ACR/ARHP 2010 Annual Scientific Meeting Overall Needs Assessment/Practice Gaps

The American College of Rheumatology and the Association of Rheumatology Health Professionals are committed to providing comprehensive education to improve the knowledge and performance of physicians, health professionals and scientists. Through evidence-based educational programs, the organization strives to enhance practice performance and improve the quality of care in those with or at risk for arthritis, rheumatic and musculoskeletal diseases. The 2010 ACR/ARHP Annual Scientific Meeting program has been developed independent of commercial influence. The following groups were involved in the planning process: the ACR Committee on Education; the ACR Annual Meeting Planning Committee; the ARHP Education Committee and the ARHP Annual Meeting Program Planning Committee.

The program is the result of a planning process that identified educational needs to change or enhance the knowledge, competence or performance of rheumatology professionals. The program's content was derived from both needs assessment and practice gap analysis based on professional activities, practice setting, ABIM recertification requirements and physician attributes.

Program Highlights

- Educational tracks to help attendees identify content targeted to them. Tracks include: business of rheumatology, clinical, clinical and research, clinical practice, educators, fellow-in-training, pediatrics, pediatrics and clinical, and research
- Latest science and best-practices presented through peer-reviewed and selected clinical and scientific abstracts, and invited speakers providing clinical, evidence-based and quality focused content
- Diverse formats of education delivery, including: didactic lectures, debates, and interactive sessions, such as poster tours, Meet the Professors and Workshop sessions
- A larger forum for discussion of practical management issues such as the Curbside Consults – Ask the Professors session and Medical Aspects lectures
- Extensive learning opportunities in the basic science of rheumatology, an area of the program developed by a subcommittee of U.S. and internationally prominent basic scientists. Offerings include: the Basic Science Symposia, State-of-the-Art Lectures, a series of Immunology Updates for the Clinicians, and a Basic Science pre-meeting course
- Clinical management sessions, including the Thieves' Market and basic management of difficult issues
- A specific pediatric rheumatology track plus content integrated throughout the program designed to provide a high-level educational program to pediatric rheumatologists; and relevant updates to adult rheumatologists
- Formal presentations of new practice guidelines provided to alert the membership and explain, in an open forum, the data supporting the guidelines and propose approaches for implementation
- Over 40 workshops designed to provide hands-on skills training

About ACR/ARHP Education

ACR/ARHP Program Objectives

The American College of Rheumatology and the Association of Rheumatology Health Professionals, a division of the ACR, are organizations of physicians, health professionals and scientists serving members through programs, including education and research. Through these programs, the ACR and the ARHP foster excellence in the care of people with rheumatic and musculoskeletal diseases.

The 2010 ACR/ARHP Annual Scientific Meeting programs have been independently planned by the ACR Committee on Education, the ACR Annual Meeting Planning Committee, the ARHP Annual Meeting Program Committee, and the ARHP Clinical Focus Course Task Force.

This program is sponsored by the American College of Rheumatology for educational purposes only. The material presented is not intended to represent the only or the best methods appropriate for the medical conditions being discussed, but rather are intended to present the opinions of the authors/presenters, which may be helpful to other healthcare professionals. Attendees participating in this medical education program do so with the full knowledge that they waive any claim they may have against the ACR for reliance on any information presented during these educational activities. The ACR does not guarantee, warrant or endorse any commercial products or services.

Program Objectives

At the conclusion of the 2010 ACR/ARHP Annual Scientific Meeting, participants should be able to:

- identify recent developments in the diagnosis and management of patients with rheumatic diseases
- outline new technologies for the treatment of rheumatologic problems
- describe potential challenges in the delivery of care to patients with rheumatic diseases and to specify possible solutions
- utilize new research data to improve the quality of care of patients with rheumatic diseases

CME Credit and Certificates of Participation

Accreditation Statement: The American College of Rheumatology is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide continuing medical education for physicians.

Statement of Designation: This activity has been approved for 48.5 *AMA PRA Category 1 Credit™*.

International Physicians: International physicians, who register as part of a group and require *AMA PRA Category 1 Credit(s)™*, must provide the following information to your tour leader: full name, mailing address, telephone and fax numbers, and e-mail address. The information will be used to verify your meeting attendance.

Health Professional participants may claim hours to receive a Certificate of Participation for an activity designated for *AMA PRA Category 1 Credit(s)™* credit.

For non-CME sessions, attendees may also request a certificate of participation.

Meeting Evaluations, CME Credit/ Certificates of Participation

Computers are available on-site for you to complete your CME/ Certificate of Participation application and meeting evaluation form online during the meeting. In addition, you can complete the evaluation and print your certificate after you return home. *Paper CME application forms will not be available.*

If you are an international physician and require a Certificate of Attendance, this is enclosed in your meeting bag. If your country recognizes *AMA PRA Category 1 Credit(s)™* in accordance with AMA PRA requirements, please complete a meeting evaluation and CME application.

Your evaluation of the meeting is very important. The ACR/ARHP annual meeting planning committees use feedback from attendees to assist in the development of future educational activities; therefore, we encourage you to complete your evaluation and CME/Certificate application online.

Conflict of Interest/Disclosure Statement

As an educational provider accredited by the Accreditation Council for Continuing Medical Education, the American College of Rheumatology must ensure balance, independence, objectivity and scientific rigor in all its educational activities. Therefore, all speakers and moderators participating in an ACR-sponsored activity are required to disclose to the planning committee and audience any financial or other relationships including, but not limited to:

None: Nothing to disclose

1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan
2. Research grants
3. Employment (full or part-time)
4. Ownership or partnership
5. Consulting fees or other remuneration (payment)
6. Non-remunerative positions of influence such as officer, board member, trustee or public spokesperson
7. Receipt of royalties
8. Speakers' bureau
9. Other

Speakers, moderators and abstract authors submitted their disclosure online prior to publication. Disclosures for invited speakers are listed in the indices by presenters' last name.

Abstract author disclosures are published online as well as in this supplement. Disclosures for the Late-Breaking Abstracts are published online and in the December issue of *Arthritis & Rheumatism*. Any individual who refuses to disclose relevant financial relationships will be disqualified from being a planning committee member, a presenter, an author of a CME activity, and cannot have control of, or responsibility for, the development, management, presentation or evaluation of the CME activity.

ACR Poster Session A
Antiphospholipid Syndrome
Monday, November 8, 2010, 9:00 AM–6:00 PM

1

Acquired Resistance to Activated Protein C Is a Feature of Both Systemic Lupus Erythematosus (SLE) and Antiphospholipid Syndrome (APS) and Is More Marked in Patients with SLE and APS. Denis Wahl[3], Stéphane Zuily[4], Agnès Brunette[2], Marie Prestat-Tilly[4], Véronique Regnault[2], Jean Devignes[1] and Thomas Lecompte[1]. [1]Biological Haematology Department, Nancy University Hospital, Vandoeuvre les Nancy, France, [2]INSERM U961, Nancy Université, Vandoeuvre les Nancy, France, [3]Vascular Medicine Unit, Vandoeuvre les Nancy, France, [4]Vascular Medicine Unit, Nancy University Hospital, Vandoeuvre les Nancy, France

Vascular manifestations of antiphospholipid syndrome (APS) include both venous (VTE) and arterial (ATE) thromboembolic events. However VTE are more frequent than ATE. Among the underlying mechanisms of VTE in APS, it has been suggested that acquired activated protein C (APC) resistance may be a candidate mechanism. However this is difficult to demonstrate with tests based on aPTT because of the effects of lupus anticoagulants on this parameter. In order to investigate APC resistance in APS we have conducted a study with a thrombin generation test (calibrated automated thrombography). APC resistance was determined with measurement of endogenous thrombin potential (ETP) at baseline and after addition of APC. The APC sensitivity ratio (sr) was defined as ETP with APC/baseline ETP.

We included 92 patients (37 with primary antiphospholipid syndrome, 15 with SLE without antiphospholipid antibodies PAPS, 11 with both APS and SLE and 29 with antiphospholipid antibodies (APA) but without APS) and 39 controls. APCsr was higher in all patient groups compared to controls indicating resistance to activated protein C: APCsr was 0.45 ± 0.20, $p=0.005$ in PAPS, 0.55 ± 0.16,$p<0.001$ in in SLE, 0.65 ± 0.16,$p<0.0001$ in patients with both PAPS and SLE and 0.53 ± 0.22,$p<0.0001$ in patients with APA without APS whereas controls 0.30 ± 0.11. Of note APCsr was also higher in patients with both SLE and APS than in patients with PAPS ($p=0.009$). Moreover APCsr in patients with venous thrombosis was higher than in controls: 0.47 ± 0.22 vs 0.30 ± 0.11, $p< 0.001$.

Overall these results suggest that acquired APC resistance is a potential risk factor for thrombosis in SLE and PAPS and is more marked when both conditions are present. Furthermore APC resistance seems to be more specifically associated with venous thromboembolism.

AGTRL1 and PRKCH Are Genetic Risk Factors for Antiphospholipid Syndrome. Hisako Nakagawa[1], Tetsuya Horita[2], Toshio Odani[2], Yuichiro Fujieda[2], Masaru Kato[2], Kotaro Otomo[2], Yasuko Nakagawa[2], Shinsuke Yasuda[2], Tatsuya Atumi[2] and Takao Koike[2]. [1]Department of Medicine II, Hokkaido University Graduate School of Medicine, Sapporo, Hokkaido, Japan, [2]Department of Medicine II, Hokkaido University Graduate School of Medicine.

Background: Single nucleotide polymorphisms (SNPs) of Angiotensin receptor-like1 (AGTRL1) and Protein kinase C eta (PRKCH) were reported to be associated with cerebral infarction in recent genomewide association study in Japanese population. AGTRL1, also named APJ, is a member of the G protein-coupled receptor gene family and has important roles for the modulation of angiogenesis and also act as a human immunodeficiency virus coreceptor. PRKCH regulates various important cellular functions including proliferation, differentiation and apoptosisis is mainly expressed in vascular endothelial cells and foamy macrophages in human atherosclerotic lesions. In this study, we investigated the possible association of the functional SNP in an Sp1-binding site of AGTRL1 gene (rs9943582, G/A) and the nonsynonymous SNP (rs223050, G/A, Val372Ile) in PRKCH gene with antiphospholipid syndrome (APS) in Japanese population.

Patients and Methods: Genomic DNA samples were obtained from 111 patients with APS (45 primary APS and 66 secondly APS), 296 patients with systemic lupus erythematosus (SLE) in the absence of APS and 428 healthy controls. Among APS group, seventy nine patients (71%) had arterial or thrombosis, 58 (52%) arterial thrombosis, 37 (33%) venous thrombosis and 52 (47%) cerebral infarction, respectively. AGTRL1 SNP (rs9943582) was genotyped using TaqMan SNP genotyping assay and PRKCH SNP (rs2230500) was genotyped using direct sequencing. Chi-square tests and Odds ratio were used for statistical analysis after evaluation for Hardy-Weinberg equilibrium. In addition, the stratification analysis by thrombotic events was performed.

Results: Both AGTRL1 rs9943582 G allele and PRKCH rs2230500 A allele frequencies were significantly increased in patients with APS (OR=1.43, 95%Cl:1.03–2.31 and OR=1.89, 95%Cl: 1.17–3.05, respectively). No association was found between these 2 SNPs and SLE in the absence of APS. In the stratification analysis by clinical manifestations of APS, both AGTRL1 and PRKCH alleles were associated with arterial or venous thrombotic events in patients with APS (OR=1.69, 95%Cl:1.15–2.49 and OR=1.58, 95%Cl: 1.04–2.38, respectively)

Conclusion: The functional SNP in an Sp1-binding site of AGTRL1 gene (rs9943582, G/A) and the nonsynonymous SNP (rs223050, G/A, Val372Ile) in PRKCH are associated with APS and thrombotic events in patients with APS. Our results suggest that these 2 SNPs are additional genetic risk factors for APS, especially thrombotic events in APS in Japanese population.

Anti-β2 Glycoprotein I Antibodies from Leprosy Patients Do Not Show Thrombogenic Effects in an In Vivo Animal Model. Ricardo Forastiero[2], Marta Martinuzzo[2], Mariano Vega-Ostertag[2], Gabriela de Larranaga[2] and Silvia S. Pierangeli[1]. [1]Univ of TX Medical Branch, Galveston, TX, [2]Universidad Favaloro, Buenos Aires, Argentina

Background: The APS-associated aPL are autoantibodies directed against β2GPI and prothrombin. Patients with leprosy present high frequency of IgM aPL that bind β2GPI, but they do not develop thrombosis. Anti-β2GPI from APS mainly bind to domain I of β2GPI while in leprosy are directed against domain V. There is convincing evidence that aPL/anti-β2GPI from APS are pathogenic in vivo and in vitro.

Objective: to investigate the thrombogenic and pro-inflammatory effects of aPL from leprosy and to compare with aPL from APS.

Methods: Sera from 6 patients with APS and 6 with leprosy were used as the source of IgM. All APS and 5 leprosy patients had strong LA activity, and high titers of IgM aCL/anti-β2GPI. The remaining leprosy patient was aPL negative (control). We treated CD1 mice, in groups of 5, at 0 hours and 48 hours later with IgM aPL/anti-β2GPI isolated from patients with leprosy (IgM-leprosy) or APS (IgM-APS) or with IgM from 2 healthy controls (IgM-NHS) or 1 leprosy aPL negative control. Seventy-two hours after the first injection, the adhesion of leukocytes (#WBC) to endothelial cells (EC) in cremaster muscle (as an indication of EC activation in vivo), as well as the size of an induced thrombus in the femoral vein of the mice were examined.

Results: IgM-APS significantly increased the thrombus size (in mum2) when compared to IgM-NHS or IgM-leprosy treated mice ($p<0.001$). There was no difference in mice injected with IgM-leprosy, IgM-NHS or IgM-leprosy control. IgM-APS increased the #WBC adhering to EC, when compared to IgM-NHS or IgM-leprosy ($p<0.001$).

	IgM-APS	IgM-leprosy	IgM-NHS	IgM-leprosy control
Mean thrombus size	4446	1378	748	851
#WBC	5.1 ± 2.2	2.0 ± 1.0	3.5 ± 1.6	1.3 ± 0.5

Conclusions: Our data shown that aPL/anti-β2GPI from leprosy patients have not thrombogenic and pro-inflammatory effects in vivo when compared with aPL derived from APS.

4

Antiphospholipid Antibodies in Children with Systemic Lupus Erythematosus – 18 Years of Clinical Experience from North India. Surjit Singh[2], Jasmina Ahluwalia[1], Shano Naseem[3], Deepti Suri[2] and Amit Rawat[2]. [1]Department of Hematology, Post Graduate Institute of Medical Education and Research, Chandigarh, India, [2]Division of Pediatric Allergy and Immunology, Advanced Pediatrics Centre, Post Graduate Institute of Medical Education and Research, Chandigarh, India, [3]Division of Pediatric Hematology, Advanced Pediatrics Centre, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Pediatric systemic lupus erythematosus (p-SLE) is usually more severe than its adult counterpart and frequently involves vital organs (e.g. kidneys). Anti-phospholipid antibodies (APLA) have been reported in 38–87% patients with p-SLE in and reports suggest that presence of APLA can modify disease expression. Higher incidence of neuropsychiatric, renal and hematological manifestations has been reported in APLA positive p-SLE, but influence of APLA on disease course remains unclear. While APLA have been extensively studied in adults with SLE, there is paucity of data on APLA in p-SLE.

Materials and Methods: We report a single centre study on 64 patients with p-SLE seen during the period June 1992 - May 2010 in whom APLA testing was performed. Diagnosis of SLE was based on ACR criteria. Mean age at diagnosis was 10.3 years (range 3–17) with a female:male ratio of 3:1. Of these 24 (37.5%) had renal, 17 (26.6%) hematological (7-hemolytic anemia, 6-thrombocytopenia and 4-leucopenia), 14 (21.9%) neurological, 8 (12.5%) pulmonary, 29 (45.3%) musculo-skeletal and 42 (65.6%) had mucocutaneous involvement. APLA tested included: i) lupus anticoagulant [by kaolin clotting time, diluted Russell viper venom time (LA Screen and LA Confirm, Dade Behring) and STACLOT-LA kit] ii) anticardiolipin antibodies (ACLA) – IgG, IgM and iii) anti-β2 glycoprotein I (β2 GPI) antibodies – IgG, IgM (Orgentec GmBH by ELISA). Our laboratory is registered in World Health Organization's United Kingdom National External Quality Assurance Scheme for these tests.

