queensland Diamantina Institute, [3]The University of Queensland Diamantina Institute, [4]University of Queensland Centre for Clinical Research

Ankylosing spondylitis (AS) is characterised by inflammation at entheses particularly in the spine and pelvis. Unlike in seropositive arthropathies in which erosion is the usual consequence of uncontrolled arthritis, in AS inflammation is followed by bony ankylosis. Although the inflammatory stages can be controlled medically, very little is known about the progression to the uncontrolled bone formation and no therapies are available that can slow this progression.

The proteoglycan-induced spondylitis model (PGISp) is a well-characterised mouse model of AS. Disease is induced by injections of a human proteoglycan extract, with axial inflammation evident after 9-weeks in the spine and sacroiliac joints. The resultant intervertebral disc destruction is followed by massive ectopic cartilage formation that eventually ossifies resulting in ankylosis, as demonstrated by toluidine blue staining and immunohistochemistry for collagen type I and osteocalcin.

To investigate the role of the Wnt-signalling pathway in this process, we studied the expression of two inhibitors of bone formation which act through the Wnt pathway, DKK-1 and SOST. Expression levels of both genes were significantly down-regulated in the spine and knee joints of PGISp mice. By week 12, DKK1 and SOST expression levels were reduced by 49% and 63% respectively in the spine, and by week 24 by 59% and 62% in peripheral joints, in PGISp compared with control mice ($P<0.05$).

We then undertook a microarray study comparing joints from control and PGISp mice. Unsupervised clustering clearly delineated between control and PGISp mice with 2600 genes being significantly differentially expressed between the two groups with 125 genes upregulated > 2-fold and 18 downregulated > 2-fold. In addition to genes involved in inflammation, and immune regulation, a significant over-representation of genes specifically involved in bone regulation including other members of the Wnt pathway was observed.

This study implicates the Wnt pathway as a likely mediator of the mechanism by which inflammation induces bony ankylosis in spondyloarthritis, raising the potential that therapies targeting this pathway may be effective in preventing this process.

Genetic and Clinical Correlates in African Americans with Ankylosing Spondylitis. Shervin Assassi[4], Julie T. Dang[3], Michael M. Ward[2], Joel D. Taurog[6], Michael H. Weisman[1] and John D. Reveille[5]. [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]NIH, NIAMS, IRP, Bethesda, MD, [3]Univ of Texas Health Science Center at Houston, [4]Univ of Texas Health Science Center at Houston, Houston, TX, [5]Univ Texas Health Sci Ctr, Houston, TX, [6]U-Texas SW Med Ctr, Dallas, TX

Background: There are few studies investigating disease characteristics of ankylosing spondylitis (AS) in African Americans (AA) because of the low prevalence of AS in this population. Furthermore, there are no previous studies, comparing disease severity between AA and white patients with AS.

The goal of this study was to compare clinical parameters in AA patients with AS to white patients and to examine associations of HLA-B, DRB1 and DQB1 alleles with AS in African Americans.

Method: Clinical data of 50 AA AS patients were derived from a cohort of 342 unrelated patients with AS. HLA class I and II alleles ascertained by DNA typing was performed on the AA AS patients as well as on 243 AA unaffected controls.

Results: AA AS patients had higher ESR, CRP, BASDAI, BASFI, and BASRI scores than white patients (Table). The difference in ESR, BASFI and BASRI remained significant despite correcting for disease duration, HLA-B27 status, gender, educational level and use of biologics. Despite higher disease burden, AA AS patients were less likely to be using biologic agents. This was especially pronounced in AA men with AS.

HLA-B27 negative African Americans with AS were older at disease onset, and had less frequently anterior uveitis compared to HLA-B27 positive AA patients.

HLA-B27 was present in 60% of AA patients, compared with 2% of AA controls. *HLA-B*4001* (B60) was the only other HLA-B allele significantly increased among patients. Marginally significant increases were also seen in *HLA-DRB1*1302* and *DQB1*0501*.

	AA-AS patients N=50	White-AS patients N=292	P-value	AA Controls N=263	P-value	OR
Education, college degree (%)	27.8	61.5	<0.001	NA	NA	NA
BASDAI(0–10)	4.85	3.48	0.009	NA	NA	NA
BASFI(0–100)	50.94	31.2	0.006	NA	NA	NA
BASRI (1.5–16)	9.26	6.56	<0.001	NA	NA	NA
CRP (mg/dl)	1.75	0.78	<0.001	NA	NA	NA
ESR (mm/hr)	32.8	14.5	<0.001	NA	NA	NA
Biologic use (%)	23	50.7	0.001	NA	NA	NA
HLA-B27 positivity (%)	62	84	<0.001	2	2.6×10^{-4}	71
B*4001 (%)	8	NA	NA	1	0.008	10
DRB1*1302 (%)	27	NA	NA	11	0.006	3
DQB1*0501 (%)	34	NA	NA	23	0.003	2.8

Conclusions: These data suggest that AA AS patients have more severe disease than whites as well as a lower frequency of HLA-B27. Also, the association with *HLA-B*4001* (B60) is seen in yet another ethnic group, in addition to whites and Asians.

Neutrophil Gelatinase Associated Lipocalin (NGAL) and Its Role in the Pathogenesis of Nephritis Induced by Pathogenic Antibodies. Rahul Pawar[4], Simona Gindea[4], Arlene T. Tieng[3], MIlena Pitashny[4], Leal Herlitz[5], Benjamin E. Levine[2], Thorsten Berger[6], Tak W. Mak[6] and Chaim Putterman[1]. [1]Albert Einstein College of Med, Bronx, NY, [2]Albert Einstein College of Medicine, Woodmere, NY, [3]Albert Einstein College of Medicine, Bronx, NY, [4]Albert Einstein College of Medicine, [5]Columbia-Presbyterian School of Medicine, [6]The Campbell Family Institute for Breast Cancer Research, Toronto, ON, Canada

Background: Anti-dsDNA antibodies are instrumental in the pathogenesis of lupus nephritis, although the mechanism by which these antibodies contribute to kidney damage has yet to be determined conclusively. We had found that treatment of mesangial cells with pathogenic anti-dsDNA antibodies induced the expression of multiple proinflammatory mediators known to be associated with lupus nephritis. One of the most highly induced genes was NGAL (AKA Lipocalin-2). NGAL is upregulated in response to a variety of inflammatory, ischemic, and other insults to the kidney, and in fact is a sensitive and early urine biomarker in several types of human disease.

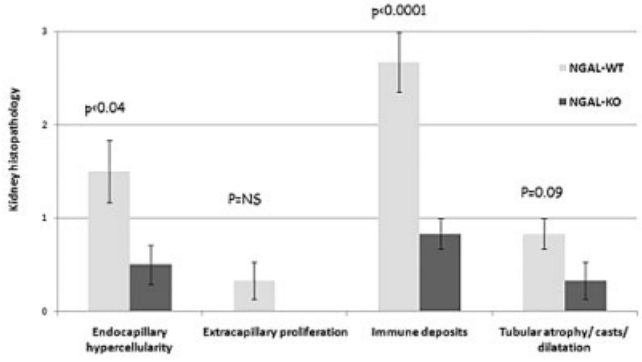
Purpose: To determine whether NGAL is expressed in the context of lupus nephritis, and investigate its role in the pathogenesis of renal injury induced by nephritogenic antibodies.

Methods: NGAL expression in serum, urine, and kidneys was analyzed serially in the MRL/lpr mouse lupus model. Nephrotoxic serum nephritis (NTS) was induced by passive transfer of preformed rabbit anti-mouse glomerular antibodies to C57Bl/6 wild type and NGAL deficient mice.

Results: With development of disease, MRL/lpr lupus mice displayed higher kidney NGAL expression than age-matched non-autoimmune mice. In addition, serum NGAL was significantly elevated in old MRL/lpr mice, as compared to young MRL/lpr, old MRL/+ and old BALB/c mice. Importantly, NGAL kidney expression in lupus mice significantly correlated with anti-dsDNA antibody titers and the renal pathology score. Significant elevations of kidney, serum and urine NGAL were observed as well in non-autoimmune mice following passive tranfer of rabbit anti-mouse glomerular antibodies and induction of NTS.

To determine if NGAL upregulation is instrumental in antibody mediated nephritis, we compared the severity of renal damage in C57Bl/6 NGAL knockout and wild type mice following induction of NTS. We found that NGAL deficient mice had significantly attenuated proteinuria, and improved renal histopathology (decreased endocapillarly proliferation and immune deposits) as compared to NGAL sufficient mice.

NGAL deficient mice display less kidney pathology following induction of NTS



Similarly, following NTS induction in non-autoimmune mice, NGAL injection significantly exacerbated nephritis (as assessed by increased proteinuria and more severe renal histopathology) and decreased survival. NGAL induced apoptosis via activation of caspase 3 and promoted the expression of inflammatory genes, in kidney cells in vitro and when injected to mice in vivo.

Conclusions: Nephritogenic antibodies upregulate kidney NGAL, which then appears to be instrumental in the pathogenesis of antibody mediated nephritis via promotion of inflammation and/or apoptosis. We are currently studying whether blocking NGAL may be a novel therapeutic approach for lupus nephritis.

Dependence of IFNα-Exaggerated Immunopathology and Clinical Disease on B Cells and BAFF in SLE-Prone NZM 2328 Mice. Noam Jacob[6], Shunhua Guo[6], Alexis Mathian[3], Michael N. Koss[6], Simona Gindea[2], Chaim Putterman[1], Chaim O. Jacob[5] and William Stohl[4]. [1]Albert Einstein College of Med, Bronx, NY, [2]Albert Einstein College of Medicine, [3]Hôpital de la Pitié-Salpêtrière, [4]Univ Southern California, Los Angeles, CA, [5]University of Southern California Keck School of Medicine, Los Angeles, CA, [6]University of Southern California Keck School of Medicine

Purpose: IFNα is a potent activator of innate and adaptive immunity, and it has been ascribed an important contributory role in SLE pathogenesis. It has previously been shown that administration of IFNα to pre-autoimmune (NZBxNZW)F1 (BWF1) mice promotes rapid development of virulent SLE, whereas identical administration to non-SLE-prone BALB/c mice has no deleterious effect. Given the known importance of B cells and BAFF to SLE, we evaluated the dependence of IFNα-exaggerated disease on B cells and on BAFF in the BWF1-derived SLE-prone NZM 2328 (NZM) mouse model.

Methods: Fully congenic B cell-deficient NZM.JHD mice and BAFF-deficient NZM.BAFFKO mice were generated through "speed congenics". At 2–3 months of age (when autoimmunity had not yet developed in wild-type [WT] NZM mice), NZM WT, NZM.JHD, and NZM.BAFFKO mice were injected i.v. with $1–1.5 \times 10^9$ viral particles of either a recombinant adenovirus (Adv) vector containing murine IFNα subtype 5 under the control of the CMV promoter/enhancer (Adv-IFN) or the identical Adv vector lacking the IFNα insert (Adv-control). Mice were assessed for serum levels of SLE-associated IgG autoantibodies by ELISA; spleen lymphocyte phenotype by flow cytometry; renal immunopathology by routine histology, immunofluorescence, and immunohistology; severe proteinuria (≥3+) by urine dipstick; and mortality.

Results: In response to Adv-IFN, NZM WT mice developed virulent disease, characterized by rapid development of proliferative GN (with wire loops and crescents), glomerular deposition of all IgG isotypes (IgG1, IgG2a, IgG2b, IgG3) and C3, and severe proteinuria followed shortly thereafter by death. In contrast, NZM.JHD mice developed neither renal immunopathology nor clinical disease, and NZM.BAFFKO mice, despite developing limited glomerular IgG and C3 deposition, also remained free of histological GN and clinical disease. Strikingly, similar T cell expansion and serum IgG responses were observed in WT and BAFF-deficient mice despite their disparate pathological and clinical responses, whereas numbers of activated B cells increased in WT mice but not in BAFF-deficient mice. Nonetheless, B cell, plasma cell, and T cell infiltration of the kidneys in Adv-IFN-treated WT mice was similar to that in WT mice treated with Adv-control. Its ability to promote SLE disease in WT mice notwithstanding, IFNα administration failed to drive the preferential expansion of CD4+ memory T cells that occurs during the natural course of disease, and glomerular infiltration of macrophages failed to associate with development of clinical disease.

Conclusions: Therapeutic targeting in SLE of BAFF and/or B cells in SLE could be successful even in states of IFNα overexpression. Moreover, our results document potentially important biological differences between IFNα-driven and spontaneous "natural" SLE disease.

IFNα Induced SLE in NZB/W Mice Is T Cell Dependent but Blockade of T_{FH} Does Not Prevent Disease. Zheng Liu[1], Ramalingam Bethunaickan[1], Weiqing Huang[1] and Anne Davidson[2]. [1]Feinstein Institute, [2]Feinstein Institute for Medical Research, Manhasset, NY

Background: IFNα accelerates SLE in several different murine models. The goal of these experiments was to investigate the mechanism for acceleration of lupus by interferon alpha (IFNα) in NZB/W F1 mice and to determine how excess IFNα influences the response to therapeutic agents.

Methods: Female NZB/W mice were given a single dose of IFNα adenovirus at 12 weeks of age. Starting the day of adenovirus injection, separate groups of mice were treated continuously with depleting anti-CD4 antibody, CTLA4Ig, anti-IL21, TACI-Ig or agonistic anti-4-1BB. Mice were monitored for autoantibodies and for proteinuria and some were sacrificed for analysis 50 days after adenovirus injection. Separate groups of mice received either anti-CD4 or combination CTX/costimulatory blockade at proteinuria onset and were sacrificed 4–6 weeks later.

Results: IFNα accelerated lupus in NZB/W F1 mice is associated with elevated serum levels of IgG2a and IgG3 anti-dsDNA antibodies, robust germinal center formation and accumulation of large numbers of short-lived plasma cells in the spleen. SLE onset is associated with an increase in B cell TLR7 expression, increased levels of BAFF and IL-6, and induction of T cells expressing IL-21. Although IFNα drives IL-6 production and a polyclonal increase in serum levels of IgG in a T-independent fashion, autoantibody induction and the development of nephritis are both completely dependent on CD4 T cell help. However, neither CTLA4Ig nor anti-IL-21 prevented proteinuria onset despite inhibiting T cell activation, germinal center formation, and production of IgG2a autoantibodies. This was due to failure to inhibit the generation of pathogenic IgG3 autoantibodies. In contrast, anti-4-1BB inhibited both IgG2a and IgG3 autoantibodies and prevented proteinuria onset. TACI-Ig did not prevent autoantibody formation, T cell activation or Ig deposition in the kidneys but still effectively delayed proteinuria onset by inhibiting renal chemokine production and preventing the activation of renal mononuclear cells. Remission could be induced with combination CTX/costimulatory blockade that depleted both IgG2a and IgG3 autoantibody producing short-lived plasma cells thereby decreasing autoantibody deposition in the kidneys.

Conclusions: IFNα induces short-lived plasma cells that produce autoantibodies in a T cell dependent manner through both germinal center and extrafollicular mechanisms. Prevention of germinal center formation is not sufficient to prevent SLE onset. Anti-4-1BB prevents both germinal center (IgG2a) and extrafollicular (IgG3) autoantibody formation and prevents SLE onset. Depletion of short-lived plasma cells producing the autoantibodies induces remission of disease. Surprisingly BAFF/APRIL blockade delays SLE onset without altering either autoantibodies or T cell activation; this is mediated via inhibition of the renal response to immune complex deposition but disease eventually ensues despite continuous treatment. These findings are relevant to interpreting results of recent clinical trials of biologic agents in SLE and suggest that the IFN signature confers a higher bar for therapeutic intervention.

Type I IFN-Dependent $CD86^{high}$ Marginal Zone-Precursor B Cells Are Potent T Cell Costimulators in the BXD2 Mouse Model of Lupus. John S. Wang[3], Qi Wu[3], PingAr Yang[1], Hao Li[1], Jun Li[1], John D. Mountz[2] and Hui-Chen Hsu[1]. [1]Univ Alabama at Birmingham, [2]Univ Alabama at Birmingham and VA Medical Center, Birmingham, AL, [3]Univ of Alabama at Birmingham

Background: We previously showed that type I-IFN producing plasmacytoid dendritic cells (pDCs) upregulated the expression of CD69 on $CD1d^{hi}CD21^{hi}IgM^{hi}CD23^{hi}$ marginal zone precursor (MZ-P) B cells in the spleens of lupus prone BXD2 mice. This action promotes the follicular migration of antigen delivering MZ-P B cells directly to the germinal centers (GC) in BXD2 spleen. In the present study, we determined if type I IFN can promote T-dependent antibody responses in BXD2 mice via its augmentation of the costimulatory function of MZ-P B cells.

Methods: Confocal imaging was used to determine the location of pDCs, MZ-Ps and CD4 T cells in the spleens of BXD2 and BXD2-*Ifnar*$^{-/-}$ mice. H&E staining of spleen and kidney was used to determine the presence of IgG^{bright} cells in BXD2 and BXD2-*Cd86*$^{-/-}$ mice. ELISA was used to determine serum levels of IFN-α, autoantibody, and NP-CGG- or NP-Ficoll-induced anti-NP_2 antibody titers. The level of type I IFN transcripts in the peripheral blood was determined by quantitative real-time PCR. [^{3}H]-thymidine was used to measure T cell proliferation.

Summary of the Results: There was increased clustering of pDCs located in the marginal sinus in the spleens of BXD2 mice, compared with B6 spleens. Consistent with this, RNA isolated from the peripheral blood of 3–6-mo-old BXD2 mice expressed >5-fold higher levels of *Ifna1*, *Ifna4*, and *Ifna11*, compared with those from B6 mice. Type I IFN receptor (IFNAR) deletion abrogated development of IgG^{bright} cell formation and suppressed a T-dependent but not T-independent antibody response in BXD2 mice. Type I IFN signaling induced the expression of CD86, but not CD80, on $CD1d^{lo}CD21^{lo}IgM^{lo}CD23^{hi}$ follicular (FO), $CD1d^{hi}CD21^{hi}IgM^{hi}CD23^{lo}$ marginal zone, and MZ-P B cells. However, MZ-P B cells demonstrated the highest expression of CD86 and the highest capacity for T-cell costimulation with intact IFNAR. In BXD2, but not BXD2-*Ifnar*$^{-/-}$ mice, MZ-P B cells clustered at the intra-follicular T-B border, an important immunological junction where GC formation is initiated. Both IFNAR and CD86 deletion

suppressed GC formation, autoantibody production, and IgG deposits in the kidney.

Conclusions Reached: Our study proposes that type I IFN can offer a new avenue by which T-dependent autoantibody responses are generated in BXD2 mice. First, type I IFN is critical in bringing MZ-Ps to the T-B border in the FO interior at the pre-GC stage. Second, type I IFN significantly increases the levels of CD86 on MZ-Ps, providing potent costimulation to CD4 T cells. Because pDCs are systemically circulated between the peripheral blood and the spleen, the present study exhibit important pathogenic and mechanistic implication for the IFN signature in the peripheral blood of human lupus patients.

Identification of a Genetic Locus on New Zealand Black Chromosome 1 Congenic Mice That Leads to Increased Generation of T Follicular Helper and TH17 Cells. Nafiseh Talaei[4], Yui-Ho Cheung[3], Carolina Landolt-Marticorena[4], Babak Noamani[1] and Joan E. Wither[2]. [1]Toronto Western Research Institute, [2]University Health Network, Toronto, ON, Canada, [3]University of Toronto, [4]University of Toronto, Toronto, ON, Canada

Purpose: Genetic loci on the New Zealand Black mouse chromosome 1 have been linked to the development of glomerulonephritis (GN) and production of anti-nuclear antibodies. Congenic mice in which a NZB chromosome 1 (c1) interval, extending from 35–106 cM, produce anti-nuclear antibodies and develop mild glomerulonephritis (GN). By creating mice with smaller overlapping NZB c1 intervals, we found that at least 5 genetic loci modulate autoimmunity in this interval. Notably, mice with a 70–100cM interval (c1(70–100cM)) developed high titre anti-dsDNA antibodies and severe GN resulting in death of ~40% of mice by 8 months of age, whereas those with a smaller 96–100 interval (c1(96–100)) produced lower levels of anti-nuclear antibodies and lacked renal disease. A prominent feature of c1(70–100) mice was increased numbers of large germinal centers, which can be seen in mice with expansion of T follicular helper cells (T_{FH}). The current study was undertaken to determine whether genetic loci on NZB c1 lead to expansion of T_{FH} and determine the cytokine profile of these cells.

Methods: c1(35–106cM), c1(70–100cM), and c1(96–100cM) congenic and B6 control mice were aged to 4 months. The proportion and number of splenic T_{FH} cells was determined by flow cytometry. To evaluate cytokine production, splenocytes were stimulated with PMA/ionomycin for 24 h and the supernatant assayed by Cytometric Bead Array or ELISA. IL-4, IFN-γ, or IL-17 producing cells were quantified by stimulating splenocytes with PMA/ionomycin for 4 h and examining intracellular cytokine expression by flow cytometry. Splenic sections were used to visualize the presence of T_{FH} and IL-17-producing $CD4^+$ T cells in the germinal centers using immunofluorescence microscopy.

Results: The proportion of T_{FH} ($CD4^+CD44^{high}CD62L^{low}CXCR5^+$) was significantly increased in c1(70–100) and c1(35–106) mice, with the highest levels seen in c1(70–100) mice. Splenocytes from all c1 congenic mouse strains demonstrated increased production of IL-21 and IL-17 following stimulation of PMA and ionomycin with the greatest increase seen in c1(70–100) mice and intermediate levels in c1(35–106) mice. Similar findings were observed for the proportion of IL-17-producing $CD4^+$ cells. No differences were seen for production of IL-4 and IFNγ between B6 controls and congenic mouse strains, although c1(70–100) and c1(35–106) mice had increased proportions of IFNγ-producing $CD4^+$ cells. Immunofluorescence microscopy confirmed the presences of increased numbers of T_{FH} cells in c1(70–100) and c1(35–106) mice, and revealed that the majority of IL-17 producing cells in c1(70–100) mice were located in the T cell zone and not the germinal center.

Conclusion: The findings suggest that a genetic polymorphism(s) on NZB c1 leads to expansion of T_{FH} and IL-17-producing T cells and that the levels of these cell populations are closely associated with the severity of disease.

Histone Deacetylase 9 Acts as an Epigenetic Switch in Aberrant CD4 T Cell Plasticity and PPAR-g Regulation in Systemic Lupus Erythematosus. Nilamadhab Mishra[3], Kailin Yan[5], Qiang Cao[6], Christopher M. Reilly[2], Jennifer Cann[4] and Benjamin A. Garcia[1]. [1]Princeton University, [2]Virginia Polytechnic Institute and State University and Edward Via College of Osteopathic Medicine, [3]Wake Forest Univ Health Scienc, Winston-Salem, NC, [4]Wake Forest University School of Medicine, [5]Wake Forest Unv Health Sciences, [6]Wake Forest UnvHealth Sciences

Pharmacological inhibition of histone deacetylase (HDAC) activity provides a therapeutic benefit in murine model of SLE, but clinical efficacy remains to be established. Understanding the role of individual HDAC that plays in lupus pathogenesis may lead to development of isoform specific HDAC inhibitors for better tolerability and efficacy in lupus. To identify which HDAC play significant role in lupus disease we first surveyed HDACs in splenocytes, T cells, kidneys in MRL/lpr mice and human lupus CD4+T cells. In this study, we report that HDAC9 is overexpressed in lupus prone MRL/lpr mice and human lupus CD4+T cells compared to controls. To explore the role of HDAC9 in pathogenesis of lupus, we generated MRL/lpr mice with systemic HDAC9 deficiency by genetic deletion approach. We demonstrated that MRL/lpr mice deficient with HDAC9 have decreased lymphadenopathy, splenomegaly, serum levels of high-affinity dsDNA autoantibodies, proteinuria, immunocomplex deposit in kidney, glomerulonephritis and increased survival. HDAC9 deficiency resulted Th2 polarization, decreased DNT cells, ICOS positive T effector cells, plasma cells and increased regulatory T cells in MRL/lpr mice. This epigenetic switch of CD4+T cells as a result of HDAC9 deletion are due to changes in lineage specific master regulator transcription factors of CD4+T effector and regulatory cells. HDAC9 deficient MRL/lpr mice have increased Foxp3, GATA3, and decreased Bcl6 expression. Increased expression of roquin, and miRNA101 contributed to the decrease expression of ICOS in HDAC9 deficient MRL/lpr mice. Upregulation of PPAR-g resulted decreased IFN-g, IL-12, iNOS, MCP1, CXCR3, CXCR4, CXCR5,CXCR6, and CXCR9 which resulted decreased inflammatory cells in kidney and peripheral tissues in HDAC9 deficient MRL/lpr mice. HDAC9 deficiency created changes in chromatin landscape selectively by increased site specific lysine histone acetylation in H3 (H3K9, H3K14 and H3K18) globally and locally in gene specific manner (IL-4, Foxp3, roquin and PPAR-γ genes). Together, our results unveil a epigenetic switch regulatory role of HDAC9 in aberrant CD4+ T cell plasticity in MRL/lpr mice. Therefore, targeting HDAC9 by a specific inhibitor may provide therapeutic benefit in lupus, possibly, with fewer side effects.Finally, measurement of levels of different histone modifications particularly site specific histone acetylations (H3k9, K14 and K18) may provide a biomarker for selecting lupus patients most likely to benefit from HDAC9 inhibitors.

Long-Term Benefit of Mycophenolate Mofetil for Treatment of Diffuse Cutaneous Systemic Sclerosis. Elizabeth Le[3], Fredrick M. Wigley[1], Ami A. Shah[2], Francesco Boin[2] and Laura K. Hummers[2]. [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins University

Background: No drug has been demonstrated to successfully control active diffuse cutaneous scleroderma, but immunosuppressive therapy, particularly if given at the early inflammatory phase of diffuse skin disease, could alter the natural course of the disease. In this observational study, we analyzed our Scleroderma Center's experience using mycophenolate mofetil (MMF) for treatment of diffuse skin disease and compared changes in skin score with data from historical controls.

Methods: Scleroderma patients in our Center's database started on MMF primarily for active skin disease were included in the analysis. Historical controls were obtained from 3 large multicenter randomized clinical trials (RCTs) of other medications (D-penicillamine (D-pen), Recombinant Human

Relaxin (Relaxin), and Oral Bovine Type I Collagen (Collagen) Trials). Data from these 3 RCTs were pooled and analyzed irrespective of treatment assignments because none of the primary and secondary outcomes differed in the active agent groups compared with the placebo or control groups. The overall mean change in modified Rodnan skin scores (mRSS) at 6 months for the Relaxin group, and at 12 months for the D-pen and Collagen groups were compared to those of our MMF cohort at 6 and 12 months, respectively, using Student's t-tests.

Results: Of 2571 patients in our database, 99 patients satisfied our inclusion criteria and were included in the primary analysis. Patients were mostly female (82%) of white (76%) or black (14%) race. The mean age at MMF initiation was 48.2 ± 11.2 years, and the mean scleroderma duration at MMF initiation was 21.8 ± 77.5 months with a median of 12 months (IQR 8–23). The median MMF dose was 3 grams daily (range 0.5–3 gm daily). The mean baseline mRSS of the MMF cohort (24.2 ± 9.5) was not significantly different from that of the Collagen group (26.1 ± 7.8, p= 0.08), but was significantly higher than the D-pen group (21.0 ± 8, p=0.006) and lower than the Relaxin group (27.3 ± 6.9, p=0.001). The mean mRSS of the MMF cohort progressively decreased over time and was statistically significant compared to baseline at 6 months (21.4 ± 10.6, p=0.0003), 9 months (17.5 ± 10.3, p<0.0001), and 12 months (17.3 ± 10.5, p<0.0001), but not at 3 months (23.4 +/− 10.1). Although the change in mean mRSS between the control population (Relaxin: −4.83 ± 6.99) and the MMF cohort (−3.07 ± 7.4) at 6 months was similar (p=0.06), a statistically significant improvement in mRSS was detected at 12 months in the MMF cohort (−7.55 ± 10.0) compared to controls (D-pen: −2.47 ± 8.6, p 0.0009; Collagen: −3.4 ± 7.12, p 0.001). Compared to baseline, at 12 months there was also a statistically significant improvement in quality of life (p<0.0001) as indicated by the Health Assessment Questionnaire disability index and in the general (p=0.006) and muscle (p=0.01) Medsger severity scores. Forced vital capacity and diffusing capacity remained stable at 1 year.

Conclusions: This study suggests that mycophenolate mofetil can be an effective therapy for active diffuse skin disease in scleroderma, but the full benefits of the drug may be evident after long-term therapy.

Imatinib Mesylate (Gleevec™) in the Treatment of Diffuse Cutaneous Systemic Sclerosis: Results of a One Year, Phase IIa, Single Arm, Open Label Clinical Trial. Robert F. Spiera[1], Jessica K. Gordon[2], Jamie Mersten[2], Cynthia Magro[3], Mansi Mehta[2], Horatio Wildman[3], Stacey Kloiber[2], Kyriakos A. Kirou[2], Stephen Lyman[2] and Mary K. Crow[2]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, [3]Weill-Cornell Medical College

Purpose: To assess the safety and effectiveness of imatinib mesylate in the treatment of diffuse cutaneous systemic sclerosis (dcSSc.)

Methods: In this phase IIa, open-label, single-arm clinical trial, 30 patients with dcSSc were treated with imatinib 400 mg daily. Patients were monitored monthly. Modified Rodnan Skin Scores (MRSS) were assessed every three months. Pulmonary function testing, chest-radiography, echocardiography, and skin biopsies were performed at baseline and after 12 months of treatment. Paired t-tests were performed to compare before and after treatment.

Results: Twenty-four of 30 patients completed 12 months of therapy. At baseline median age was 48 (range 18 to 71.) Eighty percent were female. Race/ethnicity: 73% white, non-Hispanic, 13% Hispanic, 13% African-American. Average disease duration was 3.4 ± 2.3 years. 53% had interstitial lung disease (ILD.) 30% were anti-Scl70 positive.

171 adverse events (AEs) with possible relation to imatinib were identified; 97.6% were grade 1 or 2. Twenty-four serious AEs were identified, occurring in 8 patients. Two SAEs were attributed as at least possibly related to study medication. There was one death during the course of the trial due to pneumonia with respiratory failure in a patient with severe ILD and pulmonary artery hypertension which was not felt to be medication related. The most common AEs were edema (80%), nausea (73%), myalgia (67%), and creatine kinase elevations (43%).

MRSS decreased by 6.6±4.7 points at 12 months (p=0.001.) This change was not evident at 3 months (Δ=−0.5, p=0.43), but was seen at 6 months (Δ=−4.5, p<0.001) and 9 months (Δ=−5.3, p<0.001.) This decline in MRSS was seen regardless of duration of disease. In the subgroup of early patients with <18 months from disease onset there was an improvement in the MRSS of 7.9±5.2 (p=0.006) at 12 months. The Forced Vital Capacity (FVC) improved from 82.9±21.1% predicted to 89.3±25.2%, (p = 0.008). The diffusion capacity (DLCO) remained stable from 78.0±22.9% to 83.5±29.2% predicted (p = 0.12.) Improvement in FVC was significantly greater in patients without ILD, 10.7% predicted v. 2.1% predicted (p=0.01.) Improvements were seen in the VAS global (Δ=−9.6, p<0.046), shortness of breath (Δ=−6.7, p=0.006), and pain (Δ=−18.7, p<0.001) as well as in the SF-36 mental component (Δ=−6.6, p=0.03.) Other health related quality of life measures remained stable. Physician global assessment improved from 6.3±1.6 to 4.1±2.3 (p<0.001.) Blinded dermatopathologic analysis demonstrated a significant decrease in skin thickness and improvement in skin morphology with decreased thickness of collagen bundles and increased interstitial space.

Conclusions: Patients with dcSSc treated for one year with imatinib demonstrated improvements in skin thickening and FVC in this single-group study. Although adverse events were common, most were mild to moderate in severity. The conclusions that can be drawn from this study regarding efficacy and safety are limited by the uncontrolled study-design. Further investigation of imatinib to treat dcSSc in a double-blind randomized placebo controlled trial is warranted. (ClinicalTrials.gov number, NCT00555581.)

Serious Complications and Mortality among 158 Patients with Systemic Sclerosis (SSc) in the Scleroderma Lung Study (SLS) Followed for up to 9 Years. Daniel E. Furst[4], Dinesh Khanna[3], Philip J. Clements[5], Keith Sullivan[1] and Donald P. Tashkin[2]. [1]Duke, Durham, NC, [2]UCLA, [3]University of California Los Angeles, Los Angeles, CA, [4]University of California Los Angeles Medical School, Los Angeles, CA, [5]University of California Los Angeles School of Medicine, Los Angeles, CA

Objectives: To examine the mortality and serious complications of SSc in SLS patients, in up to 9 yrs f/u.

Methods: Pt's: In 158 SSc patients(59% diffuse,41% limited), age: 47.9(1.0) yrs; dis dur:3.2(0.2)yrs;mRSS:14.7(0.9),All had alveolitis by lung HRCT of the lungs and/or BAL. FVC: 68(1.0) (SD) % pred;DLCO 47.2(1.1) % pred. Renal function was normal.They had entered the 1 yr, double-blind, study of cyclophosphamide vs. plac and then underwent usual clinical care for the ensuing 4.7(1.8) yrs, thru 11/2009 or until death or loss to f/u.

Methods: 12/08 to 11/09, all centers were repeatedly contacted regarding pt outcomes, to get complete data.Data requested were: mortality (date, cause),cancer (type, outcome), renal dialysis (dates),renal or lung transplantation (date, outcome),TPN (date, duration) and/ or requirement for oxygen (duration, continuous or intermittent use).Where needed, IRB approval and re-consenting was undertaken.

Results: 72% of pt's had complete or nearly complete data. Mortality data was available on 134 patients but complete date were available in 52 pt's.5 yr mortality was 31.4- and 23.2%-Plac(p=0.92).Cancer caused death in 2 pt's (colon and angiosarcoma) and occurred in 5 others (still alive) (breast, prostate, vulva, 2 unknown primary). 2 pts required total parenteral nutrition (2/108,1.8%),2 required dialysis(2/109,1.8%) and no pt's underwent renal transplantation. 22 pt's(32/109,20.3%) required at least intermittent oxygen therapy and 2 underwent lung transplantation (2/108, 1.9 %).

Conclusion: Among SSc pt's with alveolitis but generally moderate disease of moderate duration, mortality was surprisingly high over 9 yrs (27%). The need for oxygen occurred commonly (20.3%). Renal dialysis,TPN and lung transplantation were noted(1.8–1.9%).Cancers were not those usually associated with cyclophopsphamide or immunosuppressive therapy, despite f/u for up to 9 yrs.

Table 1. Demographics

Diffuse SSc	59%	mRSS (max: 51)	14.7 (1.5)
Age (yrs)	47.9 (1.4)	Alveolitis	100%
Disease Duration (yrs)	3.2 (0.3)	FVC (% predicted)	68.1 (1.5)
		DLCO (% predicted)	47.2 (1.6)

Productivity at Home and Work Place in Scleroderma—Analysis from the UCLA Scleroderma Quality of Life Study. Manjit K. Singh, Philip J. Clements, Daniel Furst, Paul Maranian and Dinesh Khanna. UCLA, Los Angeles, CA

Objective: Scleroderma (SSc) is associated with functional disability and poor quality of life. This study examines the productivity of SSc outside and within the home in a large observational cohort.

Methods: 162 patients completed the Work Productivity Survey (Osterhaus, J., Arthritis Research and Therapy 2009) at baseline. Patients indicated whether or not they were employed outside of the home, how many days /month they missed work (employment or household work) due to SSc, how many days/month productivity was decreased ≥ 50%, and how many days per month where SSc interfered with work. Patients also completed other patient-reported outcome (PRO) measures (HAQ-DI, Functional Assessment of Chronic Illness Therapy (FACIT), and CESD). We developed binomial regression models to assess the predictors of days missed at home per month or days missed outside the home per month. The covariates included: type of SSc, education, physician global assessment, patient global assessment, HAQ-DI, FACIT-Fatigue and CESD.

Results: The average age of patients was 51.8 years, 81% were female, 69% were Caucasian, 51% had limited SSc, 41% had diffuse SSc, and 7% had overlap syndrome. Sixty patients (37%) were employed outside of the home, with a majority employed in non-manual work (68%). Employed patients reported missing 2.6 days per month of work (absenteeism), had 2.5 days per month productivity reduced by half (presenteeism), and had 2.2 days per month where SSc interfered with their work (Table). Of the 102 patients that were not employed outside of the home, 39.4% were unable to work due to SSc related health problems, 12.1% were homemakers, 28.3% were retired and 5.05% were students. Patients missed an average of 8 days of housework per month, had home productivity reduced by more than 50% in 6 days per month, and had 4 days where SSc interfered with household work.

In the regression models, patients with lower education and greater physician assessment of disease severity were more likely to miss work outside the home. Type of SSc (limited or diffuse) did not influence productivity but those with high HAQ-DI were more likely to miss work at home.

Table 1.

Productivity in the work place†	
Work days missed (absenteeism), mean (SD)	2.6 (6.3)
Days with work productivity reduced by ≥50% (presenteeism), mean (SD)	2.5 (6.1)
Days of SSc interference with work productivity, mean (SD)	2.2 (2.9)
Productivity at home	
Household work days missed, mean (SD)	8 (10.6)
Days with household work productivity reduced by ≥50%, mean (SD)	6 (9.7)
Days with family, social, leisure activities missed, mean (SD)	2.5 (5.5)
Days with outside hired help due to SSc, mean (SD)	2 (5.0)
Days of SSc interference with household work productivity, mean (SD)	4 (3.4)

†Employed patients only. n = 60.

Conclusion: SSc has a major impact on productivity at home and at work. Nearly 40% of patients are disabled due to their SSc. Education, physician assessment and HAQ-DI were independent predictors of low productivity.

Results of the Delphi for EULAR/ACR Classification Criteria Working Group in Systemic Sclerosis. Jaap Fransen[4], Sindhu R. Johnson[5], Alan Tyndall[6], Murray Baron[1], Marco Matucci-Cerinic[8], Frank van den Hoogen[2], Janet E. Pope[3] and Dinesh Khanna[7]. [1]Jewish General Hospital, Montreal, QC, Canada, [2]Sint Maartenskliniek, [3]St Joseph Health Care London, London, ON, Canada, [4]The Radboud University Nijmegen Medical Centre, [5]Toronto Western Hospital, Toronto, ON, Canada, [6]University of Basel, [7]University of California Los Angeles, Los Angeles, CA, [8]University of Florence, Firenze, Italy

Background: Classification criteria for Systemic Sclerosis (SSc) are being updated as the previous ACR criteria did not regard all patients with limited cutaneous SSc, and did not include autoantibodies or nailfold capillaroscopy as items.

Objective: To select a set of items using Delphi procedures and the Nominal Group Technique (NGT) to be regarded for the classification of SSc.

Methods: Potential items for revising classification criteria for SSc were identified through two independent internet based consensus exercises, performed by the Scleroderma Clinical Trials Consortium (SCTC) and the EULAR scleroderma trials and research group (EUSTAR). The two first-round item lists were collated with removal of redundancies to a list of 168 items. This list was subjected to a Delphi procedure in three rounds using appropriateness scores on a 1–9 scale (1=completely inappropriate and 9=completely appropriate) and a consensus meeting using NGT.

Results: Round 1: 105 experts participated rating each of the 168 items. Items with a median score <3 were removed, resulting in a list of 102 items. Round 2: These items were again rated for appropriateness and subjected to a consensus meeting using NGT by European and North American SSc experts (n=16), resulting in 24 items. Round 3: The participants then individually scored each of the 24 items in a last Delphi round, using an appropriateness score (1–9) and by ranking their 10 favorites (top ranking 1–10). Items scored as relevant (70% of ratings in 7–9) were kept and ranked according to their top ranking while items scored as irrelevant (70% of ratings in 1–3 but less than 30% in 7–9) were discarded. This resulted in a list of 12 items that were kept (Table 1) and 12 'indecisive' items, while no item was scored as irrelevant. The indecisive items were: DLCO, FVC, dysphagia, esophageal dilatation, reflux disease, telangiectasia, finger flexion contracture, tendon friction rubs, ANA, anti-PMSCL autoantibodies, PAH, puffy fingers, finger pulp loss, calcinosis and cardiomyopathy.

Table 1.

Item	Appropriateness score (median)	TOP score	Rank
Positive anti-topoisomerase-1	9	73%	1
Presence of scleroderma	9	70%	2
Abnormal nailfold capillary pattern	9	67%	3
Positive anti-centromere	9	62%	4
Positive antiRNA polymerase III	8	43%	5
Finger tip ulcers or pitting scars	8	34%	6
Raynauds phenomenon	7	33%	7
Interstitial lung disease/pulmonary fibrosis	7	28%	8
Renal crisis	8	27%	9

Conclusion: The Delphi and NGT resulted in a set of items that will be assessed for their discriminative ability in a prospective study. Prospective data on SSc and 'mimickers' will be collected to yield further item reduction and development of new classification criteria for SSc.

2197

Antinuclear Antibody Screening in Systemic Sclerosis. Donna Rose Swistowski[2], Nicole Saddic[3], Victoria K. Shanmugam[1] and Virginia D. Steen[4]. [1]Georgetown University Division of Rheumatology, Immunology, and Allergy, Great Falls, VA, [2]Georgetown University Division of Rheumatology, Immunology, and Allergy, Bethesda, MD, [3]Georgetown University Hospital Department of Medicine, [4]Georgetown University Medical Center, Washington, DC

Purpose: Scleroderma specific antinuclear antibodies (SScAB) are helpful predictors of disease manifestations, clinical course and outcome in scleroderma. Historically, immunofluorescence (IF) antinuclear antibody (ANA) testing was the gold standard method for ANA detection, and the American College of Rheumatology continues to recommend IF for evaluation of ANA. Many commercial labs have recently adopted newer, automated, non-immunofluorescence methods (NEW ANAs), such as EIA (enzyme immunoassay) or immunobead methods to evaluate for the presence of antinuclear antibodies. These new techniques rely on a limited panel of autoantigens in the assay.

The purpose of this study was to evaluate ANAs and SScAB results performed through commercial labs, using both NEW ANA detection techniques and traditional IF, in a consecutive cohort of scleroderma patients seen in the Georgetown Scleroderma Clinic over a one year period.

Methods: Between June 2008 and June 2009, 241 scleroderma patients were evaluated. Patient charts were reviewed for results of NEW ANA, IF-ANA, isolated nucleolar ANA pattern (NuANA), and the SScAB profile including anticentromere (ACA), anti-topoisomerase (Scl-70), U1 RNP, and RNA polymerase III (Pol III) antibodies.

Results: The results of this study are summarized in table 1. NEW ANA results were available in 58 patients with 28 patients (48%) testing negative. Of these 28 patients, 22 had either positive IF-ANA or a SScAB recorded: IF-ANA only (n=7), NuANA (n=6), Pol III (n=7), SSB (n=1), U1 RNP (n=1). In the patients with a positive NEW ANA (n=30) the NEW ANA successfully detected all patients with ACA (n=4), Scl-70 (n=13), UI RNP (n=6), and SSA (n=1) antibodies. A positive NEW ANA additionally identified Pol III (n=1), NuANA with a + SSA (n=3), and nonspecific ANA (n=2). However, the NEW ANA failed to identify the NuANA, Pol III antibodies, and other IF-ANA patterns in a significant number of patients (20/22 vs. 6/30, $p<0.0001$).

The remaining 183 SSc patients did not have NEW ANA testing available. Of these patients, 156 (85%) had positive SScABs or an IF-ANA. ACA was present in 22.4%, Scl-70 in 25%, and U1 RNP in 9.6%. This accounts for 57% of patients who we predict would be identified with the NEW ANA assay. However, patients with other antibodies including Pol III (10.2%), NuANA (19.2%), and nonspecific ANA patterns (13.5%), account for 40% of the scleroderma patients in our population, and we predict these patients would not be identified using NEW ANA assays.

Conclusions: Immunofluorescence ANA should be performed in all patients in whom there is clinical suspicion for scleroderma. Physicians should remain skeptical of negative ANAs in patients with clinical evidence of scleroderma.

Table 1. NEW ANA test results on 52 patients with corresponding ANA IF data or SScABs

ACA	NEW ANA Positive (n=30)		NEW ANA Negative (n=22)	
	4		0	
Scl-70	13		0	
UI RNP	6		1	
SSA/SSB	1		1 (+SSB)	
NuANA	3 (all+SSA)	20%	6	91%
Pol III	1		7	
ANA IF	2		7	

*$p<0.0001$.

Association between Vascular Physical Examination Findings and Angiographically-Detected Arterial Lesions in Subjects with Large Vessel Vasculitis. Peter C. Grayson[4], Gunnar Tomasson[3], David Cuthbertson[11], Simon Carette[9], Gary S. Hoffman[6], Nader A. Khalidi[10], Carol A. Langford[5], Carol McAlear[4], Paul A. Monach[1], Philip Seo[7], Kenneth J. Warrington[8], Steven R. Ytterberg[8] and Peter A. Merkel[2]. [1]Boston University, Boston, MA, [2]Boston University School of Medicine, West Newton, MA, [3]Boston University School of Medicine, Boston, MA, [4]Boston University School of Medicine, [5]Cleveland Clinic Foundation, Cleveland, OH, [6]Cleveland Clinic Foundation, Pepper Pike, OH, [7]Johns Hopkins Bayview Medical Center, Baltimore, MD, [8]Mayo Clinic, Rochester, MN, [9]Toronto Western Hospital, Toronto, ON, Canada, [10]University of Hamilton, Hamilton, ON, Canada, [11]University of South Florida

Purpose: The vascular physical examination (PE) to assess for pulses, bruits, and systolic blood pressure (SBP) readings is considered essential in the clinical evaluation of patients with large vessel vasculitis (LVV), including Takaysu's arteritis (TAK) and giant cell arteritis (GCA). This study examined the relationship between findings on PE and angiographic-detected arterial lesions in subjects with established LVV.

Methods: 100 subjects (TAK=68, GCA=32) enrolled in a longitudinal, observational cohort underwent standardized PE and magnetic resonance

angiography of the aorta and its primary branches. Analysis was restricted to bilateral common carotid, subclavian, and axillary arteries. Sensitivity and specificity was calculated for the association between PE findings (absent pulse, bruit, and inter-arm SBP difference) and angiographic lesions defined as stenosis, occlusion, or aneurysm. To determine if PE findings accurately localized arterial lesions, a PE finding (e.g. left carotid bruit) was compared to angiogram findings in both the anatomically correlated vessel (e.g. left carotid artery) and in all vessels within the region (carotid or subclavian or axillary arteries).

Results: Participants were predominantly female (92%), Caucasian (87%), and had mean ages of 40 years (TAK) and 69 years (GCA). 67% had at least one PE abnormality: absent pulse (41%-TAK, 38%-GCA), bruit (54%-TAK, 28%-GCA), or ≥ 15 mmHg SBP difference (52%-TAK, 29%-GCA). Lesions in any of the carotid, subclavian, or axillary arteries were detected in 75% of subjects (82%-TAK, 59%-GCA). Individual PE findings had poor sensitivity (range 14–51%) and good-excellent specificity (range 72–98%) to detect arterial lesions. Sensitivity improved (range 52–71%) and specificity worsened (range 59–86%) if *any* of the 3 different PE maneuvers considered in combination were abnormal. Sensitivity worsened (range 6–30%) and specificity improved (range 88–100%) if *2 or more* of the PE findings were abnormal or if individual PE findings were compared to regional vessels without imposing single vessel anatomic correlation.

Physical Exam Finding	Angiogram Comparison Vessel	No.	Sensitivity	Specificity
Individual Exam Findings with Anatomic Correlated				
Absent Pulse				
Common Carotid	Ipsi CC	179	14	98
Radial	Ipsi SA	193	40	94
Bruit				
Common Carotid	Ispi CC	179	45	82
Subclavian	Ispi S	191	27	91
Blood Pressure				
BP Difference	Bilat SA	96	51	72
Any 1 Abnormal Exam Finding				
Carotid Bruit No Carotid Pulse	Ipsi CC	179	52	80
Subclavian Bruit No Radial Pulse	Ipsi SA	195	54	86
Subclavian Bruit BP Difference	Ipsi SA	195	65	59
No Radial Pulse BP Difference	Ipsi SA	195	63	61
Subclavian Bruit BP Difference No Radial Pulse	Ipsi SA	195	71	59

Physical Exam Finding	Angiogram Comparison Vessel	No.	Sensitivity	Specificity
Individual Exam Findings with Regional Correlated				
Absent Pulse				
Common Carotid	Ipsi CC/SA	195	7	99
Common Carotid	Bilat CC/SA	196	7	100
Bruit				
Common Carotid	Ipsi CC/SA	194	30	88
Common Carotid	Bilat CC/SA	195	27	91
Subclavian	Ipsi CC/SA	195	30	91
Subclavian	Bilat CC/SA	196	29	98
2 or More Combined Abnormal Exam Findings				
Carotid Bruit No Carotid Pulse	Ipsi CC	179	7	100
Subclavian Bruit No Radial Pulse	Ipsi SA	195	14	98
Subclavian Bruit BP Difference	Ipsi SA	195	14	93
No Radial Pulse BP Difference	Ipsi SA	195	25	95
Subclavian Bruit BP Difference No Radial Pulse	Ipsi SA	195	6	99

Key: Ispi=Ispilateral, Bilat=Bilateral, CC=Common Carotid, SA=Subclavian/Axillary, S=Subclavian

Conclusion: In subjects with established LVV, vascular PE findings have low sensitivity but high specificity to detect arterial disease. Abnormal PE findings are highly associated with the presence of arterial lesions, but normal PE findings do not rule out the possibility of arterial disease. Even when considering PE findings in combination, sensitivity is still inadequate to rule out arterial lesions. Specificity improves when PE findings are evaluated in association with a broader region of arterial lesions rather than a specific anatomically correlated vessel, suggesting that PE findings do not always accurately localize disease. While valuable in the assessment of arterial disease in LVV, the PE should not form the sole basis of assessment and should be supplemented by angiography.

Sex, Age, and Birth Cohort Effects on Incidence of Giant Cell Arteritis.

Maureen Dubreuil[1], Hyon K. Choi[2], Yuqing Zhang[2] and Yanyan Zhu[2]. [1]Boston Medical Center, Boston, MA, [2]Boston University School of Medicine, Boston, MA

Purpose: Giant Cell Arteritis (GCA) is a common vasculitis affecting adults. Studies have shown that incidence of GCA increases with age and is higher among women than men. Several previous studies have also reported a secular trend of increasing GCA incidence. However, these data may be confounded by birth cohort effects. The purpose of this study was to estimate effect of age, birth cohort (birth year) and period (year of diagnosis) on the incidence of GCA in a UK general population cohort.

Methods: Incident cases of GCA between 1990 and 2008 were identified from The Health Improvement Network (THIN), an electronic medical record database of 6.3 million patients from general practices across the United Kingdom. Incident cases of GCA were defined by physician diagnosis of GCA and use of glucocorticoids in 1995–2008. An incident GCA case was defined as a subject aged over 50 years with first diagnosis of GCA following at least one year of enrollment in the database. Glucocorticoid use was defined as two prescriptions for oral glucocorticoids: the first within 6 months of GCA diagnosis date, and the second within 6 months of the first. Crude incidence rates were calculated as the number of new GCA cases divided by total person-years. Age- and gender-specific incidence rates of GCA were plotted, as were relative incidence rates of GCA for age, birth cohort (birth year) and period (year of diagnosis), using age-period-cohort spline curves, based on Poisson-type likelihood. Incidence rate ratios were estimated for women compared with men and for later versus earlier birth cohorts, using proportional hazards models.

Results: Of 1.7 million subjects (men: 47.7% women: 52.3%) aged 50–90 years old in 1995–2008, 2715 subjects developed incident GCA. The crude incidence rate was 1.3 and 3.0 cases per 10,000 person-years in men and women, respectively. The incidence rate of GCA increased with age until age 80, then decreased (Figure). For every 5-year age increment, incidence of GCA increased by 41% (RR: 1.41, 95% CI: 1.38–1.44). Incidence of GCA was 1.98 times higher in women than in men (RR=1.98, 95% CI: 1.82–2.16). Furthermore, the incidence was higher for later birth cohorts, with rate ratio of 1.49 per 10-year interval (95% CI 1.38–1.60). Incidence rate of GCA did not vary materially over the study period.

Conclusion: In this UK general population, there was a significant birth cohort effect on GCA incidence, independent of age and calendar year at diagnosis. After adjusting for the birth cohort effect, incidence rates and age-gender effects remained similar to those reported previously. This is the first study to demonstrate a birth cohort effect on incidence of GCA, suggesting the presence of risk factors to which individuals born more recently were exposed. Further research should aim to identify factors that contribute to these changes in GCA incidence.

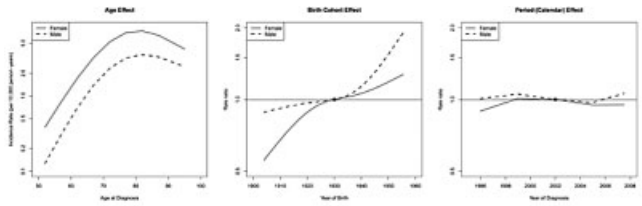

Figure. Age, birth cohort and period effects of giant cell arteritis.

Identification of JAK1 as a Candidate Inflammatory Signalling Pathway by Genome-Wide Expression Profiling in Monocytes from Patients with Behcet's Disease.

Haner Direskeneli[3], Joseph J. Boyle[1], Filiz T. Ozdemir[3], Vuslat Yilmaz[2], Emel Eksioglu-Demiralp[3], Dorian Haskard[1] and Guher Saruhan-Direskeneli[2]. [1]Cardiovascular Sciences Centre, Imperial College, London, United Kingdom, [2]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [3]Marmara University, School of Medicine, Istanbul, Turkey

Purpose: Both innate and adaptive immune responses are observed in Behcet's Disease (BD). We aimed to obtain a global view of the immune/inflammatory activity in BD compared to Familial Mediterranean Fever (FMF), a classical, autoinflammatory disease.

Method: Twenty-eight patients with BD (F/M: 9/19, mean age: 33.4 years), 13 with FMF (F/M: 9/4, mean age: 30.4 years) and 21 healthy controls (HC) (F/M: 11/10, mean age: 30.6 years) were enrolled to the study. Whole-genome microarray profiling was performed with human U133 (Plus 2.0) microarrays on an Affymetrix platform using CD14+ monocyte and CD4+T lymphocyte subsets isolated by microbeads from peripheral blood mononuclear cells. Data was analysed with Genespring (Version 10.0) software. RT-PCR was performed for the validation of JAK1 expression.

Results: Among 28792 transcripts analysed, in CD14+ monocytes, 1188 transcripts reached a significant difference level with a minimum 2-fold difference observed in 279 genes. In CD4+T-lymphocytes, 2880 transcripts showed significant difference with at least 2-fold difference in 109 genes. In CD14+ monocytes of BD patients, oxysterol binding protein-like-8 (OSBPL8)(3.8 fold), cell-division-cycle-27 homolog (S. cerevisiae) (CDC27)(3.1 fold), myeloid/lymphoid or mixed-lineage leukemia-3 (MLL3)(3.1 fold), PHD finger protein-3 (PHF3)(2.9 fold) and BCL2-associated × protein (BAX)(2.7 fold) had the highest expressions. However,

in principal component analysis, Januse-kinase-1 (JAK1)(2.6 fold) and metallothionein 1X, (MT1X)(2.1 fold) appeared to be the dominant molecules associated with immune/inflammatory signalling pathways. Validation by RT-PCR also showed an increased JAK1 expression (fold increase compared to GAPDH: BD: 9.5 vs FMF: 5.1 vs HC: 7.3, p=0.07, BD vs FMF: p=0.04).

Discussion: Whole-genome microarray analysis demonstrated a selective activation of BD monocytes compared to FMF, suggesting their critical role between innate and adaptive immune responses. Activation of JAK1 through various cytokines such as IL-2, IL-6, IL-15 and interferon-gamma may be one of the dominant signaling pathways driving inflammation in BD.

Scarlato Hospital, Scafati, Salerno, Italy, Italy

Objectives: this is the first randomized controlled trial comparing RTX with the best available treatments (i.e., cyclophosphamide, azathioprine, high-dose steroids, or plasma exchange) in MC patients with glomerulonephritis, or peripheral neuropathy or skin ulcers, where antiviral therapy failed or was contraindicated by the expert clinician. Primary end point was to evaluate the survival on treatment (due to lack of treatment failure) on RTX in comparison with the best available treatment options (as chosen by expert clinicians) on major manifestations of MC.

Patients and Methods: 59 MC patients were enrolled; 30 patients were randomized in the arm A (best available treatments), 10 nephritis, 3 skin ulcers and 17 peripheral neuropathy, while 29 patients were randomized in the arm B (RTX), 7 nephritis, 3 skin ulcers and 17 peripheral neuropathy. RTX 1 g × 2 at day 1 and 15 was administered with standard premedication. Patients were followed for 24 months. Rescue arm with RTX for non-responders to the best available treatment was permitted in any time, while withdrawn due to RTX treatment failure was introduced at the 6th month after RTX, if no response was observed. Finally, RTX retreatment was given at the time of clinical relapse.

Results: Fifty-seven patients were available for data analyses. Patients were HCV positive in 53/57 (93%), they were 46 female and 11 male, and median age was 65 years (range 37–79 years). No differences between the two randomized groups were observed in terms of age and sex distribution.

Treatment chosen in group A were: high-doses of corticosteroids in 17/29 (58.6%), plasmapheresis in 5/29 (17.2%), cyclophosphamide in 4/29 (13.8%) and azathioprine in 3/29 (10.3%).

Average survival time on treatment was (mean±SE) 76.9 ± 24.2 days on group A, while it was 529.1 ± 40.5 days in group B (p<0.0001, log Rank test). Survival rate on treatment in group B vs group A was 93% vs 14% at month +3, 3% vs 71% at month +6, 3% vs 64% at month +12, and 61% vs 3% at month +24.

When considering the following variables in a multivariate regression model (age, sex, baseline BVAS, and the baseline clinical manifestations, as defined as skin ulcers, and/or glomerulonephritis and/or neuropathy, and the treatment group), only the assigned treatment group was selected and significantly associated with the survival time on treatment (p=0.0001, OR: 7.9; 95% CI: 3.6–17.2), thus confirming the association between the survival on treatment and the assignment to the rituximab group.

Conclusion: RTX is the best choice in MC patients with active major involvements (i.e. renal, neurologic or cutaneous), when antiviral therapy failed or is contraindicated. The RTX 1 g × 2 treatment schedule was alternative to the standard hematologic regimen of 4 weekly 375 mg/m^2 infusions.

2202

A New Polymorphism of the Fibroblast Growth Factor (*FGF*)*23 Gene:* A Promising Predictor of Coronary Damage in Kawasaki Disease (KD). Fernanda Falcini[1], Laura Masi[3], Francesco Franceschelli[3], Gigliola Leoncini[3], Serena Capannini[1], Francesco La Torre[4], Giuseppina Calcagno[4], Marco Matucci Cerinic[2] and Maria Luisa Brandi[3]. [1]Department of BioMedicine, Section of Rheumatology, Transition Clinic, University of Florence, Florence, Italy, [2]Department of BioMedicine, Section of Rheumatology, Transition Clinic, University of Florence, Florence, Italy, [3]Department of Internal Medicine, Metabolic Bone Diseases Unit, University of Florence, Italy, [4]Department of Paediatrics, Rheumatology Unit, University of Messina

Background: Vascular endothelial cell damage is crucial in KD, acute systemic vasculitis complicated by arterial dysfunction. Intimal thickening and fibrosis are reported in KD coronary arteries. Several pts even timely treated with IVIG may develop coronary artery abnormalities (CAA) with risk of ischemic heart disease. Phosphatonins are new hormones involved in phosphate homeostasis and bone mineralization. FGF23, the master phosphatonin, acts through FGFr1 present in vasculature and heart. *Fgf23* knockout mice develop ectopic calcifications and vascular and heart damage assuming that FGF23 contribute to the development of vascular injury.

Aims: 1.To measure the intact FGF23 serum levels in KD pts. 2.To assess the association between FGF23 levels and CAA 3.To screen KD pts for *FGF23* gene mutation looking at a possible role of FGF23 allelic variants in cardiac damage.

Patients: 95 KD pts (58 M,37F, median age 30.5 mths) after informed consent entered the study. 30 age-sex matched healthy children acted as controls All pts had received IVIG and ASA. In all, at baseline and at study entry lipid profile (cholesterol, HDL, LDL, tryglicerides) was evaluated.

Methods: Serum intact FGF23 level was measured, using an ELISA assay (Immunotopics Inc. San Clemente, CA, USA).Genomic DNA was extracted from peripheral blood and the 3 *FGF23* exons, including the intron-exon boundary regions, were PCR-amplified and analyzed on ABI Prism 3100 Genetic Analyzer (Applied Biosystems, Foster City, CA.

Results: KD pts have higher FGF23 serum levels than controls (72+/−40SD vs 12,3+/−3.2SD pg/ml. Student's T Test: p=0.01).DNA analysis shows a new C insertion in the intronic region between −36 and −37 nucleotide close to the exon 2 (rs3832879: NM_020638.2:c.212-37_212-36insC).All pts (18M,10F) with polymorphic allelic variant have CAA (aneurysms, dilatations), and display higher levels of serum FGF23 than pts without polymorphic site (120+/− 40 vs. 38.2+/− 5).

Conclusions: From our preliminary data the segregation of FGF23 genotype with the CAA advocates a possible functional role of the new polymorphism in KD coronary artery injury. These data point to FGF23 gene polymorphism and serum FGF23 levels as two potential predictors of high

risk of CAA. So far, no individual genotype data are available for FGF23 gene polymorphism.

2203

Mepolizumab, a Humanized Anti-IL-5 Antibody, Has Steroid-Sparing Potential in Churg-Strauss Syndrome. Frank Moosig[1], Kristina Butherus[1], Bernhard Hellmich[2] and Wolfgang L. Gross[1]. [1]University Hospital Schleswig Holstein & Klinikum Bad Bramstedt, [2]University of Tübingen & Kreiskrankenhaus Plochingen

Background: In Churg-Strauss-Syndrome (CSS), a condition closely related to the hypereosinophilic syndrome (HES), high doses of glucocorticoids (GC) are often needed to control activity despite additional immunosuppression. Currently, severe cases demand treatment with cytotoxic agents such as cyclophosphamide and 15–20% of patients are refractory to standard therapy. Therefore, new targeted therapeutic options are needed. Interleukin-5 (IL-5) is the major inductor of hypereosinophilia and eosinophils (EO) are believed to mediate organ damage. In HES, a steroid-sparing effect of mepolizumab has been demonstrated. Therefore, targeting IL-5 in CSS is reasonable.

Methods: In this phase II trial, we included 10 CSS patients with active disease (Birmingham vasculitis activity score [BVAS] >3) under standard therapy. After stopping previous immunosuppressive medication, except GC, 750 mg mepolizumab was administered IV every 4 weeks for a total of 9 infusions. GC were tapered, as feasible, without loss of disease control. Methotrexate was initiated after the last mepolizumab infusion.

Results: The initial median BVAS was 9 (range 4–15), the GC dose 20 mg/d (range 12.5–70 mg/d) and the EO count 205/μl (range 13–4867/μl). One patient was excluded from the study because of non-compliance after 3 infusions. All 9 remaining patients reached remission (BVAS 0 and GC dose <7.5 mg/d prednisolone). GC dose could be reduced in all 9 patients (week 32: 4.5 mg/d [range 4–12.5 mg/d]). BVAS and EO counts improved significantly (week 32: BVAS 0 (0 ± 0), $p=0.0057$; EO 18/μl (range 4–64.8/μl), $p=0.0059$). No severe adverse events attributable to mepolizumab occurred and the overall safety profile was good. After stopping mepolizumab, 2 patients experienced major and 3 minor relapse during a follow up of 10 months (range 4–14 months).

Conclusion: This phase II trial strongly suggests that mepolizumab may be an effective and safe therapeutic option in refractory CSS and might offer benefits beyond its steroid-sparing potential.

Periodontal Disease Hampers Anti-TNF Treatment Response in Rheumatoid Arthritis. Cynthia Savioli[1], Gisele Maria Campos Fabri[2], Ana Luisa Calich[5], Ana Cristina Medeiros Ribeiro[5], Julio Cesar Moraes[5], Carla Gonçalves Saad[5], Jozélio Freire Carvalho[5], Clovis Almeida Silva[4], Eloísa Bonfá[5] and José Tadeu Tesseroli Siqueira[3]. [1]Dentistry and Rheumatology Division (CEDMAC), Faculdade de Medicina da Universidade de São Paulo, Osasco, São Paulo, Brazil, [2]Dentistry and Rheumatology Division (CEDMAC), Faculdade de Medicina da Universidade de São Paulo, [3]Dentistry Division, Faculdade de Medicina da Universidade de São Paulo, [4]Paediatric Rheumatology Unit, Rheumatology Division (CEDMAC), Faculdade de Medicina da Universidade de São Paulo, [5]Rheumatology Division (CEDMAC), Faculdade de Medicina da Universidade de São Paulo

Purpose: To evaluate prospectively the effect of anti-TNF therapy in periodontal disease and its possible association with rheumatoid arthritis (RA) treatment response.

Methods: Twenty RA (ACR criteria) patients were assessed before (BL) and after 6 months (6M) of anti-TNF treatment. A dentist performed systematic dental and facial examinations that included: orofacial clinical features, tooth decay (DMFT) index, periodontal assessment [plaque and gingival bleeding index, probing pocket depth (PPD), cementoenamel junction (CEJ) and clinical attachment level (CAL)], Helkimo's index and salivary flow. All patients were examined by a rheumatologist, blinded to dentist assessment, in order to evaluate: demographic data, clinical manifestations, drug use, disease activity (CRP, ESR, DAS 28) and quality of life (HAQ) parameters.

Results: The median age of RA patients was 50(27–70) years and 90% were female. The median disease duration was 11(2–43) years. Infliximab was used in 17(85%) patients, adalimumab in 2 and etanercept in 1. No differences were observed in the median of plaque and gingival bleeding indices, PPD, CEJ and CAL comparing BL and 6M ($p>0.05$) in spite of a significant DAS28 reduction (5.55 vs. 3.98, $p=0.008$) and a trend to ESR (24 vs.13 mm/1st h, $p=0.071$) after 6 months of therapy. Further analysis of the 9(45%) patients with periodontal disease (PD) at study entry revealed a lack of response with no significant differences in the disease activity parameters between BL and 6M ($p>0.05$). In contrast, patients without PD showed a significant improvement in disease activity [DAS 28 (5.5 vs. 3.8, $p=0.01$) and ESR (25 vs.12 mm/1st h, $p=0.05$)] comparing BL and 6M, respectively. No differences were observed in the frequencies of orofacial complaints, alteration of mandibular mobility and clinical dysfunction indices and in the median of salivary flow after 6M in both groups ($p>0.05$). DMARDs use was similar comparing whole group at BL and 6M as well as comparing patients with and those without PD ($p>0.05$).

Conclusions: This study supports the notion that an underlying periodontal disease affects TNF blockers efficacy in RA patients. The possibility that a sustained gingival inflammatory state hampers treatment response in this disease has high clinical interest, since this a treatable condition.

2205

Safety without Borders: Upper and Lower Gastrointestinal Safety of Celecoxib in a Pooled Analysis of 52 Prospective, Randomised, Double-Blinded, Parallel-Group Clinical Trials. Gurkirpal Singh[3], George Triadafilopoulos[3], Naurang Agrawal[1], Geoff Makinson[2], Chunming Li[2] and Ha Nguyen[2]. [1]KUMC, [2]Pfizer, [3]Stanford University

Objectives: Nonsteroidal anti-inflammatory drug (NSAID)-related serious upper and lower gastrointestinal (UGI/LGI) complications are well-recognized, but most clinical trials of cyclooxygenase (COX)-2 selective NSAIDs have focused on UGI outcomes as their primary endpoints. We used a novel composite endpoint measuring injury in the entire GI tract to study GI outcomes in patients enrolled in celecoxib clinical trials using individual patient-level data.

Aims & Methods: A novel endpoint – clinically-significant upper and lower GI events (CSULGIEs) – was developed. A total of 52 randomized, double-blind, parallel group studies were identified from the Celecoxib Clinical Database and included in this patient-level pooled analysis. All studies had a planned duration of continuous treatment with celecoxib and either a nsNSAID (ibuprofen, naproxen, diclofenac, ketoprofen, loxoprofen), rofecoxib or a placebo comparator arm for ≥ than 4 weeks. All included studies had their final study reports completed by October 1st, 2007. Open-label and cross-over trials, and all healthy volunteer studies were excluded from the analysis. The primary endpoint was the cumulative incidence of CSULGIEs (including perforations, obstructions, clinically significant bleeds) or symptomatic ulcers as adjudicated by an independent blinded committee. Adjudication was based on predefined criteria and available reported adverse events, laboratory data and narratives. The stratified log rank test was used to compare treatments, adjusting for studies. All doses of celecoxib (from <200 to 800 mg total daily dose) and nsNSAIDS were pooled. Asymptomatic hemoglobin or hematocrit drops were not considered as cases for this analysis.

Results: A total of 51,048 patients were included in the study: 28,614 patients were randomized to celecoxib (mean age 60.1 years), 15,278 to nsNSAIDs (mean age 59.3 years), 1,329 to rofecoxib (mean age 70.6 years) and 5,827 to placebo (mean age 57.2 years). A total of 354 cases of serious UGI/LGI complications were reviewed by the adjudication committee who confirmed 92 CSULGIEs. The number of events and the incidence rate per 100 person-years were: celecoxib [40, 0.33%], nsNSAID [38, 0.82%], rofecoxib [0] and placebo [14, 0.37%]). The difference between celecoxib and nsNSAIDs was statistically significant, using Kaplan Meier stratified log-rank test ($p<0.0015$).

Conclusion: The known UGI safety of celecoxib is also associated with a lower risk of all clinically significant GI events throughout the entire GI tract compared to patients treated with nsNSAIDs.

2206

Dose Matters: The Risk of Complicated Gastroduodenal Ulcers with Naproxen Is Dose-Dependent. Gurkirpal Singh[3], Ajitha Mannalithara, Amrita Sehgal[4], Alka Mithal[2], Mark Sostek[1] and George Triadafilopoulos[3]. [1]Astra Zeneca, [2]ICORE, [3]Stanford University, [4]University of California Berkeley

Background: Nonsteroidal anti-inflammatory drugs (NSAIDs) are widely used for the management of pain and inflammation associated with osteoarthritis, rheumatoid arthritis and other musculoskeletal disorders but they carry a risk for cardiovascular (CV) and gastrointestinal (GI) toxicity. Large outcome studies have found that high-dose naproxen is associated with GI toxicity but less serious CV toxicity than other NSAIDs and COX-2 selective inhibitors (Kearney *et al*. *BMJ* 2006;332:1302–1308). It is unclear whether lower doses of naproxen present a similar level of GI risk while maintaining a favourable CV safety profile.

Objectives: To examine the prevalence of hospitalisations for complicated gastric and duodenal ulcers (bleeding, perforation, obstruction) in patients treated with varying doses of naproxen, as used in everyday clinical practice, in order to ascertain if lower doses of naproxen are associated with a comparable risk of upper GI (UGI) complications to naproxen 1,000 mg/day.

Methods: We conducted a nested case-control study using data from MediCal, California (the largest Medicaid programme in the US, with more than 7 million participants per year). Patients were aged 18 years or older with physician-diagnosed arthritis and had received treatment with an NSAID or COX-2 selective inhibitor between January 1999 and June 2005. All hospitalisations for complicated gastric and duodenal ulcers were risk-set matched with 4 controls on the basis of age, gender and date of hospitalisation. Analyses were adjusted for potential confounders, co-medications, co-morbidities and over-the-counter use of NSAIDs, including aspirin.

Results: A total of 688,424 patients were included, contributing 2,665,611 person-years of observation time. Of these, 11,303 patients who were hospitalised due to complicated gastric or duodenal ulcers were matched to 45,212 controls (mean age 70.7 years, 35% male). Patient characteristics of users of different NSAIDs were similar, except for COX-2 selective inhibitors being prescribed to older patients with more GI risk factors, as expected. Multivariate-adjusted rate ratios (95% CI) for hospitalisation with different doses of naproxen compared with remote use (≥61 days prior to hospitalisation) were: 500 mg/day, 2.51 (1.61–3.92); 750 mg/day, 2.95 (2.34–3.73); and

1,000 mg/day, 3.1 (2.71–3.61). All rate ratios were significantly higher when compared with remote NSAID or COX-2 selective inhibitor use ($p<0.001$).

Conclusions: Although the risk of hospitalisation for ulcer complications with naproxen is dose-dependent, even low (equivalent to over-the-counter) doses are associated with a significant risk of serious UGI toxicity. Concomitant gastro-protective therapy should be strongly considered for high-risk patients, regardless of naproxen dose, in order to protect against complicated gastric and duodenal ulcers.

Disappointing Responsiveness of the SF-6D to Improvement in Patients Receiving a First TNF-Blocker: Results of the DREAM Registry. Laurien Buitinga[3], Louise M. A. Braakman-Jansen[4], Erik Taal[4], Wietske Kievit[1], Henk Visser[2], Piet L. C. M. Van Riel[1] and Mart A. F. J. van de Laar[5]. [1]Radboud University Nijmegen Medical Centre, [2]Rijnstate Hospital, Arnhem, [3]University of Twente, Enschede, Overijssel, The Netherlands, [4]University of Twente, Enschede, The Netherlands, [5]University of Twente; Medical Spectrum Twente, Enschede

Background: For reimbursement of innovative but costly treatments results of cost-utility analyses are increasingly important. Preferences for health states (utilities) can be measured with instruments as the EQ-5D or SF-6D. Evidence about which measure can be used best to detect improvement in patients with Rheumatoid Arthritis is inconclusive [1].

Objective: To examine the responsiveness of the EQ-5D and SF-6D in patients with RA receiving a first TNF-blocker.

Methods: Data of 284 RA patients included in the Dutch Rheumatoid Arthritis Monitoring (DREAM) registry starting a first TNF-blocker were used. The Wilcoxon Signed Rank test and standardized response mean (SRM) were calculated to measure internal responsiveness over 12 months and 95% CIs were estimated using bootstrapping. Receiver-operating characteristic (ROC) curves were used to assess external responsiveness and areas under the curves (AUCs) were calculated. Perceived health transition (item SF-36) and change in disease activity (DAS-28) were used as external criteria. For the ROC curves, both criteria were dichotomized. Patients were classified as 'responders' (good and moderate) or 'non-responders', based on the EULAR28 response criteria, which takes into account the individual change in DAS28 and the level of DAS28 reached. Patients were classified 'improved patients' (perceived health much better or somewhat better than a year ago) or 'non-improved patients' (perceived health the same as a year ago, or somewhat worse or much worse than a year ago), based on their health transition score.

Results: According to the EULAR response criteria, 41.2% of the patients were good responders, 36.6% moderate and 22.2% non-responders. The EQ-5D scores slightly improved over 12 months (SRM(CI) 0.46(0.32 to 0.58)), whereas the SF-6D scores did not improve at all (SRM 0.02(−0.10 to 0.13)). The EQ-5D was moderately able to correctly classify patients as 'improved' or 'non-improved' respectively 'responder' or 'non-responder' as the AUCs were 0.67 when using self-reported health transition and 0.72 when using disease activity as external criteria. The AUCs of the SF-6D did not differ from 0.5.

Conclusion: The EQ-5D was more responsive to improvement than the SF-6D. The SF-6D was poorly responsive to improvement in patients with RA receiving a first TNF-Blocker. There is a need to reconsider the SF-6D as a valid utility measure in cost utility analyses in RA.

Multiple Medications Use in Adults with Chronic Disease, with and without a Musculoskeletal Condition. Gillian A. Hawker[3], Ruth Croxford[1] and Elizabeth M. Badley[2]. [1]Institute of Clinical and Evaluative Sciences, Toronot, Canada, [2]Toronto Western Research Institute, Toronto, ON, Canada, [3]Women's College Hospital, Toronto, ON, Canada

Purpose: Musculoskeletal (MSK) conditions, which disproportionately affect older adults, are the most common cause of pain and long term disability. Chronic medication use is central to symptomatic management of MSK conditions and their downstream effects (e.g. sleep disruption and depressed mood). However, their chronic use may increase risk for adverse outcomes. This study evaluated the prevalence and correlates of use of combinations of medications (pain relievers, narcotic medications, and anti-depressants) among people with MSK and non-MSK chronic conditions.

Methods: Data from Ontario respondents to the 2001 Canadian Community Health Survey (CCHS) (Cycle 1.1), a nationally representative cross-sectional survey of the Canadian community-dwelling population, were used. Participants aged 25 years and older who responded to the questions about MSK conditions (physician diagnosed arthritis or rheumatism *and* back pain) and about their medication use in the past month, including the use of *pain relievers* (e.g., aspirin, acetaminophen, arthritis medicine or anti-inflammatories), *narcotic medications* (codeine, Demerol or morphine), and *anti-depressants* (e.g., Prozac, Paxil or Effexor), were included. The age-standardized percentage of Ontario respondents aged 25+ years who reported taking two or more of these types of medications (i.e. ***multiple medication use***) was calculated for those with a MSK condition compared to those with one or more non-MSK chronic conditions (e.g. pulmonary disease, diabetes, heart disease). Among respondents with at least 1 chronic condition, correlates of multiple medication use (yes/no) were evaluated using logistic regression. Correlates considered were: age, gender, MSK condition, number of other chronic conditions, and annual household income.

Results: Among ~ 26,000 respondents, 34.9% reported an MSK condition and 12.1% reported at least one non-MSK chronic condition. The percentage reporting multiple medication use was 16.2% in those with an MSK condition and 9.5% in those with at least one non-MSK chronic condition. Significant independent correlates of multiple medication use were: a greater number of chronic conditions (adj OR for 2 versus 1 condition 1.35; $p=0.003$; adjusted OR for 3+ versus 1 condition is 3.24; $p<0.0001$); lower income ($p=0.004$); and an age-sex interaction ($p=0.02$). Younger women were more likely to be using multiple medications than younger men, but the probabilities were similar among older men and women. Controlling for these factors, the presence of a MSK condition was independently associated with a higher likelihood of multiple medication use (adjusted OR 1.68, $p<0.0001$).

Conclusions: People with MSK conditions are almost twice as likely as adults with other chronic conditions to be using combinations of medications typically used to manage chronic pain, potentially increasing their risk for adverse drug effects leading to hospitalization and death.

Disclosure: G. A. Hawker: None; **R. Croxford:** None; **E. M. Badley:** None.

Population-Based Estimates of Common Comorbidities and Cardiovascular Disease in Ankylosing Spondylitis. Ann B. I. Bremander[2], Ingemar F. Petersson[1], Stefan Bergman[4] and Martin Englund[3]. [1]Lund University Hosp, Lund, Sweden, [2]Musculoskeletal Sciences, Department of Orthopedics, Clinical Sciences Lund, Lund University, Oskarstrom, Sweden, [3]Musculoskeletal Sciences, Department of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden, [4]Research and Development Center, Spenshult Hospital for Rheumatic Diseases, Oskarstrom, Sweden

Background: Comorbidities associated with AS contribute to the burden of the rheumatic disease. However, epidemiologic studies presenting estimates of the increased rate of comorbidities in AS are scarce.

Objective: To study the rate of common comorbidities and cardiovascular disease in ankylosing spondylitis (AS) patients compared with the general population seeking health care.

Methods: Sweden has a publicly funded health care system. All health care utilization is registered by the patients' personal identifier in databases. We studied 1374 subjects (60% men) age ≥20 years, living in the county of Skåne, Sweden, who were registered with an AS diagnosis (ICD-10 code M45) in the Skåne Health Care Register at least once during 4 calendar years (2004 to 2007). We then recorded the occurrence of physicians' diagnostic codes for a select number of comorbidities commonly associated with AS or

cardiovascular disease or its risk factors. To obtain morbidity rates we calculated the person-time from the day after the first occurrence of the AS diagnosis within the study period until the first diagnosis of the disease or another censoring event (death/relocation). We then obtained standardized morbidity ratios (SMRs) by dividing the observed morbidity rate in AS patients by the expected based on the corresponding rate of the disease in the general health care seeking population of the county (761 210 inhabitants aged ≥20); an SMR >1 equals a higher rate of the disease among AS patients than in the general population of corresponding age and sex distribution.

Results: The highest SMRs were found for uveitis 26.06 (95% CI 21.97, 30.70) and inflammatory bowel disease 8.19 (95% CI 6.47, 10.22), Figure 1. Also, we found increased SMRs for ischemic heart diseases 1.83 (95% CI 1.53, 2.18), hypertension 1.70 (95% CI 1.51, 1.91), disorders of lipoprotein metabolism 1.34 (95% CI 1.04, 1.71), and diabetes mellitus 1.34 (95% CI 1.10, 1.62). Within the group of ischemic heart diseases we also evaluated acute myocardial infarction separately and although it is a relatively rare event the SMR was close to be significantly elevated; 1.43 (95% CI 0.97, 2.03), Figure 2. Further, the SMRs for psoriasis, osteoporosis, and atrioventricular blocks were also statistically significantly elevated.

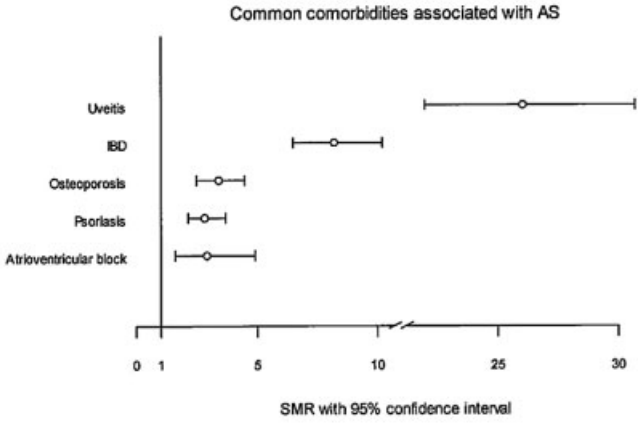

Figure 1.

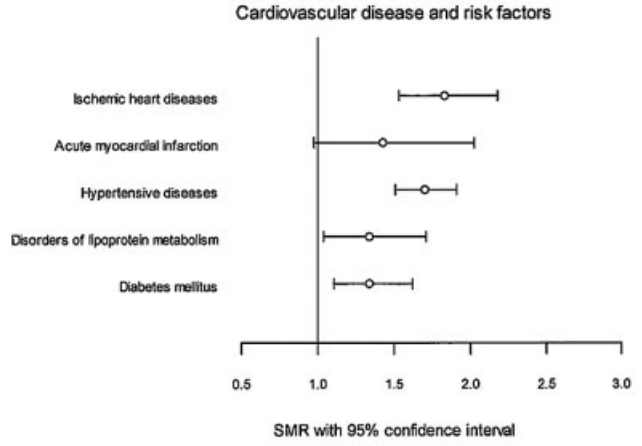

Figure 2.