Summary of Results: Patients was tested for APLA on 155 occasions - minimum being once and maximum being 10 during a mean follow-up period of 59.3 months (range 1–211 months). Thirty eight (59.4%) patients were positive for one or other APLA at some point of time of their disease. Overall LA was positive in 39.1%, IgG ACA in 23.4% and IgM ACA in 18.6%. At diagnosis, 37.8% children were positive for LA, 16.3% for IgG ACA and 20.9% for IgM ACA. During follow-up LA was positive in 26.2% patients, IgG ACA in 31%, IgM ACA in 19% patients. Anti-β2GPI (IgG and IgM) could be tested in 10 patients only and was found to be positive for anti-β2GPI IgG in 1 patient.

Thrombosis was seen in 5 patients - of these, 4 (80%) were positive for APLA. Of the 24 patients with nephritis, class II nephritis was seen in 4—of these none was positive for any of the APLA; class III nephritis was seen in 1–patient tested positive for APLA; class IV nephritis was seen in 15—of these 9 (60%) were positive for 1 of the APLA; class V nephritis was seen in 3–of these 2 (66.6%) were positive for APLA. Of the 17 patients with hematological involvement, 11 (64.7%) had positive APLA; of 14 with neurological involvement, 12 (85.7%) had positive APLA. Six (9.4%) children had a fatal course—5 (83.3%) of these had positive APLA.

Conclusion: 59.4% p-SLE patients had APLA positivity during the disease course. The commonest APLA was LA (39.1%), followed by IgG ACA (23.4%) and IgM ACA (18.6%). APLA positivity is more common in p-SLE patients with advanced nephritis, neurological involvement, thrombosis and a fatal course. Presence or persistence of these antibodies, however, may not always predict thrombosis in children with p-SLE.

Antiphospholipid Score (aPL-S): A Comprehensive Predictive Marker of Developing Thrombosis in Autoimmune Diseases. Kotaro Otomo[1], Tatsuya Atsumi[2], Yuichiro Fujieda[3], Masaru Kato[3], Olga Amengual[3], Tetsuya Horita[3], Shinsuke Yasuda[3] and Takao Koike[3]. [1]Hokkaido Graduate School of Medicine, Department of Medicine II, Sapporo, Hokkaido, Japan, [2]Hokkaido Graduate School of Medicine, Department of Medicine II, Sapporo, Japan, [3]Hokkaido Graduate School of Medicine, Department of Medicine II

Objective: We have previously defined the Antiphospholipid Score (aPL-S) by testing multiple antiphospholipid antibodies (aPL), and evaluated its efficacy for the diagnosis of antiphospholipid syndrome (APS) as well as its predictive value for the development of thrombotic events in patients with autoimmune diseases (Presentation Number 1216 in ACR 2009). In the present study, we further analyzed the associated-risk of thrombosis for each aPL assay in autoimmune diseases. Further, we investigated the relationship between the aPL-S and each single aPL test.

Patients and Methods: This study comprised 411 patients with autoimmune diseases who visited our Rheumatic and Connective Tissue Disease Department. Between 2002 and 2003, five Lupus Anticoagulant (LAC) assays (the mixing studies: activated partial thromboplastin time (APTT), kaolin clotting time, the dilute Russel's viper venom test (dRVVT), and the confirmatory tests: APTT and dRVVT) and 6 ELISAs (IgG/M anticardiolipin (aCL) antibodies, IgG/M anti-beta2-glycoprotein I (aβ2GPI) antibodies and IgG/M phosphatidylserine dependent antiprothrombin (aPS/PT) antibodies) were performed in all subjects. Among all the patients, 296 (72.0%) were followed-up with a mean duration of 67 $\pm$15 months. The disease profile of these patients was as follows; 17(6%) primary APS, 26(9%) APS associated with other autoimmune disease, 89(29%) SLE (without APS), 50(17%) rheumatoid arthritis and 114 patients with several other autoimmune diseases. To evaluate the predictive value of thrombosis for each aPL-analyzed test, positive results in each assay were contrasted with the presence of new thrombotic events during the follow-up period.

Results: Thirty-two patients newly developed thromboses during the observation period; 22 arterial thromboses and 14 venous thromboses.

Patients with either positive LAC or IgG aPS/PT had a stronger risk of thrombosis than those without. The odds ratio (OR [95%CI]) associated to each test was 3.26 [1.55–6.90, p=0.001] and 4.80 [2.03–11.04, p=0.0001], respectively. The OR values in patients with aPL-S more than 10, 30 and 50 were 2.86 [1.33–6.16, p=0.006], 5.27 [2.32–11.95, p<0.0001] and 5.31 [1.81–15.53, p=0.0008], respectively. Thus, the positive predictive values of aPL-S more than 30 and 50 were higher than any other value of each single aPL test (see figure.). The negative predictive values of aPL-S, LAC and IgG aPS/PT were within the similar levels (90.7–92.9%).

Conclusion: The aPL-S may be a useful comprehensive quantitative marker for predicting thrombosis in autoimmune diseases.

Disclosure: K. Otomo: None; **T. Atsumi:** None; **Y. Fujieda:** None; **M. Kato:** None; **O. Amengual:** None; **T. Horita:** None; **S. Yasuda:** None; **T. Koike:** None.

6

Antiphospholipid Syndrome (APS) Clinical Research Task Force (CRTF) Report. Doruk Erkan[2], Ronald Derksen[6], Roger A. Levy[3], Samuel Machin[5], Thomas Ortel[1], Silvia S. Pierangeli[4], Robert A. S. Roubey[7], Michael D. Lockshin[2] and on Behalf of APS Clinical Research Task Force. [1]Duke University Health System, Durham, NC, [2]Hospital for Special Surgery, New York, New York, NY, [3]Univ Estado Do Rio de Janeiro, Rio de Janeiro, Brazil, [4]Univ of TX Medical Branch, Galveston, TX, [5]University College London Hospitals, London, UK, [6]University Medical Centre, Utrecht, Netherlands, [7]University of North Carolina, Chapel Hill, NC

Background: The 13th International Congress on Antiphospholipid Antibodies (aPL) was held in Galveston, TX in April 2010. The APS CRTF was one of six task forces developed by the meeting organization committee with the purpose of: a) evaluating the limitations of APS clinical research and developing guidelines for researchers to help improve the quality of APS research; and b) prioritizing the ideas for a well-designed multicenter clinical trial and discussing the pragmatics of getting such a trial done (organization, ideal protocols, practical protocols, and financing).

Objective: The purpose of this abstract is to summarize the discussions and progress of APS CRTF.

Methods: The original eight members of CRTF were chosen among experienced APS researchers. The task force working algorithm was: a) a questionnaire that was sent to the members before the congress; b) a summary report that was prepared based on the responses to facilitate discussions during the pre-meeting workshop; c) a pre-meeting workshop; d) two plenary sessions based on the conclusions of the task force discussions where input from all the meeting attendees was received; and e) a final report that was circulated among all the task force chairs for final remarks.

Results: The task force identified five major issues that impede APS clinical research and the ability to develop evidence-based recommendations for the management of aPL positive patients: 1) aPL detection has been based on partially or non-standardized tests, and clinical (and basic) APS research studies have included patients with heterogeneous aPL profiles with different clinical event risks; 2) clinical (and basic) APS research studies have included a heterogeneous group of patients with different aPL-related manifestations

(some controversial); 3) thrombosis and/or pregnancy risk stratification and quantification are rarely incorporated in APS clinical research; 4) most APS clinical studies include patients with single positive aPL results and/or low-titer aPL ELISA results; furthermore, study designs are mostly retrospective and not-population based, with limited number of prospective and/or controlled population studies; and 5) lack of information on the particular mechanisms of aPL-mediated clinical events limits the optimal clinical study design.

Conclusion: The task force recommended that there is an urgent need for a true International collaborative approach to design and conduct well-designed prospective large-scale multi-center clinical trials of patients with persistent and clinically significant aPL profiles. An International collaborative meeting to formulate a good research question using "FINER" (Feasible; Interesting; Novel; Ethical; and Relevant) criteria will take place in early November and the conclusions will be presented at the ACR meeting.

7

Decreased Fibrin Clot Porosity in Patients with Antifosfolipid Syndrome. Anna Vikerfors[2], Aleksandra Antovic[1], Elisabet Svenungsson[2], Katarina Bremme[3] and Margareta Holmström[4]. [1]Department of Clinical Sciences, Karolinska Institutet/Danderyd Hospital, Stockholm, Sweden, [2]Department of Medicine, Rheumatology Unit, Karolinska Institutet/Karolinska University Hospital, Stockholm, Sweden, [3]Department of Woman and Child Health, Division of Obstetrics and Gynaecology, Karolinska Institutet/Karolinska University Hospital, Stockholm, Sweden, [4]Hematology Division, Department of Medicine, Karolinska Institutet/Karolinska University Hospital, Stockholm, Sweden

Background: It has been reported that patients with type 1 diabetes and young males with myocardial infarction form a fibrin clot which is tighter and more resistant to fibrinolysis in comparison to the fibrin clot formed by healthy controls. The structure/porosity of the fibin clot in patients with the Antiphospholipid syndrome (APS) has not previously been investigated and we hypothesised that a tight fibrin clot may contribute to the procoagulant state in these patients.

Materials and Methods: We thus evaluated fibrin clot porosity in plasma-samples from 47 patients with Antifosfolipid Syndrome (APS), strictly fulfilling the Sydney criteria for APS. Previously established flow measurement technique was used to determine the fibrin clot porosity, as expressed as the Darcy constant (Ks). A low Ks level indicates a tighter fibrin clot. Ks-levels were compared to reference Ks values used in our laboratory obtained from healthy individuals. Within the APS-group, associations between Ks-levels and clinical manifestations, specificities of antiphospholipid antibodies (aPL) were explored. For a majority of the patients data regarding markers of inflammation and on-going medication was available to guide interpretation.

Results: The mean Ks-levels were significantly lower in the samples from patients with APS (6.7, +/−2.9) as compared to reference Ks values (10.7+/−1.6), indicating a tighter fibrin network, p<0,0001. Within the APS-group Ks-levels did not vary depending on different clinical APS manifestations or aPL pattern. There was however a trend towards lower Ks-levels for the 20 patients with previous obstetric morbidity (5.7, +/−2,0) as compared to the 27 patients without this clinical manifestation (7.4 +/−3.2), p=0,09.

CRP-levels were generally low in the APS-patients (median 1.06, range 0–7.4, n=28). A majority of the patients were treated with anticoagulants: either vitamin K-antagonits or dalteparin (19/34) and many with statins (7/34). Patients treated with these two groups of drugs had all experienced a previous arterial or venous tromboembolic event. Almost half of the patients (15/34) were treated with low-dose ASA, sometimes in combination with vitamin K-antagonists or dalteparin. The majority of the ASA-treated patients (12/15) had a previous tromboembolic manifestation.

Conclusion: APS-patients form a tighter and more stable fibrin clot as estimated by Ks levels, which measure in vitro fibrin clot porosity. There was a significant difference compared to reference material obtained from healthy individuals, even though a majority of the APS-patients were treated with low dose ASA, warfarin, dalteparin, statins or a combination of these drugs. To our knowledge this is a new finding.

We observed a trend towards a tighter fibrin network in APS-patients with obstetric morbidity compared to other individuals with APS. This finding could be attributed to differences in medications between the two groups.

Future studies including larger patient materials and controls may shed further light on the aetiology of APS and may thereby contribute to better risk assessment and management for APS patients.

Global Analyses of Antiphospholipid Antibodies That Impair Antithrombin Inactivation of Procoagulant Factors. Meifang Wu[2], Jennifer M. Grossman[3], John FitzGerald[2], Bevra H. Hahn[4] and Pojen P. Chen[1]. [1]UCLA Schl of Medicine, Los Angeles, CA, [2]UCLA School of Medicine, [3]University of California Los Angeles, Sherman Oaks, CA, [4]University of California Los Angeles School of Medicine, Los Angeles, CA

Background: Previously, we reported that 6 of the 8 patient-derived IgG monoclonal anti-phospholipid antibodies (aPL) bound to thrombin, and that one such reactive aPL (CL24) significantly impaired inactivation of thrombin by antithrombin (AT). Subsequently, we found that all 6 thrombin-reactive aPL also bound to FXa; and that all 6 thrombin-reactive aPL plus two later generated IgG monoclonal aPL (i.e., B2 and P1) also interacted with FIXa. Importantly, some of these reactive aPL (such as CL24) could reduce AT inactivation of FXa and FIXa. The purpose of this study was to study the overall effects of such aPL on hindering AT from inactivating its target procoagulant factors.

Methods: First, we developed an activated-partial-thromboplastin-time (APTT)-based assay to study the overall effects of aPL on impairing AT function and shortening plasma clotting times. Second, to avoid the problem that some aPL possess lupus-anticoagulant activity (that prolongs clotting times) and could obscure shortened clotting time (from aPL-impaired AT function), we evaluated each test aPL (or purified IgG, or plasma sample) individually by determining its clotting times in plasma in the presence or absence of heparin (with optimal AT function, or little AT function, respectively), and then dividing the former clotting time by the latter clotting time, and expressing the result as a "clotting ratio". Third, as a first step to translate the above findings of AT-interfering IgG aPL into a feasible clinical assay, we adapted the above assays to study two chosen patient plasma samples. Plasma P76 contained IgG aPL that reacted with FXa and FIXa; and P80 contained IgG aPL that interacted with thrombin, FXa and FIXa.

Results: First, monoclonal antibodies B2 and CL24 at the final concentration of 27 μg/ml (representing about 0.3% of total plasma IgG) significantly shortened clotting times from 85 seconds to about 60 seconds ($p < 0.001$), most likely reflecting that B2 and CL24 impaired AT inactivation of one or more procoagulant factors in plasma. Second, using the "clotting ratio" analyses, B2 and CL24 at the physiological concentration reduced clotting ratios from 250% for normal human IgG to 144 % ($p < 0.01$) and 171% ($p < 0.05$), respectively. Moreover, purified IgG from 2 patients with antiphospholipid syndrome (APS) also reduced clotting ratio to 153% and 145%, as compared with a clotting ratio of 175% for normal human IgG. Third, when heparin was added, the clotting times of normal plasma, P76 and P80 were increased respectively to 96 seconds, 99 seconds and 166 seconds. These led to a clotting ratio of 178% for the normal plasma, while those of plasma P76 and the P80 were respectively 113% and 134% ($p < 0.001$). These data suggested that both patient plasma samples had the AT-interfering Ab. The above reduced clotting ratios apparently reflected that certain aPL reacted with the target procoagulant factors of AT and paradoxically impair AT inactivation of the involved procoagulant factors in plasma.

Conclusion: These results show the AT-interfering IgG aPL are present in some APS patients and could contribute to thrombosis in such patients.

Influenza Vaccination Can Induce New Onset Anticardiolipins but Not β2-Glycoprotein-I Antibodies among Patients with Systemic Lupus Erythematosusβ. Evan Glenn Vista[3], Sherry R. Crowe[3], Amy B. Dedeke[3], Jourdan R. Anderson[2], Linda F. Thompson[3], Gillian Air[4] and Judith A. James[1]. [1]Oklahoma Med Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]University of Oklahoma Health Science Center, Oklahoma City, OK

Background: Antiphospholipid syndrome is characterized by pathogenic autoantibodies against anticardiolipins (aCLs), lupus anticoagulant, and Independent β2-glycoprotein (β2GPI). The factors causing production of these antiphospholipid antibodies (aPLs) remain unidentified but have been documented in a large number of infectious diseases. Controversy exists as to whether vaccination triggers the same autoimmune reactions as infections in systemic lupus erythematosus (SLE) patients. Among the aPLs, β2GPI has been described as the actual target antigen for autoimmune aPLs, but conflicting reports still exist.

Methods: A total of 102 patients fulfilling the ACR criteria for SLE and 104 age, race and gender matched healthy controls enrolled in our lupus flu cohort from 2005 to 2009 and received regular seasonal influenza vaccinations. Sera were tested by ELISA for aCL IgG at the time of vaccination and 2, 6 and 12 weeks after vaccination. The international standardized ratios for aCL reactivity were calculated for each and manufacture cut-offs were used to define low, moderate, and high levels of aCL. Logistic regression was used to account randomly for those enrolled in multiple years to select the unique 206 individuals. Vaccine responses were ranked either as high or low according to an overall anti-influenza antibody response index (which includes hemagglutination inhibition, relative avidity and maximum native antibody responses). Those who have new onset reactivity to aCL IgG were further tested for β2GPI IgG antibodies. Paired t-testing for all patients with aCL reactivity was used to determine changes after vaccination at 2, 6, and 12 weeks compared to baseline.

Results: More SLE patients compared to healthy controls developed new low aCL reactivity (14/102 cases and 4/104 controls; OR 4.1, p 0.02) and new moderate aCL reactivity (13/102 cases and 3/104 controls; OR 5.1, p 0.01) after influenza vaccination. From specific timepoints after vaccination, new low aCL reactivity were significant for SLE patients after 6 weeks (11/102 cases and 1/104 control) and 12 weeks (10/102 cases and 2/104 control) (OR 12.8, p 0.02 and OR 5.7, p 0.03 respectively) and for new moderate aCL reactivity only after 6 weeks (10/102 cases and 1/104 controls; OR 11.5, p 0.02). High aCL reactivity was only seen among 2 patients with low and moderate aCL reactivity pre-vaccination. Overall, vaccine response was significantly higher among patients with new onset aCL reactivity compared to controls (p 0.02). No new β2GPI antibodies were detected post-vaccination among patients with new aCL reactivity. The normalized optical density measurements for patients with recorded aCL reactivity at any time points were significantly higher after 2 weeks (0.43±0.24, p 0.0013), 6 weeks (0.49±0.37, p 0.004), and 12 weeks (0.47±0.44, p 0.03) after vaccination compared to the baseline (0.30±0.15).

Conclusions: This study shows transient increases in aCLs, but not anti-β2GPI responses, after influenza vaccination supporting the possibility that these changes in autoantibody levels may not be clinically important for increased thrombosis risk post-vaccination.

Platelet Activation and Paradoxical Inhibition of ADP Induced Aggregation by Antiphospholipid Antibodies. Kenji Oku[4], Tatsuya Atsumi[2], Olga Amengual[3], Masahiro Ieko[1], Shin Furukawa[6], Hirohiko Kitakawa[6], Yuji Hori[6], Kazuyoshi Nihei[6], Yuuichiro Fujieda[3], Kotaro Otomo[5], Masaru Kato[3], Tetsuya Horita[3], Shinsuke Yasuda[3] and Takao Koike[3]. [1]Health Sciences University of Hokkaido, [2]Hokkaido University Graduate School of Medicine Internal Medicine II, Sapporo, Japan, [3]Hokkaido University Graduate School of Medicine Internal Medicine II, [4]Hokkaido University Graduate School of Medicine Internal Medicine II, Kushiro Red Cross Hospital, Japan, [5]Hokkaido UniversityGraduate School of Medicine Internal Medicine II, [6]Kushiro Red Cross Hospital

Purpose: Autoantibodies against beta2-glycoprotein I (β_2GPI) and those against prothrombin are two major populations of antibodies found in patients with antiphospholipid syndrome (APS). The platelet activation and aggregation are crucial procedures in the development of arterial thrombosis. There are some reports suggesting a link between platelet activation and anti-β_2GPI antibodies, but only little data are available regarding antiprothrombin antibodies and platelets. We previously showed that presence of IgG phosphatidylserine-dependent antiprothrombin antibodies (aPS/PT) was a strong risk of having arterial thrombosis in our cohort of 500 patients with autoimmune diseases, and that monoclonal aPS/PT affected ADP induced platelet aggregation *in vitro* (abstract 1594, ACR 2009).

In this study, we investigated further the *in vitro* behaviour of platelet exposed by aPS/PT and anti-β_2GPI antibodies. Additionally, we quantitatively-analyzed CD62P, a surface marker of activated platelets and thromboxane B2(TXB2), a member of eicosanoid family molecules produced by activated platelets.

Methods: A monoclonal aPS/PT, 231D, that shared the properties with autoimmune aPS/PT, a human monoclonal anti-β_2GPI antibody, EY2C9, and purified IgG from APS patients' sera were used for the following experiments. Normal platelets were treated with monoclonal antibodies or purified IgG. Conventional ADP or collagen induced platelet aggregation assay by turbidimetric method were performed using platelet riched plasma (PRP) spiked with monoclonal antibodies or purified IgG. To explore, in this system, the involvement of P2Y12, one of the ADP receptors on platelet controlling the secondary aggregation, we evaluated the activation of vasodilator stimulated phosphoprotein (VASP), using a standard assay. VASP represents P2Y12 inhibition as the intra-molecular signal protein. Positive ratio of CD62P was detected by two-colored flow-cytometry. TXB2 was quantitatively-analyzed by Enzyme-Linked ImmunoSorbent Assay (ELISA.).

Results: ADP induced secondary platelet aggregation was significantly inhibited in 231D, EY2C9, and purified IgG affected PRP, whereas collagen induced platelet aggregation was not affected by any of the antibodies. VASP activities were significantly increased in 231D and EY2C9 treated platelets ($p<0.01$).

Both positive rates of CD62P and TXB2 levels were significantly raised on platelets treated with 231D or EY2C9 in the presence of their antigen.

Conclusion: The effects of monoclonal aPS/PT on platelets were similar to those of monoclonal anti-β_2GPI antibodies and IgG fractions of APS patients' sera. Antiphospholipid antibodies activated platelets shown by CD62P expression and TXB2 production. Paradoxical inhibition of ADP induced platelet aggregation by antiphospholipid antibodies might be correlated with P2Y12 signal suppression. Those observations suggest that the platelet involvements with aPS/PT and anti-β_2GPI are paradoxical and complex, leading to the heterogeneous clinical features of patients with APS.

Prevalence and Prognostic Significance of Thrombotic Microangiopathy in Rheumatologic Patients: Clinical and Immunological Associations. Spyros Aslanidis, Athina Pyrpasopoulou, Stella Douma, Areti Triantafyllou, Michail Doumas and Chrysanthos Zamboulis. 2nd Propedeutic Dept of Internal Medicine, Hippokration Hospital, Thessaloniki, Greece

Background/Aim: The aim of this study was to assess the prevalence of microangiopathy in rheumatologic patients featuring signs of vasculopathy. As the occurrence of small-vessel occlusions (thrombotic microangiopathy) in the nail fold of patients with antiphospholipid syndrome is well documented, a major target point of this study was to evaluate capillaroscopy in the diagnosis of APS. Capillaroscopic findings and matching autoantibody profiling were subsequently correlated with the incidence of arterial and venous thrombotic events.

Materials/Methods: 738 patients from a Rheumatology Outpatients cohort were consecutively screened with capillaroscopy. Criteria for selection included Raynaud's phenomenon, livedo reticularis, diagnosis of SLE, positive antiphospholipid profile and/or previous thrombotic events, and atypical musculoskeletal symptomatology. Scleroderma patients were excluded. Patients with microhemorrhages were tested for ACL and anti-b2GP1 Abs and data was analyzed with the SPSS 16.0 software.

Results: 149 of the screened patients (85.2% ♀/14.8%♂, 49.28±14.31 yrs) exhibited capillary microhemorrhages. Running diagnosis in these patients was MCTD (24.2%), SLE (18.8%), RA (16.1%), APS (12.8%), Sjogren's syndrome (4.7%), B51 (3.4%), and vasculitis (2%). Antiphospholipid profile was tested in the affected individuals, and revealed an additional 14.7% of secondary laboratory APS in 28.6% of the SLE and 22.2% of the MCTD patients. The presence of ACL and anti-b2GP1 Abs was found to both independently significantly correlate with thrombotic events ($p<0.001$). Subanalysis of the type of anti-b2GP1 Abs indicated that the correlation with thrombotic events was significant for G-type ($p<0.001$) and M-type ($p=0.012$), but not A-type Abs ($p=0.292$, NS). No significant predilection for arterial or venous thromboses was observed in patients with ACL Abs; patients with anti-b2GP1 Abs exhibited a trend for arterial thromboses, $p=0.174$, NS.

Conclusions: Capillaroscopy is a useful microangiopathy screening tool in rheumatologic patients featuring signs of clinical vasculopathy, and can aid

diagnostically to screen for, or verify, APS in patients with a history of thrombotic events. Associations of autoantibody profiling of patients with capillaroscopic microangiopathy with clinically manifested thromboses resulted in similar findings with studies involving patients with clinical APS. The observation that, although IgA-b2GP1 Abs were detected in patients with microangiopathy, they lacked any significant association with thrombotic complications, suggests, that additional factors may be needed for the development of clinical thrombotic events.

Prevalence of Antibodies to Prothrombin (PT) and Prothrombin/Phosphatidylserine (PS) in a Cohort of Lupus Anticoagulant (LAC) Positive Samples. R. Aguilar-Valenzuela[2], J. Dlott[1], U. Khan[2], M. Belter[1], E. Doan[2], N. Gould[1], A. Schleh[2] and S. Pierangeli[2]. [1]Quest Diagnostics, Chantilly, VA, [2]Univ of TX Med Branch, Galveston, TX

Background: ELISA tests have been developed to detect anti-PT and anti-PT/PS antibodies in serum but the clinical diagnostic value and their relationship with the LAC remains elusive.

Objective: to evaluate anti-PT/PS and anti-PT antibodies in a cohort of 150 confirmed LAC and the corresponding controls.

Methods: 150 LAC positive and 150 LAC negative plasma samples were tested by ELISA for anti-PS/PT (IgG and IgM) and LAC PS/PT screening assay (kindly provided by INOVA Diagnostics) and anti-PT (IgG and IgM) in-house assay. LAC positivity was confirmed by either dRVVT Confirm (American Diagnostica) or by the STACLOT LA (Diagnostica Stago) tests (3% of samples were positive for dRVVT only and 94% were positive for STACLOT only, 3% were positive for both).

Results:

	aPS/PT IgG	aPS/PT IgM	aPS/PT Screen	aPT IgG	aPT IgM
# of positive samples (%)	43/150 (29%)	33/150 (22%)	32/150 (21%)	44/150 (29.3%)	39/150 (26%)

All negative LAC samples were negative in the anti-PS/PT and anti-PT tests. 125/150 (83%) of all LAC positive samples were positive in at least one of the PS/PT or PT ELISA. There was no correlation between any of the tests and LAC Staclot delta values or dRVVT ratios and the PT/PS or PT tests. Strong correlation was observed between anti-PS/PT IgG or IgM and LAC Anti-PS/PT screen test.

Conclusions: PS/PT and PT antibodies altogether recognize the majority of LAC positive samples and may represent an additional specific serological laboratory marker to confirm diagnosis of Antiphospholipid Syndrome.

The Influence of Thrombovascular Events on the Quality of Life in APS and SLE Patients. Amaris K. Balitsky, Valentina Peeva, Jiandong Su, Erik Yeo, Carol Landolt-Marticorena, Dafna D. Gladman, Murray B. Urowitz and Paul R. Fortin. University of Toronto Antiphospholipid Clinic, Division of Rheumatology, Toronto Western Hospital

Objective: The antiphospholipid syndrome (APS) is defined by the presence of antiphospholipid antibodies (aPLs) with clinical manifestations such as: venous or arterial thrombosis or recurrent pregnancy complications. The syndrome is either primary, or secondary due to an underlying condition, most commonly systemic lupus erythematosus (SLE). The purpose of this study was to describe and compare the characteristics and quality of life (QoL) of patients with previous thrombovascular events (TE) to those with no TE. To analyze the data, we used t-tests and one-way ANOVAs with Bonferroni post-hoc tests.

Methods: Five patient groups followed at the University of Toronto SLE and APS clinics were defined as patients with: 1) (PAPS) primary APS, 2) (SAPS) APS secondary to SLE, 3) (SLE+TE) SLE patients who had a TE, but do not have positive aPLs, (i.e., do not have APS), 4) (SLE-TE+aPL) SLE without TE, but with a persistent positive aPL defined as anticardiolipin antibody of IgG and/or IgM > 40 GPL or MPL, on two or more occasions, at least 12 weeks apart, 5) (SLE-TE) SLE without TE, and without aPL. QoL was determined using the mental component score (MCS) and the physical component score (PCS) of the Medical Outcomes Study Short Form 36 (SF-36) at the most recent visit. To analyze the data, we used t-tests and one-way ANOVAs with Bonferroni post-hoc tests.

Results: The table summarizes the data and marks significant differences with an asterisk. Mean age at the time of the questionnaire completion was similar across the five groups, except for a younger average age (42.9 years) in the SLE-TE group ($p<.05$). A high majority of patients were female across all groups, with a smaller majority (60.5%) in the PAPS group. There were more venous TEs in the PAPS group (65.8%) compared to the SAPS group (30.8%); however, the overall number of patients with arterial and venous TEs was similar. Patients with arterial events (44.7 ± 11.5) scored lower than patients with venous events (49.2 ± 11.6) in the MCS score ($t(149.5) = -2.4$, $p = .02$); however there was no difference in PCS scores between arterial and venous TE. There was a difference in PCS scores across the five groups ($F(4,897) = 3.33$, $p<.05$); however there was no difference in MCS scores. Patients in the SLE+TE group showed lower scores compared to the PAPS and SLE-TE+aPL groups (table). SLE+TE patients also scored lower on a number of QoL subscales.

Conclusions: It appears that the combination of two severe conditions, SLE and thrombotic events, has a more negative influence on reported PCS, compared to having SLE or APS alone. This influence was not seen for the MCS score.

Group	N	Age	Sex (% F)	TE type (% v)	MCS	PCS
PAPS	38	47.5 ± 15.4	60.5	65.8	48.6 ± 12.5	43.5 ± 11.1*
SAPS	39	54.8 ± 15.0	92.3	30.8	47.1 ± 10.9	38.6 ± 13.8
SLE+TE	79	51.1 ± 15.8	84.8	50.6	46.0 ± 11.7	36.5 ± 12.15*
SLE-TE+aPL	79	51.1 ± 16.8	84.8	n.a.	47.3 ± 12.2	42.5 ± 13.8*
SLE-TE	667	42.9 ± 15.2*	90.1	n.a.	46.9 ± 11.6	40.4 ± 12.2

Utility of Anti-Phosphatidylserine/Prothrombin and IgA Antiphospholipid Assays in Antiphospholipid Syndrome. Ehtisham Akhter[3], Walter L. Binder[2], Zakera Shums[2] and Michelle A. Petri[1]. [1]Timonium, MD, [2]Inova Diagnostics Inc, San Diego, CA, [3]Johns Hopkins University, Baltimore, MD

Purpose: Currently three antiphospholipid assays are in wide use clinically (lupus anticoagulant, anticardiolipin (aCL), and anti-beta2 glcyoprotein I (anti-beta2 GPI)). The lupus anticoagulant is the most specific assay, conferring the highest risk of thrombosis and pregnancy loss, but it cannot be validly performed in an anticoagulated patient. We investigated anti-phosphatidylserine/prothrombin (anti-PS/PT), which detects most lupus anticoagulants, in terms of its association with thrombosis. We also investigated the utility of IgA assays for APS in SLE.

Methods: Stored samples from SLE patients with and without past thrombosis were assayed for anti-beta2 GPI (IgG/IgM/IgA), Domain 1 (IgG) and Domain 4/5 (IgA), aCL (IgG/IgM/IgA) and anti-PS/PT (IgG, IgM and IgG/M).

Results: For any thrombosis, the highest association was with aCL IgA, followed anti-beta2 GPI IgG and anti-beta2 GPI IgA. Anti-PS/PT IgG, IgM and IgG/M were similar (Table 1).

Table 1: Any Thrombosis

		Thrombosis (n = 160)	No thrombosis (n = 166)		
	Assay	Number (% positive)	Number (% positive)	Odds Ratio 95% CI	P-value
IgG	beta2 GPI	18 (5.5%)	6 (3.6%)	3.4 (1.3, 8.7)	.0083
	beta GPI Domain 1	11 (6.7%)	9 (5.4%)	1.3 (0.5, 3.2)	.5845
	Anticardiolipin	22 (13.8%)	16 (9.6%)	1.5 (0.8, 3.0)	.2475
	PSPT	26 (16.3%)	14 (8.4%)	2.1 (1.1, 4.2)	.0315
IgM	beta2 GPI	8 (5.0%)	9 (5.4%)	0.9 (0.3, 2.4)	.8641
	Anticardiolipin	18 (1.3%)	15 (9.0%)	1.3 (0.6, 2.6)	.5077
	PSPT	42 (26.3%)	26 (15.7%)	1.9 (1.1, 3.3)	.0187
IgA	beta2 GPI	48 (30.0%)	24 (14.5%)	2.5 (1.5, 4.4)	.0007
	Anticardiolipin	10 (6.3%)	2 (1.2%)	5.5 (1.2, 25.4)	.0156
	beta2 GPI D4/5	35 (21.9%)	28 (16.9%)	1.4 (0.8, 2.4)	.2523
IgG/M	PSPT	38 (23.8%)	24 (14.5%)	1.8 (1.0, 3.2)	.0326

For venous thrombosis, the highest association was again with aCL IgA, followed by anti-beta2 GPI IgG, and then anti-PS/PT IgG and IgG/M (Table 2).