Conclusion: Inflammatory diseases affecting the eye and the digestive system were the most notable comorbidities in AS patients, but the rate for cardiovascular disease was also higher indicating that AS is a chronic rheumatic disease with strong influence of comorbidities affecting the total burden of the disease.

Elevated Maternal Serum Alpha Fetoprotein Predicts Reduction in RA Disease Symptoms during Pregnancy but Does Not Reduce Risk for Preterm Delivery. Don Nguyen[4], Gretchen Bandoli[1], Diana Johnson[3] and Christina D. Chambers[2]. [1]San Diego State University, [2]University of California San Diego, San Diego, CA, [3]University of California San Diego, [4]University of California SanDiego

Background: Mid-trimester elevated maternal serum alpha fetoprotein (MSAFP), a glycoprotein produced by the fetus, is associated with an approximately 3-fold increased risk of preterm delivery in otherwise normal pregnancies. Pregnant women with RA are at increased risk of preterm delivery, a risk that may be related to inflammatory disease activity or poor symptom control. It is suspected that the immunomodulatory effects of MSAFP represent a mechanism whereby disease symptom remission occurs in at least 2/3 of pregnant RA patients. However, it is not known if elevated MSAFP values in pregnant patients with RA are associated with the same 3-fold risk of preterm delivery as in the general population, or if high MSAFP values may lead to symptom remission and thereby reduce risk of early delivery in these patients.

Methods: The OTIS Autoimmune Diseases in Pregnancy Project, a North American-wide prospective cohort study of pregnancy outcome, enrolled 115 pregnant women with RA between 1999 and 2008 for whom mid-trimester MSAFP values were available from the obstetric record. Of these, 115 had one assessment of symptoms in the first half of gestation and 68 had a second assessment at 32 weeks' gestation, each consisting of 3 likert scale measures of interference with activity, pain, and global impact of disease based on the CLIN-HAQ and collected by maternal report. We examined the relationship between symptom scores at each time point and preterm delivery (<37 weeks' gestation), and symptom scores and elevated MSAFP (>=2.0 multiples of the median) using student's t-tests. We also evaluated elevated MSAFP as a predictor of preterm delivery using logistic regression.

Results: A total of 19.8% of women in the sample delivered preterm and 5.8% of women had a documented elevated MSAFP. All 3 symptom assessments measured in the first half of pregnancy were significant predictors of preterm delivery ($p < 0.05$). However, none of these same measures collected in the third trimester were associated with preterm delivery. Elevated MSAFP was associated with a non-significant 3-fold increased risk of early delivery (OR 3.32, 95% CI 0.69, 15.97). However, elevated MSAFP significantly predicted a reduction in symptom scores from early to late pregnancy on all 3 measures ($p < 0.05$).

Conclusion: Elevated MSAFP does appear to be linked to reduction in symptoms over the course of pregnancy, but the immunomodulatory effect of MSAFP does not appear to contribute to a reduction in risk for preterm delivery, which approximates the increased risk reported for the general population. Women with RA who have poor symptom control in early pregnancy and/or elevated MSAFP are at increased risk of preterm delivery, but those with elevated MSAFP are likely to see remission of symptoms as pregnancy progresses.

Cardiovascular Disease Prevalence in a Primary Care Cohort of Individuals with Inflammatory Arthritis, Diabetes, and Osteoarthritis: A Comparative Cross-Sectional Study. Mark M. J. Nielen[4], Alper M. van Sijl[3], Mike J. L. Peters[1], Robert A. Verheij[4], Francois G. Schellevis[4] and Michael T. Nurmohamed[2]. [1]Department of Internal Medicine, VU Medical Centre, Amsterdam, The Netherlands, [2]Department of Rheumatology, Jan van Breemen Institute, Amsterdam, Netherlands, Amsterdam, The Netherlands, [3]Department of Rheumatology, Jan van Breemen Institute, Amsterdam, Netherlands, [4]Netherlands Institute for Health Services Research (NIVEL), Utrecht, The Netherlands

Background: The evidence base for an increased cardiovascular burden in inflammatory arthritis (as in diabetes, an established cardiovascular risk factor) is growing, but data from primary care records are rare. We sought to determine the prevalence of cardiovascular (CV) events in inflammatory arthritis, diabetes, hip- and/or knee osteoarthritis (non-inflammatory comparator) in comparison to the population.

Methods: Data on CV morbidity (ICPC codes K75 (myocardial infarction), K89 (transient ischemic attack), and/or K90 (stroke/cerebrovascular accident) from patients with inflammatory arthritis (n=1.343), diabetes (n=11.784), osteoarthritis (n=3.320) and controls (n=158.439) were used from the Netherlands Information Network of General Practice (LINH), a large primary care cohort. Data were analyzed using multi-level logistic regression analyses and corrected for I: age, gender; and II: age, gender, hypercholesterolemia and hypertension.

Results: Age and gender adjusted CV disease prevalence rates were significantly higher in inflammatory arthritis (OR 1.6 (95%-CI: 1.3–2.0) and in diabetes (OR 1.8 (95%-CI: 1.6–1.9), but not in osteoarthritis (OR 0.9

(95%-CI: 0.8–1.0). These results attenuated - especially in diabetes - but remained statistically significant after adjustment for hypertension and hypercholesterolemia: OR 1.5 (95%-CI: 1.2–1.9) for inflammatory arthritis, OR 1.3 (95%-CI: 1.2–1.4) for diabetes, and OR 0.8 (95%-CI: 0.7–1.0) for osteoarthritis, respectively.

Table 1. Study characteristics

	IA	DM	OA	General population
n	1.343	11.784	3.320	158.439
Mean age, years	59*	66*	69*	51
Female gender, %	64*	52	68*	50
AMI, %	1.6*	2.7*	1.4*	0.7
TIA, %	1.6*	2.1*	1.7*	0.6
CVA, %	2.5*	3.6*	2.5*	0.9
Total CVD, %	5.4*	8*	5.3*	2
Hypertension, %	28*	48*	35*	13
Hypercholesterolemia, %	7.6*	24*	10*	4.8

* $p < 0.001$ (compared to general population). DM, diabetes mellitus; IA, inflammatory arthritis; OA, knee- and/or hip osteoarthritis; AMI, acute myocardial infarction; TIA, transient ischaemic attack; CVA, cerebro vascular accident; CVD, cardiovascular disease

Table 2. Multilevel logistic regression analyses for the association with CVD

	General population	IA	DM	OA
Crude model	1.0	2.1 (1.7–2.7)*	3.7 (3.5–4.0)*	1.9 (1.6–2.2)*
Model 1	1.0	1.6 (1.3–2.0)*	1.8 (1.6–1.9)*	0.9 (0.8–1.0)
Model 2	1.0	1.5 (1.2–1.9)*	1.3 (1.2–1.4)*	0.8 (0.7–1.0)

* $p < 0.001$. Results as odds ratios (95%-confidence interval). DM, diabetes mellitus; IA, inflammatory arthritis; OA, knee and/or hip osteoarthritis.
Model 1: Adjustment for age and gender
Model 2: Adjustment for age, gender, hypertension and hypercholesterolemia

Conclusions: These results confirm an increased CV burden in inflammatory arthritis to levels broadly similar to diabetes. By contrast, lack of excess CV disease in osteoarthritis further suggests that the systemic inflammatory load is critical to the CV disease burden in inflammatory arthritis.

Impact of Age, Gender, Obesity, and Steroid Use on Quinolone-Associated Tendon Disorders. Barton Wise[3], Christine Peloquin[2], Hyon K. Choi[4], Nancy E. Lane[5] and Yuqing Zhang[1]. [1]Boston Univ School of Medicine, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Ctr for Healthy Aging-UC Davis, Sacramento, CA, [4]Univ of British Columbia, Vancouver, BC, Canada, [5]Univ of California at Davis, Hillsborough, CA

Background: Quinolone antibiotics are associated with an increased risk of tendinopathy, including tendon rupture. However, it is unknown whether certain characteristics predispose individuals to the adverse effects of quinolones. Identifying individuals who are more susceptible to these detrimental events has important clinical implications.

Methods: Using The Health Improvement Network (THIN) database, an electronic medical record database based on 6.3 million patients from general practices across the UK, we conducted a case-crossover study to assess whether the effects of quinolone use on the risk of tendon disorders vary by age, gender, obesity, and oral glucocorticoid use. For our primary outcomes, we examined Achilles tendonitis and tendon rupture at any site, to help ensure a high level of diagnostic specificity of end points. We identified patients with Achilles tendonitis or tendon rupture between 1986–2009 based on their electronic medical records. Subjects whose Achilles tendonitis or tendon rupture occurred within the first 2 years of entry to the THIN database were excluded. For each patient, we determined whether a quinolone and comparison antibiotic (trimethoprim, amoxicillin, nitrofurantoin) had been prescribed within 30 days prior to diagnosis of Achilles tendonitis and tendon rupture (case period) as well as the prescription of the same medications within 30 days one year prior to disease diagnosis (control period). We examined potential effect modifications according to age (<60 vs. ≥60 years), sex, obesity (BMI<30kg/m^2 vs.BMI ≥30kg/m^2), and concurrent glucocorticoid use (yes vs. no) by adding an interaction term between quinolone use and each potential modifier in the conditional logistic regression model.

Results: We identified 29,312 cases of Achilles tendonitis and 7,740 cases of tendon rupture. Use of quinolone was strongly associated with an increased risk of Achilles tendonitis (OR=4.4, 95% CI: 3.3–5.8) and tendon rupture (OR=2.0, 95% CI: 1.2–3.4). No association was found between the use of other antibiotics and either outcome. The association with Achilles tendonitis was stronger among patients who were older than 60 yrs, non-obese, and who used oral glucocorticoids (p-values for interaction: <0.001, 0.01, and 0.03, respectively). The effect of quinolones appeared to be greater in women than in men although the interaction term was not statistically significant (see table). Similar subgroup effects were observed in the associations with tendon rupture, except for the age group effect.

		Achilles Tendonitis			Tendon Rupture		
Potential modifier	Quinolone use	Case period	Control period	OR (95% CI)	Case period	Control period	OR (95% CI)
Men	Yes	118	38	3.7 (2.4–5.5)	21	18	1.2 (0.6–2.3)
	No	15,605	15,685		5,261	5,264	
Women	Yes	153	39	5.1 (3.4–7.7)	28	7	4.0 (1.7–9.2)
	No	13,435	13,550		2,430	2,451	
<60 yrs	Yes	66	41	1.7 (1.1–2.6)	14	7	2.2 (0.8–5.7)
	No	21,511	21,536		4,451	4,458	
>=60 yrs	Yes	206	36	8.4 (5.4–12.9)	35	18	2.0 (1.1–3.6)
	No	7,529	7,699		3,240	3,257	
No obesity	Yes	111	21	7.9 (4.5–14.1)	23	9	2.7 (1.2–6.2)
	No	6,466	6,556		1,937	1,951	
Obesity	Yes	25	11	2.4 (1.1–5.0)	2	4	0.5 (0.1–2.7)
	No	3,910	3,924		828	826	
Glucocorticoid use	Yes	99	17	10.1 (5.1–20.1)	21	4	5.2 (1.8–15.3)
	No	732	814		364	381	
No glucocorticoid use	Yes	173	60	3.3 (2.4–4.6)	28	21	1.4 (0.8–2.5)
	No	28,308	28,421		7,327	7,334	

Conclusion: These findings from a large primary care population confirmed that quinolone use increases the risk of Achilles tendonitis and tendon rupture. These detrimental effects of quinolones appear to occur more often among women, elderly, non-obese patients, and individuals with concurrent use of glucocorticoids.

Bisphosphonate (BisP) Use May Be a Risk Factor for Osteonecrosis (ON) in Those Who Have Not Used Glucocorticoids (GCs): Data from the Health Improvement Network (THIN). Steven C. Vlad[2], Hyon K. Choi[3], Christine Peloquin[2] and Yuqing Zhang[1]. [1]Boston Univ School of Medicine, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Univ of British Columbia, Vancouver, BC, Canada

Background: BisP use has been linked to ON of the jaw in case reports. However, two epidemiologic studies suggested different conclusions about whether BisP use is associated with ON in general: one found that BisP use was associated with ON even after adjusting for GC use; the other found no association after adjusting for GC use and other factors. The latter suggests that GC use could be a strong confounder of any BisP-ON relationship. We therefore used data from THIN to investigate the association between BisP use and ON in persons who have not used GCs.

Methods: THIN collects anonymized patient data on over 3 million patients from a sample of primary care clinics throughout the United Kingdom. As all health information flows through the GP, THIN provides a complete patient record while an individual remains in a practice including medication prescriptions and refills. We created a cohort of subjects who had not been prescribed BisPs within the 1st year of entering a practice (new user population), and who had no recorded ON diagnosis within the 1st year (to exclude prevalent cases). We identified all cases of ON (index date), the diagnosis date, and the date the case entered the practice. We matched each case to 4 controls by gender, age in 10 year bands (< 16, 16–25, 26–35, . . . 86–95, ≥ 96), practice, calendar year of entry into the practice, and continuing enrollment in the practice at the index date. Subjects who used GCs before the index date could not be cases or controls. We defined BisP exposure as 1) current (including the 30 days prior to index date), recent (31–180 days), and past (> 180 days), and 2) total dose (1–180 days, 181–360 days, > 360 days), with no use as the reference in both cases. We used conditional logistic regression, adjusted for heavy alcohol use (ever, never), and tobacco use (current, past, never, missing), to calculate odds ratios for ON.

Results: We identified 608 persons with new ON (310 men, 298 women, mean age 52.7 yrs (sd 21.7)) and matched 2389 controls (51.6 yrs (sd 21.3) — 16 cases had fewer than 4 controls). 33 cases (5.4%) and 35 controls (1.5%) had at least one BisP prescription. Compared to never use the risk of ON was elevated in both current BisP users and recent users, but not in past users (see table). Compared to no use the risk of ON was elevated for all categories of total dose, with the peak from 181–360 days. The risk remained elevated after restricting the analysis to current users.

Table: Association of bisphosphonate use with osteonecrosis

Bisphosphonate use	Cases N (%) (N = 608)	Controls N (%) (N = 2389)	OR	(95% CI)
Never used (reference)	575 (94.6)	2354 (98.5)	1	–
Recency of use				
Current use (within 30 days)	24 (4.0)	21 (0.9)	6.1	(3.1, 12.0)
Recent use (31–180 days)	5 (0.8)	3 (0.1)	9.8	(2.2, 43.3)
Past use (>180 days)	4 (0.7)	11 (0.5)	1.7	(0.5, 5.4)
Duration of use				
1–180 days	10 (1.6)	13 (0.5)	2.5	(1.0, 6.2)
181–360 days	9 (1.5)	4 (0.2)	7.7	(2.3, 26.3)
>360 days	14 (2.3)	18 (0.8)	2.7	(1.1, 6.8)
Duration of use in current users				
1–180 days	9 (1.5)	4 (0.2)	10.0	(3.0, 33.2)
181–360 days	7 (1.2)	3 (0.10)	10.6	(2.7, 42.8)
>360 days	13 (2.1)	17 (0.7)	4.4	(1.9, 10.1)

Odds ratios (ORs) adjusted for heavy alcohol and tobacco use

Conclusions: Though our analysis is limited by small numbers, BisP use appears to be a risk factor for ON even in those who have not used GCs. The risk appears highest with up to 1 year of use, suggesting that those who have not had ON within 1 year may be in less danger. After 6 months off drug, the risk approaches null. Given the high correlation between osteopenia/osteoporosis and BisP use, we cannot exclude that these findings are due to confounding by indication, though no relationship between low bone mass and ON is known.

Purpose: Systemic sclerosis (SSc) is a rare and severe rheumatic disease. Different lines of evidence suggest that genetic factors may underlie not only SSc susceptibility but also the predisposition to develop certain specific disease phenotypes or clinical symptoms such as limited (lcSSc) and diffuse (dcSSc) cutaneous subtypes and the presence of auto-antibodies, such as anti-centromere (ACA) and anti-topoisomerase I (ATA). To assess the genetic component involved in the different SSc subtypes we analyzed genome-wide association (GWAS) data and replication cohorts from the US and Europe in a total of 5,471 Caucasian individuals with SSc and 10,143 healthy Caucasian controls.

Methods: After all data was quality filtered, 2,296 individuals with SSc and 5,171 healthy controls were analyzed for genetic associations with lcSSc, dcSSc, ACA positive and ATA positive subgroups. SNPs from each subphenotype with a corrected P value lower than $1\times10-4$ not previously described in the literature were selected for replication. These associations were then analyzed in 9 replication cohorts from US and Europe comprising an additional 3,175 SSc patients and 4971 healthy controls.

Results: Eighteen non-HLA SNPs were selected from the SSc GWAS analysis. Meta-analysis of all the cohorts (5,471 individuals with SSc and 10,143 healthy controls) showed a strong association of rs11642873 in the IRF8 gene ($P = 5.42\times10–12$, OR = 0.75) and a suggestive but consistent association among populations, of rs12540874 in the GRB10 gene ($P = 1.31\times10-6$, OR = 1.15) with the limited subtype of the disease. We also found a strong association of rs11047102 of the SOX5 gene ($P = 1.04\times10-7$, OR = 1.36) with the ACA positive subgroup of patients. In addition to these phenotype dependent associations, we found rs11724804 in the DGKQ gene ($P = 1.79\times10-6$, OR = 1.12), rs1868929 between the AMRC9 and PSMD1 genes ($P = 3.27\times10-6$, OR = 1.27) and rs10275834 in the JAZF1 gene ($P = 9.44\times10-6$, OR = 1.12) to be associated with SSc.

Conclusions: Outside of the HLA region, we have identified 3 new genes (IRF8, GRB10 and SOX5) associated with clinical manifestations of the disease, emphasizing the differential genetic component of each subphenotype of SSc. We also have identified 3 new genes associated overall with the disease: DGKQ (implicated in cell signal transduction), PSMD1 (the immuno-proteosome subunit which loads immunogenic peptides for MHC transfer) and JAZF1 (a transcriptional repressor previously associated with SLE).

Genetic Markers of Rheumatoid Arthritis Susceptibility in Anti-Citrullinated Peptide Antibody Negative and Shared Epitope Negative Patients. Sebastien Viatte[1], Darren Plant[2], John Bowes[2], Anne Barton[2] and Jane Worthington[1]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, The University of Manchester

Introduction: Recent genome wide and candidate gene association studies have identified over 30 confirmed single nucleotide polymorphisms (SNPs) predisposing to disease. Many of these studies have been undertaken exclusively or largely in samples from patients with anti-citrullinated peptide antibody (ACPA) (as assessed by anti-CCP status) positive RA and there is evidence that some genetic associations appear stronger in this subgroup than in ACPA negative disease. This differential association of susceptibility markers with ACPA positive/negative RA subsets or shared epitope (SE) positive/negative RA has led researchers to hypothesize that RA comprises a number of different diseases. However, due to the small numbers of seronegative or SE negative RA patients included in these studies, they lack sufficient statistical power to address the question currently. We aimed to

undertake a thorough investigation of confirmed RA susceptibility loci in a large cohort of ACPA negative subjects with RA.

Methods: RA patients from 5 different large cohorts of patients originating from the UK were pooled together to reach a number of over 8,000 cases. The comparison group comprised 7000 healthy UK controls. Serologic data was available for 5300 cases (3000 anti-citrullinated peptide antibody (ACPA) positive and 2300 APCA negative patients) and data on SE carriage was available for 6400 patients (4500 bearing at least one copy, 1900 without any copies). This corresponds to the largest pool of ACPA-negative patients studied, to date. A set of over 40 SNPs mapping to 31 confirmed RA susceptibility loci was tested for association between controls and each of the 4 following subgroups: APCA+, APCA-, SE+, SE-.

Results: As expected, strong associations were observed between RA susceptibility SNPs and APCA positive or SE positive patients. The emerging picture in the APCA negative RA subset shows a differential association. A set of SNPs is associated with RA susceptibility, irrespective of the serologic status (eg. PTPN22, TNFAIP3), whereas other RA susceptibility SNPs do not show significant association with ACPA negative RA (eg. PRDM1, CD40). A similar picture characterizes the SE negative RA subset, though a higher number of RA susceptibility loci seem to be associated irrespective of the carriage of the SE.

Discussion: In the largest sample size studied, to date, we have shown that the strength of association, the effect size and the number of SNPs associated with disease appear to be smaller in SE negative RA patients compared to SE positive patient, and these effect sizes are even smaller in APCA negative patients. This opens the question as to whether unidentified SNPs could preferentially and differentially confer susceptibility to ACPA/SE negative RA.

A Signature of Aberrant Responsiveness of the Peripheral Immune System Predicts the 6-Month Risk of Infections in Rheumatoid Arthritis. Megan L. Krause, John M. Davis III, Michael A. Strausbauch, Cynthia S. Crowson, Terry M. Therneau, Eric L. Matteson, Keith L. Knutson and Sherine E. Gabriel. Mayo Clinic, Rochester, MN

Purpose: Patients with rheumatoid arthritis (RA) experience a high burden of infectious disease, which is a leading cause of mortality. Currently there are no biomarkers that stratify the risk of infections in these patients. We have recently shown that "signatures" of aberrant functional responsiveness of the peripheral immune system are associated with RA disease severity. We performed a pilot study to assess whether a blood-based immune signature could predict incident infections in patients with RA.

Methods: We designed a prospective, population-based cohort study of patients with RA. Infections were identified first by diagnosis codes and then validated by medical records review using previously published definitions. Peripheral blood mononuclear cells were isolated and stimulated with a panel of stimuli for both the innate and adaptive immune systems. Seventeen cytokine concentrations were measured via multiplex immunoassays. The stimulation panel included anti-CD3/anti-CD28, cytomegalovirus and Epstein Barr virus lysates, CpG oligonucleotides, heat shock protein 60, phytohemagglutinin, phorbol myristate acetate with ionomycin, and Staphylococcal enterotoxins A and B. Mixed models were used to normalize log-transformed cytokine concentrations, adjust for assay effects, and to estimate and test for differences between the groups with and without incident infections. An immune signature score was created by selecting cytokine-stimulation combinations that were significantly different ($p<0.05$) between the groups. Logistic regression was used to test the association of a multi-cytokine prediction score and the risk of incident infections.

Results: In the six-month period following the index blood draw, 28 incident infections occurred among 267 patients with RA, 74.5% female, with mean age of 61 years and mean disease duration of 9.6 years. The only statistically significant variable at baseline that predicted infection was functional status defined by the Health Assessment Questionnaire (HAQ) disability index. Nine cytokine-stimulation combinations were significantly different between those with and without infection, including higher levels of TNFα, IFNγ, IL-17, IL-8, and GM-CSF and lower levels of IL-10 and IL-12 in response to various stimuli. The immune signature score was a statistically significant determinant of the 6-month risk of infections with an odds ratio of 4.0 (95% CI: 1.5 to 11, P=0.007) after adjusting for age, gender, HAQ, and use of disease-modifying medications.

Conclusion: This was one of the first studies to analyze ex vivo cytokine production and derive an immune signature that could help predict infection risk in patients with RA. The ability to predict infection risk could affect the choice of RA medications with their inherent immunosuppressive effects and the use of antibiotic prophylaxis. Reducing infection by preemptively altering therapy based on infection risk would have the potential to reduce morbidity and mortality for patients with RA.

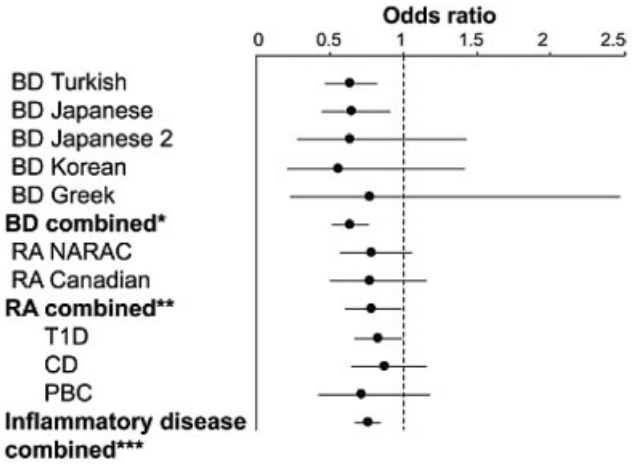
D. Anderson Cancer Center, [17]Yokohama City Grad Sch of Med, Yokohama, Japan

SNP genome-wide association studies (GWAS) are a powerful means to detect disease-associated variants, though it is difficult to detect rare or structural variants. Accumulating evidence has shown an involvement of gene copy number variation (CNV) in inflammatory diseases including systemic lupus erythematosus and psoriasis, suggesting that CNV analysis may be a promising means to identify novel disease-associated loci in rheumatic diseases. SNP marker intensity data from our previous Turkish Behcet's disease (BD) GWAS (1215 cases and 1278 controls) revealed a common 3.2kb deletion in *LEPREL1* intron1 (odds ratio (OR)=0.62, $p=6.5\times10^{-4}$), homozygous deletions of which appeared to protect individuals from disease development. This association of homozygous *LEPREL1* deletion replicated in a Japanese BD collection (382 cases and 410 controls, OR=0.64, p=0.014). Independent BD collections showed trend toward protection from the disease (combined cases n=1821, controls n=2005, OR=0.63, meta analaysis $p=2.9\times10^{-6}$). As the homozygous deletion in *LEPREL1* was found to be common in both Turkish and Japanese populations, we sought to determine whether the deletion influences other inflammatory diseases, or in other ethnicities, as well. We found that patients with rheumatoid arthritis (combined cases n=1351, controls n=1659, OR=0.76, p=0.019), and type 1 diabetes (cases n=2214, controls n=2645, OR=0.82, p=0.038) were also protected from the disease, and trend towards protection in juvenile-onset Crohn's disease and primary biliary cirrhosis was observed. A meta-analysis of these combined inflammatory diseases (cases n=6406, controls n=6309) supports our hypothesis that *LEPREL1* has a role in inflammation ($p=2.4\times10^{-7}$).



LEPREL1, a prolyl 3-hydroxylase which is also called P3H2, is involved in type IV collagen modification. This gene appears to have additional functions. Although the protein is expressed in lymph nodes, there has been no direct evidence linking LEPREL1 to inflammation. We found that *LEPREL1* is primarily expressed in dendritic cells, and peripheral lymphocytes from individuals homozygous for this deleted region produce less LEPREL1 and inflammatory cytokines following exposure to stimulators of innate immunity. Our results offer new insights into the role an intragenic copy number variation plays in repressing development of inflammatory disease and reveal a novel modulatory mechanism for inflammation.

2218

Association of IL2RB Polymorphisms with Erosive Disease in ACPA Positive Early Rheumatoid Arthritis (RA): Results from the ESPOIR Cohort. Adeline Ruyssen-Witrand[3], Delphine Nigon[4], Alain G. Cantagrel[5], Cédric Lukas[7], Jacques Morel[7], Jean Sibilia[6], Anne Cambon-Thomsen[1] and Arnaud L. Constantin[2]. [1]INSERM, U558, Toulouse, France, [2]Purpan University Hospital, Toulouse, France, [3]Rheumatology Center, Purpan Teaching Hospital, Toulouse, Toulouse, France, [4]Rheumatology Center, Purpan Teaching Hospital, Toulouse, France, [5]Rheumatology Center, Purpan Teaching Hospital, Toulouse, University Paul Sabatier, Toulouse, France, [6]Rheumatology Department, Hautepierre Teaching Hospital, Strasbourg, France, [7]Rheumatology Department, Lapeyronie Teaching Hospital, Montpellier, France

Purpose: RA is a complex disease that leads to joints erosions. The receptor of the Interleukin 2 (IL2R), a cytokine secreted by T lymphocytes implicated in the TH1 differentiation, is a quaternary complex of IL2RA, IL2RB and IL2RG. One SNP of the *IL2RA* gene (rs 2104286) and 2 SNPs of the *IL2RB* gene (rs743777 and rs3218253) were previously associated with RA susceptibility. The aim of this study was to assess the impact of these SNPs on the risk of erosions in early RA patients.

Methods: 813 patients with early arthritis (<6 months) were included in a national multicenter prospective study (ESPOIR cohort). Among Caucasian patients, 439 fulfilled the 1987 ACR criteria for RA, had radiographs at inclusion and after one year of follow-up and the 3 SNPs genotyped. Structural damage was quantified according to the Total van der Heijde modified Sharp score (TSS). Erosive RA was defined on an erosion Sharp score (ESS) >0. The 3 *IL2RA* and *IL2RB* SNPs were genotyped by KBiosciences (Herts,UK). *Statistical analysis*: we compared the proportions of patients with erosive disease at baseline and one year among patients carrying the 3 genotypes or the 2 alleles of each SNP using a chi-square test in the whole sample and after stratification on ACPA status. Crude Odds ratios (OR) with 95% confidence interval (95%CI) were calculated according to allele carriage in univariate and multivariate analyses.

Results: Of the 439 RA patients included (median age: 52 years, 76% of females, median symptom duration: 5 months, median DAS 28: 5.33, rheumatoid factor (RF) positive: 53%, anti-CCP2 positive: 48%), 268 (61%) were erosive at baseline (median TSS=3 [IQR:1–8], median ESS=1 [0–4]) and 287 (65%) at one year (median TSS=4 [1–9], median ESS=2 [0–5]). None genotype of the 3 SNPs was significantly associated with ACPA production.

In the whole RA sample, the IL2RB rs3218253 was significantly associated with erosive status at one year (CC: 69%, CT: 65%, TT:46%, p=0.023) in genotype analysis and at baseline (C allele carriage 63% vs 43%– 0R=2.205 [1.058–4.664]) and one year(C allele carriage 67% vs 46%– 0R=2.406 [1.152–5.059]) in allele carriage analysis.

In ACPA+ patients, the IL2RB rs743777 was significantly associated with erosive status at baseline (AA:71%, AG:71% and GG:36%, p=0.002) and one year (AA:78%, AG:75% and GG:44%, p=0.002) while the IL2RB rs3218253 was significantly associated with erosive status at baseline (CC: 74%, CT:66% and TT:30%, p=0.001) and one year (CC:81%, CT:71% and TT:35%, p<0.0001) in genotype analysis.

The A allele of IL2RB rs743777 was significantly associated with the risk of erosion at baseline (71% vs 36%–OR=4.313 [95%CI: 1.663–11.709]) and one year (77% vs 44%–OR=4.203 [95%CI: 1.625–10.972]). The allele C of IL2RB rs3218253 was significantly associated with the risk of erosions at baseline (71% vs 30%–OR=5.583 [1.881–18.490]) and one year (77% vs 35%–OR=6.162 [2.108–19.231]).

The A allele of the IL2RB rs743777 and the C allele of IL2RB rs3218253 remained independently associated with erosive disease in ACPA+ RA patients in multivariate analysis.

Conclusion: The A allele of the IL2RB rs743777 and the C allele of IL2RB rs3218253 were associated with the risk of erosion in ACPA+ early RA.

Discovery and Replication of JIA Predisposition Genes by Genome-Wide Association and Validation of Candidates in Fibroblast-Like Synoviocytes. Terri H. Finkel[9], Haitao Zhang[1], Benedicte A. Lie[10], Edward M. Behrens[3], Mara L. Becker[2], Carol Wise[6], Marilynn Punaro[7], Emma Reuschel[8], Debra Shivers[8], Berit Flatø[4], Øystein Førre[4], Jane Munro[11], Justine Ellis[11] and Hakon Hakonarson[5]. [1]Center for Applied Genomics, The Children's Hospital of Philadelphia, [2]Children's Mercy Hospital, Kansas City, MO, [3]Childrens Hospital of Phil, Philadelphia, PA, [4]Department of Rheumatology, Oslo University Hospital, Rikshospitalet, Norway, [5]Division of Genetics, The Children's Hospital of Philadelphia, University of Pennsylvania, [6]Division of Medical Genetics, Texas Scottish Rite Hospital for Children, [7]Division of Rheumatology, Texas Scottish Rite Hospital for Children, [8]Division of Rheumatology, The Children's Hospital of Philadelphia Research Institute, [9]Division of Rheumatology, The Children's Hospital of Philadelphia, University of Pennsylvania, Philadelphia, PA, [10]Institute of Immunology, Oslo University Hospital, Rikshospitalet, Norway, [11]Murdoch Childrens Research Institute, Royal Children's Hospital, Melbourne, Australia

Purpose: Juvenile Idiopathic Arthritis (JIA) is the #1 cause of acquired disability in children. We recently identified TRAF1-C5 as a genetic locus associated with JIA, and have undertaken a comprehensive translational approach to elucidate its genetic contribution to this disease. Here, we identify single nucleotide polymorphisms (SNPs) associated with JIA by a genome-wide association (GWA) screen of a large well-phenotyped patient cohort. We validate expression of GW significant candidates in B cells and in synovial lining cells (human fibroblast-like synoviocytes, HFLS), the tissue targeted by inflammatory arthritis. HFLS provide a readily available and renewable source of patient-derived tissues to examine JIA risk alleles/ genotypes and screen drugs that might alter the risk phenotype.

Method: We use a GWA approach to identify risk alleles that associate with JIA in a discovery cohort of 1500 cases (diagnosed by revised ILAR criteria) recruited from greater Philadelphia and internationally (Stage 1). In Stage 2, we genotype an additional 1000 existing samples from well-phenotyped JIA cases recruited by other collaborating sites. This database is leveraged against matched samples from >10,000 genotyped controls. In parallel studies, we study allele-specific gene expression in:

1) genotyped lymphoblastoid cell lines (LCLs) from HapMap-CEU population samples and 2) primary HFLS established from synovial fluid samples obtained from a subset of the >200 JIA patients undergoing arthrocentesis each year at Children's Hospital, obtained after informed consent.

Results: We have completed full genome genotyping of 1166 JIA cases and 8793 matched healthy controls using the Illumina HumanHap610Q BeadChip to track 600,000 polymorphisms, and have demonstrated significant associations of JIA to MHC loci, and to the non-MHC loci, PTPN22, IL2RA, and ANTXR2, as previously reported in inflammatory arthritidies. We have also discovered GW significant associations within a locus encoding a novel chemokine receptor (CKR; discovery p-value = 4.32×10^{-11}; odds ratio = 0.66), for which replication is pending. We have demonstrated allele-specific effects on gene expression for significantly associated loci by assaying total RNA in genotyped LCLs from HapMap-CEU population samples, comparing individuals homozygous for risk vs. non-risk genotypes, and in primary HFLS established from JIA synovial fluid samples, analyzing allele-specific changes for our most significantly associated SNPs.

Conclusion: PTPN22, IL2RA, ANTXR2, and a novel CKR are associated with all forms of JIA, thereby potentially functioning as "master switches" predisposing to arthritis. The functional role of these genes is assessed for the first time in the disease-target tissue, HFLS, from children with JIA. HFLS are quiescent synovial lining cells that become highly proliferative and invasive in arthritis, and provide us with a renewable, druggable source of patient-derived cell types/tissues expressing our gene(s) of interest.

High Frequency of Subclinical Ultrasound-Detected Synovitis in Juvenile Idiopathic Arthritis Patients with Clinically-Defined Inactive Disease. Silvia Magni-Manzoni[1], Carlo A. Scirè[3], Angelo Ravelli[2], Catherine Klersy[4], Silvia Rossi[3], Valentina Muratore[1], Chiara Visconti[1], Stefano Lanni[1], Pietro Merli[1] and Carlomaurizio Montecucco[3]. [1]Dep.Pediatrics, Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy, [2]II Pediatric Unit, IRCCS Gaslini, Genova, Italy, [3]Reumatology Unit, Fondazione IRCCS Policlinico S.Matteo, Pavia, Italy, [4]Scientific Dep, Fondazione IRCCS Policlinico S.Matteo, Pavia, Italy

Background: In children with juvenile idiopathic arthritis (JIA), it is unclear whether clinically-defined remission couples with absence of synovitis on imaging studies. Subclinical synovitis, as detected with US, has been found to be common in JIA.

Objectives: To investigate the frequency of US-detected subclinical synovitis in JIA patients with clinically-defined inactive disease (ID) and the role of US abnormalities in predicting a subsequent flare of synovitis.

Methods: The clinician established the presence of ID (active joint count =0, physician's global assessment on a 0–10 cm visual analog scale ≤0.5, and negative acute phase reactants) in 28 consecutive JIA patients. On the same day, a sonographer scanned independently 52 joints in each patient for synovial hyperplasia (SH), synovial fluid (SF), power Doppler signal (PDS), and tenosynovitis (TS). Patients were followed-up for at least 6 months; based on the subsequent disease course, they were classified having persistent ID at the last follow-up visit or a relapse of arthritis during the follow-up period (defined as a recurrence of clinically-defined active synovitis in 1 or more joints).

Results: The frequency of SH, SF, PDS, and TS in the 28 patients with ID was 75%, 71.4%, 32.1%, and 14.3%, respectively. Following the diagnosis of ID, 21 patients had persistent ID after a median of 12 months, whereas 7 patients experienced a relapse of arthritis a after a median of 6 months. The frequency of US abnormalities at the time of the diagnosis of ID in the 7 patients who had a subsequent disease flare was 100% for SH, 87.5% for SF, 14.3% for PDS, and 28.6% for TS. The main joints involved in the baseline US abnormalities were the knee and the wrist.

Conclusion: JIA patients with clinically-defined ID had a high frequency of US-detected synovial abnormalities, namely SH and SF. Of the US features, SH and SF may have a greater role in predicting a future relapse of synovitis, especially when detected in the knee and the wrist.

Ultrasonography at the Onset of Early Arthritis Predicts Joint Erosions at One Year: Results of the ESPOIR Cohort Ultrasound Study. Thomas Funck-Brentano[4], Fréderique Gandjbakhch[4], Fabien Etchepare[4], Sandrine Jousse[2], Cedric Lukas[3], Violaine Foltz[4], Alain Saraux[2], Philippe Goupille[5], Patrick Boumier[1], Pierre Bourgeois[4] and Bruno Fautrel[4]. [1]Amiens, [2]Brest Universitary Hospital, [3]Immuno-rhumatologie, Hopital Lapeyronie, Montpellier, France, [4]Rheumatology Department, Pitié-Salpetrière Hospital, Paris 6 University, France, [5]Tours Universitary Hospital

Background: Ultrasonography (US) has been shown highly sensitive to detect erosions at baseline, compared to conventional radiography (CR). However, only few longitudinal studies have investigated its capacity to predict future structural damage.

Objective: to assess the predictive value of US for future radiographic erosion on the same joint based on the ESPOIR cohort data.

Methods: ESPOIR is a nationwide early arthritis cohort that included between 2002 and 2005 813 early arthritis patients.

US was performed at baseline on 127 patients from the ESPOIR cohort in 4 centers at baseline. US characteristics: 10–13MHz linear array transducer; Power Doppler (PD): frequency of 8.3MHz and pulse repetition frequency of 750Hz. US was performed blindly from clinical and radiological findings. Targeted joints were MCP2&5 and MTP5 for erosion detection, MCP2 to 5 and MTP5 for synovitis (gray scale and power Doppler). CR of the hands, wrists and feet at baseline and one year were read by one investigator according to the van der Heijde modified Sharp score. Baseline US findings associations with joint erosions on CR at one year were tested in univariate analyses using two-by-two tables and Pearson's chi-square tests. Predictive factors for joint erosion at one year by CR were tested in multivariate analysis including age, DAS28, CRP, ESR, positivity for Rheumatoid factor (RF) and anti-CCP and corticotherapy, using a mixed procedure.

Results: Patients characteristics at baseline were (mean ± sd or %): age 50.3 ± 12.2; Female 77.2%; DAS28 5.1± 1.3; number swollen joints 7.8±5.6; number tender joints 7.4±6.4; ESR 31.2±24.0mm; CRP 19.8±32.9 mg/l; Anti-CCP antibody positive 46.8%; Rheumatoid factor (RF) positive 35.4%. CR data at one year was obtained on 1184 joints that had mode B and PD evaluation and 708 joints for US erosions. CR erosions at one year: 105(8.9%) joints were erosive by CR on the 10 targeted joints. In univariate analysis, baseline PD positive synovitis and US erosions were associated with the presence of a CR erosive joint at one year. After adjustment for the clinical and biological variables, US erosions at baseline remained predictive of the presence of CR erosive joints at one year, independently from CRP and the presence of RF, also significantly associated ($p<0.001$).

Table 1. Baseline US characteristics for the presence of CR erosion at one year:

Prediction of future joint damage on X-ray at 1 year						
			X-Ray findings at year 1			
			Eroded joint	Noneroded joint	OR (unadjusted)	OR (adjusted)*
US findings at baseline	US Synovitis (N = 1184)	Joint with Doppler + synovitis	32/105 (30.4%)	196/1077 (18.2%)	1.97 [1.26–3.07]	1.79 [1.00–3.19]
	US Erosion (N = 708)	Eroded joint	21/71 (29.5%)	57/635 (9.0%)	4.26 [2.39–7.59]	3.12 [1.65–5.87]

* Adjustment for age, DAS28, CRP, ESR, positivity for Rheumatoid factor (RF) and anti-CCP and corticotherapy

When restricted to CR non erosive joints at baseline, these associations were maintained (PD synovitis: OR=5.41[2.09–14.01];$p<0.001$; US erosion: OR=3.93;[1.35–11.43];$p=0.012$). When restricted on non erosive patients on baseline CR, US erosions became borderline significant ($p=0.052$).

Conclusion: At the joint level, baseline US findings are associated with structural damage at one year. US is a reliable and useful technique to predict future erosions in early arthritis patients.