Table 2: Venous Thrombosis

	Assay	Thrombosis (n = 102) Number (% positive)	No thrombosis (n = 224) Number (% positive)	Odds Ratio 95% CI	P-value
IgG	beta2 GPI	15 (14.7%)	9 (4.0%)	4.1 (1.7, 9.8)	.0006
	beta2 GPI Domain 1	9 (8.8%)	11 (4.9%)	1.9 (0.8, 4.7)	.1722
	Anticardiolipin	17 (16.7%)	21 (9.4%)	1.9 (1.0, 3.8)	.0571
	PSPT	21 (21.0%)	19 (8.5%)	2.8 (1.4, 5.5)	.0020
IgM	beta2 GPI	6 (5.9%)	11 (4.9%)	1.2 (0.4, 3.4)	.7145
	Anticardiolipin	13 (12.8%)	20 (8.9%)	1.5 (0.7, 3.1)	.2895
	PSPT	27 (26.5%)	41 (18.3%)	1.6 (0.9, 2.8)	.0924
IgA	beta2 GPI	31 (30.4%)	41 (18.3%)	1.9 (1.1, 3.3)	.0147
	Anticardiolipin	8 (7.8%)	4 (1.8%)	4.7 (1.4, 15.9)	.0111
	beta2GPI D4/5	20 (19.6%)	43 (19.2%)	1.0 (0.6, 1.9)	.9305
IgG/M	PSPT	29 (28.4%)	33 (14.7%)	2.3 (1.3, 4.1)	.0035

For Stroke, the only assay with a significant association was antibeta2 GPI Domain 4/5 (32.7% vs. 17%, OR 2.4, p=0.01)

Conclusion: The importance of IgA isotypes (beta2GPI, aCL) in secondary antiphospholipid syndrome has not been previously recognized. We also found that IgA antibeta2 glycoprotein domain 4/5 was associated with stroke. Domain 1 IgG is not important in secondary APS. Anti-PS/PT, either IgG or IgG/M, is a promising alternative to coagulation assays to detect the lupus anticoagulant

BAFF Expression Correlates with Idiopathic Inflammatory Myopathy Disease Activity Measures, Interferon Signature and Autoantibodies. Kelly T. McNallan[1], Hatice Bilgic[3], Cynthia S. Crowson[2], Steven R. Ytterberg[2], Shreyasee Amin[2], Peterson J. Erik[3], Emily C. Baechler[3] and Ann M. Reed[2]. [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, [3]University of Minnesota

Background: We have previously reported increased mRNA levels of B cell survival cytokines, B cell activating factor (BAFF) and its splice isoform transcript ΔBAFF, in blood cells of patients with idiopathic inflammatory myopathies (IIM.) Elevated BAFF and BAFF receptor levels influence increased survival of autoreactive B cells. We therefore investigated the relation of disease activity, autoantibody profiles and interferon pathway activation in IIM to B cell survival cytokines [BAFF, ΔBAFF and a proliferation inducing ligand (APRIL)] and their receptor expressions [BAFF receptor (BAFFR), transmembrane activator and calcium-modulator and cyclophilin ligand interactor (TACI) and B cell maturation antigen (BCMA)].

Methods: RNA was extracted from whole blood in 108 IIM subjects (74 adult and juvenile dermatomyositis, 25 polymyositis and 9 inclusion body myositis). Gene expression of BAFF, ΔBAFF, APRIL, BCMA, TACI, BAFFR and three type I interferon (IFN)-regulated genes were measured by quantitative real-time RT-PCR. The whole-blood IFN gene expression signature was defined by average expression levels of 3 IFN-regulated genes (G1P2, IFIT1 and IRF7). Autoantibodies including Jo-1, Scl-70, Ribosome P, Chromatin, Sm, RNP, SSA, SSB were measured on the Luminex platform. Disease activity was assessed using visual analog scale (VAS) ratings defined by the International Myositis Assessment and Clinical Research (IMACS) group. Associations of gene expression with IFN gene score, disease activity measures and autoantibodies were assessed by Spearman correlation analysis.

Results: We find a positive correlation of BAFF and ΔBAFF expression with disease activity measures, including the global VAS score, muscle VAS score and extraskeletal muscle VAS score. Elevated BAFF and ΔBAFF expression also correlate with increased IFN gene scores. Furthermore, we find IIM subjects with autoantibodies to SSA, SSB or any RNA-binding protein (SSA, SSB, RNP and Sm) have increased expression of BAFF and ΔBAFF. APRIL, BAFFR, TACI and BCMA expression did not correlate with disease activity measures, autoantibodies or IFN score.

	BAFF	ΔBAFF
Extraskeletal muscle VAS score	r=0.32, p=0.001	r=0.47, p<0.0001
Muscle VAS score	r=0.25, p=0.01	r=0.35, p<0.001
Global VAS score	r=0.34, p<0.001	r=0.52, p<0.0001
IFN score	r=0.28, p=0.02	r=0.31, p<0.009
Autoantibodies		
SSA	r=0.23, p=0.02	r=0.30, p=0.001
SSB	r=0.30, p=0.001	r=0.28, p=0.003
Any RNA binding protein	r=0.26, p=0.007	r=0.32, p<0.001

Conclusion: Our findings suggest that in IIM, elevated BAFF and/or ΔBAFF expression may be predictive of increased disease activity, increased type 1 interferon regulated gene expression and presence of antibodies to autoantigens SSA, SSB or any RNA-binding protein. Further work is needed on the potential role of BAFF and/or ΔBAFF expression serving as markers of disease activity or treatment response in IIM.

Blockade of TLR2 Prevents Spontaneous and Induced Cytokine Release from Rheumatoid Arthritis Ex Vivo Synovial Explant Cultures. Sinead Nic An Ultaigh[1], Tajvur Saber[1], Jerome Dellacasagrande[2], Brian Keogh[2], William McCormack[2], Mary Reilly[2], Luke O' Neill[2], Peter McGuirk[2], Ursula Fearon[1] and Douglas J. Veale[1]. [1]Dublin Academic Medical Centre, Dublin, Ireland, [2]Opsona Therapeutics Ltd, Dublin, Ireland

Objective: Toll-like receptors are involved in activation of the immune system by triggering release of inflammatory cytokines that can contribute and/or perpetuate inflammation, and have been implicated in autoimmune diseases such as Rheumatoid Arthritis (RA). The aim of this study is to examine the effect of blocking Toll-like receptor 2 (TLR2) in RA synovial cells.

Methods: RA synovial tissue (ST) biopsies, obtained under direct visualization at arthroscopy, were established as synovial explant cultures ex vivo or snap frozen for immunohistology. Mononuclear cell cultures were isolated from peripheral blood (PB) and synovial fluid (SF) of RA patients. Cultures were incubated with the TLR1/2 ligand, Pam3CSK4 (200ng, 1 and 10μg/ml), an anti-TLR2 antibody (OPN 301, 1μg/ml) or an IgG (1μg/ml) matched control. The comparative effect of OPN301 and Humira on spontaneous release of proinflammatory cytokines from RA synovial explants was determined using quantitative cytokine MSD multiplex assays or ELISA. OPN301 penetration into RA synovial tissue explants cultures was assessed by immunohistology.

Results: Pam3CSK4 significantly upregulated IL-6 and IL-8 in RA PBMCs, RA SFMCs and RA synovial explant cultures ($p<0.05$). OPN301 significantly decreased Pam3CSK4-induced cytokine production of TNF-α, IL-1, IL-6, IFN-γ and IL-8 compared to IgG control in RA PBMCs and SFMCs cultures (all $p<0.05$). OPN301 penetration of RA synovial tissue cultures was demonstrated, with expression localized to the lining layer and perivascular regions. OPN301 significantly decreased spontaneous cytokine production of TNF-α, IL-1, IFN-γ and IL-8 from RA ST explant cultures (all $p<0.05$). Importantly, the inhibitory effect of OPN on spontaneous cytokine secretion was comparable to inhibition by anti-TNF mAb Humira.

Conclusion: Our findings further support targeting TLR2 as a potential therapeutic agent for the treatment of RA.

CCL15/Leukotactin-1: A Novel Mediator of Rheumatoid Arthritis Fibroblast-Like Synoviocyte Migration Via CCR3 and MAP Kinases. Eric K. Owens[1], Karolina Klosowska[2], Michael V. Volin[2], Brian Zanotti[2] and James M. Woods[2]. [1]Midwestern University, Downers Grove, IL, [2]Midwestern University

Background: Rheumatoid arthritis (RA) fibroblast-like synoviocytes (FLS) play a key role in mediating inflammation and joint destruction. CCL15 has previously been shown to be expressed in RA synovial tissue and synovial fluids. CCL15 has been characterized to interact with its receptors, CCR1 and CCR3, where the former serves as a weak agonist and the latter serves more potent functions. We hypothesized that CCL15 induces RA FLS migration and proliferation, acting through CCR1 and/or CCR3, and signaling through mitogen-activated protein (MAP) kinases.

Methods: FLS were derived from hip or knee synovial membrane at the time of joint replacement due to RA with IRB approval, and were subsequently analyzed using Alexa Fluor 488 Phalloidin staining of F-actin, proliferation assays, chemotaxis assays, and flow cytometry. In addition, we used MAP kinase inhibitors in combination with chemotaxis assays to determine whether MAP kinase signaling was required for CCL15-induced RA FLS migration.

Results: Evaluation of F-actin staining subsequent to CCL15 stimulation demonstrates significant reorganization of the cytoskeletal structure. When stimulated with 1 or 10 nM CCL15, maximal cytoskeletal rearrangement occurs after 2 to 3 hrs, consistent with the slow migration associated with fibroblasts. Chemotaxis assays demonstrate that CCL15 is a novel chemoattractant for RA FLS, effectively inducing migration of all 4 RA patients that we tested ($p<0.05$). Concentrations of 1 to 50 nM CCL15 induced migration that was significantly higher than background, however, similar concentrations of CCL15 had no effect on RA FLS proliferation. Flow cytometry demonstrates that a significant number of RA FLS express CCR3 but not CCR1. On average, 73% of RA FLS express CCR3. Consistent with CCR3 being a G protein coupled receptor, pertussis toxin (PTX) completely abolishes CCL15-induced migration. Finally, pre-incubation of FLS with a MEK 1/2 inhibitor (U0126), the kinase which activates ERK 1/2, significantly decreased chemotaxis induced by CCL15 in RA FLS derived from 2 of 3 patients. Similarly, pre-incubation of cells with a JNK inhibitor (SP600125) likewise decreased CCL15-induced migration in FLS from 2 of 3 patients.

Conclusions: Our results suggest the novel finding that CCL15 regulates the migration and cytoskeletal structure of RA FLS. Migration is likely induced by a G protein (Gi/Go) coupled receptor, since this event is inhibited by PTX. To our knowledge, these are the first results to suggest that RA FLS express CCR3. Finally, migration of RA FLS from some patients can be significantly decreased by inhibiting the ERK and JNK pathways.

Chronic Exposure to IL-6 Amplifies Macrophage Response to Toll-Like Receptor (TLR) Ligands. Raffaele Strippoli[1], Francesco Carvello[2], Loredana De Pasquale[2], Luisa Bracci-Laudiero[2] and Fabrizio de Benedetti[2]. [1]IRCCS Ospedale Pediatrico Bambino Gesu, Rome, Italy, [2]IRCCS Ospedale Pediatrico Bambino Gesu, Rome, Italy

Background: High levels of IL-6 are a characteristic feature of chronic inflammatory arthritis. Little is known on the effect of IL-6 on innate immune responses in particular regarding TLR activation mediated by both endogenous and exogenous TLR ligands, the latter being important in the relation between infections and exacerbations. In this study, we analyzed whether prolonged exposure of mouse and human macrophages to IL-6 affects inflammatory cytokine and chemokine production upon stimulation with TLR ligands and the activation of signalling pathways involved in this event.

Methods: Splenocytes and peritoneal macrophages were isolated from IL-6 transgenic or wild tipe (WT) mice. These cells were stimulated with different TLR ligands, such as LPS, LTA, poly I:C or CpG. Cytokine production was measured by ELISA on cell supernatants or by RT-PCR on total RNA from cell lysates. Activation status of STAT3, ERK MAPK, NF-kappaB vas measured by western blot from cell lysates or by confocal analysis on fixed cells. Human peripheral blood derived macrophages were treated for 4 days in presence of IL-6 plus IL-6 soluble Receptor (sIL-6R) and then stimulated with LPS. Cells were then analyzed as above.

Results: Treatment of splenocytes from IL-6 transgenic mice with different TLR ligands led to increased production of inflammatory cytokines, such as IL-1 beta, TNF alpha, IL-6, with respect to cells from WT mice. This was accompanied by increased phosphorylation of STAT3, ERK and by increased NF-kappaB nuclear translocation. Human macrophages treated with IL-6 plus sIL-6R and then stimulated with LPS showed also increased expression of cytokines, such as IL-1 beta, and chemokines such as IL-8 and a similar increased activation of stimulatory pathways. IL-6 transgenic mice treated with LPS showed increased lethality and higher levels of IL-1 beta, TNF-alpha and IL-6 than WT mice.

Conclusions: Our results show that prolonged exposure to IL-6 alters the response of macrophages to TLR ligands suggesting that signals from IL-6 and from TLR cooperate in the amplification of the inflammatory response. Our data also show the presence of a positive amplification loop between IL-1 beta and IL-6. These results suggest that IL-6 may contribute, on the one hand, to the amplification of chronic inflammation and, on the other, to abnormal responses to infectious agents that may trigger clinical relapses or an acute manifestation such as macrophage activation syndrome in the course of systemic JIA.

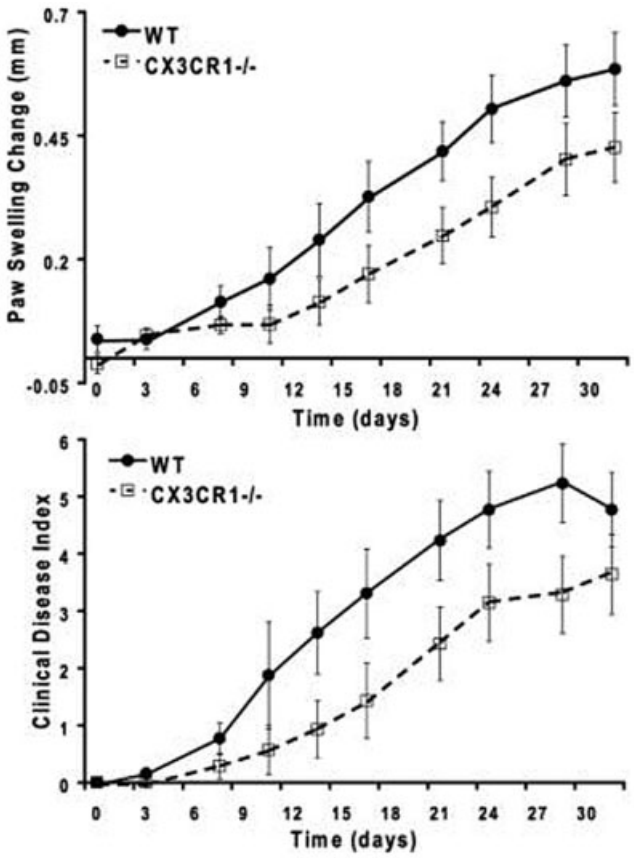
CX3CR1 Deficient Mice Have Decreased Th17 and Antigen-Specific Humoral Responses in the Collagen Induced Arthritis (CIA) Model. Teresa K. Tarrant[2], Peng Liu[3], Rishi Rampersad[3], Denise Esserman[3], Lisa Rothlein, Marcus W. McGinnis[3], David J. Fitzhugh[3], Dhavalkumar D. Patel[1] and Alan M. Fong[3]. [1]Novartis Pharma AG, Basel, Switzerland, [2]UNC School of Medicine, Chapel Hill, NC, [3]UNC School of Medicine

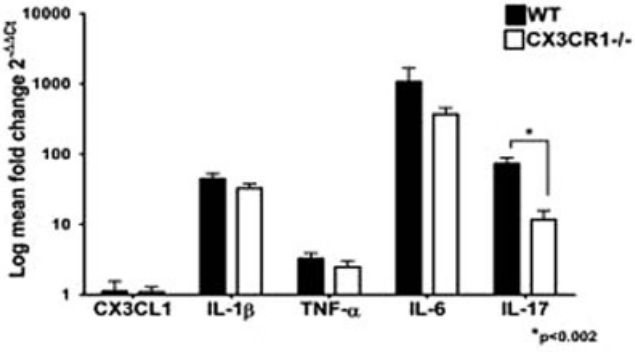
Objective: CX3CR1 is a chemokine receptor that uniquely binds to its ligand fracktalkine (FKN or CX3CL1) and has been shown to be important in inflammatory arthritis responses, largely due to effects on cellular migration. In this study, we tested the hypothesis that genetic deficiency of CX3CR1 would be protective in the chronic inflammatory arthritis model, collagen induced arthritis (CIA). Because CX3CR1 is expressed on T cells and antigen-presenting cells, we additionally examined adaptive immune functions in this model.