CRP-Levels and Duration of Morning Stiffness as Predictors of Active Rheumatoid Arthritis as Verified by Ultrasound in Routine Clinical Practice. Christian Dejaco[5], Christina Duftner[2], Edith Wipfler-Freiβmuth[3], Helmut Weiss[4], Winfried B. Graninger[5] and Michael Schirmer[1]. [1]Department of Internal Medicine I, Medical University Innsbruck, Innsbruck, Austria, [2]Department of Internal Medicine, General Hospital of the Elisabethinen Klagenfurt, Klagenfurt, Austria, [3]Department of Internal Medicine, Hospital of the Barmherzige Brüder Marschallgasse Graz, Graz, Austria, [4]Department of Radiology, General Hospital of the Elisabethinen Klagenfurt, Klagenfurt, Austria, [5]Department of Rheumatology, Medical University Graz, Graz, Austria

Objective: To identify clinical and serological parameters predicting active disease as verified by ultrasound in rheumatoid arthritis (RA) patients from routine clinical practice.

Methods: Retrospective analysis of data from 149 consecutive RA-patients subjected to ultrasound (US) examination [mean disease activity score for 28 joints (DAS-28) 4.5 (standard deviation ± 1.3); mean age 63.7 (±13.4) years; 84.6% female; median disease duration 18 months]. Each patient underwent bilateral US assessment of wrists, metacarpo-phalangeal and proximal inter-phalangeal joints (=22 joints) for the assessment of synovial hypertrophy and/or effusion (SH/E) as well as synovial vascularization as determined by power Doppler (PD). According to Balsa A et al. sonographic remission was defined as the absence of PD-signals whereas presence of hypervascularisation indicated active disease[i]. The number of tender (TJ) and swollen joints (SJ), global assessment of disease activity on a visual analogue scale by the physician (VAS-phys) or patient (VAS-pt), C-reactive protein (CRP)-levels, erythrocyte sedimentation rate (ESR), duration of morning stiffness (MS), DAS-28, clinical disease activity index (CDAI), simplified disease activity index (SDAI) and health assessment questionnaires (HAQ) were recorded. This retrospective analysis was accepted by the local ethics committee.

Results: Sonographically detected hypervascularization was observed in 117 (78.5%) of the RA-patients. CRP, ESR and MS were higher in patients with sonographic signs of disease activity than in those with remission [CRP: median 0.8 (inter-quartile range 2.1) vs. 0.3 (0.6) mg/dl, $p=0.01$; ESR: 24 (39) vs. 14 (16) mm/1st hour, $p=0.019$; MS: 30 (115) vs. 12.5 (30) minutes, $p<0.001$, respectively]. TJ- and SJ-count, VAS-phys, VAS-pt, ESR, DAS-28, CDAI, SDAI and HAQ were similar among both groups. None of the parameters differed between those 10 patients without sonographic lesion and the 22 patients showing SH/E but no PD-signals. Using backward logistic regression analysis we found an odds ratio (OR) of 3.8 (1.6–9.1, $p=0.003$) for CRP >5.0mg/L (normal values 0–5.0mg/L) and an OR of 1.6 (1.1–2.5, $p=0.024$) for MS >30min (interaction between these parameters not significant) to predict active disease. The other clinical and serologic parameters showed no association with disease activity.

Conclusion: In routine clinical practice elevated CRP-levels and longer duration of MS alone are predictors of active RA as verified by ultrasound. This observation could be helpful for the development of referring strategies in the management of these patients.

Resistant Tennis Elbow (RTE) Due to Radial Tunnel Syndrome: Clinical Presentation, Sonographic Findings and Surgical Correlation. David A. Bong[3], Jordi Palau[1], Ingrid Möller[1] and Esperanza Naredo[2]. [1]Barcelona Sonoanatomy Group, [2]Hosptial Universitario Severo Ochoa, Madrid, Spain, [3]Instituto Poal de Reumatologia, Bruce, WI

Background: Tennis elbow is a commonly encountered problem in rheumatologic practice and it is frequently resistant to the standard treatment. The resistance may be related to the misdiagnosis rather than an actual lack of therapeutic response. We present, to our knowledge, the largest series of patients with RTE due to radial nerve entrapment in the radial tunnel. Radial tunnel syndrome is a pain syndrome characterized by point tenderness distal to lateral epicondyle(LE) with radiation distally into the dorsal forearm due to compression of the deep motor branch of the radial nerve (posterior interosseus nerve or PIN) as it courses through the radial tunnel. With longstanding compression these patients may go on to develop motor findings.

Methods: Our study group consist of 23 patients, that were referred for evaluation of ongoing lateral elbow region pain unresponsive to conservative or invasive treatment. Evaluation consisted of thorough history and clinical examination. Ultrasound (US) examination of the elbow was performed by one of two experienced sonographers with a LOGIC E(General Electric, Waukesha, Wisconsin) using a 12-7 MHz linear probe. In addition the radial nerve was examined from its origin to the wrist in both upper extremities. All patients subsequently underwent surgical exploration by the same hand surgeon with release of the compressive structures.

Summary of the Results: US findings included: positive "sonopalpation" in 19/23 patients at the proximal radial(proximal to Arcade of Frohse) and in 4/23 patients at the distal radial tunnel. The nerve was enlarged in relationship with the contralateral nerve, in the proximal tunnel in 9/23 patients and distal to the exit of the tunnel in 3/23 patients. No US changes were observed in 11/23 patients. In the 10 patients that underwent electrophysiologic testing only one was positive and in all 8 patients that had MRI there no evident changes of the PIN. At surgery all patients were found to have enlargement of the radial nerve. In 19/23 the enlargement was noted proximal to the Arcade of Frohse. In 3/23 patients the enlargement was noted distal to the exit of the nerve from the distal radial tunnel. In the final patient enlargement was evident throughout the entire course of the radial nerve between the two heads of the supinator muscle.

Conclusion: High resolution US enables us to visualize the peripheral nervous system and is an important part of the evaluation of entrapment neuropathies. This study is the most extensive report of radial tunnel syndrome and confirms the value of US in the diagnosis of this entity prior to the onset of motor weakness. US was able to localize the precise point of involvement by sonopalpation. US was helpful to the surgeon in localizing the area of entrapment and in planning the most appropriate surgical approach.

We also propose the following classification criteria for Radial Tunnel Syndrome: Type l- Radial nerve involvement in the proximal portion of the tunnel proximal to the arcade of Frohse; Type ll – involvement of the distal portion as it emerges from the supinator heads; Type lll – diffuse enlargement throughout its couse between the supinator heads.

Clinic Based MSK Ultrasound in the Diagnosis and Treatment of Shoulder Pain—A Randomized Prospective Study. Aamir Saeed[2], Mumtaz Khan, Siobhan Morrissey and Alexander D. Fraser[1]. [1]Castleroberts, County Limerick, Ireland, [2]Mid Western Regional Hospital, Limerick, Ireland, Ireland

Introduction: Local corticosteroid injections are accepted by rheumatologists to be an effective option in the treatment of shoulder pain. Clinic based high frequency ultrasonography has been postulated to have a role in the diagnosis of shoulder pathology and guiding injections.

Aim: This randomized prospective study aims to assess whether clinic based MSK Ultrasound significantly improves the accuracy of diagnosis, treatment choices and positioning of injections in shoulder pain and if so whether this improves outcome.

Methodology: 100 consecutive patients with 125 painful shoulders were selected. Patients were randomized to receive either sonographic assessment and blind subacromial injection of 40 mg depomedrone (Group 1, n = 66) or a sonographic assessment and guided injection of 40 mg depomedrone (Group 2, n = 59). A blinded consultant rheumatologist performed all clinical assessments at baseline, 6 and 12 weeks including the hawkin-kennedy test, supraspinatous tendon tenderness, patient and physician global visual analogue score for pain (0–10). All differences between clinical and ultrasound diagnosis for shoulder pain and incidental ultrasound findings for asymptomatic shoulders were recorded.

Results: 80 patients with 90 symptomatic shoulders (46 blinded and 44 guided groups) completed the study. Mean age 57.7 years, 65% female; mean

shoulder pain duration was 18 weeks (14–22). Shoulder function tests (SFT), improved significantly from baseline in both groups at 6 and 12 weeks. However significantly greater improvements were noted at both time points in the guided versus the blind injection groups (Delta BL $p<0.01$ and $p<0.05$) respectively. Patient VAS scores and PGA for pain also improved significantly in both groups at 6 and 12 weeks but again improvements were significantly greater at both time intervals in the guided group $p<0.05$. 20 patients, 11(19 shoulders) from blinded and 9(16 shoulders) from guided group were excluded from study at 6 weeks either due to repeat injection or surgical referral. About 10% of asymptomatic contra-lateral shoulders significant pathology on ultrasonography ranging from shoulder impingement to full thickness tears. 8% of clinical diagnoses differed significantly from the ultrasound diagnosis and with clinical relevance.

Conclusions: Both blind and guided steroid injections are associated with significant improvements in shoulder function and pain when assessed at 6 and 12 weeks. Guided injections are more effective and should at least be considered in non-responders. 2 Clinically relevant differences between clinical and ultrasonographic diagnosis may occur and significant pathology may be identified in contra-lateral asymptomatic shoulders raising interesting insights into the historical pathophysiology of shoulder pain.

Sonographic Needle Guidance and Cost-Effectiveness of Intraarticular Injections for Osteoarthritis of the Knee. Natalia R. Chavez-Chiang[3], Wilmer L. Sibbitt[4], Suzanne Delea[2], Kye Park[6], Arthur D. Bankhurst[5], Philip A. Band[1] and Hillary Norton[3]. [1]New York University School of Medicine, [2]University of New Mexico, Albuquerque, NM, [3]University of New Mexico, [4]University of New Mexico HSC, Albuquerque, NM, [5]University of NM Med Ctr, Albuquerque, NM, [6]Univresity of New Mexico, Albuquerque, NM

Objective: The present randomized controlled study addressed whether sonographic needle guidance affected the outcomes of intraarticular injection for osteoarthritis of the knee.

Methods: 94 non-effusive knees with osteoarthritis were randomized to injection by conventional palpation-guided anatomic injection or sonographic image-guided injection enhanced with a one-handed RPD (the reciprocating procedure device) syringe. A one needle, two-syringe technique was used. After intraarticular placement and synovial space dilation were confirmed by sonography, a syringe exchange was performed, and 80 mg of triamcinolone acetonide was injected with the second syringe through the indwelling intraarticular needle. Baseline pain, procedural pain, pain at outcome (2 weeks and 6 months), responders, therapeutic duration, reinjection rates, total cost, and cost per responder were determined.

Figure 1.

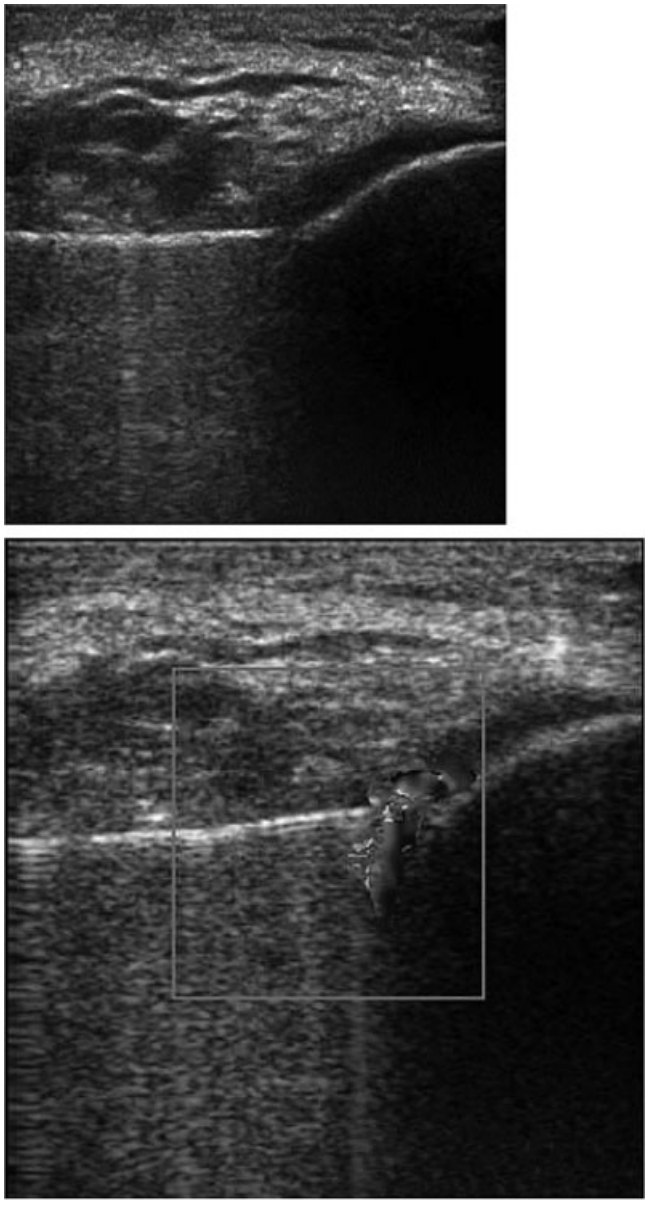

Figure 2.

Results: Relative to conventional palpation-guided methods, sonographic guidance for injection of the knee resulted in 47.7% reduction in procedural pain ($p<0.001$), a 41.7% reduction in pain scores at outcome ($p<0.03$), 107% increase in the responder rate ($p<0.001$), 51.6% reduction in the non-responder rate ($p<0.001$), a 35.5% increase in therapeutic duration ($p=0.01$), a 14.6% reduction ($48) in cost/patient/year, and a 58.8% ($593) reduction in cost/responder/year for a hospital outpatient ($p<0.001$).

Conclusions: Sonographic needle guidance improves the performance, clinical outcomes, and cost-effectiveness of intraarticular injections of the osteoarthritic knee.

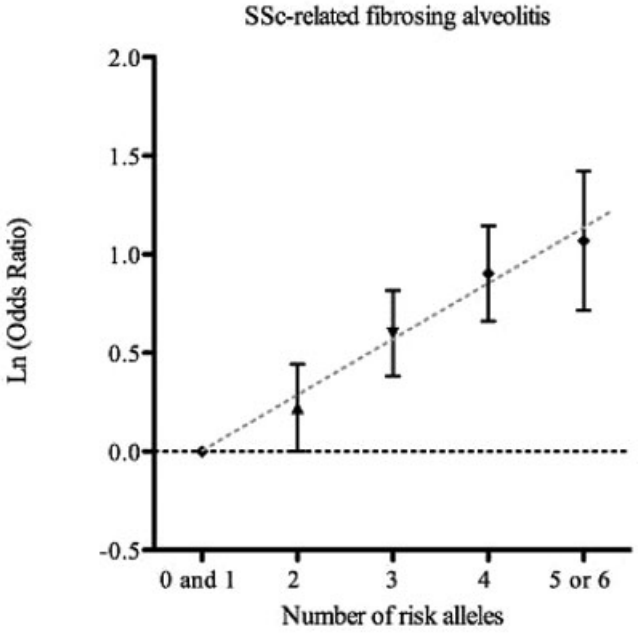
Identification of NLRP1 as a Systemic Sclerosis Susceptibility Gene: A New Clue for the Contribution of Innate Immunity in SSc Pathogenesis. Philippe Dieudé[7], Mickaël Guedj[4], Julien Wipff[6], Gabriela Riemekasten[2], Paolo Airo[8], Inga Melchers[1], Marco Matucci-Cerinic[10], Eric Hachulla[5], Catherine Boileau[9], Yannick Allanore[3] and and the GENESYS Consortium. [1]Clinical Research Unit for Rheumatology, University Medical Center, Freiburg, Germany, [2]Department of Rheumatology and Clinical Immunology, Charité University Hospital, Schumannstr. 20/21, D-10117, Berlin, Germany, [3]Hopitaux de Paris Cochin, Paris, France, [4]Laboratoire Statistique et Génome, UMR CNRS-8071/INRA-1152/Université d'Evry Val d'Essonne, France, [5]National Scleroderma Centre, Lille Cedex, France, [6]Paris Descartes University, Department of Rheumatology A, Cochin Hospital, Paris, France, [7]Paris Diderot University, Department of Rheumatology, Bichat Claude Bernard Hospital, APHP, Paris, France, [8]Rheumatology and Clinical Immunology, Spedali Civili, Brescia, Italy, [9]Saint Quentin Yvelines University, Laboratoire de Biochimie Hormonale et Génétique, Ambroise Paré Hospital, AP-HP, Boulogne, France, [10]University of Florence, Firenze, Italy

Background: Recent evidence has highlighted a potential role of interleukin 1 beta (IL-1β) in systemic sclerosis (SSc). NLRP1 provides a scaffold for the assembly of the inflammasome that promotes the processing and maturation of pro-IL-1β. In addition, NLRP1 variants were found to confer susceptibility to autoimmune disorders.

Objective: To test for association the NLRP1 SNPs rs6502867, rs26706600, rs8182352, rs12150220, rs4790797 with SSc in the European Caucasian population.

Methods: NLRP1 SNPs were genotyped in 3227 individuals comprising a Discovery set (870 SSc patients and 962 controls) and a Replication set including individuals from Germany (532 SSc patients and 324 controls) and Italy (527 SSc patients and 301 controls), all individuals being of European Caucasian origin.

Results: Conditional analyses revealed a significant association only for the NLRP1 rs8182352 variant. Both the NLRP1 rs8182352 C allele variant and the CC genotype were found to be associated with SSc-related fibrosing alveolitis (FA+) in the combined population: OR 1.19 95% CI [1.05–1.36], P=0.0065 and OR 1.43 95% CI [1.10–1.84], P=0.0063, respectively. Significant differences were also found when the FA+ SSc patients were compared to the FA- SSc patients. Linear regression analysis showed an additive effect of IRF5 rs2004640, STAT4 rs7574865 and NLRP1 rs8182352 risk alleles on SSc-related fibrosing alveolitis.



Conclusions: Our results establish NLRP1 as a new genetic susceptibility factor for SSc. This provides new insights into the pathogenesis of SSc, underlining the potential role of innate immunity in particular in the FA+ SSc sub-phenotype, which represents a severe subset of the disease.

MASP-1 and Pro-Factor D Proteins Are Present in Synoviocytes and May Locally Activate the Complement Alternative Pathway To Induce Inflammatory Arthritis in Mice. Nirmal K. Banda[4], Minoru Takahashi[2], Magdalena J. Glogowska[4], Kazue Takahashi[3], Gregory L. Stahl[1], Teizo Fujita[2], William P. Arend[4] and V. Michael Holers[4]. [1]Center for Experimental Therapeutics and Reperfusion Injury, Brigham and Women's Hospital, Boston, MA, [2]Department of Immunology, Fukushima Medical University School of Medicine, Fukushima, Japan, [3]Department of Immunology, Massachusetts General Hospital for Children, Boston, MA, [4]Division of Rheumatology, University of Colorado at Denver, Aurora, CO

Purpose: Mannose-binding lectin-associated serine proteases 1/3 (MASP-1/3) can cleave pro-factor D (pro-Df) into active factor D (Df), which is required for activation of the alternative complement pathway (AP). The AP is both necessary and sufficient for mediation of collagen antibody-induced arthritis (CAIA) in mice. We have recently shown that *MASP1/3*$^{-/-}$ mice are resistant to CAIA due to a defective AP and MASP-1/3 protein is the predominant mechanism to cleave pro-Df in vivo. The objectives of this study were to examine whether MASP-1/3 not bound to mannose-binding lectin (MBL) or ficolins (FCN) can activate the AP, and if MASP-1 and pro-Df proteins are present in the joint.

Methods: Sera from wild type (WT), *MASP-1/3*$^{-/-}$, *MBL*$^{-/-}$*/FCN A*$^{-/-}$ and *FCN A*$^{-/-}$ C57BL/6 mice were used. CAIA was induced in WT and *MASP-1/3*$^{-/-}$ mice by injecting 4 anti-type II collagen (CII) mAb i.p. on day 0 and LPS i.p. on day 3. All mice were sacrificed on day 10. Sera from CAIA mice (with and without disease) and *MBL*$^{-/-}$*/FCN A*$^{-/-}$ mice were analyzed by western blot analysis for the presence of pro-Df and Df. Immunohistochemical (IHC) analysis was performed for the presence of MASP-1/3 and pro-Df proteins in the knee joints of mice with or without CAIA. Sera from *MBL*$^{-/-}$*/FCN A*$^{-/-}$ mice were examined for the presence of MASP-1 using a gel filtration assay followed by western blot analysis. Additionally, sera from *MBL*$^{-/-}$*/FCN A*$^{-/-}$ and *FCN A*$^{-/-}$ mice were examined in vitro for AP activation induced by anti-CII antibodies, zymosan and mannan.

Results: In the sera of WT and *MBL*$^{-/-}$*/FCN A*$^{-/-}$ mice, factor D existed exclusively in its active form, indicating that pro-Df is cleaved by MASP-1 in both sera. Conversely, sera from *MASP1/3*$^{-/-}$ mice contained only pro-Df. There was no conversion of pro-Df to Df between day 0 (without disease) and day 10 (with CAIA) in *MASP1/3*$^{-/-}$ mice. MASP-1/3 proteins are normally bound to MBL or FCN; however, we detected MASP-1/3 in the sera of *MBL*$^{-/-}$*/FCN A*$^{-/-}$ mice which might be bound to an unknown protein. Anti-CII mAb, zymosan and mannan particles all induced C3b deposition and C3a and C5a generation in vitro using sera from *MBL*$^{-/-}$*/FCN A*$^{-/-}$ and *FCN A*$^{-/-}$ mice under conditions where only the AP was active. These results suggest that MASP-1/3 is present in the circulation of *MBL*$^{-/-}$*/FCN A*$^{-/-}$ mice and can initiate the AP of complement in vitro. IHC analysis showed the presence of MASP-1/3 in the synovium, but not on chondrocytes, in the knee joints of WT mice with CAIA. Pro-Df was found by IHC both in the synovium and on chondrocytes in the knee joints of *MASP1/3*$^{-/-}$ mice without CAIA. These results indicate that MASP-1/3 protein is the predominant mechanism for cleavage of pro-Df in vivo and may activate the AP locally. Future studies will examine whether MASP-1 and pro-Df proteins are produced by the same cell in the synovium and whether conversion of pro-Df to Df occurs locally inside the cell or in the microenvironment.

Conclusions: MASP-1/3 protein predominantly cleaves pro-Df *in vivo* in CAIA. This study demonstrated that MASP-1/3, in the absence of MBL or FCN, can act locally in the knee joint and in the circulation to initiate the AP and inflammatory disease.

Mutated NLRP3 in Cryopyrin-Associated Periodic Syndromes Is Released from Restriction by CARD8. Sayaka Ito[2], Yukichi Hara[3], Yukio Shima[1] and Tetsuo Kubota[3]. [1]Kyorin University, [2]Tokyo Medical and Dental University, Tokyo, Japan, [3]Tokyo Medical and Dental University

Purpose: NLRP3 in monocytes and other cell types plays a role in innate immunity as one of the intracellular pathogen recognition receptors, and its mutation is responsible for cryopyrin-associated periodic syndromes (CAPS). Once activated, NLRP3 forms a protein complex called the inflammasome with procaspase-1 and an adaptor protein ASC, leading to activation of caspase-1 and production of mature proinflammatory cytokines IL-1β and IL-18. Some experiments using cells expressing truncated NLRP3 indicated interaction between the NACHT domain of the NLRP3 and the FIIND domain of another adaptor protein CARD8, but involvement of CARD8 in NLRP3 inflammasome remains controversial. We herein aimed to clarify the role of CARD8 in NLRP3 inflammasome and its relevance to the pathophysiology of CAPS.

Methods: HEK 293 cells were transiently transfected with ASC, CARD8, procaspase-1, proIL-1β, and NLRP3 in wildtype or with CAPS-associated mutation. 24h later, whole cell lysates were provided for immunoprecipitation and western blotting. 48h after transfection, IL-1β in the culture supernatant was measured by ELISA.

Results: Wild type full-length NLRP3 was immunoprecipitated with CARD8, but interestingly, this interaction was inhibited by coexpression of ASC in a dose-dependent manner, suggesting that affinity between NLRP3 and ASC is higher than that between NLRP3 and CARD8. In contrast, NLRP3 with CAPS-associated mutation R260W or H312P was unable to interact with CARD8. Cells expressing wildtype NLRP3, ASC, procaspase-1 and proIL-β spontaneously produced IL-β, and it was significantly suppressed by cotransfection with full-length CARD8. Cotransfection of the FIIND domain of CARD8 showed less, but still significant, suppressive effect on the IL-1β production.

Conclusions: CARD8 interacts with full-length wildtype NLRP3, and may prevent the NLRP3 inflammasome from unristricted activation. Disability of CARD8 to interact with mutated NLRP3 may explain continuous release of IL-1β by monocytes from CAPS patients.

2229

Complement Component C5 Plays a Central Role in Osteoarthritis. William Robinson[3], Andrew L. Rozelle[1], Tamsin M. Lindstrom, Reuben Gobezie, V. Michael Holers[4], David M. Lee[2] and Qian Wang. [1]Menlo Park, CA, [2]Brigham and Womens Hospital, Boston, MA, [3]Stanford Univ School of Med, Stanford, CA, [4]Univ of Colorado School of Med, Aurora, CO

Background/Purpose: Osteoarthritis (OA) is characterized by the breakdown of articular cartilage and is generally believed to result from "wear and tear". Although low-grade inflammatory responses are observed in OA, their contribution to its pathogenesis is unclear. We investigated a role for the complement system—and specifically complement component C5 and the membrane attack complex (MAC)—in the pathogenesis of OA.

Methods: Proteins present in synovial fluids derived from OA patients were surveyed by mass spectrometry. ELISA analysis was used to assess activation of the complement cascade in OA synovial fluid and in serum incubated with cartilage proteins. Immunohistochemical staining with antibodies specific for the MAC (comprising complement components C5b-9) was performed on remnant cartilage tissue from patients with OA. Bioinformatic analysis was performed on RNA profile datasets from OA and healthy synovial membrane to determine relative levels of expression of the complement effectors and inhibitors identified by mass spectrometry. A murine model of OA, generated by surgical medial meniscectomy, was used to determine the susceptibility of mice deficient in complement component C5 to OA. Arthritis severity was assessed by histological analysis of toluidine-blue-stained joint sections and by gait analysis performed using the CatWalk System. Finally, qPCR and immunoassays were used to determine the effects of sublytic MAC on chondrocyte gene and protein expression.

Results: Mass spectrometry analysis revealed the presence of multiple complement effectors and inhibitors in the synovial fluid of OA patients. ELISA analysis demonstrated elevations of C3a and C5b-9 in OA synovial fluids, indicating activation of the complement cascade. Further, synovium derived from OA patients was found to express complement components, whereas synovium from healthy individuals expressed complement inhibitors, suggesting that the synovium contributes to a local imbalance in the complement system in OA joints. Using an *in vivo* model of OA, we found that mice deficient in the central complement component C5 are protected against the development of degenerative arthritis, as assessed histologically and by gait analysis. Wild-type mice treated with an anti-C5 antibody were similarly protected. Moreover, the MAC (the cell-bound form of C5b-9) was detected on chondrocytes in cartilage from OA patients, and deposition of sublytic MAC on chondrocytes derived from OA cartilage induced the production of matrix–degrading enzymes, cell cycle regulators, inflammatory mediators, and complement components.

Conclusions: Our results suggest that local dysregulation of complement in synovial joints plays a critical role in the development of OA. Further, we demonstrate a critical role for the complement component C5 in the pathogenesis of experimental OA.

Toll-Like Receptor 2 Negatively Regulates FCg Receptor Response in Macrophages and Inhibits FCgR-Mediated Arthritis. Shahla Abdollahi-Roodsaz[3], Marije I. Koenders[2], Fons A. J. van de Loo[4] and Wim B. Van Den Berg[1]. [1]Radboud Univ Nijmegen Med Cntr, Nijmegen, The Netherlands, [2]Rheumatology Research and Advanced Therapeutics, Radboud University Nijmegen Medical Centre, Nijmegen, [3]Rheumatology Research and Advanced Therapeutics, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, Nijmegen, The Netherlands, [4]Rheumatology Research and Advanced Therapeutics, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands

Current evidence indicates that Toll-like receptors (TLRs) and FCg receptors (FCgRs) are involved in the pathogenesis of arthritis and mutual regulatory functions for these innate immune receptors have been suggested as well. In the present study, we investigated the involvement of TLR2 in regulation of FCgR response and assessed the functional consequences for the development of arthritis.

Peritoneal macrophages from naïve wild-type (WT) and TLR2$^{-/-}$ mice were stimulated with heat-aggregated gamma globulins (HAGGs) and immune complexes, and cytokine production was evaluated. Although no clear shift was noticed in the expression pattern of activating and inhibitory FCgRs, macrophages from TLR2$-/-$ mice showed a greatly exaggerated functional response (>6 fold) and produced much more TNFa, IL-1b and IL-6 upon FCgR triggering compared to WT cells.

To assess the functional consequence of enhanced FCgR response in TLR2$^{-/-}$ condition for arthritis, FCgR-driven serum-transfer arthritis was induced by i.p. injection of serum from arthritic K/BxN mice. TLR2$^{-/-}$ mice showed an accelerated onset of arthritis and had a strikingly enhanced disease severity. Marked increase in inflammation was also obvious in the knee joints in addition to the paws. Furthermore, gene expression of several proinflammatory cytokines, including TNF, IL-1 and IL-6, and certain matrix metalloproteinases was enhanced in synovial tissue of TLR2$^{-/-}$ mice compared to WT.

PCR analysis revealed that basal expression of activating and inhibitory FCgRs in peritoneal macrophages, spleen and synovial tissue of arthritic mice was not affected by TLR2 deficiency. Furthermore, regulation of FCgR expression in macrophages upon stimulation with K/BxN serum and HAGGs was not affected. However, macrophages from arthritic TLR2$^{-/-}$ mice released significantly more TNF and IL-6 upon general PMA/ionomycin stimulation, while having similar levels of IL-10 compared to WT cells. This indicates a potentiated M1 and similar M2 profile in macrophages from arthritic mice in the absence of TLR2. Importantly, FCgR triggering of macrophages isolated briefly after disease induction and before appearance of clinical differences using immune complexes resulted in markedly higher levels of TNF and IL-6, but not

IL-10, in TLR2$^{-/-}$ condition. Unaltered response of TLR2$^{-/-}$ macrophages to IL-1 as control excluded a non-specific effect.

These findings indicate an important regulatory function of TLR2 in macrophage FCgR response with remarkable consequences for arthritis expression. A protective role of TLR2 in immune-complex driven arthritis beyond its previously-described role in promoting regulatory T cell function may provide a relevant therapeutic intervention for the future treatment of RA.

A Novel Role of Endothelin-1 in Linking Ro60-ssRNA Immune Complexes to Cardiac Fibrosis in Congenital Heart Block. David Alvarez-Carbonell[4], Jiri Zavadil[5], Rosanna Abellar[1], Franck Barrat[2], Robert Clancy[3] and Jill Buyon[5]. [1]Columbia University Medical Center, [2]Dynavax Technologies, [3]New York University School of Mediciine, [4]New York University School of Medicine, New York, NY, [5]New York University School of Medicine

Passively acquired anti-Ro associated congenital heart block (CHB) likely results from pathologic crosstalk between inflammatory and fibrosing pathways eventuating in scarring. The target, Ro60, complexed with uridine rich ssRNA induces TLR7-dependent macrophage production of supernatants capable of trans-differentiating human fetal cardiac fibroblasts. This study addressed the molecular components responsible for the TLR-dependent profibrosing effects. In seeking the link between an inflammatory response of macrophages and the profibrotic effect on fibroblasts, a microarray analysis comparing the mRNA expression profile of macrophages stimulated with hY3 (ssRNA associated with Ro60) or immune complexes consisting of Ro60-hY3-IgG fraction containing anti-Ro60 antibodies (IC) in the presence or absence of IRS661 (antagonist of TLR7) was performed. Gene expression of the vasoconstrictor endothelin-1 (ET-1), recently shown to promote dermal fibrosis, was significantly up-regulated by $\sim$ 4 fold and confirmed by RT-PCR. Incubation of macrophages with either hY3 or IC increased secretion of ET-1 from 2.64 pg/mL (baseline) to 9.67 pg/mL ($p < .0001$) and 7.52 pg/mL ($p = .0003$) respectively. Pre-treatment with IRS661 decreased hY3-induced secretion to 3.83 pg/mL and IC to 3.98 pg/mL. The direct effect of ET-1 (100 nM) on these fibroblasts (shown to express both ETa and ETb receptors) resulted in a profibrosing phenotype as demonstrated by a) TGFbeta secretion (13 pg/mL vs. 772 pg/mL, $p = .03$), b) increased collagen release (18 ng/mL baseline vs. 772 ng/mL, $p = .05$, and c) expression of α-smooth muscle actin (α-smac). ET-1-induced TGFbeta secretion was significantly decreased ($p = .03$) by each of the following: BQ-123, an ETa antagonist (119 pg/mL), BQ-788, an ETb antagonist (145 pg/mL), and anti-ET-1 antibody (211 pg/mL), but not isotype control antibody (691 pg/mL). Similarly, ET-1-induced collagen secretion was significantly decreased ($p = .05$) by BQ-123 (147 ng/mL collagen), BQ-788 (247 ng/mL), anti-ET-1 antibody (253 ng/mL), and anti-TGFbeta antibody (239 ng/ml), but not isotype control (815 ng/mL). Predictably, pretreatment of fibroblasts with either BQ-123, BQ-788 or incubation of supernatants with anti-ET-1 antibody, but not isotype control, significantly inhibited the profibrosing readouts (increased TGFbeta, collagen and α-smac) induced by supernatants from macrophages stimulated with either hY3 or IC. Additionally, fibroblasts transfected with either ETa or ETb siRNA, but not scrambled siRNA, also significantly inhibited the profibrosing readouts induced stimulated macrophages. Immuno-histochemistry of a heart from a fetus dying with CHB revealed ET-1/2/3 antibody staining but not isotype IgG control in the septal region in areas showing calcification, fibrosis, and mononuclear cell infiltrates (not seen in an age-matched fetal heart). In conclusion, these data suggest that macrophage secretion of ET-1 may be one mechanism linking TLR inflammatory signaling to subsequent fibrosis and provide new insight in considering therapeutics for CHB.

Mucosal Associated Invariant T Cells Contribute to the Pathogenesis of Arthritis. Asako Chiba, Ryohsuke Tajima, Yusei Miyazaki, Takashi Yamamura and Sachiko Miyake. Department of Immunology, National Institute of Neuroscience, NCNP

Background: MR1-restricted mucosal associated invariant T (MAIT) cells are a subset of innate lymphocytes which express an invariant TCRα chain (Vα 19-Jα 33 in mouse and Vα 7.2-Jα 33 in human) with a limited set of TCRβ chains. We previously reported the regulatory role of MAIT cells in experimental autoimmune encephalomyelitis, an animal model of multiple sclerosis. To understand their role in animal models of arthritis, we generated MR1$^{-/-}$ DBA1/J mice and analyzed their disease susceptibility to collagen-induced arthritis(CIA). We also investigated if MAIT cells are involved in the effector phase of arthritis by using two animal models of antibody-induced arthritis (AIA). Finally we studied mechanisms by which MAIT cells modulate autoimmune responses.

Methods: To obtain MR1$^{-/-}$ DBA1/J mice, MR1$^{-/-}$C57BL/6 mice were backcroosed to DBA1/J mice for ten generations. To induce CIA, MR1$^{-/-}$ DBA/1J mice or WT littermates were immunized intradermally with bovine type II collagen (CII) (150μg) in Freund's complete adjuvant containing 250μg of H37Ra *Mycobacterium tuberculosis* on day 0 and CII in IFA on day 21. AIA was induced in MR1$^{-/-}$ C57BL/6 mice and WT littermates by injecting either K/BxN serum i.p. or a mixture of anti-type II collagen antibodies i.v. followed by lipopolysaccharide i.p. Vα 19i T cells (mouse MAIT cells) were sorted from liver or spleen cells of Vα19iTCR-Transgenic (Vα 19iTg) CD1d$^{-/-}$ mice by using anti-TCRβ and anti-NK1.1 monoclonal antibodies. In adoptive transfer studies, NK1.1^{+} TCRβ^{+} Vα19i T cells sorted from Vα19iTg CD1d$^{-/-}$ mice were injected i.v. into MR1$^{-/-}$ mice on one day before the induction of arthritis. Cytokine producing capacity of MAIT cells stimulated with or without anti-CD3mAb in the presence of various types of cytokines was evaluated by ELISA or cytokine bead assay kit.

Results: MR1$^{-/-}$ DBA/1J mice were more resistant to CIA compared to WT littermates, as demonstrated by clinical and histological scores of arthritis. CII specific antibody levels in the serum were reduced in MR1$^{-/-}$DBA/1J mice compared to WT controls. The severity of clinical and pathological features of AIA was reduced in MR1$^{-/-}$ mice compared to control WT mice. MR1$^{-/-}$ mice reconstituted with MAIT cells developed severe forms of arthritis to the similar level of arthritis in WT mice. IL-17 production by anti-CD3mAb-stimulated MAIT cells was highly augmented in the presence of IL-23. In addition, MAIT cells were activated and produced IL-17 upon IL-23 stimulation even without TCR stimulation.

Conclusions: MAIT cells contribute to the pathogenesis of arthritis. MAIT cells may be activated by cytokines which are abundant in inflammatory arthritis, and this may in turn amplify autoimmune responses.

An Endothelium-Specific NF-kappaB Inhibitor Ameliorates Inflammatory Joint Diseases. Bettina Sehnert[4], Harald Burkhardt[2], Falk Nimmerjahn[5], Johannes Wessels[1], Agnes Machnik[5], Dietmar Vestweber[6], Jochen Zwerina[5], Georg Schett[5], Stefan Dübel[3] and Reinhard Voll[5]. [1]Georg-August-University of Göttingen, [2]Johann Wolfgang Goethe University Frankfurt am Main, [3]Technical University of Braunschweig, [4]University of Erlangen-Nürnberg, Erlangen, Germany, [5]University of Erlangen-Nürnberg, [6]University of Münster

Background: Therapeutical strategies that systemically block nuclear transcription factor-kappaB (NF-kappaB)-signalling may cause serious side effects due to the important role of NF-kappaB in a variety of homeostatic regulatory pathways, for instance in the central nervous system, the liver and the immune system. NF-kappaB is a key player in inflammatory disorders such as rheumatoid arthritis. Activation induces the expression of multiple mediators involved in the initiation and perpetuation of inflammatory processes. We developed a novel class of NF-kappaB inhibitors, designated as ligand-sneaking construct (LSC), that interfere with the NF-kappaB signalling

pathway selectively in endothelial cells. We have choosen this cell population, because of its essential role in the extravasation of leukocytes in inflammation.

Methods: The LSC is a multimodular recombinant protein that consists of three domains: 1) an oligopeptide specifically binding the cytokine-activated endothelium 2) the translocation domain of pseudomonas exotoxin A (ETA II) that facilitates the endosomal release of the construct into the cytosol and 3) the NEMO-binding peptide (NF-kappaB inhibiting effector domain) (5). The effectiveness of this E-selectin specific construct (LSC1) on NF-kappaB activation was analysed in vitro by an NF-kappaB-luciferase reporter gene assay and EMSA. In vivo binding of LSC1 to the cytokine-activated endothelium was proven by using the Olympus OV100 whole-mouse imaging system. The therapeutic effect of LSC1 in vivo was investigated in the antigen-induced arthritis and the KBN serum transfer model.

Results: E-selectin mediated internalization of LSC1 inhibited the transcriptional NF-kappaB activity in E-selectin expressing cells (CHO_E cells). Additionally, EMSA indicated a reduced nuclear translocation of NF-kappaB upon cytokine activation in LSC1-pretreated CHO_E cells. In vivo imaging emphasized specific LSC1 binding to the activated endothelium. By whole mount immunofluorescence microscopy of tissue specimens derived from cytokine-activated mouse skin, nuclear form of NF-kappaB p65 was strongly suppressed in mice pretreated with LSC1 but not in control mice that had received the MutNBP2 construct. In the mouse model of antigen-induced arthritis, we observed a reduced joint swelling after LSC1 treatment. Moreover, LSC1 leads to an amelioration of inflammatory joint disease induced by anti-glucose 6 phosphoisomerase (anti-G6PI) mouse serum. Histological studies confirmed the clinical data.

Conclusions: We presented for the first time an endothelium specific NF-kappaB inhibitor that shows therapeutic potential to treat inflammatory joint diseases in different mouse models of arthritis. This proof of concept study can be employed for targeting other cell types and to interfere with distinct signalling pathways.

Citrullination of Mouse Collagen Breaks Tolerance and Induces an Inflammatory Arthritis in the Absence of Adjuvant. Jordan P. Lacy, Michael J. Duryee, Carlos D. Hunter, James R. O'Dell, Ted R. Mikuls, Geoffrey M. Thiele and Lynell W. Klassen. University of Nebraska Medical Center

Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune inflammatory disease that primarily affects the synovial joints. Anti-citrullinated protein antibodies (ACPA) are predictive markers of the disease and its severity. Previous studies have demonstrated that ACPA can be induced in mice following injection of citrullinated type II collagen (Cit-Coll) in the presence of Freund's complete adjuvant (FCA). Therefore, it was the purpose of this study to determine whether mouse Cit-Coll in the absence of adjuvant can break tolerance and initiate an inflammatory arthritis in DBA/1 mice.

Methods: Mouse type II collagen was citullinated using peptidyl arginine deiminase (PAD) and injected into DBA/1 mice at a concentration of (100 μg) in the base of the tail weekly for 5 weeks. Control groups were immunized with PBS, collagen, and collagen FCA. Animals were evaluated weekly for inflammation of the joints and serum was collected for the presence of anti-collagen or modified collagen antibodies. At week 6, animals were sacrificed paws removed for histology and spleens collected. The CD3+ T cells were then isolated and proliferated against collagen, albumin, Cit-Coll or Cit-albumin. Supernatants from the proliferation assays were collected and assayed for the presence of cytokines.

Results: Following 6 weeks of immunization, a significant increase in inflammation was observed as assessed by paw thickness and scoring in the Cit-Coll mice compared to controls. An increase in serum antibodies to Cit-Coll and Cit-albumin was present. However, no significant increase in antibodies to collagen was observed. In contrast, the immune response to Cit-Coll was predominantly T cell as shown by the increase in proliferative response to collagen and Cit-Coll. Assessment of cytokines from the proliferation supernatants reveled increases in IL-6 and IL-23 following from Cit-Coll immunized mice. Finally, histological analysis of joints from these animals showed an increase in joint erosion an inflammation in the Cit-Coll immunized mice.

Conclusions: These data support the observation that citrullination of proteins increases the risk of this erosive inflammatory disease. Also, that citrullinated mouse type II collagen immunized in the absence of adjuvant causes an increase in T-cell proliferation with minimal antibody response to native collagen. The T-cell cytokine responses generated an IL-6 and IL-23 profile indicating an autoimmune response. Also, joint erosion and inflammation is evident in the Cit-Coll immunized mice as determined by scoring, paw thickness, and histology. Thus, this report suggests that citrullinated self-proteins may result in the abrogation of tolerance and the induction of an autoimmune response.

Differentiation and Activation of Regulatory T-Lymphocytes in a TNF-alpha Transgenic Model of Arthritis, and the Impact of Passive or Active Anti-TNF Therapies. Jerome Biton[2], Luca Semerano[3], Laure Delavallée[2], Geraldine Grouard-Vogel[1], Delphine Lemeiter[2], Marie-Christophe Boissier[3] and Natacha Bessis[2]. [1]Neovacs, Paris, France, [2]Paris 13 University, Bobigny, France, [3]Paris 13 University and APHP, Bobigny, France

Background: TNF-alpha is a critical cytokine in rheumatoid arthritis (RA). We recently demonstrated the efficacy of active immunotherapy against TNF-alpha (TNF-K) in a human TNF-alpha transgenic (TTg) mouse model of arthritis. Studies with anti-TNF-alpha treatments in autoimmune diseases suggest that TNF-alpha and TNF-alpha antagonists might act through the involvement of a T cells subset, namely $CD4^+$ $CD25^+$ $FoxP3^+$ regulatory T cells (Tregs).

Objectives: In the present study, we aimed to better characterize the impact on the Treg population of (1) a TNF-alpha driven disease, specifically arthritis in TTg mice, and (2) active or passive anti-TNF-alpha immunotherapy in this same model.

Methods: First, untreated TTg mice were euthanized sequentially at the age of 7 weeks, 12 weeks, 17 weeks and 24 weeks. 7 week-old and 24 week-old C57Bl/6 wild type (WT) mice were used as controls. Subsequently, three groups of mice were used: TTg mice given three doses of TNF-K at 15, 16 and 19 weeks of age, TTg mice treated with infliximab and untreated TTg mice. Then half the mice in each group were euthanized at 24 weeks and the other half at 31 weeks. After each euthanasia, the percentage and number of Tregs and the percentage of Tregs cells expressing CTLA-4, TNFR2 and CD62L from the spleen and lymph nodes (LN) were determined. Finally, the immunosuppressive activity of the Treg cells was studied.

Results: hTNF-alpha overexpression induced an initial decline in Tregs. Then, once chronic inflammation was established, the frequency and the number of Tregs cells slightly increased with time, although it remained lower than in WT mice. We also observed a progressive and dramatic increase in TNFR2 expression (65.8% to 88.6% at weeks 7 and 24, respectively, $P<0,0001$) and MFI on Tregs from LN during the course of arthritis. We also confirmed that TNF-K was as effective as infliximab in treating established arthritis in TTg mice. Compared to untreated mice, hTNF-alpha blockade with either infliximab or TNF-K resulted in an increased Tregs frequency both in 24 and 31 week-old mice. Our study also showed that hTNF-alpha blockade induces an up-regulation of CTLA-4 expression by Treg cells in LN, accompanied by an increased Tregs suppressive activity on $CD4^+$ $CD25^-$ effector T cell proliferation. Finally, in LN of infliximab and TNF-K treated TTg

mice, we observed an expansion of induced Treg cells defined by the $CD4^+$ $CD25^+$ $FoxP3^+$ $CD62L^-$ phenotype.

Conclusion: In this study, in a strictly hTNF-alpha dependent inflammation model, we show for the first time that TNF-alpha can have different effects on Tregs, depending on the duration of exposure and on disease phase. Our work also shows that TNF-alpha blockade either by TNF-K or infliximab could depend not only on TNF-alpha neutralization but also on Treg upregulation.

The TRAF6 Binding Molecule p62/SQSTM1 Controls Inflammatory Bone Destruction in hTNFtg Mice. Adelheid Korb[7], Marianne Niedermeier[3], Anja Hillmann[7], Susanne Bürgis[1], George Kollias[5], Sven Herrmann[2], Thomas Pap[4], Thomas Weide[7], André Gessner[6] and Herrmann Pavenstädt[7]. [1]Department of Immunology, University Erlangen, Erlangen, Germany, [2]European Institute of Molecular Imaging, University Muenster, Germany, [3]Institute for Experimental Musculoskeletal Medicine, University Hospital Muenster, Muenster, Germany, [4]Institute for Experimental Musuculoskeletal Medicine, University Hospital Muenster, Muenster, Germany, [5]Institute of Immunology, Biomedical Science Research Center, Vari, Greece, [6]Institute of Microbiology - Clinical Microbiology, Immunology and Hygiene, University Hospital Erlangen, Erlangen, Germany, [7]Internal Medicine D, Department of Nephrology and Rheumatology, University Hospital Muenster, Muenster, Germany

Background: Activation of NF-kappaB via RANK is essential in regulating osteoclastogenesis. This process is enhanced by pro-inflammatory cytokines such as TNFalpha. P62/SQSTM1 directly modulates these pathways through complex formation with TRAF6, aPKCs and ubiquitin. However, the function of p62/SQSTM1 in regulating bone turnover under inflammatory conditions and specifically the role of the signal transduction domains of p62/SQSTM1 in this process is not known.

Methods: Mice carrying a mutant of p62 with functional ubiquitin-binding but defective signal transduction domains ($p62^{aa\Delta 69-251)}$ were interbreed with arthritic hTNFtg mice. All resulting genotypes were scored for clinical parameters for 14 weeks. For quantification of inflammation, cartilage degradation and number of osteoclasts, joints of 14 wks old mice were stained with toluidin-blue and TRAP. To identify abnormalities in bone metabolism and bone structure high resolution micro-CT and Fluoride/FDG-PET analyses were performed. In addition, bone marrow derived monocytes (BMDMs) of wt and $p62^{aa\Delta 69-251}$ mice were isolated and osteoclastogenesis was studied using an established osteoclast formation assay. To investigate the underlying signalling pathways, cells were treated with TNFalpha and RANKL at different time points, and the activation of MAPKs was studied by Western Blot analysis.

Results: Histology and in vivo PET/CT studies revealed an increase in bone metabolism and bone mass in the hind paws, knees and vertebrae of $p62^{aa\Delta 69-251}$ mice, but the number and size of osteoclasts of $p62^{aa\Delta 69-251}$ and wt animals showed only minor changes suggesting that under physiological conditions the lack of the signal transduction domains of p62 is compensated by regulatory mechanisms. Compared to wt cells, however, BMDMs of $p62^{aa\Delta 69-251}$ mice showed a significantly increased osteoclastogenesis, especially when stimulated with TNFalpha. Crossing of $p62^{aa\Delta 69-251}$ mice with hTNFtg animals resulted in a dramatic increase in the severity of joint damage in the hTNFtg/$p62^{aa\Delta 69-251/wt}$ mice as determined clinically, by histomorphometry and PET/CT analysis. This was accompanied by an increase in the number and size of osteoclasts in vivo. During osteoclastogenesis, BMDMs from $p62^{aa\Delta 69-251}$ mice showed an enhanced TNFalpha- induced ERK1/2 and p38 MAPK phosphorylation compared to that of wt mice.

Conclusion: In summary, our data suggest that p62 plays a relevant role in regulating TNFalpha mediated joint damage. They indicate that the loss of the TRAF6 and aPKCs binding domains has essential consequences for osteoclastogenesis under inflammatory conditions.

Low Blood Concentration of Hydroxychloroquine Is Associated with Failure of Hydroxychloroquine Treatment in Patients with Cutaneous Lupus: Results of a Prospective Study. Camille Francès[1], Anne Cosnes[1], Pierre Duhaut[2], Noël Zahr[3], Boutros Soutou[1], Saskia Oro[1], Didier Bessis[1], Jacqueline Chevrant-Breton[1], Nadege Cordel[1], Dan Lipsker[1] and Nathalie Costedoat-Chalumeau[3]. [1]Department of Dermatology, Hôpital Tenon, Paris, France, [2]Department of Dermatology, Hôpital Tenon, [3]Internal Medicine Department, French National Reference Center for SLE, Pitié-Salpêtrière Hospital (GHPS), Paris, France

Introduction: We have previously demonstrated that low whole-blood concentration of Hydroxychloroquine [HCQ] is a marker for and a predictor of disease exacerbations in SLE patients, and we proposed 1,000 ng/ml as the target [HCQ] (Costedoat-Chalumeau, Arthritis Rheum, 2006). Very low [HCQ] (i.e. [HCQ] < 200 ng/ml) is a marker for poor adherence to HCQ treatment (Costedoat-Chalumeau, Ann Rheum Dis, 2007).

We studied for the first time, the relationship between [HCQ] and efficacy of HCQ in patients with cutaneous lupus.

Methods: Patients treated with HCQ for a cutaneous lupus were prospectively included in this multicentric study. Clinical status was determined by a dermatologist who was blinded for [HCQ]. Complete remission was defined by the disappearance of all cutaneous lesions, partial remission by an improvement > 50% and failure by other cases. At the end of the study, [HCQ] was measured by HPLC.

Results: We included 300 patients: 253 (84%) women and 47 (16%) men, median age 44 years [12–86]. Cutaneous lupus included discoid lupus (n=160), subacute cutaneous lupus (n=86), lupus tumidus (n=52), chilblain lupus (n=26), and panniculitis (n=16), and 41 patients had 2 or more associated forms. Most patients (83%) were treated with 400 mg/d of HCQ. Clinical status was complete remission (n=114), partial remission (n=86) or failure (n=100).

The median [HCQ] was 758 ng/ml [<50–3057]. [HCQ] was significantly higher in patients with complete remission (910 [<50–3057] vs 692 [<50–2843] if partial remission, and 569 [<50–2242] if failure; p=0.007).

[HCQ] was significantly lower in men (557 [<50–1572] vs 801 [<50–3057] in women; p = 0.006) who more frequently reported poor adherence to HCQ treatment (28% vs 11%; p = 0.002). [HCQ] correlated with the number of reported omissions of HCQ (p = 0.01).

Thirty patients (10%) had [HCQ] below 200 ng/ml and were considered as non-adherent. There were 8 patients in complete remission group, 8 in partial remission group, and 14 in failure group. Number of self-reported omissions of HCQ was significantly higher (p = 0.0001) in non-adherent patients.

After exclusion of non-adherent patients, [HCQ] was 850 ng/ml [201–3057] in the remaining 270 patients. [HCQ] remained significantly higher in patients with complete remission (952 [224–3057] vs 755 [212–2843] if partial remission and 692 [201–2242] if failure, p=0.026).

In the whole group, [HCQ] was significantly correlated to BMI (p = 0.02), weight (p = 0.002) and height (p = 0.05). There was no correlation between [HCQ] and cigarette smoking, daily dose of HCQ or number of omissions of HCQ.

In multivariate analysis, factors associated with complete remission were higher [HCQ] (p=0.005), and the absence of discoïd lesions (p=0.037). This remained true when analysis was performed after

exclusion of non-adherent patients (p=0.01 and p=0.016 respectively).

Comment: [HCQ] allowed detection of non-adherence to treatment in 10% of cases. Even after exclusion of non-adherent patients, low [HCQ] was associated with failure of HCQ treatment in patients with cutaneous lupus. Regular drug assaying and individual tailoring of treatment might help to improve the efficacy of HCQ treatment in patients with cutaneous lupus.

Factors Associated with Low Blood Concentration of Hydroxychloroquine in 523 Patients with Systemic Lupus Erythematosus: Data from the PLUS Study. Nathalie Costedoat-Chalumeau[2], Lionel Galicier[2], Camille Francès[2], Olivier Aumaître[2], Frédéric Lioté[2], Véronique Le Guern[2], Nicolas Limal[2], Amar Smail[2], J. Ninet[2], Laurent Perard[2], Du Le Thi Huong[2], Bouchra Asli[2], Catherine Grandpeix[2], Laurent Sailler[2], F. Ackermann[2], Thomas Papo[2], Benoit Brihaye[2], Olivier Fain[2], Jérome Stirnemann[2], Moez Jallouli[2], Gaelle Leroux[2], Jean-Sébastien Hulot[2], Philippe Lechat[2], Lucile Musset[2], Jean-Charles Piette[2], Zahir Amoura[2] and The Investigators of the PLUS Study[1]. [1]Internal Medicine Department, French National Reference Center for SLE, Pitié-Salpêtrière Hospital, Paris, France, [2]Internal Medicine Department, French National Reference Center for SLE, Pitié-Salpêtrière Hospital

Objectives: We have previously demonstrated that low whole-blood Hydroxychloroquine concentration [HCQ] is a marker for and predictor of systemic lupus erythematosus (SLE) flares [1]. The French multicenter randomized PLUS study (NCT 00413361) is currently assessing the potential benefits of individualized HCQ dosing schedules aimed at maintaining the [HCQ] above 1,000 ng/ml in SLE patients. According to the design of PLUS study, all patients have a measurement of [HCQ]. We studied the relationship between [HCQ] and epidemiological data at baseline.

Methods: Among the 569 included in the PLUS study, 523 patients who were treated with the same dose of HCQ (400 mg/d) were studied. [HCQ] was measured at the time of inclusion, and the patients were divided into 2 groups according to their [HCQ]: group A ([HCQ] $<$ 750 ng/ml), and group B ([HCQ] $\geq$ 750).

Results: The following parameters were similar between group A (179 patients) and group B (344 patients): mean age and duration of SLE, current smoking status, family history of SLE, frequency of associated antiphospholipid syndrome, values of C3, anti-nucleosome antibodies and anti-DNA antibodies, % of patients treated with immunosuppressive drugs, and mean daily dose of prednisone

In group A (low [HCQ]), the % of men (14.6 vs 6.2, p=0.004), weight (69±15 vs 62±12 kg, p<0.0001), BMI (25.4±4.2 kg/m2 vs 23.2±5.3; p<0.001) and estimated creatinine clearance (114±35 vs 99±29 ml/min; p<0.0001) were significantly higher compared to group B. After exclusion of men, the difference remained significant for weight and creatinine clearance.

At inclusion, 106 patients in group A (58%) were treated with steroids vs 238 in group B (69%, p = 0.02). Adherence to the prescription of HCQ assessed by the investigator on a VAS (from 0 to 10) was significantly lower in group A (8.99±1.3) compared to group B (9.3±1.03, p=0.003). Even though patients were excluded if they had a SLEDAI $>$ 12, we found a significantly higher SLE activity in group A (mean SLEDAI: 2.41±2.5 vs 1.88±2.34, p = 0.016). This difference held on even in the subset of patients treated with steroids (2.94 ± 2.62 vs 2.16±2.54, p=0.019). Platelet counts were significantly lower in group A (225,000± 75,000 vs. 268,000±71,000/mm3, p<0.0001).

In multivariate analysis, factors associated with low [HCQ] were low level of platelets (p<0.0001), high clearance of creatinine (p<0.001), absence of treatment with steroids (p=0.003), poor adherence (p=0.003), high BMI (p=0.007) and SLE activity (p=0.024).

Conclusion: This preliminary analysis confirms in a new set of patients our previously reported association of low [HCQ] with a higher SLE activity [1]. This was not expected given that patients included in PLUS study have low SLE activity according to inclusion criteria. Other parameters associated with low [HCQ] included high BMI, poor adherence assessed by the investigator, low platelet count, and high estimated creatinine clearance.

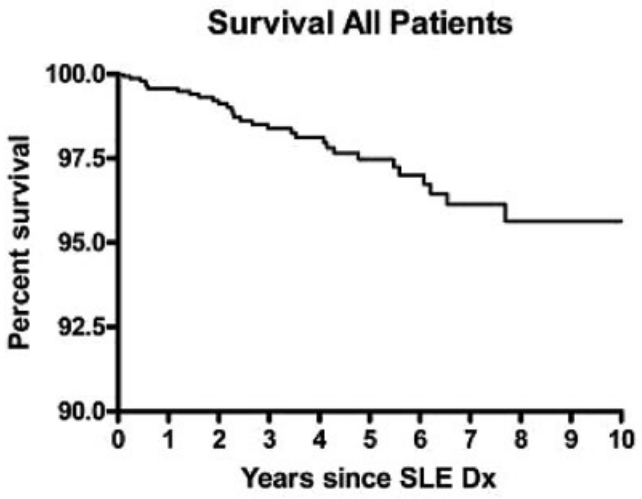
Background: A large multicentre multinational inception cohort was established to study risk factors for atherosclerosis (AS) in SLE. This study describes survival, mortality and causes of death during the first 10 years of observation of the SLICC inception cohort.

Methods: Patients enter the cohort within 15 months of SLE diagnosis (≥4 ACR criteria). Clinical and laboratory features of SLE and comorbidities are gathered in a standardized protocol at yearly intervals. Deaths are recorded as they occur and the cause of death is determined according to the ICD9 code. Demographic and disease related factors present at enrolment were compared in patients who died and in survivors using descriptive statistics, Kaplan-Meier curve as well as life table analysis.

Results: Since 2000, 1593 patients have been entered into the cohort (89.4%F, age at SLE 34.6y, mean followup of 3.7 years). 30 patients have died during the course of follow-up. Survival was 99.6% at 1 year, 98.4% at 3 years and 97.5% at 5 years (figure 1)

Causes of death included coronary artery disease (CAD) in 7, SLE in 9, infection in 9, 1 from other causes and 4 unknown. Patients who died were older at diagnosis, more often had CAD, and had higher SLICC/ACR damage index scores at enrolment and a decreased physical components score (PCS) of the SF-36 at enrolment. Patients who died were also more likely to have used corticosteroids (HR=6.4 p=0.01) and immunosuppressives(HR=2.4 p=0.02) and less likely to have used antimalarials(HR=0.3 p=0.001) at enrolment.



Conclusion: This multinational inception cohort of SLE patients demonstrates the improved survival noted among patients with SLE. Causes of death in the first 10 years of observation of the SLICC inception cohort with an average followup of 3.7 years include CAD, SLE and sepsis. Even early on in the course of SLE, CAD is an important cause of death. Older age, history of CAD, early damage and impaired physical function, use of corticosteroids and immunosuppressives are associated with mortality.

Mycophenolate Mofetil and Hydroxychloroquine but Not Azathioprine Improve HDL Function in Women with SLE. Maureen McMahon[3], Jennifer M. Grossman[4], Jessica Gomez[3], Lori Sahakian[3], Weiling Chen[3], John Fitzgerald[3], Brian Skaggs[2], Joan T. Merrill[1] and Bevra H. Hahn[5]. [1]Oklahoma Med Research Foundation, Oklahoma City, OK, [2]UCLA, Los Angeles, CA, [3]UCLA School of Medicine, Los Angeles, CA, [4]University of California Los Angeles, Sherman Oaks, CA, [5]University of California Los Angeles School of Medicine, Los Angeles, CA

Objective: Women with SLE have an unexplained increase in CAD compared to controls. Normal HDL protects against plaque by preventing oxidation of LDL and the resulting inflammatory response. Pro-inflammatory HDL (piHDL) are abnormal HDL that cannot protect LDL from oxidation. We previously reported that 45% of SLE women vs. 5% of controls have piHDL In addition, SLE patients with piHDL are 16 times more likely to have plaque on carotid ultrasound than patients with normal functioning HDL. SLE function is stable over time; however, it is unknown how disease modifying agents affect HDL function.

Methods: This prospective observational study included any SLE subject from our cohort who was started on a new immunosuppressive agent. Cryopreserved plasma samples were taken at three time points: baseline (prior to initiation of drug), 6 weeks, and 12 weeks post initiation of therapy. To determine the antioxidant function of HDL, we measured change in fluorescence intensity caused by oxidation of DCFH by OxLDL in the presence or absence of test HDL. Fluorescence in the absence of HDL was normalized to 1.0. Values greater than 1.0 after the addition of HDL indicated piHDL. (In previously published studies, mean HDL function in healthy controls ranges from0.44 to 0.66).

Results: 13 subjects were started on mycophenolate (MMF), 11 subjects on azathioprine (AZA), and 22 subjects on hydroxychloroquine (HCQ). The mean SLEDAI score at baseline was 8.9 $\pm$ 5.4 in the MMF group vs. 9.2 $\pm$ 4.1 in AZA vs. 6.4 $\pm$ 3.2 in HCQ (p=ns among all groups). In MMF treated subjects, HDL function improved from baseline, with a score of 2.18 $\pm$ 1.46 prior to therapy dropping to 1.28 $\pm$ 0.87 after 6 weeks of therapy (p=0.04,paired t-test), and to 0.89 $\pm$ 0.56 after 12 weeks of therapy (p=0.02). In hydroxychloroquine treated subjects, HDL function did not significantly change from baseline at 6 weeks of therapy from 1.66 $\pm$ 1.16 to 1.31 $\pm$ 1.27 (p=0.19); however, it did significantly improve after 12 weeks of therapy, 0.96 $\pm$ 0.71(p=0.027). In those treated with azathioprine, HDL function remained relatively stable (1.07 $\pm$ 0.53) vs. 1.30 $\pm$ 0.77 at 6 weeks (p=ns), and 1.00 $\pm$ 0.99 at 12 weeks (p=ns). In addition, there was a trend towards a correlation between change in HDL function and improvement in SELENA-SLEDAI in all groups, (r=0.367, p=0.09), although this did not reach statistical significance.

Conclusions: In conclusion, HDL function is significantly improved by therapy with mycophenolate mofetil, although not to normal levels. There was also improvement with hydroxychloroquine, but not with azathioprine.

Screening for Cognitive Impairment in Systemic Lupus Erythematosus. John G. Hanly[2], Li Su[3], Vern Farewell[3], Tina Linehan[1] and John D. Fisk[2]. [1]Capital Health, Halifax, NS, Canada, [2]Capital Health and Dalhousie University, Halifax, NS, Canada, [3]MRC Biostatistics Unit, Institute of Public Health, University Forvie Site, Cambridge, UK

Purpose: Cognitive impairment is frequent in patients with systemic lupus erythematosus (SLE). In order to make an accurate diagnosis of cognitive impairment formal neuropsychological assessment is required which is not universally available. Our objective was to determine the accuracy of a screening questionnaire for the detection of cognitive impairment in patients with SLE.

Methods: Ambulatory patients with SLE and rheumatoid arthritis (RA) were studied at a single academic medical center. Each subject completed a cognitive symptom inventory (CSI), which provides a total score and 4 subscale scores, and the hospital anxiety and depression scales (HADS). The SLEDAI and ACR/SLICC damage index were used to assess global SLE disease activity and severity respectively. In addition the Automated Neuropsychological Assessment Metrics (ANAM) which is a computerized test battery that takes 45 minutes to administer was used to evaluate the cognitive performance of SLE and RA patients. ANAM measures reaction time and accuracy in Simple Reaction Time (SRT), learning and recall using Code Substitution subtests (CDS and CDD), working memory using the Mathematical Processing (MTH) and the Sternberg Memory Scanning (ST6) subtests, sustained attention using a Continuous Performance subtest (CPT), visual-spatial processing using the Matching Grids (MSG) subtest, and short-term visual memory using the Match to Sample subtest (MSP). Efficiency of performance on each subtest was examined by "throughput"(TP) (number of correct responses per minute) and "inverse efficiency" (IE) (response speed/proportion of correct responses). Linear regression was applied to the log-transformed CSI scores to examine their associations with ANAM scores as well as other factors.

Results: Sixty-eight patients with SLE and 33 with RA were studied. Both groups were predominantly female (92.7% and 97.0 %) with a mean $\pm$ SD age of 45.5$\pm$13.4 and 49.8$\pm$10.2 years respectively. SLE patients had significantly higher total CSI scores (33.6$\pm$10.5 vs. 29.4$\pm$6.8; p=0.041) and attention/concentration subscale CSI scores (15.7$\pm$5.3 vs. 13.3$\pm$3.4; p=0.016) compared to RA patients. There was a positive association overall between CSI scores and HADS anxiety ($p<0.0001$) and depression ($p<0.0001$) scores. After adjusting for age and education, there was no significant association ($p>0.05$) between ANAM global and subscale scores and CSI scores in SLE and RA patients. The results were similar using either "throughput", "inverse efficiency" or the number of impaired ANAM subscales after adjusting for simple reaction time.

Conclusion: The use of self-report questionnaires of cognitive symptoms does not reliably screen for cognitive impairment in SLE patients. The results obtained with such instruments are confounded by the presence of anxiety and depression.

Purpose: Neuropsychiatric (NP) events are frequent in patients with systemic lupus erythematosus (SLE) and can occur unpredictably at any time over the disease course. The availability of validated biomarkers for NP events would be advantageous. Our objective was to determine if the presence of selected autoantibodies at enrollment predicted the occurrence of NP events in a large disease inception cohort of SLE patients.

Methods: The study was conducted by an international research network of 30 academic centers. Patients were enrolled within 15 months of SLE diagnosis and assessed annually for up to 10 years for the occurrence of NP events using the ACR case definitions for 19 NP syndromes. These were categorized into diffuse/focal and central/peripheral NP events. Decision rules of different stringency (model A and model B) were used to determine the attribution of NP events to SLE and non-SLE causes. Plasma/serum samples were available from 1047 patients for the determination of the following autoantibodies in a central laboratory: lupus anticoagulant, IgG anticardiolipin, anti-β_2 glycoprotein-I, anti-ribosomal P and anti-NR2 glutamate receptor antibodies. The association between the presence of autoantibodies and the risk of the first occurrence of NP events was examined by Cox regression.

Results: Of the 1047 patients 89.1% were female and the mean ($\pm$ SD) age was 35.2 $\pm$ 13.7 years. The mean disease duration at enrollment was 5.4 $\pm$ 4.2 months and the mean length of followup was 3.27 $\pm$ 2.8 years. Over the period of study 495/1047 (47.3%) patients had 1 or more NP events (total of 917 events) encompassing 17 of 19 NP syndromes. The proportion of NP events attributed to SLE varied from 15.4% (model A) to 28.2% (model B). The frequency of autoantibodies at enrollment was 21.9% (lupus anticoagulant), 13.4% (anticardiolipin), 15.1% (anti-β_2-GPI), 9.2% (anti-ribosomal P) and 13.7% (anti-NR2 antibodies). There was no significant positive association between any of the autoantibodies and first occurrence of NP events overall, or events attributed to SLE (model A or model B). Clustering of NP events into diffuse/focal and central/peripheral manifestations did not change the outcome. However, LA at baseline was associated with the occurrence of stroke/sinus thrombosis (total n=22) attributed to SLE (model B) (Hazard ratio (95% CI): 2.54 (1.08–5.94); p=0.03). Furthermore anti-ribosomal P antibodies at enrollment were associated with psychosis (total n=14) attributed to SLE (model B) (Hazard ratio (95% CI): 3.92 (1.23–12.5); p=0.02).

Conclusion: The detection of LA and anti-ribosomal P antibodies near the time of diagnosis of SLE is associated with an increased risk for intra-cranial thrombosis and lupus psychosis respectively.

Patellofemoral Osteoarthritis in Middle-Aged Adults: What Are the Best Measures of Physical Performance and Pain for Use in the Clinic and in Research? Lisa T. Hoglund[3], Margery A. Lockard[1], Jinsup Song[2] and Mary F. Barbe[2]. [1]Drexel University, Dresher, PA, [2]Temple University, Philadelphia, PA, [3]University of the Sciences in Philadelphia, Morrisville, PA

Purpose: Osteoarthritis (OA) of the knee is common in Western society. The prevalence of knee OA in adults in the US is estimated to be 23–33%, totaling more than 9 million adults. The patellofemoral (PF) compartment of the knee is frequently involved. Isolated PF OA is present in 24% of persons aged $\geq$ 50 years with knee pain; 40% have combined PF and tibiofemoral OA. The presence of PFOA is associated with pain and disability. Activities that load the PF compartment by strong quadriceps contraction with a flexed knee can be particularly painful. This includes the task of rising from a chair, i.e., sit-to-stand. It is unknown if a physical performance test including sit-to-stand is a more sensitive test of function in persons with PFOA versus a test of ambulation. Clinicians need tests of physical performance, perceived function, and pain to measure the impact of disease in patients. One goal of this study was to examine the impact of PFOA on physical performance, perceived function, stiffness, and pain in persons with bilateral PFOA compared to healthy, painfree subjects without PFOA. A second goal was to determine the best clinical tests to quantify physical performance and pain.

Methods: Thirty-two adults, aged 40– 65 years, underwent radiographic screening for PF and tibiofemoral OA; 15 remained after radiographic exclusions. This cross-sectional study compared 2 groups: subjects with bilateral, symptomatic, radiographic PFOA (PFOA) and age- and gender-matched asymptomatic subjects with no radiographic PFOA (control). There were 8 PFOA subjects and 7 control subjects remaining after radiographic analysis. Both groups completed questionnaires regarding knee pain, stiffness, and function [WOMAC for the past 48 hours and Visual Analog Scale (VAS) for knee pain severity in the past 30 days]. Subjects performed the Timed Up and Go (TUG) and fifty-foot walk (FFW) physical performance tests; subjects rated knee pain severity before and after these tests with a VAS. WOMAC and VAS data were analyzed with Mann-Whitney U-tests, $p < 0.05$; TUG and FFW results were analyzed with t-tests, $p < 0.05$.

Results: The PFOA group reported significantly greater knee pain severity versus the Control group for the past 30 days, post-TUG and post-FFW (VAS). Results of the WOMAC indicated that the PFOA group had greater knee pain and stiffness and significantly less physical function in the past 48 hours. The PFOA group required a significantly longer time to complete the TUG versus controls. No significant difference was found between the groups in time to complete the FFW.

Conclusions: The results of this study demonstrate that middle-aged adults with PFOA have significant functional deficits, greater knee stiffness, and greater knee pain versus painfree adults without PFOA. The TUG is more sensitive than the FFW to detect physical performance deficits in persons with PFOA. The best test of function in this population is the TUG as it is more sensitive than the FFW and has been shown to be reliable and valid in persons with knee OA. The TUG is simple, quick and requires less clinical space than the FFW. Clinicians should use the TUG, accompanied by a VAS rating of pain, to capture the impact of PFOA on an individual's function and pain.

Differences in Muscle Strength and Pain Thresholds between Postmenopausal Women with and without RA. Ulrika Thoors, Christina H. Opava, Birgitta Glenmark, Eva Kosek, Ingrid E. Lundberg and Cecilia Fridén. Karolinska Institutet, Stockholm, Sweden

Muscle weakness, in particular loss of muscle mass, pain and tenderness are common symptoms in rheumatoid arthritis (RA). This seems to be the case even when inflammation is well controlled and may result in increasing disability with increasing age. Increased pain and increased loss of muscle mass is also found among healthy women at the time of menopause. The aim of our study was to examine differences in muscle strength and pain thresholds between postmenopausal women with and without RA.

Ten postmenopausal women with early (<2 years) RA (median age 57.5, median BMI 24) and ten healthy women (median age 58.5, median BMI 25) were recruited for the study. All women were independent in daily living, had passed menopause and did not use hormone replacement therapy. The median DAS 28 score was 2.7 (range 1.3–4.0) and the median HAQ score was 0.57 (range 0–1) in the RA group.

Measurements of isokinetic muscle strength in knee flexors and extensors, grip strength, timed standing, pressure pain thresholds (PPT), supra threshold pressure pain rated as 4/10 and 7/10 respectively on a Borg CR-10 scale, and segmental and plurisegmental endogenous pain inhibitory mechanism during muscle contraction were assessed in all participants.

No significant difference in knee extensor strength was detected between the women with RA and the healthy ones. Participants with RA were significantly weaker in the knee flexors ($p=0.01$) and in grip strength ($p=0.007$), and they were slower in the timed standing ($p=0.05$). Compared to the healthy women, those with RA had increased sensitivity to threshold pain ($p=0.007$) and to supra threshold pressure pain at both levels measured ($p=0.001$ and $p=0.004$ respectively). PPTs increased at the contracting muscle as well as at a distant resting muscle during standardized static contractions in both groups alike.

Our results indicate that previously noted difference in muscular strength between women with and without RA is present in early disease, in patients with low disease activity and seems to remain even after menopause. Further, the women with RA have generalized allodynia and hyperalgesia, but no dysfunction of segmental and plurisegmental pain inhibitory mechanisms. The normal function of endogenous pain inhibitory mechanisms despite chronic pain in women with RA might contribute to the good effects of physical activity in this group of patients.

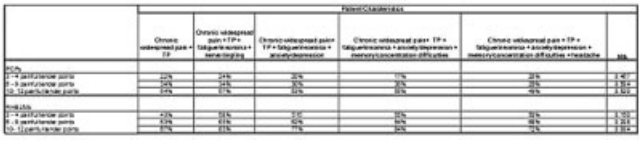
Fibromyalgia Diagnosis Is Significantly Impacted by the Number of Tender Points Presented on Patient Physical Exam. Terence W. Starz[1], Robert J. Sanchez[2], Bruce Duncan[3], Kaite Ka[3], Elizabeth Pinner[2], Shera D. Gruen[2] and Dennis C. Turk[4]. [1]Arthritis & Internal Med Associates, Pittsburgh, PA, [2]Pfizer, [3]Roger Green and Associates, [4]University of Washington, Seattle, WA

Statement of Purpose: To evaluate whether the number of tender points (TP) in simulated case vignettes influenced the likelihood of primary care physicians (PCPs) and rheumatologists (RHEUMs) diagnosing fibromyalgia (FM).

Methods: 200 PCPs and 100 RHEUMs experienced in treating chronic pain were recruited from an online panel to review simulated patient cases. All simulated patient cases included chronic wide spread pain (CWP) + varying degrees of painful TPs (3–4, 6–8, and 10–12) on physical examination and various constellations of other FM related-symptoms (Table 1).



Each physician evaluated 20 cases and was asked to provide a diagnosis. The primary outcomes of interest were the diagnosis of FM, which was based on groups that include descriptions of varying numbers of TP present on physical examination and symptoms, by PCPs and RHEUMs. Bivariate statistics were used to examine the association between TPs and symptoms. Logistic regression models were used to examine predictors of FM diagnoses.

Results: 300 physicians reviewed 6000 simulated patient case vignettes. The overall FM diagnosis rate was 35% for PCPs and 63% for RHEUMs. The rate of FM diagnosis for the PCPs did not change among the different constellation of symptoms; however, as the number of painful TPs increased, the FM diagnosis also increased (Table 1). Among the RHEUMs, there was no significant difference in the dx rate among the different constellations of patient symptoms for those experiencing 3–4 or 6–8 painful TPs. However, among those with 10–12 painful TPs, a significant difference in diagnosis (67%–84%, $p = 0.004$) among the different constellation of patient symptoms were seen. The FM diagnosis rate for RHEUMs also increased as the number of TPs increased (Table 1). After controlling for covariates, the odds of an FM diagnosis among PCP was significant for those experiencing 6–8 painful TPs (odds ratio 1.82, $p < .001$) and 10–12 painful TPs (odds ratio 4.64, $p < .001$). Among the RHEUMs, the odds of an FM diagnosis was significant for those experiencing 6–8 painful TPs (odds ratio 1.57, $p < .001$) and 10–12 painful TPs (odds ratio 3.20, $p < .001$). The presence of 3–4 TPs did not impact the likelihood an FM diagnosis.

Conclusion: Although not all simulated patient cases met the ACR FM diagnosis criteria, the diagnosis of FM by RHEUMs was consistently higher than the diagnosis by PCPs across the different patient TPs and symptom groups. When evaluating simulated patients with FM who are describing widespread pain with or without other FM symptoms and a variable number of tender points on physical examination, the number of tender points is the most significant patient characteristic that leads both primary care physicians and rheumatologists to make the diagnosis of FM. Further analysis is needed to understand reasons behind misdiagnosis.

Measuring Pain in Systemic Sclerosis: The Short-Form McGill Pain Questionnaire or a Single Item Measure of Pain? A Confirmatory Factor Analysis. Ghassan El Baalbaki[1], Janie Lober[2], Marie Hudson[4], Murray Baron[1], Brett D. Thombs[3] and Canadian Scleroderma Research Group (CSRG). [1]Jewish General Hospital, Montreal, QC, Canada, [2]McGill University, [3]McGill University, Montreal, QC, Canada, [4]McGill University and Jewish General Hospital

Background: Pain is common in patients with systemic sclerosis (SSc), and severity levels are comparable to other rheumatic diseases. Patients with SSc report a number of painful symptoms. Existing studies of pain in SSc have used a variety of pain assessment tools, including a single-item pain Visual Analog Scale (VAS), a pain numerical rating scale (NRS), and the longer 15-item short-form McGill Pain Questionnaire (MPQ-SF). OMERACT 6 reported that the pain VAS is valid to measure pain related to Raynaud's phenomenon and digital ulcers in SSc, but has not been examined as a general pain measure. VAS and NRS measures have been shown to function similarly in other patient groups. Despite being longer, the MPQ-SF would be a potentially attractive measure if it were to demonstrate more robust validity characteristics than single-item measures or if it were able to differentiate between sensory and affective components of pain, as has been suggested in some patient groups. The objectives of this study were (1) to assess whether the MPQ-SF has stronger validity characteristics among patients with SSc compared to two single-item measures, the pain NRS and the Present Pain Index (PPI), a single Likert item, and (2) to determine whether the MPQ-SF differentiates meaningfully between sensory and affective components of pain in SSc patients.

Methods: Patients with SSc were recruited from the Canadian Scleroderma Research Group Registry. To assess convergent validity compared to the NRS and PPI, Pearson's correlations, with 95% confidence intervals (CIs), were computed between the MPQ-SF, NRS, and PPI with other outcome measures, including the Center for Epidemiologic Studies Depression scale (CES-D), the Health Assessment Questionnaire – Disability Index (HAQ-DI), and the Mental andd Physical Component Summaries(MCS and PCS) scores of the Short-Form 36 Health Survey Questionnaire. To assess the degree that the MPQ-SF differentiated between sensory and affective factors, confirmatory factor analysis (CFA) models were conducted using MPlus, treating items as ordinal data. In addition, Pearson's correlations with 95% CIs of sensory and affective factor scores with CES-D, the HAQ-DI, the MCS and PCS were calculated to test for differences between the sensory and affective correlations.

Results: A total of 1,091 patients were included. The MPQ-SF, NRS and PPI correlated similarly to all other outcome measures with no significant or substantive differences. Model fit for the two-factor model (sensory and affective) was good ($c^2(55) = 198.3$, $P < 0.001$; CFI = 0.97, TLI = 0.99, RMSEA = 0.05), but a single-factor model that did not differentiate sensory and affective pain fit similarly well ($c^2(54) = 234.2$, $P < 0.001$; CFI = 0.96, TLI = 0.99, RMSEA = 0.06). Sensory and affective factor scores correlated similarly with other outcome measures.

Conclusion: The MPQ-SF did not improve on the PNRS or PPI as a measure of pain in SSc. In addition, no evidence was found that the MPQ-SF provides substantively different assessment of sensory and affective pain. The PNRS is a reliable and valid measure of pain in SSc, and is advantageous for use because of its brevity in administration and scoring.

Daily Electronic Reports of Pain and Activity Difficulties in Children with JIA Versus Children with Other Rheumatic Diseases. Mark Connelly[1], Maggie H. Bromberg[4], Kelly K. Anthony[3], Lindsey Franks[2], Karen M. Gil[4] and Laura E. Schanberg[2]. [1]Children's Mercy Hospital and Clinics, Kansas City, MO, [2]Duke University Medical Center, Durham, NC, [3]Duke Unviversity Medical Center, Durham, NC, [4]University of North Carolina at Chapel Hill

Purpose: To compare children with JIA vs juvenile rheumatic disease (JRD) across daily measures of pain and associated symptoms. The role of pain in predicting activity difficulty also was examined in both disease groups.

Method: Children participated in a larger study to evaluate pain and functional limitations using electronic reports on handheld computers. Children with polyarticular JIA (26) and children with JRD (15), aged 8–18 yrs, were recruited from a pediatric rheumatology clinic. For 7 days, children completed morning, afternoon, and evening reports of pain characteristics (pain locations on a body map, pain duration on a 4-point scale ranging from "just a few minutes" to ">4 hours", pain intensity and unpleasantness on a visual analog scale [VAS]), fatigue (VAS), and difficulty in school, social, and physical activities (4-point scale ranging from "not at all difficult" to "extremely difficult"). A pediatric rheumatologist provided a diagnosis and disease severity score. Independent sample t-tests were used to evaluate differences in patients' average responses across all assessments between patients in both groups. Hierarchical linear modeling was used to evaluate whether activity difficulty increased at times of greater pain intensity, and whether this relationship differed in direction or magnitude as a function of diagnostic group.