Methods: Autoantibody formation, clinical, histologic, T cell proliferative, and cytokine responses were evaluated in DBA-1J mice deficient in (−/−) or wildtype (+/+) for CX3CR1 after immunization with heterologous type II collagen.

Results: CX3CR1−/− mice had an approximately 30% reduction in arthritis by two independent measures of paw swelling ($p<0.01$) and clinical disease index($p<0.0001$).



CX3CR1−/− mice had an approximate 50% decrease in anti-type II collagen antibody formation ($p<0.05$). Additionally, CX3CR1−/− mice had a unique 5-fold decrease in intra-articular levels of IL-17 ($p<0.002$), as measured by RT-PCR, despite a preserved capacity to induce Th17 de novo responses *in vitro*.



Proinflammatory MMP-13 and cytokines IL-6, IL-1β, and TNF-α were reduced in CX3CR1−/− mice, but were not statistically significant.

Conclusions: Deficiency of CX3CR1 is protective in inflammatory arthritis and may have effects that extend beyond migration that involve adaptive immune responses.

Cytokine Expression in Synovial Tissue of Psoriatic Arthritis and Its Relation to Lymphoid Neogenesis, Erosive Disease and Disease Activity: A Longitudinal Study. Raquel Celis[1], Julio Ramírez[1], Raimon Sanmarti[1], José L. Pablos[2] and Juan D. Cañete[1]. [1]Servicio Reumatología, Hospital Clinic and IDIBAPS, Barcelona, Spain, [2]Unidad de Investigación, Hospital 12 de Octubre, Madrid, Spain

Objective: To analyse the expression of a wide range of cytokines in synovial tissue (ST) of patients with psoriatic arthritis (PsA) and its relation with synovial lymphoid neogenesis (LN), erosive disease and EULAR response to therapy.

Methods: ST samples were obtained by needle arthroscopy from the inflamed knee joint of 30 patients fulfilling the CASPAR criteria for PsA. Five samples from each patient were paraffin-embedded and sections were immunostained with CD3 (T cell), CD20 (B-cell) and MECA-79 (high endothelial vessels).

Total RNA was extracted from ST samples from 30 patients and from 2 controls without synovial inflammation following the recommendations of the Rneasy FFPE Kit (Qiagen). mRNA was measured by TaqMan Gene Expression Assay (Applied Biosystem). Relative changes in gene expression were assessed by comparative analysis of quantitative PCR by the delta-delta Ct method using GAPDH as a endogenous control gene. The following genes were analysed: CCR7, Lymphotoxin (LT)-beta, IL-7, IL-10, IL-1beta, IL-6, TNF-alpha, IL-17 A, IL-21, IL-22 and IL-23. Data were collected at inclusion and at the end of follow-up.

Results: Clinical and demographic data of patients are in Table 1.

Table 1. Clinical and demographic data of PsA patients (n=30) at time of arthroscopy*

Age (years) at time of arthroscopy	47	(*37; 60*)
Disease duration before arthroscopy (months)	110	(*30; 170*)
Time of follow-up after arthroscopy (months)	35	(*22:45*)
Tender Joint Count	2	(*1; 2*)
Swollen Joint Count	2	(*1; 3*)
CRP (mg/dL)	1.77	(*0.30; 5.51*)
ESR (mm/1st hour)	18.5	(*8; 52*)
ACPA (UI/mlL) (n, positive > 25)	0	
Rheumatoid Factor (UI/ml) (n, positive >20)	2	
DAS28 3v	3.63	(*2.73; 4.59*)
Joint Pattern		
Polyarthritis; n (%)	11	*36.7*
Oligoarthritis, n (%)	19	*63.3*
Type of Psoriasis		
Type I (<40 years), n (%)	22	*70.3*
Type II (>40 years), n (%)	8	*29.7*

* Data are expressed as median and IQR. CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; ACPA: anti-citrullinated peptide/protein antibodies; DAS: disease activity score.

LN. Twelve out of 30 patients (40%) had LN. These patients had significantly higher expression of CCR7 and LT-beta than patients without LN ($p<0.005$ and $p<0.04$, respectively). LN positive patients had a trend to higher IL-23 ($p=0.051$) and TNF-alfa ($p=0.075$) expression than patients LN negative. There was no association between LN and clinical or biological variables.

Erosive disease. Fifteen out of 30 (50%) of patients had erosive disease at end of follow-up. Disease duration, DAS28, PCR and SJC at inclusion were all correlated with erosive disease ($p<0.05$).

Disease activity. There was a positive correlation between IL-6 expression and SJC, CRP and DAS28 at inclusion ($p=0.02$, $p=0.001$ and $p=0.034$, respectively) and between IL-1b expression and CRP levels at inclusion ($p=0.015$). We found also a strong negative correlation between IL-10 expression at inclusion and ESR levels ($p=0.008$).

Conclusion: PsA patients with LN have a different profile of cytokine expression in ST compared with patients without LN, with significantly higher expression of CCR7, LT-beta, which are implicated in the follicular organization, and higher expression of IL-23, a relevant cytokine in joint inflammation and damage. Also IL-6 and IL-1 are positively and IL-10 negatively correlated with markers of inflammation and/or disease activity.

DNA Hypomethylation Upregulates CXCL12 in Rheumatoid Arthritis Synovial Fibroblasts. Emmanuel Karouzakis[1], Yvonne Rengel[1], Astrid Jüngel[1], Christoph Kolling[3], Renate E. Gay[1], Beat A. Michel[1], Paul P. Tak[2], Steffen Gay[1], Michel Neidhart[1] and Caroline Ospelt[1]. [1]Center of Experimental Rheumatology and Zurich Center of Integrative Human Physiology (ZIHP), University Hospital Zurich, [2]Department of Clinical Immunology and Rheumatology, University of Amsterdam, [3]Schulthess Clinic, Zürich

Objective: Previously we described global genomic hypomethylation in rheumatoid arthritis synovial fibroblasts (RASF). Now, we searched for specific genes that are induced by DNA hypomethylation in RA. Since CXCL12 was reported to be upregulated in RA, we investigated its expression in SF as well as the DNA methylation status of its promoter and determined the contribution of this chemokine to the expression of matrix metalloproteinases (MMPs).

Methods: DNA was isolated from SF and methylation was analysed by bisulphite sequencing. CXCL12 protein was quantified by ELISA before and after treatment with the DNA hypomethylator 5-azacytidine. RASF were stimulated with CXCL12 recombinant protein (100 ng/ml). Expression of MMPs was analysed by Real-time PCR.

Results: Basal expression of CXCL12 was higher in RASF (85±12 pg/ml, n=9, $p<0.05$) than osteoarthritis (OA) SF (52±10 pg/ml, n=7). In normal SF (n=1), the promoter region −477 to −741 had a CpG methylation percentage of 52%. In OASF treated with different concentrations of 5-azacytidine (0, 0.5 and 1 μM), the percentage of CpG methylation in the 1μM 5-azaC treated cells was reduced (0 μM: 45.2±11.2% and 1 μM: 15.0±3.3% percentage of CpG methylation of 6 clones). CXCL12 protein expression was dose dependently upregulated (0 μM: 29.3±5.3 pg/ml, 0.5 μM: 41.6±4.9 pg/ml, 1 μM: 53.0±6.1, n=4, $p<0.05$). A lower percentage of CpG methylation was found in the CXCL12 promoter of RASF (21.0±7.2%, percentage of methylation of 9 clones per pool of 4 patients) compared to OASF (42.0±7.8%, percentage of CpG methylation of 9 clones per pool of 3 patients, $p<0.05$). Stimulation of RASF (n=6) with CXCL12 significantly increased the expression of MMP-1 (6±3 fold), MMP-3 (2±0.2 fold) and MMP-13 (4±1 fold) ($p<0.05$).

Conclusion: We show here that RASF produce more CXCL12 than OASF due to promoter hypomethylation and that stimulation with CXCL12

induces the expression of MMPs in SF. Thereby we describe an endogenously activated pathway in RASF which promotes joint destruction.

22

Downregulation of the Chemokine Receptor CX3CR1 in Active RA Associated with a Pro-Osteoclastognic Phenotype. Grainne Murphy[1], John Ryan[1], Harney Sinead[1], Fergus Shanahan[1], Michael Molloy[1] and Noel Caplice[2]. [1]Cork University Hospital, Cork, Ireland, [2]University College Cork, Cork, Ireland

Monocytes are the primary source of inflammatory cytokines in RA. They can be further defined by their surface expression of CD14 and CD16.CD16+cells are more inflammatory in nature and possess discordantly high surface CX3CR1, the receptor for the chemokine fractalkine (FKN). The interaction of FKN with CX3CR1 contributes to the chemotaxis and transmigration of the CD16+ monocytes and subsequent cytokine release. The FKN-CX3CR1 interaction has been implicated in the pathological T cell response in RA, however little is known about this relationship in monocytes, despite CX3CR1s ubiquitous expression.

Objective: To characterize the expression of CX3CR1 on monocyte sub-populations in early and established RA. To assess the functional consequences of FKN interactions with CX3CR1 in relation to osteoclastogenesis and cytokine release.

Methods: We recruited 83 subjects with early (21), established active (46) or inactive RA (16) and 13 healthy controls as a comparator group. Monocyte subsets (CD14+CD16- and CD14+CD16-) were defined by flow cytometry and CX3CR1 surface expression was determined by its Relative Fluorescent Intensity(RFI). Soluble FKN(sFKN) was quantified in peripheral blood (PB) and synovial fluid (SF) by ELISA. The effect of membrane-bound FKN (mbFKN) on osteoclast differentiation of monocyte subsets was assessed in vitro. Serum from subjects with the combination of elevated CD16+ monocytes and increased sFKN were analysed using a multiplex cytokine array and compared with controls.

Results: The CD16+ monocyte subset was expanded in the active RA groups [early, mean (+/−SEM) 24.22% (3.9) and active RA, 21.99% (2.61] in comparison with inactive disease 12.9% (2.2), $p=0.04$, and healthy controls 11.1% (0.89), $p=0.03$. Furthermore, individuals with elevated CD16+ monocytes and increased sFKN had significantly more circulating Il1a,-1b,-2,-10 and TNFα than controls.

CX3CR1 surface expression was down-regulated on CD16+ monocytes in established RA but not in early arthritis, $p=0.004$. Downregulation of CX3CR1 on the osteoclast progenitor CD16- sub-population was restricted to active RA, $p<0.005$. Similarly in active RA there was a significant increase in serum and SF sFKN, $p=0.02$. CX3CR1 down-regulation was replicated in vitro by co-incubation with sFKN. MbFKN significantly enhanced the osteoclastogenesis of the CD16-monocyte subset ($p<0.0001$) potentially mediated by a decrease in CX3CR1 surface expression.

Conclusion: These findings support the presence of a unique monocyte phenotype in established RA. The downregulation of CX3CR1 on osteoclast precursors is mediated by the inteaction with FKN. In addition the pro-osteoclastogenic effect of mbFKN strongly supports that this chemokine partnership is critical to the erosive process in RA.

Downstream Targets of IL-17 in Rheumatoid Arthritis. Sarah R. Pickens[4], Richard M. Pope[3], Michael V. Volin[1] and Shiva Shahrara[2]. [1]Midwestern University, [2]Northwestern Univ Feinberg, Chicago, IL, [3]Northwestern Univ Med School, Chicago, IL, [4]Northwestern University

Introduction: IL-17 plays an important role in the pathogenesis of rheumatoid arthritis (RA) since anti-IL-17 therapy ameliorates the clinical symptoms of RA. However, the downstream targets of IL-17 are undefined in RA.

Purpose: Studies were performed to identify the downstream targets of IL-17 in human microvascular endothelial cells (HMVECs), macrophages and RA synovial tissue (ST) fibroblasts, and subsequently the expression of the identified factors were confirmed in RA ST explants.

Methods: HMVECs, peripheral blood in vitro differentiated macrophages and RA ST fibroblasts were treated with IL-17 for 0–8h. Real-time RT-PCR was used to identify IL-17-induced downstream molecules in these cell types. Next, expression of IL-17-induced factors was verified by real-time RT-PCR in RA ST explants that were activated with IL-17.

Results: Genes differentially regulated by IL-17 in HMVECs were neutrophil chemokines such as CXCL1, CXCL2, CXCL3, CXCL12 and monocyte chemokines including CCL7, CCL20 and CXCL16 and adhesion molecule VCAM1. Similarly, IL-17 was able to modulate neutrophil (CXCL1, CXCL3 and CXCL5) and monocyte (CXCL16, CCL20 and CCL2) chemokines in peripheral blood in vitro differentiated macrophages. In RA ST fibroblasts, in addition to neurophil (CXCL1, CXCL2, CXCL3 and CXCL5) and monocyte (CCL2, CCL7 and CCL20) chemokines, IL-17 greatly upregulated expression of proangiogenic factors such as VEGF and FGF. Further, to determine which of these factors may play an important role in the pathogenesis of RA, IL-17-activated RA ST explants were screened for the identified molecules. Factors that were induced by IL-17 in two or more cell types were highly upregulated in RA ST explants compared to those expressed in only one cell type. Among the factors that were greatly induced by IL-17 in RA ST explants were CXCL1 (150 fold increase), CXCL3 (10 fold increase), CXCL5 (360 fold increase), CCL2 (20 fold increase), CCL7 (14 fold increase) and CCL20 (30 fold increase). Since neutrophil and monocyte chemokines are strongly induced by IL-17 in the RA synovium, cell trafficking may be an important mechanism by which IL-17 contributes to inflammation.

Conclusion: These results suggest that IL-17 may play an important role in acute and chronic inflammation seen in patients with RA in part through promoting neutrophil and monocyte migration. Therefore, the decrease in clinical symptoms seen with anti-IL-17 treatment of RA may be in part due to this decrease in leukocyte migration.

Elevated BLyS Levels Are Associated with an Increase in Autoantibody Specificites and ANA Titer in Systemic Lupus Erythematosus. Lauren L. Ritterhouse[3], Amanda R. Moyer[3], Virginia C. Roberts[2], Amy B. Dedeke[2], Sherry R. Crowe[3], Gillian M. Air[4], Linda F. Thompson[3], Joel M. Guthridge[3] and Judith A. James[1]. [1]Oklahoma Med Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Oklahoma Medical Research Foundation, [4]University of Oklahoma Health Sciences Center

B Lymphocyte Stimulator (BLyS) is a cytokine that belongs to the TNF ligand family, and has been shown to play an important role in the proliferation and differentiation of B cells. Elevated serum levels of BLyS have been demonstrated in autoimmune disease patients, including those with SLE. BLyS is hypothesized to contribute to SLE pathogenesis by affecting survival signals and apoptosis of autoantibody-producing B cells. In this study we seek to investigate the relationship between serum BLyS levels and humoral autoimmunity, as well as the effect of serum BLyS on an antigen-specific humoral immune response.

This study enrolled 61 female SLE patients who met ACR criteria. BLyS levels were measured by a quantitative sandwich enzyme immunoassay. Lupus-associated autoantibodies (Ro, La, Sm, nRNP, ribosomal P, dsDNA, ANAs and phospholipid antibodies) and influenza vaccination humoral immune response parameters including Bmax (relative amounts of anti-influenza antibodies against native antigen), Ka (relative affinity), and hemagglutination inhibition (relative protective antibody response) were measured. SLE patients were given a cumulative index score based on these three vaccination response parameters and classified as being either a “high responder” (greater than the median cumulative index score) or a “low responder” (less than the median cumulative index score).