Results: Children were predominantly Caucasian (81% JIA, 73% JRD) and female (85% JIA, 67% JRD). Children with JIA on average reported significantly greater pain intensity (m=30.6 vs m=9.1, p <.05), pain unpleasantness (m=31.4 vs m=9.8, SD=20.6, p<.05), and pain duration (m=1.7 vs m=.7, SD=1.05, p<.05) than children with JRD. The JIA group experienced pain in more locations (m=.8 vs m=.3, p<.05), greater stiffness intensity (m=30.7 vs m=7.4, p<.05), and higher levels of fatigue (m=43.6 vs m=17.7, p<.05) across all days. Children with JIA on average reported comparably mild levels of activity difficulty relative to children with JRD (m=0.4 vs m=0.6, ns). However, results of hierarchical linear modeling suggested that activity difficulty increased reliably at moments of greater pain intensity for both groups with the magnitude of this relationship greater for children with JIA ($t(240)=3.2$, $p<.01$).

Conclusions: Although children with JIA experience comparably mild difficulty in daily activity participation relative to children with JRD, pain appears to uniquely influence the extent of difficulty these children have participating in daily activities. Pain management should therefore be a focus of JIA treatment to enable children to participate as fully as possible in normative social, academic, and physical activities.

How Do Patients Approach Risk-Benefit Trade-Offs: A Qualitative Analysis Using a Think Aloud Protocol. Liana Fraenkel, Paul Falzer and Kristin Mattocks. Yale University, Newtown, CT

Purpose: Eliciting patient preferences and incorporating them into treatment strategies can be beneficial for treatment adherence, patient empowerment, and clinical outcomes. Despite the importance of incorporating patient preferences into treatment strategies, little is known regarding the factors that influence how patients evaluate risk-benefit trade-offs. The purpose of this study was to gain a more complete understanding of how patients approach trade-offs using a think aloud protocol.

Methods: Patients with chronic pain were randomly drawn from primary care and women's clinics at a large medical center. Participants were audiotaped as they performed an Adaptive Conjoint Analysis survey and were instructed to: "Think out loud as you answer the questions on the computer. Just say out loud everything that comes into your head. Remember there is nothing right or wrong to say". Participants were reminded by the research assistant to say their thoughts aloud after silent periods of 15 or more seconds. Audiotapes were transcribed and two analysts independently read and coded the transcripts using the constant comparative method.

Results: Ninety-eight transcripts were analyzed. Four themes emerged regarding how patients approach risk-benefit trade-offs: 1) Selection of a dominant attribute to guide decision-making: Some participants evaluated all risk and benefits against one dominant attribute: "When you are in pain and you want to get rid of it you make that your top priority and worry about the side effects later." 2) Leveraging values and worldviews: Many participants were influenced by personal values: "I am thinking. . .I have a son and I don't want to leave him without me." 3) Influence of personal experience: Personal experience with specific side effects had variable effects on risk aversion: "I have experienced nausea and dizziness and it is not a party. It really knocks you out and I want to avoid that if I can." Vs. "The nausea and the dizziness and trouble thinking clearly that is not that big of a deal. I know what that is like and it is not that big of a deal." 4) Use and manipulation of numerical information: Participants also varied significantly in their use of numbers: "The differences in pain and the improvement percentages were really close together and these were further apart being 3 out of 10 compared to 8 out of 10." Vs. "Well, it is the percentage: 3 in 10 as opposed to 1 in 10 which is a little bit less risky."

Conclusions: Our findings suggest that patients draw on a range of strategies and values to evaluate risk-benefit trade-offs. Understanding of how patients approach trade-offs may enable physicians to better understand how their patients consider competing treatment options in clinical practice.

ACR Concurrent Abstract Sessions
Antiphospholipid Syndrome
Thursday, November 11, 2010, 11:00 AM–12:30 PM

2250

Evaluation of 'Non-Criteria" Antiphospholipid (aPL) Assays at a Wet Workshop during the 13th International Congress on Antiphospholipid Antibodies. Roger Albesa[1], Victoria Nelson[1], Zakera Shums[1], Gary Norman[1], X.-X. Gu[2], Jacob Rand[2], Walter Binder[1], Bas deLaat[4] and Silvia S. Pierangeli[3]. [1]INOVA Diagnostics, San Diego, CA, [2]Montefiore, Albert Einstein School of Medicine, New York, NY, [3]Univ of TX Med Branch, Galveston, Galveston, TX, [4]Utretch Medical Center, Utrecht, The Netherlands

Background: Recently new assays for the detection of Antiphospholipid antibodies (aPL) have been developed. These include immunoassays that detect antibodies directed to domain I (DI) of β2glycoprotein, that has been shown to be detect "thrombosis-related" anti-β2glycoprotein I (aβ2GPI) antibodies and a new clotting/mechanistic test named the Annexin A5 resistance assay (A5R), that measures the ability of aPL antibodies to reduce the anticoagulant activity of A5 in vitro. Recent studies have shown a good correlation between aPL antibodies that recognize domain I of β2GPI and the reduction of the A5 anticoagulant activity.

Objective: to evaluate the performance of two different ELISAs for the detection of DI (one in-house method and one commercial kit) and the A5R

test in a wet workshop at the 13th International Congress on Antiphospholipid Antibodies in Galveston, TX (April 13th, 2010).

Methods: An in-house method developed by B de Laat and colleagues that utilizes hydrophobic microtiter plates coated with recombinant domain I and a commercial kit (INOVA) were evaluated for the detection of anti-DI antibodies. Samples were also evaluated simultaneously in an IgG aβ2GPI (INOVA) for comparison purposes. Aliquots of 26 APS patients and 21 controls (14 from healthy individuals and 7 from patients with infectious diseases) were distributed to the participants/groups. For the two-step A5R assay, procedure was carried out as published (Blood 2004; 104:2783–2790). Five plasmas from APS patients and five controls were tested prior to the workshop and at the workshop. In addition, normal plasmas were "spiked" with dilutions of various aPL monoclonal antibodies (MoAbs) IgG and IgM: a) HCAL and EY2C9 [Center for Diseases Control (CDC)]; b) AbyD05045 and AbyD03892 (Phadia); c) "Sapporo" (INOVA). The workshop was open to all congress attendees who registered for this event.

Results: 18 out of the 26 APS samples were positive in the IgG aβ2GPI (INOVA) ELISA. Fourteen and 10 out of the 18 APS samples that were positive in the IgG aβ2GPI, were positive in the DI ELISA (INOVA) and in-house respectively. This discrepancy is likely due to the fact that the in-house method is not calibrated for serum samples. All the samples that were positive in the DI ELISA (either in-house or INOVA kit) had evidence of thrombosis associated with aPL antibodes. All the APS plasmas as well as the IgM and IgA MoAbs (Phadia, INOVA and CDC) as well as the IgG INOVA MoAb reduced significantly the A5 anticoagulant activity. All negative plasmas were negative in the A5R.

Conclusions: In this workshop, the A5R showed to be a sensitive and specific new mechanistic assay for aPL antibodies. Samples tested in the DI assays, which were tested single-blinded, appear to correctly identify a subset of "pathogenic" aβ2GPI antibodies. Both assays appear to be promising assays for detecting patients at risk for thrombosis.

2251

Evaluation of the Performance of Monoclonal and Polyclonal Antibody Standards in Different Assays for the Detection of Antiphospholipid (aPL) Antibodies: Report of a Wet Workshop at the 13th International Congress on Antiphospholipid Antibodies. Ricardo Forastiero[8], Elizabeth Papalardo[6], Michael Watkins[1], Hoang Nguyen[1], Maria Crisostomo[1], Wendy Vandam[1], JOel Hardy[1], Roger Albesa[2], Victoria Nelson[2], Zakera Shums[2], Gary Norman[2], Walter Binder[2], Kerrie Morin[3], Catherine Kirbach[3], Karl Mattias[4], Gabriella Lakos[5] and Sivia S. Pierangeli[7]. [1]Bio-Rad Laboratories, Hercules, CA, [2]INOVA Diagnostics, San Diego, Ca, [3]Instrumentation Laboratories, Bedford, MA, [4]Phadia GMBH, Freiburg, Germany, [5]TherTest, Lombard, IL, [6]Univ of TX Med Branch, Galveston, Galveston, TX, [7]Univ of TX Med Branch, Galveston, TX, [8]Universidad Favaloro, Buenos Aires, Argentina

Background: The standardization of tests used in the diagnosis of Antiphospholipid Syndrome (APS) [anticardiolipin (aCL) and the anti-β2glycoprotein I (aβ2GPI)] is still a matter of debate and concern. One important topic of discussion is whether to use monoclonal (MoAbs) or polyclonal antibody preparations for the calibration and/or quality control of these assays. However, the proper cross-validation and evaluation of the available preparations is lacking.

Objective: to evaluate the performance of various MoAbs and polyclonal antibody calibrators for the detection of aCL and aβ2GPI antibodies (IgG, IgM) at a wet workshop at the 13th International Congress on Antiphospholipid Antibodies.

Methods: Polyclonal standards G2 and M3 for IgG, IgM aCL [Louisville APL Diagnostics, Inc.(LAPL)], MoAbs IgG and IgM: a) HCAL and EY2C9 [Center for Diseases Control (CDC)]; b) AbyD05045 and AbyD03892 (Phadia); c) "Sapporo" (INOVA) were distributed to the groups for evaluation. All serum and calibrator preparations were from the same lot and were tested in the following aCL and aβ2GPI IgG and IgM assays: QUANTA LITE™ (INOVA), TheraTest, Phadia, Bio-Rad (ELISA PhD™ lx and Multiplex BioPlex™ 2200), in the APhL ELISA® [an assay that utilizes a mixture of negatively charged phospholipids and β2GPI (LAPL)] and in a new chemiluminescent assay HemosIL® AcuStar Antiphosphilipid assay panel [Instrumentation Laboratory, IL)]. Calibrators and kits were assayed as per the manufacturers' instructions. The workshop was open to congress participants who registered for the event and the groups evaluated the calibrators at least on two occasions.

Results: All groups reported values of the polyclonal aPL calibrators within the expected range including the new chemiluminescent and the multiplex assays. Excellent correlation and linearity was observed with two monoclonal preparations (AbyD05045 IgG and IgM and Sapporo INOVA IgG and IgM). As expected, AbyD3092 showed negative results in various tests (this antibody has aCL activity only). The "Sapporo" and the "CDC" monoclonal antibodies, although originally derived from the same hybridoma sources showed apparent different concentration, specificity and presentation (liquid affinity purified Ig for the Sapporo and freeze-dried hybridoma supernatant for the CDC). A large variability of the results of the CDC MoAbs was reported by the groups at this workshop when tested at the same final concentration (HCAL: from 8.2 to 75.3 GPL units for IgG aCL and 20.9 to 424.5 Units for IgG aβ2GPI; EY2C9: from 30.4 to 145.3 MPL units for IgM aCL and from 0 to 520.4 Units for IgM aβ2GPI). Participants reported difficulties with the reconstitution of the CDC MoAb freeze-dried material, indicating problems with the stability and variability between vials of the preparations. Those included not only differences among any given assay but also within the same test, run in more than one occasion.

Conclusions: The LAPL polyclonal and the Phadia and INOVA monoclonal preparations are suitable sources for calibration of aCL and aβ2GPI assays. Based on results obtained at this wet workshop, the use of the CDC MoAbs is questionable and not recommended at this time.

Comparative Evaluation of Different Immunoassays for the Detection of Antiphospholipid Antibodies: Report of a Wet Workshop during the 13th International Congress on Antiphospholipid Antibodies. Ricardo Forastiero[9], Elizabeth Papalardo[8], Kerrie Morin[4], Catherine Quirbach[4], Gabriella Lakos[6], Karl Mattias[5], Roger Albesa[3], Victoria Nelson[3], Zakera Shums[3], Gary Norman[3], Walter Binder[3], Bruno Larida[1], Maria Crisostomo[2], Michael Watkins[2], Hoang Nguyen[2], Wendy Vandam[2], Joel Hardy[2] and Silvia S. Pierangeli[7]. [1]Bio-Rad Laboratories, Hercules, CA, [2]Bio-Rad Laboratories, Her, [3]INOVA Diagnostics, San Diego, CA, [4]Instrumentation Laboratories, Bedford, MA, [5]Phadia GMBH, Freiburg, Germany, [6]TheraTest Laboratories, Lombard, IL, [7]Univ of TX Med Branch, Galveston, Galveston, TX, [8]Univ of TX Med Branch, Galveston, TX, [9]Universidad Favaloro, Buenos Aires Argentina

Background: The performance and standardization of antiphospholipid (aPL) laboratory tests used in the confirmation of diagnosis of Antiphospholipid Syndrome (APS) is still a matter of debate and concern. In addition, recently novel methodologies and platforms for the detection of aPL antibodies have become available, but proper inter-assay simultaneous comparisons have not been carried out. Objective: to evaluate the performance of different ELISAs and other new immunoassays for the detection of aCL and aβ2GPI antibodies (IgG, IgM) in a wet workshop at the 13th International Congress on Antiphospholipid Antibodies.

Methods: Aliquots of 26 un-identified APS serum samples (diagnosis according to Sapporo modified criteria) and 21 controls (14 from healthy individuals and 7 from patients with infectious diseases) were distributed to all participants/groups. All serum samples were evaluated in various aCL and aβ2GPI ELISAs, in the APhL ELISA® (an assay that utilizes a mixture of negatively charged phospholipids instead of cardiolipin, Louisville APL Diagnostics (LAPL)] and in in three fully automated methodologies: HemosIL® AcuStar Antiphospholipid assay panel, a chemiluminescent immunoassay panel on the ACL AcuStar™ [Instrumentation Laboratory (IL)] a fluoro-enzyme immunoassay (Phadia) and in the BioPlex 2200, random access, multiplex testing immunoassay system (Bio-Rad), using either an automated or "manual" platforms (see table). All kits were evaluated as per the manufacturers' instructions and results were expressed in their respective units of measurement. The workshop was open to congress participants who registered for the event. Samples were evaluated in the different assays at least on two separate occasions.

Results: Clinical sensitivities and specificities and positive predictive values were calculated.

Manufacturer	Assay	Method/Instrumentation	Clinical sensitivity (%)	Clinical Specificity (%)	PPV
Bio-Rad	aCLGM	Multiplex/BioPlex2200	100	95	0.95
Bio-Rad	aβ_2GPIGM	Multiplex/BioPlex2200	100	95	0.95
Bio-Rad	aCL GM	ELISA/PhD	100	95	0.95
Bio-Rad	aβ_2GPIGM	ELISA/PhD	100	91	0.92
IL	HemoSIL aCL GM	Chemiluminescent/Acustar	100	95	0.95
IL	HemoSIL aβ_2GPIGM	Chemiluminescent/Acustar	100	100	1.0
INOVA	QUANTA LITE™aCL GM	ELISA/manual	96	91	0.92
INOVA	QUANTA LITE™ aβ_2GPIGM	ELISA/manual	88	100	1.0
LAPL	APhL GM	ELISA/manual	100	100	1.0
Phadia EliA	aCL GM	ELISA/Phadia 250	100	100	1.0
Phadia EliA	aβ_2GPIGM	ELISA/Phadia 250	100	95	0.95
Theratest	aCL GM	ELISA/DSX2	100	100	1.0
Theratest	aβ_2GPIGM	ELISA/DSX2	100	95	0.9

Although not all the assays reported the titers of aCL and aβ2GPI antibodies in the same units, the correlation of positive titers among the assays was excellent. All the healthy control samples were correctly identified by all groups as negative. Some of the aβ2GPI tests reported positive one of the infectious disease sample. All the assays, but in particular the AcuStar chemiluminescent immunoassay panel and the BioPlex2200 assays showed excellent intra-assay variation (<10 % CV).

Conclusions: All aCL and β2GPI tests showed excellent clinical sensitivities, specificities and positive predictive values and good agreement with respect to the levels of the IgG and IgM antibodies, regardless of assay type, or whether tests were done using automated or "manual" systems. New methodologies for the detection of aPL antibodies look promising and comparable to currently approved ELISA tests. This study validates current recommendations of the Sapporo revised criteria to use aCL and aβ2GPI for proper confirmation of diagnosis of APS.

Elevated Cytokines and Chemokine Levels in Antiphospholipid Antibody (aPL)-Positive Patients. Vijaya L. Murthy, Shraddha Jatwani, Renan A. Aguilar-Valenzuela, Ellis D. Doan, Elizabeth Papalardo, Emilio B. González and Silvia S. Pierangeli. University of Texas Medical Branch, Galveston, TX

Background: Based on *in vitro* and animal studies, certain cytokines and chemokines such as tissue factor (TF), vascular endothelial growth factor (VEGF), soluble (s) E-selectin (sE-sel), and tumor necrosis factor (TNF)-α have been shown to be associated with antiphospholipid syndrome (APS) and systemic lupus erythematosus (SLE). Here we examined the levels of cytokines/chemokines in aPL-positive patients with or without SLE, and compared them to controls.

Methods: Baseline sera/plasma of persistently aPL-positive patients [IgG/M Anticardiolipin antibody (aCL) > 40U, IgG/M anti-β_2 glycoprotein-I antibody (aβ_2GPI) > 20U, and/or positive lupus anticoagulant test] were obtained from an ongoing pilot interventional clinical study (clinical trials. gov #: NCT00674297). The biomarker levels of these 22 aPL-positive patients (primary APS: 8, APS with SLE: 8, asymptomatic aPL without SLE: 4 and asymptomatic aPL with SLE: 2) were compared to 22 matched healthy controls with no evidence of autoimmune, infectious, or inflammatory diseases. Interleukin (IL)-1b, IL6, IL8, TNF-α, VEGF, interferon inducible protein (IP)-10 and sCD40L were measured in serum using a Multiplex Assay (Millipore Milliplex™); titers of sE-sel, and sTF were detected by ELISA. The Kruskal-Wallis test was used to compare the levels of biomarkers in aPL-positive subjects as compared to the controls. Spearman test was used to correlate the levels of the biomarkers in the different subgroups of patients.

Results: As compared to controls, we found an increase in the levels of IL-1b, IL6, TNF- α, IP-10, sCD40L and sTF in patients with APS. In a subgroup analysis, patients with aPL/APS and SLE (n=10) had significantly higher levels of TNF-α, IP10 and sCD40L as compared to aPL/APS patients without SLE (n=12) (p= 0.05, 0.029 and 0.05, respectively).

Biomarker	# Of aPL (+) samples elevated above cut-off points/(%)	Means of aPL positive samples	Means of controls	p
IL1b	16/22 (73)	7.65	0.35	<0.0001
IL6	17/22 (77)	42.15	0.71	<0.0001
IL8	9/22 (41)	27.44	40.87	0.1763
TNF-α	22/22 (100)	14.71	0.46	<0.0001
VEGF	12/22 (54)	208.78	113.59	0.9778
IP-10	22/22 (100)	683.43	106.7	<0.0001
sCD40L	21/22 (95)	1070.19	24.67	<0.0001
s TF	16/16 (100)	449.59	13.05	<0.0001
sE-sel	3/16 (19)	20.78	42.04	0.0006

Conclusions: Our results underscore the importance of biomarkers in aPL-positive patients. This may help better understand the pathogenic mechanisms involved, and the development of targeted treatments.

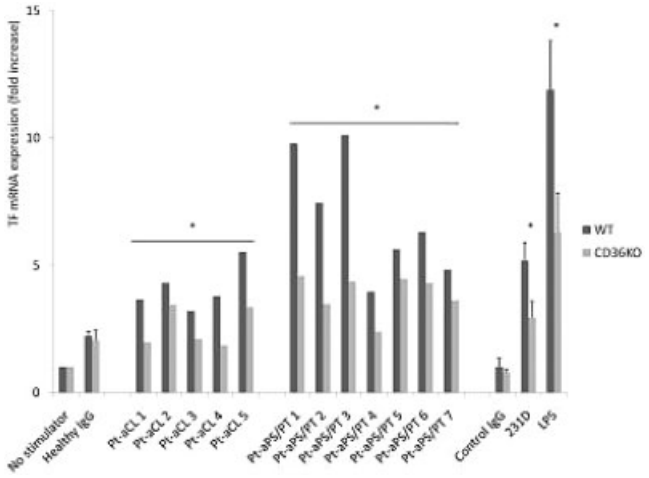
2254

The Involvement of CD36 in the Monocyte Activation by Antiphospholipid Antibodies. Masaru Kato[1], Tatsuya Atsumi[2], Kenji Oku[3], Olga Amengual[3], Yuichiro Fujieda[3], Kotaro Otomo[3], Tetsuya Horita[3], Shinsuke Yasuda[3] and Takao Koike[3]. [1]Department of Medicine II, Hokkaido University Graduate School of Medicine, Sapporo, Hokkaido, Japan, [2]Department of Medicine II, Hokkaido University Graduate School of Medicine, Sapporo, Japan, [3]Department of Medicine II, Hokkaido University Graduate School of Medicine

Purpose: CD36, known as a scavenger receptor, is a transmembrane glycoprotein expressed on monocytes, macrophages, platelets and capillary endothelial cells. CD36 recognizes multiple ligands, including phosphatidylserine, and is a mediator of both atherogenesis and thrombosis. However, little data are available regarding the correlation between CD36 and thrombotic diseases. The purpose of this study is to investigate the possible involvement of CD36 in the pathophysiology of thrombosis in patients with antiphospholipid syndrome (APS).

Methods: This study comprised two sets of experiments. Firstly, a genomic polymorphism of CD36 was explored. Rs3765187, a single nucleotide polymorphism (SNP) linked to CD36 deficiency, was investigated by TaqMan PCR genotyping method in 795 Japanese, including 108 patients with APS, 265 with systemic lupus erythematosus (SLE) in the absence of APS, and 422 healthy subjects. In the second part of this study, the involvement of CD36 in antiphospholipid antibody (aPL)-induced tissue factor (TF) expression was examined using CD36 deficient mice or anti-CD36 antibody with the CD36 signal blocking property (FA6–152). Purified IgG from APS patients either anticardiolipin antibodies or phosphatidylserine dependent antiprothrombin antibodies positive (Pt-aCL and Pt-aPS/PT, respectively) and monoclonal aPS/PT (231D) were used in the experiments. The aPL-induced TF expression was tested by real-time PCR method on peritoneal macrophages from CD36 deficient mice or human peripheral blood mononuclear cells (PBMC) from healthy donors pretreated with FA6–152.

Results: The minor allele frequency of rs3765187 was less frequent in APS patients (2.8% p = 0.024), but not in SLE patients (7.9% p = 0.32), compared with healthy subjects (10.2%). Pt-aCL, Pt-aPS/PT and 231D-induced TF mRNA expressions were not completely but significantly suppressed in peritoneal macrophage from CD36 deficient mice compared to wild type mice (WT).



FA6–152 dose-dependently inhibited Pt-aCL, Pt-aPS/PT and 231D-induced TF mRNA expressions in human PBMC from healthy donors.

Conclusion: The SNP linked to CD 36 deficiency was less frequent in APS patients, suggesting that CD36 insufficiency is protective for developing APS. The deficient or suppressed CD36 function significantly reduced aPL-induced TF expression in vitro. Taken together, scavenger receptor function may be involved in the thrombotic pathophysiology in APS patients. CD36 is a new potential therapeutic target of the affected patients.

Potential Protein Targets for the Treatment of the Antiphospholipid Syndrome with Statins and Hydroxychloroquine. Anastasia Lambrianides[2], Silvia S. Pierangeli[1], Katie Bell[3], Wendy Heywood[3], David S. Latchman[3], David A. Isenberg[3], Anisur Rahman[3] and Ian Giles[3]. [1]Univ of TX Medical Branch, Galveston, TX, [2]University College London, London, United Kingdom, [3]University College London, London, UK

Introduction: A major mechanism of hypercoagulability in the antiphospholipid syndrome (APS) is antiphospholipid antibody (aPL)-mediated up-regulation of tissue factor (TF) on monocytes. Recent attention has been focused on other therapeutic tools for the APS to ameliorate the risk of the hemorrhagic compications associated with the use of anticoagulant drugs currently used for treatment. Statins have been shown to modify the function of endothelial cells and platelets by decreasing the expression of adhesion molecules, inhibiting TF expression and down-regulating inflammatory cytokines after treatment with aPL. Similarly, hydroxychloroquine (HCQ) has been shown to reduce the extent of thrombosis in an animal model of injury-induced thrombosis in APS and reversed aPL-induced platelet activation. Using proteomic analysis, our aim was to identify the effects of simvastatin and HCQ in protein expression in monocytes treated with IgG aPL from patients with vascular thrombosis (VT).

Methods: IgG was purified from 7 patients with the APS who had experienced VT but no pregnancy complications and 7 healthy controls. A human monocyte cell line was treated with 100μg/ml IgG for 6 hours. In some experiments, cells were pretreated with simvastatin (5μM) or with HCQ (1μg/ml). The cell extracts were examined by fluorescence 2D difference gel electrophoresis (DIGE).

Results: We have identified that there are 24 proteins showing significant differences in expression in monocytes treated with IgG from patients with VT in the presence of simvastatin – the majority with decreased expression between 2.1 and 5.2 fold. Furthermore, there are five proteins with altered protein expression patterns in monocytes treated with IgG from patients with VT in the presence of HCQ – four proteins with decreased expression between 2.1 and 2.3 fold and one protein with increased expression 2.6 fold.

Conclusion: Our findings demonstrate, for the first time, that statins and HCQ significantly altered the expression/modification of proteins in monocytes. These proteins may be critical targets that might be involved in the pathogenesis of the APS and supports the possibility that statins and HCQ may offer an alternative nonanticoagulant therapeutic approach for treating the APS.

Irreversible Physical Disability in Rheumatoid Arthritis (RA) Is Determined by Cartilage Damage Rather Than Bone Destruction. Josef S. Smolen[2] and Daniel Aletaha[1]. [1]Medical University of Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background: RA is characterized by joint damage leading to irreversible disability (assessed by health assessment questionnaire [HAQ]). Joint destruction is comprised of cartilage and bone damage, consequences of distinct pathogenetic mechanisms. They are evaluated by joint space narrowing (JSN) and erosion (ERO) components of the Sharp score. We aimed to determine the contribution of cartilage and bone damage to irreversible disability.

Methods: We evaluated data from randomized controlled clinical trials (ASPIRE, ATTRACT, DE019, ERA, Leflunomide, PREMIER, TEMPO). We extracted patients who were in stringent remission by the simplified disease activity index (SDAI≤3.3) to eliminate the activity-related component of disability. In these patients, we determined the residual HAQ at the time of remission (irreversible disability[1]) and the JSN and ERO scores at baseline. We then compared effects of ERO and JSN on residual HAQ (across tertiles using ANOVA, and in regression models).

Results: Mean residual HAQ in remission increased across tertiles of JSN and ERO (ERO: 0.21, 0.25, 0.35 JSN: 0.19, 0.24, 0.39; $p<0.001$ for both). In patient groups formed according to JSN tertiles, increasing ERO scores did not lead to an increase in irreversible HAQ (for example, mean residual HAQ in the middle JSN tertile: 0.24, 0.24 and 0.23 for 1st, 2nd and 3rd ERO tertile, respectively; p=ns). In contrast, within each ERO tertile, increasing JSN was associated with an increase in residual HAQ (Figure 1). This relationship was maintained when adjustments for residual disease activity, age or disease duration were done (data not shown).

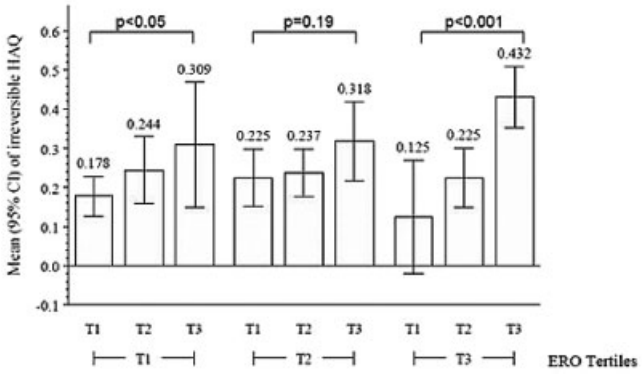

Figure 1. HAQ values in remission ("irreversible HAQ") as attained when grouping patients by ERO or JSN tertiles and within each ERO terile by JSN tertiles and vice versa. Note that increasing JSN conveyed higher irreversible HAQ within each ERO tertile but not vice versa.

Conclusion: Irreversible physical disability is primarily mediated by cartilage and not bony damage, suggesting that therapeutic attention should be given to interference with cartilage destruction.

The Impact of Body Weight on the Progression of Radiographic Joint Damage in Rheumatoid Arthritis Patients. Axel Finckh[4], Almut Scherer[1], Anne Lubbeke-Wolff[3], Hans Schwarz[1] and Cem Gabay[2]. [1]SCQM Foundation, Switzerland, [2]Univ Hosp of Geneva, Geneva, Switzerland, [3]University of Geneva, Switzerland, [4]University of Geneva, Geneva, Switzerland

Background: Obese individuals experience elevated levels of circulating pro-inflammatory cytokines. While obesity might be associated with an increased risk of developing RA and with impaired quality of life, the role of obesity on the progression of RA disease severity is not well established.

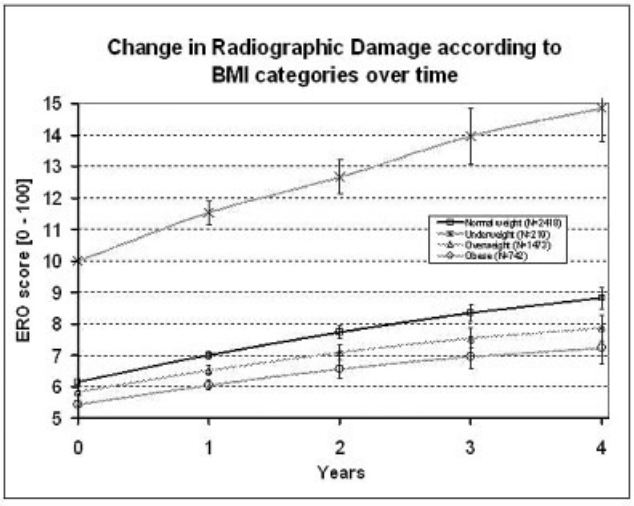
Objective: To examine if obesity is associated with more radiographic joint damage progression.

Methods: This is a prospective cohort study of the Swiss RA cohort (SCQM-RA) including all patients with available Body Mass Index (BMI) and complete sets of radiographs of the hand and feet. Patients were categorized according to the WHO BMI categories as "underweight" (BMI < 18.5), "normal weight" (BMI ≥ 18.5, < 25), "overweight" (BMI ≥ 25, < 30) and "obese" (BMI ≥ 30, < 35). The primary outcome of this analysis is the progression of ERO over time. Joint erosions (ERO) were assessed in 38 joints of hands and feet with a validated scoring method (Ratingen score, expressed in % of the maximum score) by a single experienced reader, blinded to clinical information. The evolution of ERO is analyzed using regression models for longitudinal data, adjusting for potential confounders.

Results: The mean BMI of the 4852 RA patients included was 25. The groups were similar for most disease characteristics, but for baseline radiographic damage, which was significantly higher for underweight patients.

	Underweight BMI<18.5	Normal weight (BMI 18.5–25)	Overweight (BMI 25–30)	Obese (BMI > 30)
N patients (%)	219 (5%)	2418 (50%)	1473 (30%)	742 (15%)
Age [yrs]	52	54	58	58
Disease duration [yrs]	6.1	4.3	3.7	3.4
% Female	94	81	66	73
% RF+	77	77	73	70
DAS28(ESR) [0–10]	4.6	4.5	4.5	4.6
HAQ-DI [0–3]	1.05	0.96	1.01	1.17
ERO score [% of max]	10	6.2	5.8	5.4
Estimated ERO rate at baseline [%/yr]	2.1	1.6	1.5	1.3
% Steroid	31	26	24	29
% Biologics	23	20	20	21

Patients were followed over a median duration of 4 years and assessed radiographically on average 3.3 times. After adjusting for baseline differences in prognostic markers of disease progression, underweight patients developed significantly more erosions over time then the other weight groups (p <0.001).



At 4 years, underweight patients ERO score progressed by 4.9 % (95% CI: 3.8–5.9), compared to 2.7 (CI: 2.3–3.0) in normal weight patients, 2.0 (CI: 1.6–2.4) in overweight patients and 1.8 (CI: 1.3–2.3) in obese patients.

Conclusion: Underweight was associated with more joint damage over time, probably reflecting uncontrolled disease and 'rheumatoid cachexia'. Obesity and overweight was not associated with more rapid progression of radiographic damage in hand and feet joints.

Clinical Rather Than Serologic Measures of Inflammation Determine Radiographic Progression in Rheumatoid Arthritis (RA). Daniel Aletaha[1] and Josef S. Smolen[2]. [1]Medical University of Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background: Disease activity in RA can be measured clinically by assessing joint inflammation, typically swollen joint counts (SJC), or systemically by evaluating the acute phase reactants, typically C-reactive protein (CRP). It has been suggested that both SJC and CRP contribute to progression of joint damage[1;2]. However, since these measures are interrelated, it is not sufficiently clear, which of them is of primary relevance in driving radiographic changes. We aimed to determine the contribution of SJC and CRP to joint damage progression.

Methods: We evaluated data from methotrexate (MTX) monotherapy arms of recent randomized controlled clinical trials kindly provided by the respective sponsors (ASPIRE, ERA, Leflunomide, PREMIER, TEMPO). We pooled patients with complete clinical and radiographic data at baseline and 6, 9 and 12 months (n=871). In these patients, we determined the average SJC and average CRP levels from 6–12 months. We then dichotomised both variables into active and not active, where non active was defined as a mean SJC of <1 joint, or a mean CRP of <1mg/dL. Radiographic progression was calculated based on the baseline and 12 months Sharp score readings. We cross-tabulated the mean radiographic progression in 2×2 tables according to activity/non activity of the two variables, SJC and CRP. We assessed the differences using the Wilcoxon two sample test.

Results: As shown in the Table, progression of joint damage in patients with mean CRP≥1 was higher if SJC were also active, and vice versa. If there was no joint activity (SJC<1), radiographic progression was unaffected by CRP status. However, if there was no serologic activity (CRP<1mg/dL), SJC status still determined radiographic progression.

Table. Radiographic progression ± standard deviation (n) in accordance to SJC/CRP activity status.

	CRP active	CRP non active	
SJC active	4.6 ± 16.4 (n = 259)	2.0 ± 5.9 (n = 477)	p < 0.0001
SJC non active	0.9 ± 5.9 (n = 24)	0.7 ± 4.4 (n = 111)	p = 0.146
	p = 0.015	p = 0.005	

Conclusions: Joint swelling rather than CRP contributes to progression of joint damage in RA.

Coronary Atherosclerosis in Patients with RA and Acute Coronary Events: No Different Than in the Rest of Us? Marie E. Holmqvist[1], Lennart T. H. Jacobsson[3], Lars Alfredsson[1], Stefan James[4] and Johan Askling[2]. [1]Karolinska Institutet, [2]Karolinska University Hospital, [3]Malmö University Hospital, [4]Uppsala University Hospital

The risk of ischemic heart disease (IHD) and the prevalence of atherosclerosis is increased in patients with rheumatoid arthritis (RA) compared to the general population. Based on individuals with clinical manifestations of IHD, few, and conflicting, studies that compare patients with RA and general population comparators with respect to extent of coronary artery disease (CAD) have been published.

Objective: To investigate whether angiographic patterns differ between patients with RA, known to be at increased risk of CAD, and the general population, at the time of clinical manifestations of acute CAD (unstable angina, ST-elevation myocardial infarction [STEMI], silent infarction and central chest pain).

Methods: RA patients diagnosed 1995–2006 with<18 months symptom duration at diagnosis included in the Swedish RA register were identified, n=6,919. For each patient, 5 sex/age/residential area/calendar time-matched general population comparators were identified, n=34,638. Participants were linked to the national Swedeheart register, which includes information on indication for angiography and number of vessels with>50% stenosis for all subjected, and also presenting symptoms, status at admission and discharge diagnosis for all admitted to coronary care units (CCU). Relative risks (RR) and 95% CI were estimated using proportional hazards models. To compare the odds of different angiography patterns, logistic regression models were fitted with RA (yes/ no) as the independent variable, and extent of atherosclerosis classified according to the number of vessels with significant stenosis as the dependent variable.

Results: 218 (3.2%) patients and 737 (2.1%) controls underwent angiography due to any ischemic heart disease (stable and unstable angina, STEMI, silent infarction or central chest pain) after study entry, RR=1.5 (95% CI 1.2, 1.7). Of those, 168 (77%) patients with RA and 534 (72%) comparators were investigated due to acute CAD. The proportion of patients with RA that underwent angiography due to STEMI was slightly higher, although no statistically significantly so, than in the population comparator (33% of the patients with RA and 26% of the comparators underwent angiography due to STEMI). There was no difference in the extent of atherosclerosis when patients with RA were compared to general population comparators.

Logistic regression modeling the risk of having significant stenosis in the below specified vessels comparing patients with RA who underwent angiography due to unstable angina, STEMI, central chest pain or silent myocardial ischemia to general population comparators who underwent angiography for the same reasons. Odds ratios (OR) and 95% confidence interval (CI) adjusted for age at angiography and sex.

	Patients with RA with outcome, n (% of all with angiography results)	Comparators with outcome, n (% of all with angiography results)	OR (95% CI)
Left main artery*	13 (8.2)	30 (5.9)	1.4 (0.7, 2.8)
-LMA	0 (0)	1 (0.2)	–
-LMA+1 coronary	1 (0.6)	4 (0.8)	0.7 (0.08, 6.8)
-LMA+2 coronary	3 (1.9)	6 (1.2)	1.6 (0.4, 6.4)
-LMA+3 coronaries	9 (5.7)	19 (3.8)	1.5 (0.7, 3.4)
1 coronary	47 (29.8)	162 (32.0)	0.9 (0.6, 1.3)
2 coronaries	37 (23.4)	110 (21.7)	1.1 (0.7, 1.7)
3 coronaries	26 (16.5)	90 (17.8)	0.9 (0.6, 1.4)
Normal coronaries	35 (22.2)	115 (22.7)	1.0 (0.6, 1.6)

* including all with afflicted LMAs regardless of status of other vessels. 10 patients with RA were missing on findings on angiography and 27 comparators.

Conclusion: These results confirm the increased risk of ischemic heart disease in RA, and further suggest that the angiographic pattern is similar among patients with RA and general population controls who develop acute CAD. This indicates that the increased risk of IHD/CAD in RA is not explained by more widespread atherosclerosis in those who develop acute IHD/CAD.

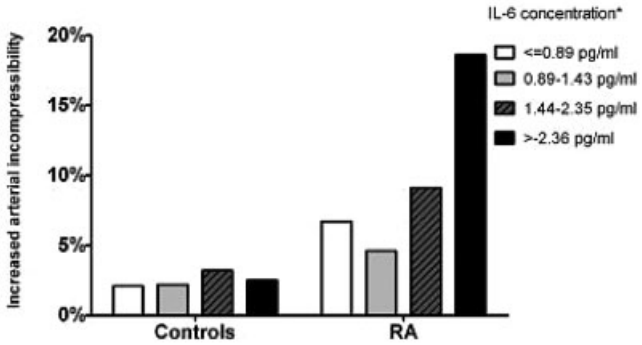
Interleukin-6 Levels Are Associated with Elevated Ankle Brachial Index in Rheumatoid Arthritis. Cecilia P. Chung[4], Jon T. Giles[3], Moyses Szklo[5], Wendy Post[5], Michelle A. Petri[1], Roger Blumenthal[5], Allan C. Gelber[2], Russell Tracy[6] and Joan M. Bathon[4]. [1]Timonium, MD, [2]Baltimore, MD, [3]Johns Hopkins Univ, Baltimore, MD, [4]Johns Hopkins University, Baltimore, MD, [5]Johns Hopkins University, [6]University of Vermont

Purpose: Recent evidence suggests that arterial incompressibility, determined by elevated ankle brachial index (ABI), is associated with poor cardiovascular outcomes and increased mortality. Patients with RA may have an increased risk of arterial incompressibility, partially explained by the use of systemic corticosteroids. However, little is known about the role of inflammation in arterial incompressibility. Thus, we tested the hypothesis that arterial incompressibility is more prevalent in patients with RA than in control subjects and is associated with disease activity and markers of inflammation.

Methods: ABI, a reliable marker of peripheral and generalized subclinical atherosclerosis, was measured in 196 patients with RA enrolled in the Evaluation of Subclinical Cardiovascular Disease and Predictors of Events in Rheumatoid Arthritis (ESCAPE) study and in 1062 control subjects enrolled in the Multi-Ethnic Study of Atherosclerosis (MESA) study. Patients and control subjects were classified into three groups as follows: ABI >0.9 and ≤1.3 (normal), ABI >1.3 (incompressible), ABI ≤ 0.9 (obstructed). Demographic and clinical data were obtained and in patients with RA the disease activity score based on 28 joints (DAS28) calculated. Venous blood was drawn to measure the concentration of interleukin-6 (IL-6), C-reactive protein (CRP), e-selectin, and intercellular adhesion molecule-1 (ICAM-1).

Results: Arterial incompressibility was more prevalent in patients with RA (n= 27, 13.8%) than in control subjects (n=25, 2.4%), p<0.001. This association was independent of age, sex, and race (OR=7.5, p<0.001) and remained significant after adjustment for Framingham risk score, IL-6, fibrinogen and CRP (OR=5.8, p<0.001). RA patients with increased arterial incompressibility were more frequently male (66.7%) than those without (36.7%), p=0.005. Increasing quartiles of IL-6 concentrations were associated with higher prevalences of arterial incompressibility in patients (p for trend=0.04) but not in controls (p for trend=0.59). (Figure) The association between arterial incompressibility and IL-6 in RA patients remained significant after adjustment for HAQ (OR=1.9, p=0.04), but was attenuated after adjustment for DAS28 (OR=1.8, p=0.06). There was a trend towards higher cumulative doses of systemic corticosteroid use in patients with increased arterial incompressibility (median of 3.2 grams) compared to patients with normal ABI (2.8 grams), p=0.09. No statistically significant differences were observed in DAS28 (p=0.89), CRP (p=0.87), e-selectin (p=0.63), or ICAM-1 (p=0.63) between those with normal ABI vs. those with arterial incompressibility.