African Americans (AA, $n=24$) had significantly ($p=0.021$, unpaired t-test) higher serum BLyS levels than did European Americans (EA, $n=35$) (1649 ± 224 pg/mL in AA versus 1045 ± 144 pg/mL in EA). No differences were seen in BLyS levels between high responders to influenza vaccination ($n=31$) and low responders ($n=30$) ($p=0.72$, unpaired t-test). SLE patients with greater than or equal to 2 autoantibody specificities had higher BLyS levels than those patients with less than 2 specificities ($p=0.035$, unpaired t-test with Welch’s correction). Additionally, BLyS levels were increased in patients with an ANA titer of greater than 1:120 ($p=0.0012$, unpaired t-test with Welch’s correction). ACR classification criteria and disease activity measures were assessed in relation to serum BLyS levels. Increased serum

BLyS correlated with an increase in disease damage as measured by SLICC (r2=0.12, p=0.006), and an increase in disease activity as measured by PGA (r2=0.10, p=0.013), and SLAM (r2=0.07, p=0.046). Patients with the criteria discoid rash, proteinuria, and lymphopenia had higher serum BLyS levels than did those patients without these criteria (p=0.029, p=0.011, and p=0.008, respectively, unpaired t-test).

Increased serum BLyS levels were observed in African Americans, but were not associated with the ability to make a humoral response to influenza vaccination. Elevated BLyS levels were also associated with an increase in number of autoantibody specificities, as well as an increase in ANA titer. Additionally, increased disease activity measures correlated with increased serum BLyS levels. This evidence strongly supports the role for BLyS in humoral autoimmunity and SLE disease pathogenesis.

Elevated Levels of CXCL9 or CXCL10 in Sera of Patients with Early RA Predict Greater Difficulty in Achieving Remission during the First Year of Treatment. Gregory R. Emkey[5], Klemen Strle[6], Christopher R. Antolini[3], Deborah S. Collier[5], Margaret Seton[5], Arezou Khosroshahi[5], Mark Fisher[2], Nancy D. Kim[4], John H. Stone[1], Andrew D. Luster[4] and Allen C. Steere[5]. [1]Massachusetts General Hospital, Sudbury, MA, [2]Massachusetts General Hospital, Haddon Heights, NJ, [3]Massachusetts General Hospital, Denver, CO, [4]Massachusetts General Hospital, Charlestown, MA, [5]Massachusetts General Hospital, Boston, MA, [6]Massachusetts General Hospital

Purpose: The inflammatory immune response in patients with early rheumatoid arthritis (RA) is not well characterized. Depending on the series, dominant Th1-, Th2-, or Th17-type immune responses have been reported. We hypothesized that cytokine and chemokine levels, which act as indicators of these types of responses, may serve as biomarkers to help stratify subgroups of RA patients and predict their disease course. Here we report a preliminary analysis of a prospective study evaluating immune responses in early RA patients.

Methods: Patients who met EULAR criteria for RA, had symptoms for <12 months, and had not yet received DMARD therapy, were entered into the study and followed at 3, 6, and 12 months. They were treated with DMARDs, primarily methotrexate; and with a TNF inhibitor if the response was incomplete. At each visit, clinical parameters were determined (HAQ and DAS28 [CRP]), and serum samples and synovial fluid, if available, were collected. The levels of 20 cytokines and chemokines were determined in all samples at the same time using bead-based Multiplex assays. Elevated levels of each factor were defined as >2SD above the mean value of 40 control subjects.

Results: To date, 35 patients have been enrolled in the study; 30 patients have completed 3 months follow-up, and 12 have completed 12 months follow up. Of the 20 cytokines and chemokines measured, elevated levels of CXCL9 or CXCL10 (IFN-inducible chemoattractants for Th1 effector cells) or IL-23 (a marker for Th17 responses) were most common. In the initial visit, prior to DMARD therapy, 17 patients (49%) had elevated levels of CXCL9 or CXCL10, 17 (49%) had elevated IL-23 levels, and 26 (74%) had one or both of these responses. At study entry, patients who had elevated levels of CXCL9 or 10 had similar DAS28 scores (median, 5.2) as patients who did not have elevated levels of these chemokines (4.8). However, at the 3 month follow-up, patients with elevated levels of CXCL9 or 10 had a median DAS28 score of 3.1 compared with 2.2 in patients without elevated levels (P=0.03), and by 12 months, the 2 groups had diverged more (3.1 versus 1.25, P=0.004). Similar differences between the 2 groups were observed with HAQ scores. All 5 patients in whom it was possible to obtain joint fluid had elevated levels of both CXCL9 and 10 in serum and at least 10-fold higher levels of both chemokines in joint fluid. Elevated serum levels of IL-23 alone, without CXCL9 or 10, were not a risk factor for more severe disease.

Conclusions: Patients with early RA who had elevated serum levels of CXCL9 or CXCL10 prior to DMARD therapy had greater difficulty in achieving remission during the first year of treatment. This predictive information was not apparent from standard biomarkers of disease activity. Measurement of these chemokines at disease onset may help in the management of patients with early RA.

Elevated Serum CX3CL1 Levels in Adult-Onset Still's Disease: Potential Involvement in Hemophagocytic Syndrome. Tsuyoshi Kasama[1], Kumiko Ohtsuka[2], Michihito Sato[2], Ryo Takahashi[2], Kuninobu Wakabayashi[2] and Takeo Isozaki[2]. [1]Showa University School of Med, Shinagawa-ku Tokyo, Japan, [2]Showa University School of Med

Objective: Adult-onset Still's disease (AOSD) is a rare systemic inflammatory disease of unknown etiology characterized by chronic and fluctuant fever with accompanying rash, polyarthritis and involvement of multiple organs, especially lymphoid tissues. To investigate the prevalence of AOSD and its clinical characteristics, serum chemokines levels and the associated systemic manifestations, especially hemophagocytic syndrome (HPS), were assessed in patients complicated with AOSD.

Methods: Seventeen patients diagnosed with AOSD and 20 healthy controls were enrolled after obtaining informed consent, and clinical and laboratory findings were analyzed. Serial serum samples were collected from patients with active and inactive AOSD and from the controls, after which levels of the chemokines including CXCL8, CXCL10, CCL2 and CX3CL1, and soluble IL-2 receptor (sIL-2R) were determined by ELISA. Multivariate analysis was used to evaluate the correlation between serum chemokine levels and disease activity and the clinical features of AOSD.

Results: Serum CXCL8, CXCL10, CCL2 and CX3CL1 levels were significantly higher in patients with active untreated AOSD than in healthy controls. The elevated CX3CL1 levels seen in AOSD patients correlated positively with either CRP, sIL-2R or ferritin levels. While, there were no significant correlations between serum levels of the other chemokines and either CRP or ferritin. Among the 17 AOSD patients, 4 were complicated with HPS, and serum levels of both CX3CL1, sIL-2R and ferritin were significantly higher in AOSD patients with HPS than in those without HPS. Notably, serum CX3CL1 levels were significantly diminished following successful treatment and clinical improvement.

Conclusion: The serum CX3CL1 level may be a useful clinical marker of disease activity in AOSD. We suggest that especially high levels of CX3CL1 as well as either ferritin or sIL-2R reflect the presence of HPS, and that the association between chemokine profiles and distinct clinical manifestations reflects the heterogeneity of the pathogenesis of AOSD.

Gallic Acid Diminishes Cellular Proliferation and Pro-Inflammatory Gene Expressions in Fibroblast Like Synoviocytes from Patients with Rheumatoid Arthritis. Soo-Jin Chung[1], Tae-Yeon Kim[2], Yong-Jin Kwon[2], Yong-Beom Park[2], Soo-Kon Lee[2] and Min-Chan Park[3]. [1]Division of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, South Korea, [3]Division of Rheumatology, Yonsei University College of Medicine, Seoul, Korea, Republic of

Purpose: Gallic acid is the naturally occurring substance which is found in gallnuts, grapes, tea leaves, and oak bark. Gallic acid has been known as an antioxidant and to exhibit anti-tumor activity through regulation of tumor cell differentiation and induction of apoptosis by suppression of NF-κB. NF-κB regulates the expression of several genes involved in inflammation, thus these anti-inflammatory properties of gallic acid can be used for treatment of immune-mediated diseases. A previous study showed that gallic acid treatment inhibited the production of inflammatory mediators in oral epithelial cells, indicating a certain role of gallic acid in immune response. This study was performed to investigate the efficacy of gallic acid in regulating cellular proliferation and pro-inflammatory gene expressions in fibroblast like synoviocyte (FLS) from patients with rheumatoid arthritis (RA).

Method: Synovial tissues were obtained from patients with RA during total knee replacement surgery. RA FLS were subsequently isolated and cultured. RA FLS were treated with various concentrations of gallic acid (1 μM, 10 μM, and 100 μM) with or without TNF-α (10 ng/mL) stimulation. The mRNA expression of pro-inflammatory cytokines (IL-1β, IL-6), chemokines (CCL-2, CCL-7), cyclo-oxygenase2 (COX-2), and matrix metalloproteinase-9 (MMP-9) were determined using quantitative real-time PCR. The proliferation of RA FLS in response to gallic acid treatment was measured by the MTT assay.

Results: Gallic acid treatment induced dose-dependent reduction in constitutional mRNA expression of IL-6 in RA FLS. Constitutional mRNA expressions of CCL-2, CCL-7, IL-1β, COX-2, and MMP-9 were increased by treatment with lowest dose (1 μM) of gallic acid, but these expressions were decreased as the doses of gallic acid were escalated. After stimulating with TNF-α, gallic acid treatment inhibited the mRNA expression of all pro-inflammatory genes tested in dose- and time-dependent manner in RA FLS. Gallic acid treatment also suppressed the cellular proliferation of RA FLS (10% by 1 μM, 18% by 10 μM, 39% by 100 μM, at 72 hr).

Conclusion: In this study, we found that gallic acid treatment suppressed cellular proliferation and mRNA expressions of pro-inflammatory mediators in RA FLS. These findings suggest that gallic acid may play a role in regulation inflammation and synovial hyperplasia in RA patient and can be considered as a potential candidate for RA treatment.

Interleukine 34 Is Expressed in the Synovial Tissue from OA and RA Patients. Celine Cozic[1], Benoit Le Goff[1], Anne Riet[1], Marie-Francoise Heymann[1], Celine Charrier[1], Regis Brion[1], Sophie Touchais[3], Marguerite Chemel[4], Dominique Heymann[1] and Jean-Marie Berthelot[2]. [1]INSERM UMR S 957, [2]INSERM UMR S 957 and Rheumatology Unit, CHU Nantes, Nantes, France, [3]Orthopedic Surgery Unit, CHU Nantes, [4]Rheumatology Unit, CHU Nantes

Background: Interleukin 34 (IL-34) is a recently discovered cytokine involved in monocyte differentiation and survival. This cytokine can bind to M-CSF receptor and induce colony-forming-unit macrophages (CFU-M) formation from human bone marrow cells. Interestingly, IL-34 also promotes osteoclastogenesis and can be substituted for M-CSF in RANKL induced osteoclastogenesis. It is expressed in spleen, skin, brain, and other tissues. The aim of this study was to assess the expression of IL-34 in the synovial tissue of rheumatoid arthritis (RA) and osteoarthritis (OA) patients by immunohistochemistry.

Methods: Synovial biopsy specimens were obtained surgically at the time of an arthroplasty in 17 RA patients, 4 patients with other inflammatory athritis and 3 patients with OA. The mean duration of the RA was 11+/−5 years, with 15 patients treated with Methotrexate and 3 with anti-TNF alpha therapy. All the samples were embedded in paraffin and immunohistochemistry for IL34 expression was performed using an automated staining system. The histopathological severity of synovitis was graded using the synovitis score described by Krenn et al, which quantitatively evaluates on a scale from 0 to 3 the hyperplasia of the synovial lining layer, activation of synovial stroma, and inflammatory infiltrates, giving a total score ranging from 0 to 9. Clinical and biological characteristics of the patients were also recorded. Statistical analysis was performed using a Mann-Whitney non parametric test. $P<0.05$ was considered as statistically significant.

Results: Overall, 27 biopsies were available for the histological analysis. The mean synovitis score was 4.7+/− 1.9 (range 2–8). The mean score of synovial hyperplasia, stroma activation and inflammatory infiltrates was 1.42+/−1.2, 1.58+/−0.6 and 1.7+/−0.5 respectively. According to the grading system, of all the biopsies, 9 had slight synovitis, 8 had moderate synovitis, and 7 had strong synovitis. IL-34 was detected in 24 of the 27 biopsies with 3 samples from RA patients being negative. In the synovial tissue, IL-34 was expressed by the synovial fibroblasts (SFs), endothelial cells and the smooth muscular cells. A significant correlation was found between IL-34 expression by the SFs and the proliferation and infiltration of the synovial lining layer: the mean score of synovial hyperplasia was 2.15+/−0.8 and 0.54+/−0.3 in the biopsies with and without IL34 positive SFs respectively ($p=0.0013$). We found also an association between IL34 expression and the histological severity of the synovitis with a mean score of 5.5+/−1.9 and 3.7+/−1.5 in the IL34 SFs positive and negative biopsies respectively ($p=0.026$). No significant association was found between IL34 expression and any of the clinical or biological parameters.

Conclusion: IL-34 is expressed in the synovial tissue from RA and OA patients. Interestingly, we found a significant correlation between IL-34 expression by the synovial fibroblasts and the histological severity score of the synovitis. Considering the importance of IL-34 in monocyte maturation and osteoclastogenesis, the role of this cytokine in the pathogenesis of OA and RA should be further explored.

Oncostatin M, Acting through Oncostatin M Receptor, Is a Potent Regulator of IL-6 and RANKL Expression in Mouse Synovial Fibroblasts. Benoit Le Goff[3], Narelle M. McGregor[1], T. John Martin[2], Evange Romas[1], Natalie A. Sims[1] and Nicole C. Walsh[1]. [1]St Vincent's Institute, Fitzroy, VIC, Australia, [2]St Vincent's Institute, Fitzroy, Australia, [3]St Vincent's Institute and INSERM, UMR-S 957, Fitzroy, VIC, Australia

Background: In rheumatoid arthritis, synovial fibroblasts (SF) mediate many effects of inflammatory cytokines that contribute to focal bone loss within the arthritic joint. The IL-6 family cytokine oncostatin M (OSM) is produced at high levels by macrophages and T cells in RA synovial fluid and synovial tissues, and is known to induce osteoclast formation via its action on osteoblasts. OSM acts by binding to the signal transducer gp130 and recruiting its ligand specific receptor α-chain, OSM Receptor (OSMR) or the leukemia inhibitory factor receptor (LIFR). It is not known which receptor complex mediates OSM effects on gene expression in SFs. In this study we sought to identify the effects of murine (m) OSM signalling via OSMR on SF expression of modulators of inflammation and osteoclast function, in comparison with the prototypical inflammatory cytokine, TNF.

Methods: Immunohistochemical staining (IHC) for OSMR was performed in tissues from mice induced with mono-articular antigen induced arthritis (AIA). Synovial fibroblasts (SFs) were isolated from hind paws of mice deficient in OSMR (OSMR KO) and strain-matched wildtype control mice (WT). Isolated SFs were passaged at least 4 times prior to stimulation with mOSM (2 ng/mL and 50 ng/mL) or TNF (7.5 ng/mL, maximal, non-apoptotic dose). Cells were harvested at 1, 6 and 24 hours following stimulation, and RNA was isolated for subsequent quantitative RT-PCR analyses.

Results: OSMR protein expression detected by IHC staining was observed in SFs within normal knee joints and its expression was increased with the induction and progression of AIA, indicating a possible role in mediating AIA. OSMR mRNA expression was observed in WT SFs but as expected, was absent in OSMR KO SFs. mOSM treatment increased OSMR mRNA levels in WT SFs at 6 and 24 hrs. In contrast, gp130 and LIFR mRNA levels were similar in OSMR KO and WT SFs and were not modified by mOSM treatment. TNF did not modify OSMR, gp130 or LIFR mRNA expression but did increase LIF mRNA expression at 1, 6 and 24 hrs in both OSMR KO and WT SFs. mOSM treatment increased IL-6 mRNA expression 50–100 fold in WT SFs at 1, 6 and 24 hrs. This effect was absent in OSMR KO SFs. In contrast, TNF transiently induced IL-6 expression by both WT and OSMR KO SFs at 1 and 6 hrs (10–15 fold), with no effect at 24hrs. In WT SFs, mOSM significantly increased expression of the osteoclast differentiation factor RANKL at 1, 6 and 24hrs, with only a maximum of 2 fold increase in expression of the RANKL inhibitor, OPG. This effect was not observed in SFs derived from OSMR KO mice. In contrast, TNF treatment resulted in increased RANKL mRNA expression at 1 and 6 hrs with expression returning to baseline by 24 hrs in both OSMR KO and WT SFs.

Conclusion: Our results demonstrate that OSM acts on SFs, through the OSMR, to stimulate sustained IL-6 and RANKL expression in SFs. Induction of OSMR mRNA expression in SFs by OSM suggests that this may contribute to the sustained effect on RANKL and IL-6 expression. Increased expression of OSMR protein in SFs in arthritic tissues and OSM's dependence on OSMR for its effects on IL-6 and RANKL expression identifies OSMR as a potential therapeutic target in the treatment of RA, which could reduce both inflammation and bone erosion.

Oral Bisphosphonates and Risk of Atypical Femur Fractures in a Population-Based Cohort: A Propensity Score-Matched Analysis. Seo Young Kim[2], Sebastian Schneeweiss[3], Jeffrey N. Katz[1], Raisa Levin[4] and Daniel H. Solomon[2]. [1]Brigham and Women's Hosp, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, [4]Brigham and Women's Hospital

Background: Bisphosphonates are the primary therapy for postmenopausal and glucocorticoid-induced osteoporosis. While case series suggest a potential link between prolonged use of bisphosphonates and low-energy atypical fracture of the femur, a recent study based on three randomized clinical trials found no significant risk of atypical femur fracture in patients taking bisphosphonates. We assessed this potential association using a large population-based observational cohort.

Methods: Using health care utilization data, we conducted a cohort study to examine the risk of atypical (subtrochanteric or diaphyseal) femur fractures in new users of oral bisphosphonates compared with those of raloxifene or calcitonin nasal spray. Oral bisphosphonates included in the study were alendronate, risedronate, and etidronate. Subjects were followed until they experienced either subtrochanteric or diaphyseal femur fracture based on the primary hospital discharge diagnosis code. The incidence rates (IRs) and hazard ratios (HRs) of atypical femur fractures with the 95% confidence interval (CI) were calculated in the propensity score-matched cohorts. A Cox proportional hazards model evaluated the risk of atypical femur fractures associated with duration of osteoporosis treatment.

Results: Among 33,815 patients (17,028 in the bisphosphonates and 16,787 in the raloxifene/calcitonin group), a total of 104 atypical femur fractures occurred during a mean 2.13-year follow-up. The estimated IR of atypical femur fractures was 1.46 per 1,000 person-years among the bisphosphonate users and 1.43 per 1,000 person-years among the raloxifene/calcitonin users. Overall, no significant association between bisphosphonate use and atypical femur fractures was found (HR 1.03, 95% CI 0.70–1.52), compared with raloxifene/calcitonin. We had little precision in the subgroup analysis estimating the risk of atypical femur fractures in patients treated with bisphosphonates for longer than four years (HR 1.46, 95% CI 0.59–3.62, Figure 1).

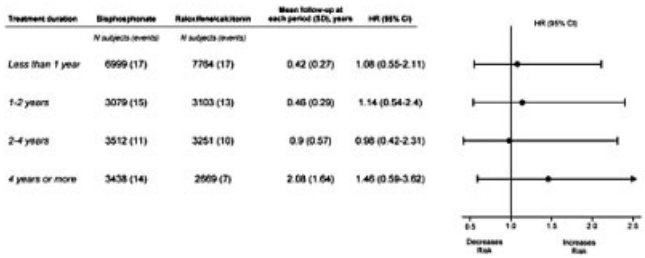

Figure 1. Hazard ratios for atypical (subtrochanteric or diaphyseal) femur fractures, according to osteoporosis treatment duration.

Conclusions: The occurrence of atypical femur fracture was rare. No evidence of an increased risk of atypical femur fractures was found in bisphosphonate users, compared to raloxifene/calcitonin users. We, however, cannot fully rule out an increased risk for these fractures associated with long-term bisphosphonate use even with this large-scale cohort.

Selective Involvement of ERK and JNK MAP Kinases in the Synovial Tissue of Patients with Early Arthritis. Daphne de Launay, Marleen van de Sande, Gijs van de Sande, Carla Wijbrandts, Danielle Gerlag, Paul Peter Tak and Kris Reedquist. Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands

Little is known about mitogen-activated protein kinase (MAPK) contribution to disease in rheumatoid arthritis (RA), although inhibitors targeting one of these enzymes, p38, have already entered the clinic. Here we investigated synovial MAPK activation status in disease-modifying antirheumatic drug (DMARD) -naïve early arthritis patients.

Methods: 50 DMARD -naïve early arthritis patients (disease duration $<$ one year) were prospectively followed and diagnosed at baseline and after 2 years according to criteria for undifferentiated arthritis (UA), rheumatoid arthritis (RA), or spondyloarthritis (SpA). Synovial biopsies from actively inflamed joints were obtained at baseline by needle arthroscopy and examined by immunohistochemistry for expression and phosphorylation of p38, ERK 1/2 and JNK MAPKs, using computer-assisted image analysis. Results were compared between patients with different diagnoses and disease outcomes.

Results: Activation of ERK was enhanced at inclusion in patients meeting RA criteria after two years (n = 27) compared to SpA (n = 7) ($P < 0.05$) and UA (n = 16) ($P < 0.005$). JNK activation was significantly higher in RA than in SpA ($P < 0.005$) and UA $P< 0.01$). p38 activation was similar between diagnostic groups. Logistic regression analysis demonstrated that synovial JNK activation, but not p38 or ERK activation, predicts fulfillment of RA classification criteria after two years (R^2 = 0.59, P = 0.02). Comparing patients diagnosed with UA at baseline who fulfilled RA classification criteria after two years (n = 8) with those who remained UA (n = 16), activation of JNK ($P < 0.005$), but not p38 or ERK was significantly enhanced. Activation of ERK ($P < 0.01$) and JNK ($P < 0.01$) at baseline was also enhanced in RA patients with progressive joint destruction as assessed by comparison of X-rays at baseline and after two years. Comparing all early arthritis patients, activation of p38 ($P < 0.05$), ERK ($P < 0.005$) and JNK ($P < 0.001$) was elevated in patients with erosive disease.

Conclusions: In patients with early arthritis, elevated ERK and JNK activity distinguish RA from other forms of arthritis, and JNK activation is already elevated in patients with RA even before classification criteria of RA are met. Activation of MAPKs is also associated with development of erosive disease, and JNK activation predicts the development of erosive disease in early arthritis patients. Together, our data suggest that strategies targeting ERK and JNK, rather than p38, may be beneficial in treating RA and preventing joint destruction early in the disease process.

Serum Concentrations of Cytokines in the IL-23/IL-17A Pathway May Be Modulated by Polymorphisms in *IL-23R*. Lisa K. Stamp[1], Jody Hazlett[2], Tony Merriman[2], John Highton[2] and Paul Hessian[2]. [1]University of Otago, Christchurch, New Zealand, [2]University of Otago

Purpose: The IL-17/IL23 pathway has been recognised as an important pro-inflammatory system in RA. IL-23 is required for maintenance of Th17 cells whereas IL-12 inhibits IL-17A production from Th17 cells. Polymorphisms of the IL-23 receptor (IL-23R) and IL-21 have been associated with RA. The aims of this study were to determine the effect of polymorphisms in interleukin (IL)-23R, IL-12 and IL-21 on serum cytokine concentrations in patients with RA and to assess the relationship between serum cytokines in the IL-17/IL-23 pathway and these genes.

Methods: Serum and DNA were collected from 81 patients with RA. Concentrations of IL-1β, IL-12, IL-17A, IL-21, IL-22, IL-23, and TNF–α were measured using a bead-based multiplex assay. Genotyping of individual SNPs was determined by Taqman assays and PCR-RFLP. Data were analyzed using Prism software. For statistical analysis the genotypes were grouped as positive or negative for the minor allele.

Results: The mean age was 57.7 years (22–80), 74% female, 70% RF +ve and 58% CCP +ve. In 18 patients none of the cytokines were detectable.

There was no significant difference in serum concentrations of any of the cytokines examined in patients with the major vs minor alleles of IL-23R rs11209026, IL-12B rs3213337, IL-12bpro rs17860508 and IL-21 rs6822844.

In the subgroup of 48 patients who had detectable IL-17A, patients homozygous for the *IL-23R rs11209026* major allele had significantly higher

IL-17A concentrations as compared to patients with the IL-23 minor allele (394.51 ± 529.72pg/ml vs 176.11 ± 277.32pg/ml; p= 0.017). Similar differences were not observed in IL-21 or Il-22 concentrations. There was a strong positive correlation between serum IL-17A concentrations and IL-23 in patients with the IL-23R major allele (p=0.0003), which was not present with the IL-23R minor allele. Similarly, while there was a significant positive correlation between serum IL-12 and IL-23 in patients with the IL-23R major allele (p=0.036), this was not evident in patients with the IL-23R minor allele (p=0.24).

Conclusions: These data suggest that the *IL-23R rs11209026* polymorphism may have an impact on IL-23R function. However, this SNP as not been associated with RA. In patients with the variant higher concentrations of IL-23 may be needed to produce similar IL-17A concentrations as seen in patient with the major allele IL-23R, indicating reduced IL-23R function in those patients with the minor allele.

Synovitis in Rheumatoid Arthritis: Paradoxical Inverse Relationship between Kinase Phosphorylation Status and CXCL13, a Biomarker of Inflammation. Sanna Rosengren and David L. Boyle. UCSD School of Medicine, La Jolla, CA

Purpose: Serum levels of the B-cell attracting chemokine, CXCL13 has been proposed as a marker of synovitis in rheumatoid arthritis (RA). In previous studies, we observed a strong correlation between serum CXCL13 protein and synovial CXCL13 mRNA. Hence, we sought to examine the relationship of synovial CXCL13 expression to putative markers of synovitis: 1) expression of inflammatory markers, and 2) the synovial phosphorylation state of several inflammation-associated signaling kinases.

Methods: RA synovial tissues were obtained during arthroplasty. Message RNA expression levels were determined by qPCR and were normalized to GAPDH yielding relative expression units (REU). Synovial kinase phosphorylation status was determined by Western blot. Phospho-Stat3 and MMP3 protein levels were measured by ELISA on synovial extracts. All statistical analysis was performed on log-transformed data.

Results: A screen of 58 individual RA synovial tissues revealed that CXCL13 REU ranged over 2600 fold, and when log-transformed, exhibited a bimodal distribution with two distinct maxima. From these, twelve each were selected from the upper and lower tertiles of the CXCL13 expression to yield High and Low CXCL13 sets. When compared to the Low CXCL13 tissues, significantly higher expression of TNF and MMP3, as well as the B- and T-cell markers CD19 and CD3E, respectively, were observed in High CXCL13 expression synovia ($p < 0.0028$ for all). In parallel, MMP3 protein levels also differed significantly between the two sets. Interestingly, no difference in expression of IL6 or MCP1 was observed between High and Low CXCL13 synovia. Surprisingly, p38, Erk, Stat3, and Akt were significantly less phosphorylated in High CXCL13 synovia. For example, when normalized to the Low CXCL13 within-gel mean, the phospho/total p38 ratios were 0.55±0.086 and 1.00±0.077, respectively, for High and Low CXCL13 tissues ($p < 0.001$). For Stat3, the corresponding numbers were 0.46±0.077 and 1.00±0.11, respectively ($p = 0.001$). No difference was observed in total p38/GAPDH or total Stat3/GAPDH protein ratios between the two synovial sets. The phospho-Stat3 results were confirmed using phospho-ELISA. Interestingly, expression of the anti-inflammatory factors SOCS1, SOCS3, and IL10 was significantly higher in High CXCL13 synovia. For example, the geometric mean (95% confidence interval) for SOCS1 REU was 0.074 (0.048–0.11) and 0.015 (0.010–0.025) for High and Low CXCL13 tissues, respectively ($p < 0.0001$).

Conclusions: Rheumatoid synovial tissues with elevated CXCL13 express higher levels of inflammatory mediators and contain more infiltrating cells. Unexpectedly, the same tissues display reduced phosphorylation of several kinases crucial to pro-inflammatory signaling, such as p38, Erk, Stat3, and Akt, when compared to synovia with low CXCL13 levels. These data might be explained by signaling kinetics or the fact that High CXCL13 tissues also contain elevated levels of anti-inflammatory factors, such as SOCS and IL10. These findings might be relevant to the therapeutic application of kinase inhibitors in RA synovitis, suggesting that stratification of patients might lead to improved clinical response.

Disclosure: S. Rosengren: None; **D. L. Boyle:** None.

The microRNA 18a Enhances IL-6 Signaling through Inhibition of PIAS3. Matthias Brock[2], Michelle Trenkmann[1], Renate E. Gay[3], Beat A. Michel[4], Steffen Gay[5], Rudolf Speich[6] and Lars C. Huber[6]. [1]Center for Experimental Rheumatology and Zurich Center for Integrative Human Physiology (ZIHP), University Zurich, Zurich, Switzerland, [2]Center for Experimental Rheumatology and Zurich Center for Integrative Human Physiology (ZIHP), University Zurich, Zürich, Switzerland, [3]Rheum Clinic, Univ Hospital, Zurich, Switzerland, [4]University Hospital, Zurich, Switzerland, [5]University Hospital Zurich, Zurich, Switzerland, [6]Working Group for Pulmonary Hypertension, Department for Internal Medicine, University Hospital Zurich, Zurich, Switzerland

Introduction: Interleukin-6 (IL-6), a key proinflammatory cytokine in the pathogenesis of certain diseases, mediates the hepatic production of cytokines and acute phase reactants such as fibrinogen gamma chain (FGG) and haptoglobin (Hp). We have shown that signal transducer and activator of transcription 3 (STAT3), which is the major intracellular mediator of IL-6 signaling, regulates the expression of the microRNA (miRNA) cluster miR-17/92. Here we addressed whether miRNAs derived from this cluster might modulate IL-6 signaling and acute phase response in human hepatoma (HepG2) cells.

Methods: Overexpression of miRNA precursor molecules (pre-miR-17-5p, −18a, −19a, −20a and −92a) in HepG2 cells (n=6) was achieved by nucleofection (AMAXA). Following an incubation period of 72h, cells were stimulated with IL-6 for 4h. Gene expression of FGG, Hp, suppressor of cytokine signalling 3 (SOCS3), and protein inhibitor of activated STAT 3 (PIAS3) were measured by SYBR Green real-time PCR. HepG2 cells (n=5) were further transfected with reporter gene constructs of FGG or Hp promoters. 4h after stimulation with IL-6, cells were lysed and promoter activities were measured using the Dual-Luciferase Reporter Assay System (Promega).

Novel miRNA targets were identified by a computational algorithm (TargetScan) and validated by constructing a luciferase-based reporter gene system which contained the 3'UTR of the predicted target gene. Luciferase expression was assessed after co-transfection of HEK293 cells (n=7) with precursors of miR-18a and the respective reporter gene constructs.

Results: Stimulation of HepG2 cells with IL-6 for 4h resulted in overexpression of mRNA levels of SOCS3 (48.11 ± 15.3), FGG (2.86 ± 0.93) and Hp (4.43 ± 1.0) as compared to unstimulated control cells. Additional transfection with miR-18a further increased these expression levels (SOCS3: 81.49 ± 20.84, $p < 0.05$; FGG: 3.89 ± 1.35, $p = 0.08$; and Hp: 6.31 ± 0.75, $p < 0.05$). These data could be confirmed by performing reporter gene assays revealing 15.96 ± 4.62 fold change in the promoter activity of FGG for mock transfected cells upon stimulation with IL-6 and 26.67 ± 4.15 fold change in pre-miR-18a transfected cells ($p < 0.05$). For Hp, similar results were achieved showing 15.48 ± 4.51 in mock and 26.4 ± 4.47 fold change in pre-miR-18a transfected cells ($p < 0.05$). Next, we identified PIAS3 as a novel target of miR-18a. Transfection of miR-18a resulted in reduced mRNA expression levels of PIAS3 (0.86 ± 0.09, $p < 0.05$). Similarly, the activity of Luciferase containing the 3'UTR of PIAS3 was reduced in pre-miR-18a transfected cells (0.127 ± 0.038) when compared to mock transfected cells (0.21 ± 0.044, $p < 0.05$). Conversely, this effect could be abrogated by mutation of the miR-18a seed match (0.247 ± 0.049 for mock and 0.265 ± 0.063 fold change for pre-miR-18a transfected cells).

Conclusion: We show here that miR-18a enhances IL-6 signaling in HepG2 cells thereby increasing the production of acute phase proteins. We further identified PIAS3, an endogenous inhibitor of STAT3, as a direct target of miR-18a. Our data emphasize an important link between miR-18a and STAT3 activity in the regulation of inflammation and acute phase response.