*IL-6 concentration was categorized according to quartiles based on the whole dataset.

Conclusions: Patients with RA are at an increased risk of arterial incompressibility than control subjects. In patients with RA, higher concentrations of IL-6 are associated with a higher risk of arterial incompressibility.

2261

Diagnostic Accuracy of the 2010 ACR/EULAR Used at Baseline after a 10 Year Follow Up in a Cohort of Patients with Recent-Onset Arthritis. Divi Cornec[5], Sophie Varache[6], Johanne Morvan[5], Valérie Devauchelle-pensec[5], Jean-Marie Berthelot[7], Sandrine Jousse-joulin[5], Catherine Le Henaff[2], Sylvie Hoang[4], Jean-Baptiste Thorel[1], Antoine Martin[3], Gérard Chalès[8], Pierre Youinou[5] and Alain Saraux[5]. [1]CH Lorient, [2]CH Morlaix, [3]CH St Brieuc, [4]CH Vannes, [5]CHU Brest, [6]CHU Brest, [7]CHU Nantes, [8]CHU Rennes

Objective: We recently (EULAR 2010) evaluated the diagnostic accuracy of the 2010 ACR/EULAR and 1987 ACR criteria (unmodified and modified by Liao et al. Ann Rheum Dis 2008;67:1557–61) for rheumatoid arthritis (RA) in a cohort of patients with recent-onset arthritis after a 2 year follow up. Our goal is now to verify the results after a ten year follow-up.

Methods: 164 patients with recent-onset arthritis of less than 1 year's duration were prospectively included between 1995 and 1997 and followed

for 10 years. The diagnosis of RA was defined at follow-up completion as having a diagnosis of RA made by an office-based rheumatologist. All items of the unmodified and modified 1987 ACR criteria sets [criteria: 1-Morning stiffness≥1 hour, 2-Arthritis of three or more joint areas, 3-Arthritis of hand joints, 4-Symmetric arthritis, 5-Rheumatoid nodules, 6-Rheumatoid factor (positive), 7-Radiographic changes and 8-Anti-CCP antibodies (positive)] and of the ACR/EULAR 2010 criteria set (algorythm and scoring) were evaluated in each patient. Unmodified 1987 ACR criteria set were considered positive ≥4 of the 1–7 criteria, and the modified 1987 ACR criteria set for ≥4/7 of the 1–2-3–4-6–7-8 criteria (Liao 1) or ≥3/6 of the 1–2-3–4-6–8 criteria (Liao 2). We compared the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of the criteria sets.

Results: At baseline, 60 of the 164 patients had alternative diagnoses better explaining the arthritis and 13 had erosions typical for RA; of the 91 remaining patients, 33 had more than 6 ACR/EULAR points (indicating definite RA), and 58 had fewer than 6 points. After 10 years, 9/13 patients with erosions and 25/33 with more than 6 points had RA. Sensitivity, specificity PPV, and NPV of ACR/EULAR 2010 were 34/57 (59.6%), 95/107 (88.8%), 34/46 (73.9%), 95/118 (80.5%), respectively, i.e., better than both un modified (34/57, 78/107, 34/63 and 78/111) and modified 1987 ACR criteria (47/57, 58/107, 47/96 and 58/68 for Lioa2 and 37/57, 78/98, 37/66 and 78/98 for Liao1, respectively). After 10 year, of 9 patients who received biologics, 7 were detected by ACR/EULAR criteria. Similar results were observed for prediction of joint replacement.

Conclusion: ACR/EULAR 2010 criteria perform clearly better than the ACR 1987 criteria to predict a diagnosis of RA at 10 years. Much of the improvement was ascribable to the use of exclusion criteria.

Tocilizumab (TCZ) Plus Methotrexate (MTX) in Rheumatoid Arthritis (RA) Patients (pts) Who Increased TCZ Dose from 4 mg/kg to 8 mg/kg: LITHE Radiographic and Safety Data. Roy M. Fleischmann[4], Ricardo Blanco[2], Geraldo Castelar-Pinheiro[3], Emma Vernon[5], Christopher Mela[5] and Joel M. Kremer[1]. [1]Albany Medical College, Albany, NY, [2]Hospital Marqués de Valdecilla Cantabria, [3]Hospital Universitario Pedro Ernesto, Rio de Janeiro, Brazil, [4]Metroplex Clinical Research Center, Dallas, TX, [5]Roche, Welwyn, United Kingdom

Purpose: Results of the TCZ clinical development program have shown that for most endpoints, the 8 mg/kg dose is more effective than the 4 mg/kg dose. In the US, TCZ 4 mg/kg has been approved as the starting dose with a subsequent escalation to 8 mg/kg based on clinical response. This analysis evaluated the effect of increasing the TCZ dose from 4 to 8 mg/kg on inhibition of radiographic progression and safety in the LITHE study.

Methods: RA pts with inadequate responses to MTX were randomly assigned to TCZ 4 or 8 mg/kg (TCZ4 or TCZ8) or placebo Q4W + MTX. From wk 16, blinded first-step rescue was allowed if pts had <20% improvement in SJC and TJC (eg, pts on placebo went to TCZ4, pts on TCZ4 or TCZ8 went to TCZ8). If <20% improvement persisted after 3 doses of blinded first-step rescue, pts received second-step rescue with TCZ8. At wk 52, pts were treated with open-label (OL) TCZ8 except those with ≥70% improvement in SJC and TJC, who could continue blinded therapy to wk 104. X-rays were performed at baseline and wks 24, 52, 80, and 104. Data were analyzed in pts whose dose increased from TCZ4 to TCZ8. Data from this TCZ dose-escalation analysis must be interpreted with caution because 78 pts who withdrew (44 for safety, 8 for insufficient response, 26 for other reasons) from the study before dose escalation are not included. In addition, criteria for dose escalation and/or dose continuation were based on efficacy results that were predetermined per study protocol. Safety data are provided for all randomly assigned pts who received ≥1 TCZ dose and who had at least 1 post-randomization safety assessment.

Results: Of 1190 pts (393, 399, and 398 randomly assigned to placebo, TCZ4, and TCZ8, plus MTX, respectively), 451 pts increased their dose from TCZ4 to TCZ8. In these 451 pts, annualized rate of progression of Genant-modified Total Sharp Score, erosion, and joint space narrowing slowed after the dose increased from TCZ4 to TCZ8 (Table A). Rates/100 patient-years (PY) of serious adverse events (AEs) and serious infections were lower than previously reported (Kremer et al, EULAR 2010) before dose escalation but increased to rates comparable to those of the TCZ pooled groups (TCZ4, n =597, includes pts who received TCZ4 as initial or rescue therapy; TCZ8, n=983 pts, includes those who received TCZ8 as initial and/or rescue and/or OL therapy) after dose escalation (Table B). The low predose escalation event rates for the TCZ4 group are influenced by a selection bias—ie, pts who withdrew while on TCZ4 do not contribute safety data to the analysis of the switching group but continue to contribute to the rates in the TCZ4 pooled analysis.

Conclusions: For this analysis of pts who increased dose, the annualized rate of progression was reduced after pts increased their TCZ dose from 4 to 8 mg/kg; safety in these pts after dose escalation was comparable to that in the TCZ pooled groups.

Table A. Mean (SD) Annualized Rate of Radiographic Progression by Treatment Increase up to Week 104 (n = 451)

	Predose increase (TCZ4) n = 451	Postdose increase (TCZ8) n = 451
n	336	346
Genant-modified Total Sharp Score	0.31 (1.07)	0.10 (0.52)
Erosion	0.20 (0.83)	0.04 (0.36)
Joint space narrowing	0.11 (0.53)	0.06 (0.36)

Data collected after study withdrawal are excluded

Table B. Safety up to Week 104 Before and After TCZ Dose Increase and by Pooled Treatment Groups

	Dose escalation group n = 451[a]		Pooled treatment group[b]	
	Predose increase (TCZ4)	Postdose increase (TCZ8)	TCZ4 n = 597[c]	TCZ8 n = 983[d]
Exposure, PY	338.6	475.9	521.9	1320.4
Serious AEs/100 PY	5.9	11.3	12.1	11.4
Serious infections/100 PY	0.9	2.7	3.1	3.2

[a] 78 patients who received TCZ4 and withdrew (44 for safety, 8 for insufficient response, 26 for other reasons) from the study before dose escalation are not included.
[b] Patients in pooled treatment groups could be in both pooled groups and also in the dose-escalation group.
[c] All patients who received ≥1 TCZ4 dose, including those initially assigned to placebo who received rescue with TCZ4 and those initially assigned to TCZ4, and whose only TCZ dose was 4 mg/kg; data are up to study withdrawal, when dose increased to TCZ8, or wk 104.
[d] All patients who received ≥1 TCZ8, including patients initially assigned to placebo who received second-step rescue with TCZ8, patients initially assigned to TCZ4 who received rescue with TCZ8, patients initially assigned to TCZ8, patients whose only TCZ dose was 8 mg/kg, and patients on OL TCZ8; data are up to study withdrawal or wk 104.

Rituximab Treatment Induces the Expression of Genes Involved in Healing Processes in the Rheumatoid Arthritis Synovium. Ilse Gutierrez-Roelens[4], Christine Galant[3], Ivan Theate[3], Rik J. Lories[2], Patrick Durez[4], Adrien Nzeusseu Toukap[4], Benoît Van den Eynde[1], Frédéric A. Houssiau[4] and Bernard R. Lauwerys[4]. [1]de Duve Institute & Ludwig Institute for Cancer Research, Brussels Branch, [2]Department of Musculoskeletal Sciences, Division of Rheumatology, Laboratory for Skeletal Development and Joint Disorders, Katholieke Universiteit Leuven, [3]Department of Pathology, Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, [4]Department of Rheumatology, Cliniques Universitaires Saint-Luc, Université Catholique de Louvain

Objectives: In previous experiments, we performed transcriptomic analyses on synovial biopsies obtained from anti-TNF resistant rheumatoid arthritis (RA) patients prior to (T0) and 12 weeks (T12) after initiation of rituximab therapy. We found that genes down-regulated between T0 and T12 were significantly enriched in immunoglobulin genes, and genes involved in chemotaxis, leucocyte activation and immune responses. By contrast, genes

up-regulated between T0 and T12 were significantly enriched in transcripts involved in cell development and wound healing. We wondered whether up-regulation of the latter genes was a true effect of rituximab therapy, or whether the relative decrease in inflammatory cells and relative increase in resident synovial fibroblasts resulted in a biased appreciation of global gene expression profiles at T12.

Methods: Paired synovial biopsies were obtained from the affected knee of 20 anti-TNF resistant RA patients at T0 and T12. Fresh synovial biopsy tissue samples were fixed overnight in 10% formalin buffer and embedded in paraffin. Immunolabeling experiments were performed using the following antibodies: BMPR1A (Bone Morphogenetic Protein Receptor 1A), MEOX2 (Mesenchyme Homeobox2), LAMA4 (Laminin alpha 4), phospho-SMAD1/5 and phospho-SMAD3. Quantitative analysis of the antibody immunostained sections was performed using ImageJ software, according to the Digital Image Analysis process.

Results: BMPR1A, MEOX2 and LAMA4 are markers of mesenchymal cell differentiation. Immunolabeling experiments and digital quantification of the slides indicated that synovial expression of the three molecules is significantly induced by rituximab therapy in RA synovial tissue.

Up-regulation of these genes triggered us to investigate whether administration of rituximab resulted in synovial activation of TGF-β or BMP signaling. To explore this hypothesis, we performed phospho-SMAD3 (a marker of TGF-β activation) and phospho-SMAD1/5 (a marker of BMP activation) immunohistochemistry studies. No significant difference in phospho-SMAD3 staining was observed between T0 and T12. The phospho-SMAD1/5 signal significantly decreased between T0 and T12. These results indicate that synovial up-regulation of genes involved in healing processes is not associated with an increased TGF-β or BMP activity through its canonical pathways at T12.

Conclusion: Rituximab induces the expression of molecular markers of mesenchymal cell differentiation in the synovium. We did not find evidence of increased TGF-β and BMP signalling in the synovium at T12. Further studies are needed in order to investigate the possibility of increased BMP or TGF-β signaling at earlier time-points or the presence of alternative mechanisms of induction of mesenchymal cell differentiation.

Golimumab and Methotrexate Combination Therapy Significantly Improves Synovitis, Osteitis and Bone Erosion Compared to Methotrexate Alone—A Magnetic Resonance Imaging Study of Methotrexate-Naïve Rheumatoid Arthritis Patients. Mikkel Østergaard[6], Paul Emery[4], Philip G. Conaghan[5], Roy M. Fleischmann[7], Weichun Xu[2], Elizabeth C. Hsia[3], Anna Beutler[1] and Mahboob U. Rahman[3]. [1]Centocor Research and Development, Inc., Collegeville, PA, [2]Centocor Research and Development, Inc., [3]Centocor Research and Development, Inc./Univ. of Pennsylvania School of Medicine, Malvern, PA, [4]Chapel Allerton Hospital, Leeds, United Kingdom, [5]Chapel Allerton Hospital, Leeds, United Kingdom, [6]Copenhagen University Hospital at Glostrup and Hvidovre, Hvidovre, Denmark, [7]University of Texas SW Medical Center, Dallas, TX

Background: In the GO-BEFORE study, golimumab (GLM) improved signs and symptoms of RA, improved physical function, and slowed the progression of structural damage in patients who were methotrexate (MTX) naïve.

Objective: To evaluate the effect of GLM on the inflammation and structural damage detected by magnetic resonance imaging (MRI) in patients with RA who were MTX naïve.

Methods: Patients (n=637) were randomly assigned to receive placebo (PBO) + MTX, GLM 100 mg + PBO, GLM 50 mg + MTX, or GLM 100 mg + MTX. A subset of study sites capable and willing participated in the MRI substudy. All patients from each substudy site were eligible for substudy participation (n=318). GLM and PBO were administered via subcutaneous injection every 4 weeks. The primary comparison was between the PBO + MTX and combined GLM + MTX groups. MRIs of the patient's dominant wrist and metacarpophalangeal joints were obtained at baseline and weeks 12, 24, 52, and 104 using 1.5T MRI with contrast enhancement. Results through week 24 are presented here. Images were scored by two independent expert readers blinded to image time point or sequence, patient identity, or treatment group. Readers scored synovitis (0–21), bone edema (osteitis) (0–69), and bone erosions (0–230), using the Rheumatoid Arthritis MRI Scoring (RAMRIS) system; the average of each RAMRIS score provided by the readers was used in the analysis.

Results: Mean baseline RAMRIS bone edema and RAMRIS bone erosion scores were numerically slightly lower in the PBO than GLM groups. Significant improvements in RAMRIS synovitis, osteitis and bone erosions were observed at weeks 12 and 24 in the combined GLM + MTX groups relative to PBO + MTX (Table). Significant improvements in synovitis and bone edema were observed in both GLM + MTX dose groups at both weeks 12 and 24 versus the PBO + MTX group. Significantly less bone erosion progression was documented at week 12 for the GLM 50 mg + MTX group and at 24 weeks for both GLM + MTX doses. Comparison of radiographic data (using the van der Heijde modification of the Sharp score) within the MRI substudy patients (n=318) showed no significant difference between the PBO + MTX and combined GLM + MTX groups (mean ± SD changes from baseline to week 28 of 0.92 ± 2.96 and 0.49 ± 3.23, respectively; p=0.19), thus demonstrating MRI to be superior to x-rays in terms of sensitivity to changes in erosive progression.

Conclusion: Results of this MRI substudy of the GO-BEFORE trial demonstrated that patients who received GLM + MTX had improvements in inflammation (synovitis and osteitis) and improvements in erosions exceeding those observed with PBO + MTX as early as week 12 and continuing through week 24, confirming the clinical and radiological findings previously reported for the overall study population. MRI assessment was superior to x-ray in terms of sensitivity to change in erosive progression.

RAMRIS scores: values are mean/median (interquartile range)	Placebo+MTX (n = 82)	GLM 100mg+PBO (n = 77)	GLM 50mg+MTX (n = 78)	GLM 100mg+MTX (n = 81)	Combined GLM+MTX (n = 159)

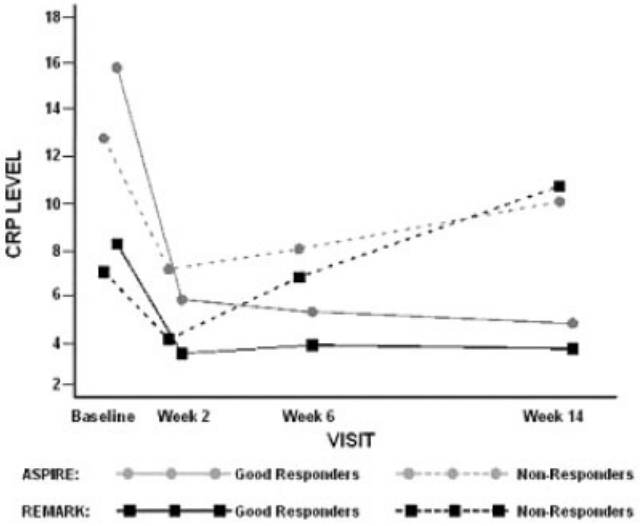
Changes in CRP Levels Are Associated with Clinical Response Patterns during Treatment with Infliximab—A Potential Role for CRP in Guiding Dose Optimization. Cees Meeuwisse[5], Josef S. Smolen[4], Dimitrios Boumpas[7], E. William St Clair[2], Mahboob U. Rahman[1], Nathan Vastesaeger[6], Wilbert van Duijnhoven[5], Robert L. H. Nelissen[5] and Ronald Van Vollenhoven[3]. [1]Centocor, Malvern, PA, [2]Duke University Medical Center, Durham, NC, [3]Karolinska University Hospital, Stockholm, Sweden, [4]Krankenhaus Lainz, Vienna, Austria, [5]MSD, Oss, The Netherlands, [6]MSD, Brussels, Belgium, [7]University Hospital of Heraklion, Crete, Greece

Background: Infliximab (IFX) can be used in RA at a range of doses and frequencies. Biomarkers to guide dose optimization would be of clinical

importance. Our objective was to investigate CRP kinetics during 14 weeks of IFX treatment to determine whether CRP can be used as a biomarker to guide dose optimization in RA patients.

Methods: This was a phase-IV, multicenter, observational study conducted in Europe. Adult patients with RA for whom treatment with IFX 3 mg/kg had been chosen per label were invited to participate. Patients were classified as good-responders (GR), moderate-responders (MR), or non-responders (NR) according to EULAR response at week 14. We built a statistical model to estimate mean (95% CI) CRP levels prior to each infusion by response group, and adjusted it for baseline CRP values and patient characteristics. We then analyzed CRP change among patients and CRP differences between groups. To confirm our results, we performed a similar analysis using data from the 3-mg/kg arm of the blinded randomized controlled ASPIRE study in early RA (St. Clair, 2004).

Results: 481 patients from the study were included in the analysis—79.8 % female; mean age 53 (SD 13) years. Baseline mean DAS28 was 5.2 (SD 1.1). At week 14, 34.5% of patients were GR, 41.2% MR and 24.3% NR. CRP levels steeply declined in all groups from baseline to week 2. In the GR group, CRP remained stable at low levels during weeks 2 to 14. In the NR group, a CRP-rebound started at week 2 and reached near-baseline levels at week 14 (see figure; for clarity only GR and NR profiles are shown, CRP levels for MR were higher but close to those for GR).



Estimated CRP levels adjusted for baseline value and patient characteristics. Values at baseline are geometric means of original data.

This rebound showed significant increases in CRP from weeks 2 to 6 and again from weeks 6 to 14 ($P < 0.0001$). Between-group differences were significant at weeks 6 and 14 for both GR and MR groups compared to the NR group. The confirmatory ASPIRE analysis included 277 patients who received IFX 3 mg/kg. At week 14, 27.4% of patients were GR, 46.9% MR, and 25.6% NR. CRP levels showed a similar pattern, with an initial improvement from baseline to week 2 in all groups and a significant increase in the NR group from weeks 2 to 14. Between-group differences were observed at weeks 6 and 14 for both the GR and MR groups compared to the NR group.

Conclusion: CRP kinetics during the first 14 weeks may help guide IFX treatment. Good response is characterized by stabilization of CRP at low levels, and non-response by a CRP rebound between weeks 2 and 14 during which time the infusion interval is increased. Studies of dose/frequency adjustments in non-responders to optimize therapy are needed.

Comparative Effectiveness of Biologic Therapies for Treating Rheumatoid Arthritis (RA) in Patients Who Failed an Anti–Tumor Necrosis Factor Agent: A Meta-Regression Analysis. A. Benedict[2], D. J. Vanness[3], S. Roy[1] and M. A. Cifaldi[1]. [1]Abbott Laboratories, [2]United BioSource Corporation, [3]University of Wisconsin

Background and Purpose: In the absence of clinical studies involving all agents, evaluating comparative efficacy of biologic therapies for patients with RA who failed an anti–tumor necrosis factor (anti-TNF) agent is difficult. Assessing comparative effectiveness of these interventions is challenging. We used meta-regression (MR) methods to estimate probability of clinical response for biologic therapies abatacept, adalimumab, anakinra, etanercept, golimumab, infliximab, rituximab, and tocilizumab, all in combination with methotrexate (MTX), for patients who failed prior anti-TNF therapy.[1,2]

Methods: We updated earlier systematic reviews of biologic therapies in longstanding RA to identify relevant randomized controlled trials (RCTs) that reported American College of Rheumatology (ACR) response criteria. Prospective, open-label studies were included. Dose-finding RCTs and safety studies were excluded. A hierarchical Bayesian mixed effects MR model was estimated (WinBUGS 1.4.3); adjustments for study-arm level heterogeneity included concomitant MTX, age, RA duration, baseline Health Assessment Questionnaire (HAQ) score, follow-up time, % failing prior anti-TNF therapy, and whether assigned treatment was a subsequent biologic. ACR responses in each arm were modeled simultaneously to reflect their nested nature (ie, patients with ACR70 also attain ACR50 and ACR20). Adalimumab, etanercept, golimumab, and infliximab were grouped for this analysis and overall efficacy for anti-TNF agents was compared with non-TNF biologics.

Results: The final dataset included 96 comparator arms from 32 studies. Covariate estimates indicated that prior anti-TNF agent failure was associated with a reduction in the log odds ratio (LOR) of ACR response for all treatments, but subsequent biologic treatment offset much of that reduction. Controlling for other factors, longer duration of disease and greater baseline HAQ score increased the LOR of ACR response for biologic relative to nonbiologic treatment. Likewise, longer follow-up decreased the LOR of ACR response. The table summarizes posterior mean predicted ACR response rates for patients with mean baseline HAQ score of 2.0, disease duration of 11 years, and at 6 months of follow-up.

	Placebo/ None+MTX	anti-TNF+ MTX	Anakinra+ MTX	Abatacept+ MTX	Rituximab+ MTX	Tocilizumab+ MTX
ACR20	27.4%	66.5%	49.9%	54.3%	64.1%	66.6%
ACR50	12.0%	43.1%	27.7%	31.4%	41.5%	43.4%
ACR70	4.8%	22.9%	13.0%	15.2%	22.3%	23.2%

Conclusions: This MR analysis drew on a large body of clinical data and statistically controlled for heterogeneity to reliably estimate the relative treatment effects of a second biologic therapy in patients with RA who failed prior anti-TNF therapy. Patients treated with a second anti-TNF agent achieved comparable or superior clinical response compared with non-TNF agents. As such, for patients failing their first anti-TNF, a second anti-TNF agent should be considered an appropriate treatment option before switching to a non-TNF biologic therapy.

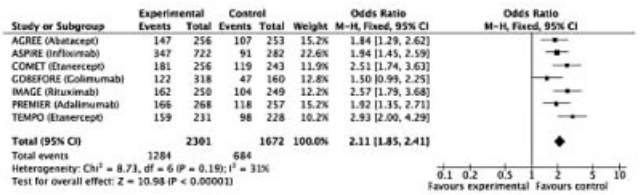
Clinical and Radiological Efficacy of Biologics in Rheumatoid Arthritis Patients Naive or Inadequate Responders to Methotrexate: A Metanalysis. Pierreisnard Audrey, Issa Nahema, Barnetche Thomas, Richez Christophe and Schaeverbeke Thierry. Bordeaux University Hospital, Rheumatology Department, France

Purpose: Recently, an overview of Cochrane reviews comparing efficacy and safety of six biologics in rheumatoid arthritis (RA) was published. However, this study did not include tocilizumab, certolizumab and golimumab, and was not stratified based on previous methotrexate (MTX) use. Our objective was to perform a metanalysis of all biologics available in RA into two situations: MTX naive patients and MTX inadequate responders

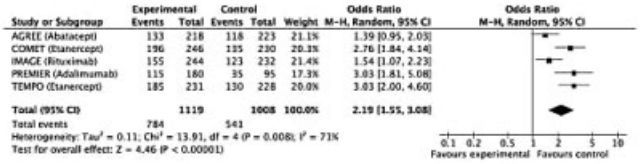
(IR). Furthermore, there are no randomized controlled trials (RCT) comparing biologics head to head. In this study, we performed indirect comparisons of biologics for efficacy.

Methods: A comprehensive literature review was performed by searching Medline for RCTs from 1995 to December 2009 and conference abstracts from ACR Annual Scientific Meetings and EULAR's. We included studies evaluating the five anti-TNF, tocilizumab, rituximab and abatacept, in combination with MTX in MTX naive patients and in IR, using the standard dosing regimens of each product. The primary clinical outcome was ACR50 response. Indirect comparisons of biologics were performed for efficacy using the number needed to treat (NNT) for ACR50 criteria. The primary radiological endpoint was the proportion of patients with no progression of total Sharp score at one year. Statistical analyses were based on odds ratio (OR) for efficacy. Using these combined estimates, we calculated the NNT for each product.

Results: 22 studies were included, 7 in MTX naive patients and 15 in IR. In MTX naive patients, biologics therapy showed significantly increased efficacy compared to MTX with OR for achieving an ACR50 response: OR: 2.11 (95%IC: 1.85, 2.41).



In IR, the same OR was 4.79 (95% IC: 3.49,6.59). The NNT for ACR50 for etanercept were: 5 for MTX naive patients and 3 for IR; for adalimumab were: 7 and 3, respectively; for infliximab were: 7 and 4, respectively; for abatacept were: 7 into the two groups; for rituximab were: 5 into the two groups; for tocilizumab: 4 for IR; for certolizumab were: 4 for IR. NNT were not evaluable for golimumab as the confidence intervals for the risk comprised null or negatives values. The radiographic primary endpoint is shown in figure 2.



Conclusions: Response to biologic therapy in combination with MTX, compared to MTX alone was significant in IR and MTX naive group, but to a lesser extent in the MTX naive group. This difference could be explained by a relative efficacy of MTX in MTX naive patients. Interestingly, patients treated by anti-TNF therapy had significantly less radiograpghic progression than those with cellular therapy, in MTX naive patients.

Outcome of an Education and Home Exercise Program for Ankylosing Spondylitis Patients: A Nationwide Randomized Study. Carlos Rodríguez-Lozano[2], Xavier Juanola[2], Juan Cruz-Martínez[1], Andrés Peña-Arrébola[4], Juan Mulero[2] and Eduardo Collantes[3]. [1]for the Spondyloarthropathies Study Group of the Spanish Society of Rheumatology (GRESSER), [2]for the Spondyloarthropathies Study Group of the Spanish Society of Rheumatology (GRESSER), [3]for the Spondyloarthropathies Study Group of the Spanish Society of Rheumatology (GRESSER); Hospital Ramón y Cajal. Madrid, [4]Hospital Ramón y Cajal. Madrid

Purpose: To assess the impact of a structured education and home exercise program on different outcome measures in patients with ankylosing spondylitis attended in daily practice.

Methods: Patients with ankylosing spondylitis (modified New York criteria 1984) aged 18–70 years participated in a 6-month nationwide prospective study, in which they were randomized to an education intervention (education group) or standard care (controls). The intervention included a 2-hour session in which professionals provided information about the disease and its management, and the implementation of a physical activity program at home. Patients received a printed leaflet and a fitness DVD to take home. All patients completed a diary card and received monthly remainder phone calls. Main outcome measures included a 0–10 cm visual analog scale (pain, global disease activity); Bath Ankylosing Spondylitis Disease Activity and Functional Index (BASDAI, BASFI); Patient Acceptable Symptomatic State (PASS); and quality of life (ASQoL). Data at 6 months were compared with baseline.

Results: A total of 622 patients (EG group 308, controls 314) participated (73% males, mean age 45 years, mean duration of disease 17 years). Regular medications included NSAIDs in 52% of patients and anti-TNF agents in 40%. Fifty-four percent of patients used to exercise regularly (mean [SD] 3.2 [3.3] hours/week). At baseline, both groups were well balanced (table). At 6 months, mean improvements in all outcome measures were statistically significant in both study groups except for ASQoL and patients in PASS condition, which were only significant in the education group. Between-group mean differences were statistically significant for ASQol, BASFI, and percentage of patients changing from negative to positive PASS (table). Patients in the education group practiced more regular exercise than controls ($P = 0.002$) and increased their knowledge about the disease significantly

Table. Outcome Measures at Baseline and after 6 Months

Variable	Baseline, mean (SD)		Mean difference at 6 months		Between-group differences mean (95% CI)
	Education group	Control group	Education group	Control group	
VAS global pain (0–10)	3.77 (2.59)	4.01 (2.67)	−0.68*	−0.47*	−0.21 (−0.57 to 0.15)
VAS nocturnal pain (0–10)	3.35 (2.83)	3.61 (2.99)	−0.62*	−0.52*	−0.09 (−0.47 to 0.28)
VAS patient activity (0–10)	3.98 (2.58)	4.17 (2.56)	−0.68*	−0.39*	−0.28 (−0.63 to 0.07)
BASDAI (0–10)	3.34 (2.27)	3.61 (2.26)	−0.62*	−0.52*	−0.24 (−0.51 to −0.03)
BASFI (0–10)	3.51 (2.54)	3.61 (2.62)	−0.51*	−0.21*	−0.30 (0.52 to −0.08)*
ASQoL (0–18)	6.50 (4.87)	6.24 (4.82)	−0.96*	−0.19	−0.76 (−1.23 to −0.30)†
PASS (positive)	58.9%	61.3%	12.7%*	3.2%	17.5% vs 11.8%‡

* $P < 0.001$ versus baseline; † $P < 0.01$; ‡ Patients changing from negative to positive PASS, $P = 0.026$

Conclusions: An education session and a structured exercise home program for patients with ankylosing spondylitis with relatively low disease activity improved physical function, quality of life and patients who were in PASS condition. Besides drug treatment, incorporating education and exercise in daily practice is feasible and reported substantial benefits.

Meyer[8] and Daniel Wendling[5]. [1]CH Brive, France, [2]CH La Roche sur Yon, France, [3]CH Saint-Brieuc, France, [4]CHU Besançon, France, [5]CHU Besançon, for the "Club Rhumatismes et Inflammation", Besancon, France, [6]CHU Bichat, Paris, France, [7]CHU Bichat, Paris, France, [8]CHU Bichat, Paris, Tunisia, [9]CHU Marseille, France, [10]CHU Nantes, France, [11]CHU Strasbourg, France, [12]Private Office, Paris, France, [13]UC Lille, France

Objectives: To evaluate the efficacy and safety of TNF-α-blocking agents in SAPHO syndrome.

Methods: A retrospective study was conducted by the "Club Rhumatismes et Inflammation" (depending from the French Society of Rheumatology) to find and analyse all the case records from patients suffering from SAPHO syndrome, who had been treated with at least one of the three following TNFα-blocking agents: adalimumab (ADA), etanercept (ETN), or infliximab (IFX). Demographic and clinical data were collected, including previous treatments and incident side effects. The efficacy of anti-TNFα

treatment was evaluated at last follow-up visit, based on the decrease of SAPHO syndrome-related symptoms, appreciated by each patient on a visual analogic scale (VAS). A score decrease of more than 80% was considered as a remission. An improvement comprised between 50 and 79% indicated a partial efficacy and a reduction less than 50% was interpreted as a lack of response.

Results: The case records of 45 patients (33F/12M; mean age 45) were available for analysis. The mean age at disease onset was 31 years (range 11–61). In all patients, SAPHO syndrome was previously considered as refractory to at least three of the five following types of treatments: non steroidal anti-inflammatory drugs, corticosteroids, antibiotics (various regimens), synthetic disease modifying anti-rheumatic drugs (methotrexate or sulfasalazin), and bisphosphonates. Forty-four patients also had active cutaneous manifestations when TNF-α-blocking agent was started. Thirty patients received ETN (25 mg biw or 50 mg qw SC; first biologic to be used in 17 patients; follow-up: 3–60 months). Remission was observed in 11 patients, and partial efficacy in 10. Twenty-two patients were treated with ADA (40 mg SC eow; first biologic in 7 patients; follow-up: 2 to 17 months). Remission and partial efficacy were registered in 12 and 2 patients, respectively. IFX was administered to 18 patients (5 mg/kg, infusions at week 0, 2 and 6, then every 8 weeks; first biologic in 12 patients; follow-up: 3–65 months). Remission and partial efficacy were noted in 5 and 5 patients, respectively.

The treatment with TNF-α-blocking agents was stopped 11 times for a side effect, in 9 patients: 3 times with ETN (1 papillomavirus cutaneous and genital infection, 1 psoriasis vulgaris, 1 optic neuritis); 4 times with ADA (2 allergic reactions, 1 pyelonephritis, 1 hidradenitis suppurativa of the breast) and 4 times with IFX (1 psoriasis vulgaris, 1 flare of palmoplantar pustulosis, 1 hidradenitis suppurativa of the breast and 1 peritonitis).

Conclusion: TNF-α-blocking agents seem to represent an interesting therapeutic option in refractory cases of SAPHO syndrome, without unpredicted side effects.

Radiographic Findings after 5 Years of Infliximab Treatment in Patients with Ankylosing Spondylitis. Xenofon Baraliakos[6], Frank Heldmann[6], Desiree M. Van Der Heijde[4], Joachim Listing[3], Joachim Sieper[2], Alessandra Oortwijn[1], Rebecca Bolce[1] and Juergen Braun[5]. [1]Centocor Inc, [2]Charite Campus Benjamin Frankl, Berlin, Germany, [3]German Rheumatism Research Center, [4]Leiden University Medical Center, Meerssen, The Netherlands, [5]Rheumazentrum Ruhrgebiet, Herne, Germany, [6]Rheumazentrum Ruhrgebiet Herne

Background: Anti-TNF therapy with infliximab significantly reduces inflammatory activity (clinical assessments, MRI) in patients with active ankylosing spondylitis (AS) but does not seem to have a major impact on radiographic progression over 2 years. Recent studies have indicated that patients where structural changes have already occurred show higher rates of radiographic progression as compared to those without occurrence of radiographic chagnes. The European Infliximab AS cohort (EASIC) has been started after the end of ASSERT and patients were treated with infliximab in a real-life setting for 5 years.

Objectives: To study the long-term effect of anti-TNF treatment with infliximab on the chronic AS related radiographic changes over 5 years.

Methods: Complete sets of radiographs of the cervical (CS) and the lumbar (LS) spine at baseline (BL) and after 2 (FU1) and 5 years (FU2) were available from 53 patients from EASIC. Images were mixed with images from different studies and scored blinded for time order and treatment by an experienced reader using the mSASSS.

Results: At baseline, the mean age was 42.4±7.9, 45/53 patients (85%) were HLA-B27 positive and 46/53 (86.8%) were male. The mean BASDAI was 6.3±1.3, the mean BASFI was 4.0±1.7 and the mean BASMI was 5.9±1.6. The mean mSASSS score at BL was 20.5±19.9 units and the number of patients with syndesmophytes in the cervical and/or lumbar spine was 31/53 (59%). Radiographic progression was observed in almost all patients, with a mean mSASSS change of 1.0±2.0 and 2.1±2.7 at FU1 and FU2, respectively, in the entire group (both $p<0.05$ as compared to BL). There were no differences between the CS and the LS.

Overall, there was a trend for more severe radiographic progression at BL for the group with syndesmophytes at BL, as compared to the group without. New syndesmophytes were found in 14/31 patients (45.2%) when BL syndesmophytes were present vs. 9/22 patients (40.1%) without. Similarly, the overall mSASSS progression at FU2 differed between patients with (2.4±2.7) and without (1.6±2.8) syndesmophytes at BL.

Conclusion: In constrast to RA, patients with AS show ongoing radiographic progression under anti-TNF treatment. Future studies with head-to-head comparisons with historical cohorts may indicate whether the velocity of this process of new bone formation is changed by this medication.

2271

Effects of Etanercept vs. Sulfasalazine on Acute Inflammatory Lesions as Detected by Whole Body MRI in Early Axial Spondyloarthritis—A 48 Week Randomized Controlled Trial. In-Ho Song[2], Kay-Geert Hermann[4], Hildrun Haibel[3], Christian Althoff[4], Joachim Listing[7], Gerd-Rüdiger Burmester[5], Andreas Krause[6], Martin Bohl-Bühler[9], Bruce Freundlich[8], Martin Rudwaleit[3] and Joachim Sieper[1]. [1]Charite Benjamin-Franklin, Med. Clinic I, Rheumatology, Berlin, Germany, [2]Charite Campus Benjamin, Med. Clinic I, Rheumatology, Berlin, Germany, [3]Charite Campus Benjamin-Franklin, Med. Clinic I, Rheumatology, Berlin, Germany, [4]Charite Campus Mitte, Radiology, Berlin, Germany, [5]Charite Campus Mitte, Rheumatology, Berlin, Germany, [6]Clinic Buch Rheumatologie, Berlin, Germany, [7]German Rheumatism Research Center, Berlin, Germany, [8]Pfizer-Wyeth, PA, [9]Private Practice, Rheumatology, Potsdam, Germany

Purpose: To evaluate the potential of etanercept (ETA) versus sulfasalazine (SSZ) to reduce active inflammatory lesions on whole-body magnetic resonance imaging (wb-MRI) in active axial spondyloarthritis (SpA) with a symptom duration of short symptom duration.

Method: 76 patients with NSAID-refractory axial SpA were randomized to etanercept (ETA 25 mg given twice weekly subcutaneously; n= 40) or sulfasalazine (SSZ 2–3 g per day orally; n= 36) treatment over 48 weeks. All patients fulfilled the recently published ASAS-classification criteria for axial SpA, showed active inflammatory lesions (bone marrow edema) on whole-body MRI (wb-MRI) in either the sacroiliac joints (SIJ) or the spine and had a symptom duration of less than 5 years. All patients underwent wb-MRI at week 0, 24 and 48. MRIs were scored by two radiologists, blinded for treatment arm and MRI time point, resulting in a score for the SIJ of between 0 and 24 and for the spine between 0 and 69. The primary endpoint was the reduction of active inflammatory lesions on wb-MRI, clinical outcome parameters were secondary endpoints.

Results: Patients' characteristics were similar for the ETA group (mean age 35, 58% male, 85% HLA-B27 positive, mean symptom duration 2.6 years), and the SSZ group (mean age 33 years, 58% male, 78% HLA-B27 positive, mean symptom duration 3.0 years). At baseline, 92% of the patients showed active inflammatory lesions in the SIJ, 41% in the spine, but only 5% in the spine but not in the SIJ. According to the early disease stage, the mean score in the SIJ with 6.6 (standard deviation SD 5.9) out of 24 was relatively higher compared to a mean score of 1.8 (SD 3.3) out of 72 for the spine. In the ETA group, the reduction of the SIJ score from 7.7 at baseline to 2.0 at week 48 was significantly ($p=0.003$) larger compared to the SSZ group from 5.4 at baseline to 3.5 at week 48. A similar reduction of inflammation was found in the spine: 2.2 to 1.0 in the ETA group vs. 1.4 to 1.3 in the SSZ group between baseline and week 48, respectively ($p=0.0024$). Enthesitis improved also significantly ($p= 0.027$) better in the ETA compared to the SSZ group. Inflammation on the posterior segments showed no significant difference between the two treatment groups. 50% of the patients reached ASAS clinical remission and 70% ASAS 40 response in the ETA group vs 19% and 31% in the SSZ group at week 48.

Of the 6 patients who became completely free of inflammation both in SIJ and spine in the ETA group all patients were also in clinical remission. In contrast, none of the 2 patients reaching remission on the SULFA group were free of inflammation as shown by wb-MRI.

Conclusion: In patients with early axial SpA active inflammatory lesions detected by wb-MRI improved significantly more in ETA- versus SSZ-treated patients. This effect correlated with a good clinical response in the ETA group.

A Prospective Inception Cohort Study of the Clinical Presentation and Response to Treatment of Undifferentiated Spondyloarthritis Versus Ankylosing Spondylitis and Psoriatic Arthritis.

Jacqueline E. Paramarta[2], Leen E. De Rycke[3], Carmen A. Ambarus[3], Paul P. Tak[1] and Dominique L. Baeten[2]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Division of Clinical Immunology and Rheumatology, Academic Medical Center/University of Amsterdam, Amsterdam, The Netherlands, [3]Division of Clinical Immunology and Rheumatology, Academic Medical Center/University of Amsterdam, Amsterdam, The Netherlands

Background: Ankylosing spondylitis (AS) and psoriatic arthritis (PsA) are the best described and studied subtypes of spondyloarthritis (SpA). A significant proportion of SpA patients, however, does not fulfil the classification criteria for AS and PsA and are at risk to be diagnosed and treated late. The aim of this study was to assess whether patients with undifferentiated SpA (USpA) are different from AS and PsA in terms of patient characteristics, disease activity and response to treatment.

Methods: 175 patients presenting on a dedicated SpA outpatient clinic fulfilling the European Spondyloarthropathy Study Group (ESSG) criteria were recruited in a prospective inception cohort. Global assessment of disease activity visual analogue scale (VAS) patient and physician, Bath Ankylosing Spondylitis Disease Activity (BASDAI), 68 swollen and tender joint count, Schober, ESR and CRP were measured every 3 months. Parametric tests were used for normally distributed data and non-parametric tests for non-normally distributed data.

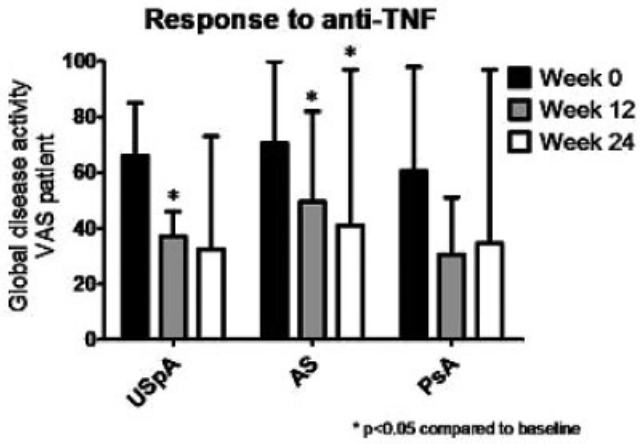
Results: The baseline demographic and clinical data are shown in Table 1.

Baseline demographics and disease activity

	USpA (n = 40)	AS (n = 74)	PsA (n = 45)
Median age of onset (yrs) (range)	31.7 (11.2–62.1)	36.5 (8.1–75.6)	44.2 (20.9–68.2)**
Median disease duration (yrs) (range)	1.3 (0.0–36.1)	4.2 (0.0–46.8)**	4.5 (0.0–29.1)**
Male sex (%)	17 (42.6)	43 (68.1)	30 (66.7)**
Inflammatory back pain (%)	35 (87.6)	72 (97.3)**	22 (48.9)**
Peripheral arthritis (%)	25 (62.5)	26 (35.1)**	37 (82.2)**
HLA-B27 positive (%)	17 (42.6)	49 (68.1)**	11 (36.5)
Sacroiliitis high grade (%)	1 (2.5)	74 (100.0)**	10 (22.2)**
Sacroiliitis low grade (%)	18 (45.0)	0 (0.0)**	5 (11.1)**
Positive family history for SpA (%)	20 (50.0)	23 (31.1)**	16 (35.6)
NSAIDs (%)	31 (77.5)	51 (68.9)	24 (53.3)**
DMARDs (%)	15 (37.5)	8 (10.8)**	26 (57.8)*
Anti-TNF (%)	4 (10.0)	19 (25.7)**	18 (40.0)**
VAS patient (mm) median (range)	62.5 (10–100)	50 (1–98)**	38 (0–98)**
VAS physician (mm) median (range)	51 (4–82)	45 (1–90)	30 (2–84)**
BASDAI median (range)	5.3 (0.9–9.1)	6.0 (0.3–9.2)	3.2 (0.0–7.8)**
BASDAI ≥ 4 (%)	27 (69.2)	45 (63.4)	20 (45.5)**
SJC (68) median (range)	0 (0–8)	0 (0–26)**	0 (0–26)
TJC (68) median (range)	1 (0–34)	0 (0–16)	3 (0–21)
Schober (cm) mean (SD)	4.1 (1.1)	3.6 (1.2)**	4.2 (1.0)
Chest expansion (cm) mean (SD)	4.6 (1.4)	4.3 (1.5)	4.5 (1.2)
ESR (mm/h) median (range)	7 (1–64)	10.6 (2–61)	5 (1–61)
CRP (mg/l) median (range)	2.0 (1.0–53.9)	4.0 (1.0–38.0)	2.2 (1.0–37.0)

Normally distributed: unpaired t-test not-normally distributed: Mann-Whitney; Categorical data: Chi2
* Trend ($0.05<p<0.1$) and ** significant difference ($p<0.05$) versus USpA

The cohort included 40 USpA, 74 AS and 45 PsA patients. The age of onset (median 32 years; range 11–62), disease duration (1.3 years; 0–36), and proportion of male patients (42.5%) were lower in USpA than in AS and PsA. USpA patients had more axial and less peripheral disease than PsA, but less axial and more peripheral disease than AS. The presence of HLA-B27 (43%) and either high or low grade sacroiliitis (47.5%) were less frequent in USpA than in AS. Only 25% of the USpA patients fulfilled the ASAS criteria for pre-radiological AS, although it should be noted that MRI was not systematically performed. Half of the USpA group had a positive family history. Despite the atypical presentation, the baseline disease activity (VAS patient/physician and BASDAI) was higher in USpA than in the other groups. Upon initiation of TNF blockade in patients with high disease activity, we observed a significant and sustained decrease of the disease activity in USpA, which was similar in amplitude to the response in AS and PsA (Figure 1).



Conclusion: USpA displays an intermediate phenotype between AS and PsA, with only part of the patients representing pre-radiological axial SpA. Despite the atypical presentation and shorter disease duration, a large majority of USpA patients have high disease activity. The apparent efficacy of TNF blockers in this observational study, together with the emerging data of RCT in pre-radiological AS pleas for systematic assessment of novel treatments not only in AS and PsA but also in axial and peripheral USpA.

2273

Do Patients with Psoriatic Arthritis Who Present Early Fare Better Than Those Presenting Later in the Disease?

Dafna D. Gladman[1], Arane Thavaneswaran[2] and Vinod Chandran[2]. [1]Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto Psoriatic Arthritis Clinic, Toronto Western Hospital

Background: Psoriatic arthritis (PsA) is an inflammatory arthritis associated with psoriasis often seronegative for rheumatoid factor. Over the past few decades it has become clear that the disease is more common and more severe than previously appreciated. PsA causes deformities and joint damage leading to impaired quality of life and function and is associated with an increased mortality risk. It remains to be determined whether early diagnosis and treatment would alter the course of the disease. The aims of this investigation were 1) to determine whether patients presenting to a PsA clinic early in the course of the disease had less severe disease at presentation, and 2) whether disease duration at presentation predicts progression of joint damage.

Methods: Patients with PsA have been followed prospectively in a specialized clinic for 32 years. Patients were divided into those first seen within 2 years of diagnosis (group 1) and those seen with more than 2 years of disease (group 2). The two groups were compared with regards to demographics and disease characteristics at presentation to clinic. A multivariate analysis using a negative binomial model was conducted to determine whether patients with early disease had less progression of joint damage. The outcome variable was progression of clinical joint damage and the variables entered in the model were age, sex, group, clinical joint damage at first visit, NSAIDS at first visit, DMARDs at first visit, treatment with biologics at first visit, treatment with NSAIDS after the first visit, treatment with DMARDS, and treatment with biologics after the first visit.

Results: 436 patients were identified in group 1 and 641 patients in group 2. Demographic and disease characteristics at first visit are shown in Table 1.

Table 1. Demographic and disease characteristics of study subjects.

Variable	Early PsA ≤ 2y	Late PsA >2y	P values
No. Patients	436	641	
Gender M/F (%)	57.6/42.4	55.2/44.8	0.447
Age at Psoriasis Diagnosis (yrs)	30.3	27.2	0.001
Age at PsA Diagnosis (yrs)	40.3	34.2	<0.0001
Age at 1st Visit (yrs)	41.1	45.2	<0.0001
Duration PsA at 1st Visit (yrs)	0.92	11.0	<0.0001
Mean No. Actively inflamed Joints	10.5	11.7	0.239
Mean No. Damaged Joints	3.5	9.2	<0.0001
Mean PASI score	6.2	5.5	0.254
Sacroiliitis	26.4%	38.4%	<0.0001
Radiographic damage	39.2%	65.9%	<0.0001
Treatment at first visit			
NSAIDs	56.4%	61.6%	0.089
DMARDs	28.0%	56.8%	<0.0001
Biologics	4.1%	6.7%	0.061

Thus patients in group 2 (late PsA) were older, had longer duration of psoriasis and PsA, more joint damage and were less likely to be treated with DMARDs, but had similar degree of psoriasis severity. Results of multivariate regression analysis on predictors for progression of joint damage are shown in Table 2.

Table 2. Results of multivariate analysis on predictors for progression of clinical joint damage in patients with PsA.

Variable	Relative Rate of joint damage progression	95% CI	P-value
Group (PsA>2 yr vs. PsA≤ yrs)	1.62	(1.28, 2.03)	<0.0001
Age	1.02	(1.01, 1.03)	<0.0001
Sex	1.15	(0.93, 1.42)	0.173
Clinical Joint Damage at 1st visit	1.03	(1.01, 1.05)	0.0003
NSAIDS at first visit	1.04	(0.84, 1.30)	0.690
Biologics at first visit	0.89	(0.543, 1.45)	0.630
DMARDS at first visit	1.20	(0.950, 1.51)	0.130
NSAIDS after first visit	1.22	(0.89, 1.68)	0.230
Biologics after first visit	1.15	(0.90, 1.46)	0.250
DMARDS after first visit	1.52	(1.16, 1.99)	0.002

After adjusting for age, sex, clinical joint damage at first visit and treatment, Group 2 has significantly more rate of clinical damage progression compared to Group 1.

Conclusions: Patients who present within 2 years of diagnosis have less severe disease at presentation than those presenting later in their course. Disease progression is more marked in those patients presenting with established disease of > than 2 years duration. These results suggest that patients with PsA should be treated earlier in the course of their disease.

Identification of cis-Regulatory Element Binding Differences in the C8orf13/BLK Promoter Region Linked with Risk of SLE. Rufei Lu[5], Nicolas Dominguez[6], Susan Macwana[5], Celi Sun[5], Jennifer A. Kelly[5], Kenneth M. Kaufman[5], Carl D. Langefeld[11], Marta Alarcon-Riquielme for BIOLUPUS Network[5], Sang-Cheol Bae[2], Elizabeth E. Brown for PROFILE[9], Gary S. Gilkeson[3], Timothy B. Niewold[10], Betty P. Tsao[8], Nan Shen[7], Kathy L. Moser[4], John B. Harley[1], Slegen, Carol Webb[5], Judith A. James[5], Swapan K. Nath[5], Patrick M. Gaffney[5] and Joel M. Guthridge[5]. [1]Cincinnati Children's Hospital Medical Center, [2]Hanyang University Hospital for Rheumatic Diseases, [3]Medical University of South Carolina, [4]Oklahoma Med Research Foundation, [5]Oklahoma Medical Research Foundation, [6]Oklahoma Medical Reserch Foundation, [7]Shanghai Ren Ji Hospital, [8]UCLA School of Medicine, [9]University of Alabama at Birmingham, [10]University of Chicago, [11]Wake Forest University Health Sciences

Background: SLE is a complex autoimmune disease with immunological abnormalities that target B cell function and development. Previous genome-wide association studies identified C8orf13/BLK as a SLE risk factor, however the molecular mechanism associated with increased SLE risk is unknown.

Methods: Over 300 SNPs from the C8orf13/BLK region were evaluated in 3546 unrelated SLE patients and 3980 controls of European-decent (EA), 1270 unrelated Asian (AS) SLE patients and 1272 controls, and 1734 unrelated African American (AA) patients and 1406 Controls. The quality of the genotype data was determined by the following inclusion criteria: MAF > 1%, SNP call rate > 90%, and HWE (P >.001) among the controls. Case-control associations were analyzed using PLINK. Population-specific haplotype block structures were examined by Haploview using the HapMap phase 2 release 23 dataset. Both the squared correlation statistic (r2) and Lewontin's D' statistic were used as measures of LD strength within the C8orf13/BLK region. We identified a risk haplotype for C8orf13/BLK across all three populations based on SNPs rs13277113 and rs2736345, which we used to identify homozygous risk cases and homozygous non-risk controls for resequencing of the 20kb regulatory region of BLK. Electrophretic mobility shift assays were performed to assess cis-regulatory binding elements at polymorphisms defined by the genotyping. Probes of ~200 bp flanking each associated SNP within the region were end-labeled by T4 polynuleotide kinase and ^{32}P-ATP and incubated with nuclear extracts from seven cell lines representing different stages of B cell development, epithelial cells, and mature T cells.

Results: We successfully analyzed 259 SNPs in EA, 201 in AS, and 329 SNPs in AA populations in the C8orf13/BLK genomic region. Transracial mapping results demonstrated that the strongest association peak was observed in the AA population and was centered in the proximal promoter region of BLK. The peak association in the AA population was at SNP rs2736345 ($p=1.09\times10^{-6}$, OR= 1.296, C.I.=1.17–1.436). The peak association in the EA population was at SNP 13277113 ($p=2.18\times10^{-12}$, OR= 1.32, C.I.=1.216–1.434). SNPs within the peak association region are tightly linked with r^2 values > 0.98. Resequencing of the 20 kb regulatory region failed to identify any new SLE associated variants. EMSA probes flanking SNP rs13277113 demonstrated a loss of transcription factor binding in risk individuals when using nuclear extracts from cell lines that represent immature B cells, mature B cells, and T cells. Probes spanning the SNPs in the proximal promoter region also showed different nuclear factor DNA binding profiles in all cell types tested.

Conclusion: Our results suggest that multiple polymorphisms in the genomic interval upstream of the BLK gene, including the promoter, influence the binding of nuclear factors at cis-regulatroy elements critical for regulating BLK expression in a cell type and developmental stage specific fashion.

The HRES-1/RAB4 Lupus Susceptibility Gene Promotes Nitric Oxide Production in Human T Cells through Direct Interaction with Endothelial Nitric Oxide Synthase Interacting Protein. Tiffany N. Telarico[1], Edward H. Doherty[1], David R. Fernandez[1], Adam Bartos[1], Stephanie Oess[2], Werner Muller-Esterl[2] and Andras Perl[3]. [1]SUNY, [2]University of Frankfurt, [3]Upstate Medical Univ, Syracuse, NY

Purpose: Polymophic haplotypes of the HRES-1 endogenous retrovirus influence lupus susceptibility. One of its gene products, HRES-1/Rab4 is overexpressed in lupus T cells and contributes to altered T cell activation via regulating endosomal recycling of cell surface CD4 and transferrin receptors as well as the CD3 zeta chain that transmits signals from the immunological synapse (IS). Increased production of nitric oxide (NO) has been linked to abnormal activation of lupus T cells and NO production has been localized to the IS. Here we investigated the role of HRES-1/Rab4 in compartmentalized production of NO.

Methods: Expression of proteins involved in NO production was investigated by RNA microrray and western blot analysis of negatively isolated T cells from 44 Caucasian female lupus patients and 23 age-matched Caucasian female controls. NO production was measured by flow cytometry. The effect of HRES-1/Rab4 on NO production and expression of proteins involved in

NO synthesis was investigated by overexpression of a wild-type HRES-1/Rab4 and its dominant-negative form HRES-1/Rab4S27N. Direct interaction of HRES-1/Rab4 with potential binding partners was assessed by pull-down assays.

Results: NO production was increased in lupus T cells by 32% ($p=0.009$) Expression of endothelial NO synthase (eNOS) interacting protein (NOSIP) was reduced by 61% in lupus T cells ($p=0.010$). Over-expression of HRES-1/Rab4 suppressed NOSIP expression and shifted it to the cytosol, enhanced eNOS expression, and NO production while dominant-negative HRES-1/Rab4S27N had the opposite effects in human T cells. NOSIP was efficiently pulled down by HRES-1/Rab4-GST but not by GST alone in Jurkat cells and human peripheral blood lymphocytes.

Conclusion: The results indicate that over-expression of HRES-1/Rab4 promotes NO production through direct interaction with NOSIP and its targeting to the cytosol which may activate eNOS and modulate IS formation in human T cells.

Transcriptional Inflammatory Mechanism in Murine Lupus Nephritis: An Insight into Human Disease. Tania C. Gonzalez Rivera[3], Celine C. Berthier[3], Viji Nair[3], Ramalingam Bethunaickan[1], Matthias Kretzler[3], Anne Davidson[2] and ERCB Consortium. [1]Feinstein Institute, Manhasset, NY, [2]Feinstein Institute for Medical Research, Manhasset, NY, [3]University of Michigan, Ann Arbor, MI

Despite advances in immunosuppressive regimens, lupus nephritis (LN) remains a significant cause of morbidity and mortality in lupus patients. Murine LN models have been used to study this heterogeneous disease but the failure of human trials to reproduce the results seen in mice has raised concerns whether these models truly reflect human disease. Using a transcriptional network comparison we aim to define similarities and differences between three LN murine models and human LN.

Affymetrix based expression profiles from prenephritic vs. nephritic kidneys from 3 LN mouse models (NZB/W, NZM2410, and NZW/BXSB, total n=40) and human renal biopsies from 15 living donors (LD) vs. 32 LN patients underwent disease model specific transcriptional network analysis (Bibliosphere).

Transcriptional networks were compared using the *T*ool for *A*pproximate *L*arg*E* graph matching (TALE) to define cross-species conserved functional interactions. The NZM2410 model shared the highest number of nodes with human LN, followed by the NZB/W and the NZW/BXSB models (70, 46 and 37 major transcriptional network nodes, respectively). Pathway analysis of the 17 nodes shared by the human and murine models highlighted macrophage activation pathways ($p<0.001$).

To distinguish the components of the macrophage-specific signature that were due to an alteration in cell phenotype rather than to infiltration with increased numbers of cells per se, gene expression profiles of macrophages isolated from prenephritic and nephritic NZB/W kidneys were generated and compared with corresponding murine and human LN kidney profiles. A total of 406 transcripts were concordantly regulated between NZB/W kidney isolated macrophages and whole kidneys. Of those, 132 transcripts were regulated in the tubulointerstitium of human LN kidneys, consistent with macrophage-derived expression. This signature was used to define the transcriptional state of kidney resident macrophages in murine and human LN. Network analysis defined Stat3, Anxa2 and TIMP1 as major hubs in the network. Application of the MESH filter "macrophage activation" on the network highlighted Lyn, Spp1 and CD44.

The response of tissue resident macrophages to treatment was assessed in NZB/W mice treated with cyclophosphamide/CTLA4Ig/anti-CD154. From the defined renal macrophage signature, Lyn, Anxa2, and CD44 were major hubs of repressed genes in isolated kidney resident macrophages with induction of remission (histologic remission and absence of proteinuria) with triple therapy.

We were able to define key regulators of inflammation shared between human and murine LN using an integrative transcriptional network analysis approach. Given the similarities between mice and humans highlighted by our studies, therapeutic agents that target macrophage activation should represent a focus in the development of therapies for human LN.

SLE Serum Deposits C4d on Red Blood Cells, Decreases Red Blood Cell Membrane Deformability, and Promotes NO Production. Ionita C. Ghiran[1], Ourania Kampagianni[1], Mark L. Zeidel[1], Sergey S. Shevkoplyas[2], Jennie M. Burns[2], George C. Tsokos[1] and Vasileios C. Kyttaris[1]. [1]Beth Israel Deaconess Medical Center, [2]Tulane University

Background: Systemic lupus erythematosus (SLE) is characterized by intravascular activation of the complement system and deposition of complement fragments (C3 and C4) on plasma membranes of circulating cells, including red blood cells (RBC). We have recently shown that deposition of complement fragments on RBC in vitro is associated with decreased deformability of the RBC membrane (Karnchanaphanurach P. et al, J Clin Invest 2009). We therefore hypothesized that exposure of RBC to immune complexes present in SLE serum leads to decreased RBC deformability via complement fragment deposition.

Methods: Serum and red cells were isolated from patients with SLE, and healthy controls. RBC from healthy 0Rh- individuals were incubated with SLE or control serum. We used flowcytometry to assess complement fragment deposition on RBC. RBC membrane deformability was measured by 2-D microchannel arrays. Protein phosphorylation levels were quantified by western blotting.

Results: Incubation of healthy donor RBC with sera from patients with SLE but not control sera led to deposition of C4 fragments on the RBC. These complement decorated RBC showed a significant decrease in their membrane deformability. Moreover, RBC from patients with SLE showed a significant decrease in their deformability as compared to healthy donor RBC. As deformability depends on the calcium-mediated phosphorylation of skeletal proteins, we evaluated whether RBC skeletal protein phosphorylation is altered after incubation with SLE sera. We found that sera from SLE patients triggered Ca++ influx in RBC that was followed by decreased phosphorylation of the cytoskeletal protein β-spectrin, and increased phosphorylation of Band 3. Furthermore, RBC membrane flickering, which has been shown to be important for the progression of RBC through capillaries, was irreversibly inhibited by SLE serum-induced complement fragment deposition on RBC membrane. Finally, the complement fragment decorated RBC produced significant amounts of nitric oxide (NO), an important mediator of immune function and vascular tone.

Conclusion: Taken together our data suggest that during periods of high disease activity in SLE, complement activation negatively impacts the ability of RBC to flow through capillaries and thus potentially affects the delivery of oxygen to the tissues. Disruption of complement fragment deposition on RBC may improve hemorrheology and alleviate vasculopathic phenomena often associated with SLE.

What Are the Pathways by Which Interferon-alpha Decreases Vasculogenesis in Lupus? Seth G. Thacker[2], Celine Berthier[2], Deborah Mattinzoli[1], Maria-Pia Rastaldi[1], Matthias Kretzler[2] and Mariana J. Kaplan[3]. [1]Fondazione IRCCS Ospedale Maggiore Policlinico & Fondazione D'Amico per la Ricerca Sulle Malattie Renali, [2]University of Michigan, [3]University of Michigan Medical Center, Ann Arbor, MI

Objectives: SLE is characterized by accelerated vascular risk due to premature atherosclerosis which is not explained by traditional risk factors. Our group previously proposed that type I Interferons (IFNs) play a crucial role in premature vascular damage by altering the balance between endothelial cell apoptosis and vascular repair mediated by endothelial progenitor cells(EPCs) and myeloid circulating angiogenic cells (CACs). We have now characterized the putative pathways by which type I IFNs interfere with proper vascular repair in SLE.

Methods: EPC/CACs from control and SLE patients were treated with IFN-α for 6 hours and corresponding changes in gene expression were analyzed with Affymetrix Human U133 Plus 2.0 Genechips. Expression levels of genes of interest were validated with real time PCR. Effects on EPC/CAC function were tested utilizing functional in vitro assays. Proliferation and apoptosis were determined by XTT assay and caspase3/7, activation, respectively. DC phenotype was assessed by FACS. In vivo angiogenesis and validation of putative markers at the protein level was assessed by immunohistochemistry staining of kidney sections from lupus nephritis biopsies and controls. STAT2 and STAT6 activation was assessed by FACS.

Inhibition of JAK and PI3K tested abrogation of the antiangiogenic signature induced by interferon-alpha.

Results: Microarray data analysis revealed alterations in various molecules associated to IL-1 mediated signaling and of vascular endothelial growth factor-A (VEGF-A). Downregulation of IL-1β, IL-1 receptor-1 (IL-1R1) and VEGF-A and upregulation of IL-1RN (IL-1 receptor antagonist) and IL-1R2 (decoy receptor) were observed. This indicates a global downregulation of IL-1β function induced by type I IFNs. These abnormalities were more marked in the IFN-treated lupus EPCs/CACs than in the IFN-treated control cells, suggesting that lupus cells were more sensitive to IFN-α effects. Results were confirmed at mRNA and protein level. Treating lupus EPCs/CACs with IL-1β resulted in a significant improvement in their capacity to differentiate into a mature endothelium, therefore abrogating the deleterious effects of IFN-α. The beneficial effects from IL-1β are mediated, at least in part, by increases in EPC/CAC proliferation, decreases in apoptosis, and by preventing the skewing of CACs towards non-angiogenic pathways. IFN-α induces STAT2 and 6 phosphorylation in EPCs/CACs and JAK inhibition abrogates the transcriptional antiangiogenic changes induced by IFN-α in these cells. Immunohistochemistry of renal biopsies from patients with lupus nephritis, but not ANCA-positive vasculitis, showed this pathway to be operational *in vivo*, with increased IL-1RN, downregulation of VEGF-A and glomerular and blood vessel decreased capillary density, compared to controls.

Conclusions: Our study introduces a novel putative pathway by which type I IFNs may interfere with vascular repair in SLE through repression of IL-1-dependent pathways. This could promote atherosclerosis and loss of renal function in this disease.

The Nurse's Role in Treatment and Management of Patients with Rheumatoid Arthritis: A Delphi-Based Recommendation on Patient Unmet Needs. Jane E. D. Cottrell[2], Monique Jonas[1] and Leeanna M. Bulinckx[3]. [1]Charité University Hospital, Berlin, Germany, [2]Mount Sinai Hospital, Toronto, ON, Canada, [3]PerCuro Clinical Research Ltd, Victoria, BC, Canada

Background: Nurses serve many critical roles in the management and treatment of patients with rheumatoid arthritis (RA), including educating and counseling the patient and liaising between the patient and rheumatologist. Examining how these roles differ among practices can help clarify areas in which nurses can optimize patient outcomes. The objective of this Delphi project was to assess the role of rheumatology nurses in addressing the unmet treatment and management needs of the RA patient

Methods: A modified Delphi method with two rounds of questionnaires was followed by an in-person meeting to explore issues on which consensus had not been reached. A steering committee of 3 nurses developed and refined the questionnaires. An international group of 12 nurses with extensive experience (clinical or research) with patients receiving biologic therapy for moderate to severe RA served as panelists and completed the questionnaires. Prior to the meeting, all responses were anonymous and confidential. Focal topic areas included the nurse's roles as caregiver, provider of information, and assessor of disease status and treatment outcomes. Special attention was paid to understanding patient physical and emotional needs.

Results: In most European and Canadian practices/clinics, nurses spend substantially more time with the patient than the physician. In their interactions with patients, nurses initiate discussions about personal well-being and disease impact on quality of life—topics not always addressed by physicians due to time constraints or comfort level with these issues. Patients are more likely to discuss emotional and social issues related to their diagnosis with a nurse than a doctor and tend to expect the nurse to provide disease and treatment education to them and their families. The panelists agreed that it is critical to customize this information for each patient rather than provide written materials with no verbal explanation. The nurse is in a unique position to judge what level of support or education a patient may need at any given time. Although the benefits of support networks and peer-to-peer interactions were recognized, such interactions need not be limited to structured groups. While all panelists agreed that the doctor is more likely to recommend a particular therapy, the nurse has a critical role in educating the patient on efficacy, potential side effects, method and frequency of administration, product storage, and, if applicable, comfort with self-injection, including demonstrating proper device technique. Additionally, the nurse determines the patient's readiness for and understanding of the treatment, monitors safety and progress, and coordinates care within a multi-disciplinary setting.

Conclusion: The nurse's role in the management and treatment of patients with RA is complex and diverse, yet vitally important to optimal care. Although this Delphi initiative included a small group of nurses, it is clear that information shared across clinics and countries is both useful and practical in terms of improving patient care.

Self-Efficacy and Follow-Up with Nursing, Medical or Shared Care for Outpatients with Rheumatoid Arthritis. Jette Primdahl[3], Lis Wagner[2] and Kim Hørslev-Petersen[1]. [1]King Christian X's Hospital for Rheumatic Diseases in Graasten and University of Southern Denmark, Graasten, Denmark, [2]Research Unit of Nursing, University of Southern Denmark, Odense, Denmark, [3]University of Southern Denmark, Sønderborg, Denmark

Introduction: Traditionally, people with rheumatoid arthritis (RA) are administered by scheduled medical consultations every 3–12 months. Treatment aims to control disease activity, but also to enable the patients to achieve perceived control over the disease and disease related problems. The latter may be reflected in the patient's self-efficacy (SF) - the belief in one's ability to carry out a task with a desired outcome.

Aim: To explore whether RA outpatients' SF develops differently, depending on whether they have follow-up care in the form of nursing consultations, medical consultations or in a shared care setting with no planned rheumatologic consultations.

Material and Methods: Outpatients (n=287) with low active RA (Disease Activity Score, DAS-28 <3.2 and Health Assessment Questionnaire, HAQ < 2.5) from two Danish hospitals were randomized for one of the three types of follow-up care. The participants' SF was measured by the Danish version of the Rheumatoid Arthritis Self-Efficacy questionnaire (RASE) and the Danish version of the Arthritis Self-Efficacy Scale (ASES). Data were collected at randomization, after three months and at one year. The relation between SF beliefs, outpatient setting, socio-demographic and disease related variables were explored in mixed models. A Wilcoxon signed-rank test was used to test the significance of differences.

Results: For both the RASE and the ASES the three outpatient settings varied significantly over time. During a one year follow-up, the RASE scores decreased in the medical group (mean diff. −5.30, SD 1.29, p=0.0002) and the shared care group (mean diff −4.14 (SD 1.26), p=0.0002). Contrary to this, the participants in the nursing group maintained their SF beliefs at the same level (mean diff. -1.08 (SD 1.32), p=0.47). The RASE score at randomization and time were significant predictors for the development of the RASE scores the first year.

SF measured by the ASES was maintained at the same level in the medical group (mean diff. −17.73 (SD 23.54), p=0.48) and the shared care group (mean diff. −54.56 (SD 27.52), p=0.14), whereas a significant increase was seen in the nursing group (mean diff. 74.56 (SD 19.73), p=0.0001). Disease duration, HAQ, DAS-28 and ASES at randomization were significant predictors for the development of the ASES scores the first year. An increase of 1 in HAQ or DAS-28 at randomization predicted a significant decrease in the ASES of 48.28 (p=0.009) and 38.96 (p=0.002) respectively. No significant differences in disease activity or physical disability between the three outpatient settings were detected at any time.

Conclusion: Outpatients with stable RA, attending three nursing consultations during a one year follow-up stabilized or increased their SF beliefs depending on the questionnaire in use. This differed from medical consultations and shared care cohorts, where the patients' SF beliefs decreased or did not change. The use of ASES as a response variable in longitudinal studies can be problematic because of its high correlation to disease activity and physical disability. The RASE, independent of disease activity and physical disability, confirmed the effect of nursing interventions.

Future Expectations and Worst Case Scenarios of Patients with Rheumatoid Arthritis: A Focus Group Study in Patients. Laurien Buitinga[3], Louise M. A. Braakman-Jansen[1], Erik Taal[2] and Mart A. F. J. Van de Laar[4]. [1]University of Twente, Enschede, The Netherlands, [2]University of Twente, Enschede, The Netherlands, [3]University of Twente, [4]University of Twente; Medical Spectrum Twente, Enschede

Background: Rheumatoid Arthritis (RA) has a great impact on patients' daily lives. Because of the unpredictable progressive nature of the disease, it is imaginable that people worry about the impact of their disease in the future. Many studies have shown the prevalent difficulties patients experience now. Little attention has been paid to future expectations in RA.

Objective: To examine future expectations, and to reveal worst case future scenarios in patients with RA.

Methods: A qualitative focus group approach was used. Three heterogeneous focus groups of RA patients were composed on the basis of age group (18–40, 40–65, 65–80), gender and having a paid job or not. Eventually, 16 people participated. Transcripts were individually coded by three researchers, including the moderator and note-taker. Participants were asked about their future expectations and worst case future scenarios. Afterwards, the codes were discussed until agreement was reached about all codes. For categorization of the coded expressions, a distinction was made between body functions and structures, activity participation, environmental factors and personal factors, in line with the International Classification of Functioning, Disability and Health (ICF).

Results: This qualitative study revealed that people expected the impact of their RA to be the same or to deteriorate slightly in the future, also in relation to the process of aging. Most people expressed hope for the future and positive feelings because of continuously improving medication. However, also feelings of uncertainty and fears were expressed about the future course of the disease. A major concern was about becoming dependent on others. One of the focus groups particularly expressed concerns about becoming dependent on others with regard to self-care (e.g. toileting, bathing). Concerns were also raised about side effects of medication and losing mobility. For many participants, becoming dependent on others would be the worst imaginable RA-related future scenario, for one participant it would be even worse than dead.

Conclusion: In this study, dependency on others was the most prevailing RA-related worst case future scenario. Many participants expressed their concerns in relation to dependency side effects of medication and losing mobility. Although pain was a prevalent symptom in daily life, no future concerns about pain were raised. Most people in these focus groups also held a positive view of the future because of continuously improving medication.

Mapping Pathways through Care: Accounts of Help-Seeking in Early Rheumatoid Arthritis (RA). Anne Townsend[2], Catherine L. Backman[3], Paul Adam[1], Susan M. Cox[4], Linda C. Li[3] and Erahse Team. [1]Mary Pack Arthritis Centre, [2]Maurice Young Centre for Applied Ethics, University of British Columbia, Vancouver, BC, Canada, [3]University of British Columbia, Vancouver, BC, Canada, [4]University of British Columbia

Timely treatment can control RA, alter the disease course, and limit its impact on daily life. Prompt intervention with DMARDS is linked to improved outcome, yet there is an avoidable time lag between individuals experiencing the onset of RA and receiving DMARDS1. This delay is influenced by a range of individual and system based factors: accessing the GP consultation; the time between the initial family physician (FP) visit and gaining a rheumatologist referral; and the wait between referral time and the rheumatologist visit1. However, little is known about the relative significance of factors associated with delays along the continuum of care. The current study aims to understand the process of help-seeking for early symptoms of RA from the patient perspective.

38 people (37 women, 1 man), who were diagnosed with RA within the past 12 months, were recruited from offices of rheumatologists and family physicians (FP) and from newsletters of patient advocacy groups. In-depth face-to-face interviews were organized around three overlapping topics: 1) onset of symptoms and initial illness actions; 2) seeking help from health professionals leading to diagnosis; and 3) post-diagnosis experiences. Follow-up phone calls were made to check and elaborate on the interview generated data. Analysis was informed by grounded theory and a narrative approach.

Four stages of delay were identified: 1) onset of symptoms to the FP visit; 2) gaining a referral; 3) waiting for the specialist meeting; 4) gaining the diagnosis and treatment plan. Participant accounts featured delays characterized by a complex array of interlocking bio-psychosocial factors in the personal and broader health care setting. E.g. the nature of symptoms, the impact of symptoms on function, and the ability to fulfill social obligations and maintain daily life and identities; the ability to mobilize effective self-management strategies; patient-professional interactions, access to medical care and knowledge about arthritis and treatment options coalesced to impact the course of help-seeking. A key theme was the impact of personal philosophy and attitude (e.g. stoicism) and self-management practices (e.g. adapting to symptoms, use of over-the-counter medications, and use of the Internet to gain symptom related knowledge) on accessing medical help and specialist referrals.

Our findings concur with the literature on the points of delay in RA care1 and are in line with research on chronic illness, which reveals a direct link between self-management and formal help-seeking 2. Patients typically entered the health-care system as self-managers and continued to self-manage as illness developed. Given the central role of self-management of chronic illness in research, policy and practice, together with the importance of early diagnosis and treatment in RA, further research is required to address the nature and role of self-management along the continuum of care.

Home-Based Exercise Therapy in Patients with Rheumatoid Arthritis: A Systematic Review. Emalie J. Hurkmans[3], Florus J. van der Giesen[2], Thea P. M. Vliet Vlieland[1], Jan W. Schoones[5] and Cornelia H. M. van den Ende[4]. [1]Department of Rheumatology and Orthopaedics, Leiden University Medical Center, Leiden, The Netherlands, [2]Department of Rheumatology, Groene Hart Ziekenhuis, Gouda, The Netherlands, [3]Department of Rheumatology, Leiden University Medical Center, Leiden, The Netherlands, [4]Department of Rheumatology, Sint Maartenskliniek, Nijmegen, The Netherlands, [5]Walaeus Library, LUMC, Leiden, The Netherlands, The Netherlands

Objective: To assess the effectiveness and safety of home-based (HB) exercise therapy in patients with rheumatoid arthritis (RA).

Method: A literature search up to December 2009 within various databases was performed to identify randomized controlled trials (RCTs) fulfilling the criteria: a) exercise program is performed by patients at home; b) instructions are given at least once; c) program is evaluated not more than once in two weeks; d) the program includes aerobic capacity, muscle strength, joint range of motion, and/or stretching exercises. Two blinded reviewers independently selected studies, rated the risk of bias, categorized the RCTs and extracted data regarding outcome measures of effectiveness (functional ability, aerobic capacity, muscle strength) and safety (self-reported pain, disease activity, radiological damage). A qualitative data analysis was performed.

Results: Eleven RCTs were included; 8 had a low risk of bias. Two RCTs compared a HB program including aerobic capacity and/or muscle strength exercises (8 and 12 months, respectively) with no exercises. Qualitative analysis showed that there is low and moderate quality evidence that a HB program is more effective than no intervention with regard to functional ability and muscle strength, respectively, directly after the intervention. Four RCTs compared a HB program including aerobic capacity and/or muscle strength exercises (8, 12, 24 weeks and 24 months, respectively) with a supervised program. Qualitative analysis showed that there is low quality evidence that a HB program is less effective with regard to aerobic capacity and muscle strength than a supervised program directly after the intervention. Five RCTs compared a HB program including muscle strength exercises and/or stretching exercises (12 weeks, 3, 6, 12 and 24 months, respectively.) with another HB program. Qualitative analysis showed that there is low quality evidence that a HB program including strength and stretching exercises is more effective with regard to functional ability compared to a HB stretching program directly after the intervention. With respect to safety, there

is low and moderate evidence that HB exercise programs have no deleterious effects (see Table I).

Table 1.

Study	Functional ability	Aerobic capacity	Muscle strength	Self-reported pain	Disease activity	Radiological damage
Home-based program versus no intervention						
Masiero 2007	++*		−	++*	−	
Brodin 2008	−		+*	−	−	
Home-based programs versus supervised programs						
Van den Eude 1996	=	++**	+**		=	
Hansen 1993	−	−	−	−	−	−
Hsieh 2009	−	+**	−	−	−	
Lemmey 2009	=		+**		=	
Home-based programs versus other home-based programs						
Van den Berg 2006	−				−	
Stenstrom 1994	−				+#	
O'Brien 2005	+#		=		=	
Stenstrom 1996, 1997	−		−		−	
Hakkinen 1998, 2001, 2003, 2004, 2004	+#		=	+#	=	=

Significant ($p < 0.001$) difference: ++
Significant ($p < 0.05$) difference: +
No significant difference: =
* In favor of home-based program
** In favor of supervised program
# In favor of the home-based program including strengthening and stretching exercises versus exercise programs with only stretching exercises

Conclusion: HB exercise therapy is more effective with regard to functional ability and muscle strength than no exercise therapy. HB exercise therapy is less effective than supervised exercise with regard to aerobic capacity and muscle strength, but equally effective with regard to functional ability. When comparing different types of HB exercise programs, a combined program including strengthening exercises is more effective with regard to functional ability compared to a program without strengthening exercises. No detrimental effects were found in any of HB exercise programs. More research is needed with regard to the specific content and duration of HB exercise program.

An Interactive Website Reduces the Information Need Regarding the Accessibility of Health Care Services in RA Patients. Jorit J. L. Meesters[1], Ingeborg G. de Boer[2], Marta Fiocco[2] and Thea P. M. Vliet Vlieland[1]. [1]Leiden University Medical Center, Leiden, The Netherlands, [2]Leiden University Medical Center

Purpose: Sufficient knowledge about health care services is mandatory for effective self-management in RA patients (1). This study concerns the effects of an information intervention regarding the accessibility of 18 regional health care services on RA patients' self-perceived knowledge and information need.

Methods: The intervention consisted of a weekly updated interactive internet site covering practical aspects of regional health care services for patients with rheumatic diseases, including an email helpline and a telephone helpline. The intervention also comprised an information kiosk with access to the aforementioned website in the outpatient clinic. Moreover, patients were invited to an information meeting in the hospital, and they received a set of information leaflets based on their individual needs.

A random sample of 400 RA patients from the outpatient clinic of our rheumatological department was asked to fill in a questionnaire before the internet site was launched (T1) and 24 months thereafter (T2) (pretest-posttest design).

The questionnaires concerned socio-demographic data, information need (yes / no), and the level of knowledge (insufficient / sufficient) regarding the accessibility of 18 regional health care services.

Results: 251 patients (response rate 63%) and 200 patients (50%) returned the questionnaire before and after the intervention, respectively, with 160 paired observations (112 females (70%), mean age 60.4 (SD9.9)). Table 1 shows the percentages of patients reporting insufficient knowledge or an information need regarding the accessibility of a health care service (T1) and the changes in these percentages (T2-T1) (Mc-Nemar test). Only the results of the top 10 health care services (highest percentages insufficient knowledge at T1) are shown. At T1, the percentages of patients reporting insufficient knowledge were higher than those reporting an information need in all health care services.

Table 1 shows that there is a significant decrease of the patients who reported insufficient knowledge for 2 out of 10 health care services (in total: 2 / 18 services), and for information need 9 out of 10 health care services (in total: 15 / 18 services).

Table 1 Baseline (T1) respondents reporting insufficient knowledge and information need on the accessibility of health care services and changes (T2-T1)

% Insufficient knowledge	*SP*	*HN*	*SW*	*PS*	*OT*	*SM*	*PO*	*IG*	*HT*	*EC*

SP: Specialized physical therapist, *HN:* Home nurse, *SW:* Social worker, *PS:* Psychologist, *OT:* Occupational Therapist, *SM:* Self-management programs, *PO:* Podiatrist, *IG:* Intensive Group exercise, *EC:* Exercise for chronic diseases, *HT:* Hydrotherapy.

Conclusions: In RA patients an interactive internet site and the tailored provision of written information leaflets appear to decrease self-perceived information need on regional rheumatology health care services. The effects on self-perceived knowledge were limited. These findings suggest that supplying practical information about health care services should play a greater role in the treatment of RA patients. More research into the optimal strategies to inform patients is needed.

This project was financially supported by a ZonMw Research Grant (project no.: 32060125).