TL1A Expressed on the Rheumatoid Fibroblast-Like Synoviosytes Mediates Signalling Induced by DcR3. Masayasu Takahashi. Dept. of Orthopaedic Surgery, Kobe Univ. Graduate School of Medicine, Kobe, Japan

Background: TNF-like ligand 1A (TL1A)/ vascular endothelial growth inhibitor (VEGI)-251, is a member of the TNF superfamily(TNFSF-15) and exerts its effects by binding to its specific receptor, death receptor 3 (DR3). TL1A activates multiple signalling pathways including NFkB, p38MAPK,

ERK, and FADD for mitosis, inflammation, and apoptosis. Recently, it is reported that TL1A is expressed in rheumatoid fibroblast-like synoviosytes(RA-FLS) and synovial fluids of rheumatoid factor (RF) seropositive patients. TL1A aggravate collagen-induced arthritis in mice. Meanwhile, decoy receptor 3 (DcR3)/TNFRSF6b, a soluble receptor binding to TL1A, LIGHT, and FasL, does not only inhibit the signals by competitively binding to these ligands, but also directly induces the differentiation of macrophage to osteoclasts as a ligand. In this study, we tested the interaction of DcR3 and TL1A in RA-FLS for cell proliferation and activation of MAPKs.

Methods: The relative expression levels of DcR3-specific ligands (TL1A, LIGHT and FasL) in RA-FLS were quantified by real-time PCR. RA-FLS were starved for 24h in OPTI-MEM media and incubated with various concentrations of recombinant DcR3-Fc protein, TNFα, IL-1β, anti-TL1A Ab, and control Ig for 24h, and the proliferation rate was analysed by WST assay. RA-FLS pretreated with anti-TL1A Ab or control Ig for 24h was stimulated with DcR3-Fc for 30sec, 2 and 5min, and the phosphorylation of p38MAPK and ERK was detected by Western blotting.

Results: Real-time PCR showed that mRNA of TL1A s expressed in RA-FLS 140 times of FasL and 14 times of LIGHT. DcR3-Fc significantly inhibited the proliferation of RA-FLS induced by 0.1ng/ml TNFα (7.8% with 100ng/ml and 25.4% with 1000ng/ml) or 0.05ng/ml IL-1β (33.6% with 100ng/ml and 40.7% with 1000ng/ml) in a dose dependent manner. DcR3-Fc did not inhibit the proliferation of RA-FLS induced by TNFα or IL-1β when the cells were pre-treated with anti-TL1A Ab. p38 MAPK and ERK signalling was activated 3.32 times and 5.20 times of control at 2min by 1000ng/ml of DcR3-Fc, and the activation was suppressed by the pre-treatment with anti-TL1A Ab.

Conclusion: DcR3 activates p38MAPK and ERK in RA-FLS and inhibits the proliferation of RA-FLS induced by the inflammatory cytokines. TL1A expressed on RA-FLS is essential for the effect. Hence, DcR3 may directly bind to TL1A on RA-FLS and activate p38MAPK and ERK resulting negative regulation of cell proliferation induced by the inflammatory cytokines. DcR3 overexpressed in RA-FLS stimulated by TNFa protects the cells from Fas-induced apoptosis. Further, TL1A binds to DR3 and act mainly pro-inflammatory, but also induce apoptosis. Both DcR3 and TL1A have reciprocal functions in RA-FLS and DcR3/DR3-TL1A axis may play a critical role for the regulation of RA-FLS proliferation.

Disclosure: M. Takahashi: None.

Visfatin/NAMPT-Mediated NGF Stimulation in Articular Chondrocytes: A Potential Link between Pain and Obesity-Induced Osteoarthritis. Sabrina Priam[2], Emilie Pecchi[3], Marjolaine Gosset[3], Xavier Houard[2] and Francis Berenbaum[1]. [1]Faculty of Medicine P&M Curie, Paris, France, [2]UPMC, Paris, France, Metropolitan, [3]UPMC

Background and Aim: Obesity is the main risk factor for knee OA. The two main features of the pathophysiology of obesity-induced OA are based on a local component (mechanical stress) and a systemic component (pro-inflammatory adipokines). Nerve growth factor (NGF) is present within OA synovial fluid and may be involved in pain associated with OA. We previously showed that visfatin/NAMPT, an adipokine, has pro-degradative effects (Gosset et al. Arthritis Rheum. 2008). However, its role in OA pain has not been evaluated yet.

Methods: Primary cultures of newborn mouse articular chondrocytes or cartilage explants were stimulated by increasing amounts of visfatin/NAMPT, IL-1 beta, prostaglandin E_2 (PGE_2) or by cyclic mechanical compression (0.5 Hz, 1 MPa). mRNA NGF levels were assessed by real-time quantitative PCR and NGF released into media was determined by ELISA.

Results: Unstimulated articular chondrocytes expressed low levels of NGF. Mechanical stress induced NGF mRNA expression and release in conditioned media. Visfatin/NAMPT, a pro-inflammatory adipokine produced by chondocytes in response to IL-1 beta, stimulated NGF expression (2 fold) and release (3.7 fold). When stimulated by IL-1 beta, a dose-dependent increase in NGF mRNA expression (5.7 fold increase with 10 ng/ml IL-1) and NGF release (19 fold increase with 10 ng/ml) in chondrocyte conditioned media was observed. Neither siRNA visfatin/NAMPT nor APO 866, an inhibitor of NAMPT enzymatic activity, prevented the production of NGF induced by IL-1 beta. Interestingly, PGE_2, which is produced by chondrocytes in response to IL-1 beta and visfatin/NAMPT, did not stimulate NGF production. Consistently, indomethacin, a cyclooxygenase inhibitor, did not counteract IL-1-induced NGF production.

Conclusion: These results suggest that obesity-induced OA pain may involve NGF mediated by the overexpression of visfatin/NAMPT and mechanical stress. These effects seem to be independent of the well-known pro-inflammatory mediators involved in OA pain, IL-1b and PGE_2. Thus, along with reduction of weight, visfatin/NAMPT could be an interesting target for pain in OA.

Vitamin D Suppresses Th17 Cytokines Via Down Regulation of ROR-gammat and NFATC2 and by Differential Regulation of GATA3. Anne-Marie Mus[2], Jan Piet van Hamburg[2], Patrick Asmawidjaja[2], Johanna M. W. Hazes[2], Hans van Leeuwen[2], Louis Boon[1], Edgar Colin[2] and Erik Lubberts[2]. [1]Bioceros, [2]Erasmus MC, University Medical Center

Introduction: Recently, we showed that vitamin D modulated Th17 polarization and IL-22 expression by memory T cells from patients with early rheumatoid arthritis and stimulates IL-4 production by PBMC from early RA patients. Furthermore, it has been shown that vitamin D inhibited collagen-induced arthritis and diminished the severity of existing CIA, although the mechanism is unknown.

Objective: To identify the molecular mechanism of vitamin D on suppression of Th17 cytokines and Th17 differentiation in an ex vivo model using CD4+ T cells from the prone autoimmune DBA-1 mice with and without collagen-induced arthritis or naïve CD4+ cells from DBA-1 mice.

Methods: Splenic CD4+ T cells of non-immunized DBA-1 and type II collagen immunized DBA-1 mice were isolated using the MACS system. In addition, naïve splenic CD4+CD62L+ T cells were FACS sorted from DBA-1 mice. These cells were stimulated *in vitro* under either Th0, Th1 (IL-12/anti-IL-4) or Th17 (IL-23, TGF-β, IL-6, anti-IL-4 and anti-IFN-γ) conditions with or without the presence vitamin D. Intracellular flowcytometric stainings for the detection of cytokine and transcription factor expression were performed. In addition, cytokine expression in supernatant was detected by specific ELISA. Moreover, mRNA expression of factors involved in Th differentiation and function was analyzed by Q-PCR.

Results: Higher percentages of IL-17+IFN-g- (Th17) cells were obtained after Th17 polarizing cultures of splenic CD4+ T cells of CII-immunized mice, compared to non-immunized mice DBA-1. In cultures of both non-immunized mice and CII-immunized DBA-1 mice, Vitamin D significantly inhibited Th17 polarization, as indicated by reduced IL-17A and IL-17F cytokine expression. Moreover, reduced RORgt expression and enhanced GATA3 expression was noted. Interestingly, vitamin D showed an increase in IL-4 and IL-10 positive cells under Th17 polarizing conditions of both non-immunized and CII-immunized DBA-1 mice. However, using FACS sorted naïve CD4+ T cells, vitamin D enhanced IL-4 and GATA3 under Th0 conditions, but not under Th17 polarizing conditions. Interestingly, in this latter condition, RORgt and NFATC2 were markedly suppressed. No effect of vitamin D on T bet and RUNX1 expression was noted.

Conclusion: These data show that vitamin D is a strong inhibitor of Th17 polarization and Th17 cytokine expression of splenic CD4+ T cells from non-immunized and CII-immunized DBA-1 mice. Furthermore, Th17 differentiation from naïve T cells was affected by Vitamin D. These data implicate a regulatory mechanism on Th17 cells by Vitamin D, through the reduction of RORgt expression. This regulatory function of Vitamin D in memory Th17 cells, may in part be dependent on the induction of GATA3 expression leading to a induced Th2 cytokine expression profile.

XCL1/Lymphotactin Induces Rheumatoid Arthritis Fibroblast-Like Synoviocytes Migration through MAP Kinases. Karolina Klosowska and James M. Woods. Midwestern University, Downers Grove, IL

Purpose: Chemokines are small secreted molecules that function in leukocyte recruiting and trafficking during an immune response. They play a key role in rheumatoid arthritis (RA), a chronic disorder that results in joint destruction. Fibroblast-like synoviocytes (FLS) are key contributors to the pathogenesis of RA, and they accumulate in the synovial lining, where they are positioned to aid in driving perpetual inflammation. XCL1 (Lymphotactin) is a chemokine known to be prominently present in the synovial tissue and

fluid of RA patients. In this study, we investigated the effect of XCL1 on FLS migration, proliferation, F-actin localization, and the role of MAP kinases in RA FLS stimulation.

Methods: RA FLS were obtained with IRB approval from knee or hip synovial membrane at the time of joint replacement and were employed in chemotaxis assays, proliferation assays, and Alexa Fluor 488 Phalloidin staining of F-actin. Further, MAP kinase inhibitors were utilized in conjunction with chemotaxis assays to evaluate whether MAP kinases played a role in signaling that contributed to RA FLS migration.

Results: Chemotaxis assays revealed that XCL1 is a novel chemoattractant for RA FLS, effectively inducing significant migration for RA FLS derived from 4 different patients. Moreover, concentrations of 1 nM to 50 nM all induced significant migration above background chemotaxis ($p<0.05$). Consistent with this finding, exposure of RA FLS to XCL1 results in a significant restructuring of F-actin, most noticeable after 2 hours. Specifically, cytoskeletal staining appeared as diffuse actin cables that were barely noted in non-stimulated cells, but upon stimulation with 10 nM XCL1 intense concentrations of F-actin could be seen in most cells along with a complete change in cell morphology. While we did not detect a proliferative effect of XCL1 on RA FLS, we did note that pertussis toxin (PTX) could completely abolish XCL1-induced migration, suggesting that migration is induced through a G protein (Gi/Go) coupled receptor. Additionally, pre-incubation of cells with U0126, an inhibitor of MEK 1/2 (the kinase known to activate ERK 1/2), significantly reduced XCL-1-induced migration of FLS from 2 of 3 RA patients tested. Similarly, pre-incubation of cells with the JNK inhibitor (SP600125) significantly repressed chemotaxis induced by XCL-1 in 2 of 3 RA FLS.

Conclusions: We have identified a novel role for XCL1 in regulating RA FLS migration, which is consistent with changes in cytoskeletal structure. XCL1 induces RA FLS migration in a dose dependent manner, where application of PTX, a MEK1/2-, or a JNK-specific inhibitor significantly reduces cell migration. This suggests involvement of ERK and JNK pathways in XCL1-induced RA FLS migration, presumably through its receptor, XCR1. A better understanding of XCL1 and FLS is warranted, since FLS are recognized to be directly responsible for cartilage destruction and driving inflammation and autoimmunity in RA, where XCL1 is present.

An Audit on Patients' Knowledge of Methotrexate. Evin Sowden, Wajeed Hassan, Ann Gooden, Bridget Jepson, Tamsheela Kausor, Ifraz Shafait, John Brockbank, Robert Ley and Lee-Suan Teh. Royal Blackburn Hospital, Blackburn, United Kingdom

Background: Methotrexate is a first line disease modifying agent and anchor drug for biologics therapy used in rheumatoid arthritis and other inflammatory rheumatic disorders. Adverse effects may occur in patients and are a common cause of drug discontinuation. Analysis of serious and fatal toxicity incidents led the National Patient Safety Agency (NPSA) to issue an alert identifying patient education and drug monitoring as an important part of a harm reduction strategy. In view of this, we audited patients prescribed methotrexate to assess adherence to patient education and patient knowledge in the rheumatology clinic setting of a district general hospital in the north of England.

Methods: All patients prescribed methotrexate for inflammatory rheumatic disease were eligible to take part. A proforma to record clinical and demographic characteristics, provision of patient education and monitoring, knowledge of drug administration, potential side effects and drug interactions was completed by case record review and patient self-administration. Questionnaire answers were discussed and an information leaflet on methotrexate given to the patient at the end of their audit participation.

Results: 51 patients were audited. The mean age was 58.6 ±13.1 years and median duration of disease 3.7 (IQR 1.7–7.6) years. Counselling by specialist nurses prior to starting methotrexate was documented in 94.1%, written information was provided in 94%, methotrexate dose and frequency were known to the patient in 84% and 100%, folic acid was co-prescribed in 90% and awareness of pregnancy and breastfeeding risks was 87.5% in females of reproductive age (<45 years). There was limited awareness of methotrexate's mode of action (60%), true side effects (21.6%-62.7%), false side effects (5.9%-37.3%), risks related to alcohol (68.4% in drinkers), risks related to male conception (47.1%), true drug interactions (7.8–11.8%) and false drug interactions (11.8–19.6%). The mean patient global knowledge score was 6.3 ±1.2 on a scale of 0–10 points. Univariate and multivariate analyses identified male gender, non-speakers of english as a first language and a trend toward longer duration of therapy as significant predictors of lower levels of patient knowledge.

Conclusion: Our audit shows that despite systematic patient education interventions as part of routine care, knowledge of important aspects of methotrexate therapy is limited. A number of recommendations are suggested: 1. Use of clearer safety-driven booklets such as that produced by the National Patient Safety Agency (NPSA); 2. Provision of information in languages other than English and in audio or audiovisual formats; 3. Regular knowledge assessments using validated tools; and 4. Targeted education to ensure consistent levels of knowledge to prevent unnecessary methotrexate-related harm.

Educating Primary Care Providers on Rheumatoid Arthritis Translates to Changes in Practice and Referrals: Results from the RAPID Continuing Medical Education Program. Clifton Bingham[3], Karen Costenbader[1], Steven Bender[2], Daniel Duch[2] and Michael Weinblatt[1]. [1]Brigham and Women's, [2]Curatio CME Institute, [3]Johns Hopkins, Baltimore, MD

Background: To determine whether a continuing medical education (CME) program focused on rheumatoid arthritis (RA) changed primary care provider (PCP) new patient (pt) referrals to rheumatologists.

Background: The impact of rheumatology CME on physician behavior is not well known. The Rheumatoid Arthritis Primary Care Initiative for Improved Diagnosis and Outcomes (RAPID) is a multi-supported CME initiative developed in 2007 to educate PCPs on the benefits of screening/diagnosing pts with suspected RA and co-managing those pts with a specialist for optimal evidence-based care. More than 49,274 physicians, nurse practitioners (NPs), and physician assistants (PAs) have completed RAPID activities. These were live CME activities with a multi-disciplinary faculty (rheumatologists and generalists),mobile Epocrates CME activities, and journal supplements.

Methods: Short-term learning for knowledge, confidence, and competence used audience response questions before and after live presentations. The same measures were used for online and printed materials. To evaluate impact, we matched 6,000 learners from the 2007 program with medical claims data from a data aggregator (multiple source clearinghouse representing claims for approximately 300,000 clinicians) to determine if there was a change rheumatologist office visit rates for pts with an RA diagnosis ("referral rate"). We compared before and after the CME activity by tracking ICD9 codes to compare rheumatology referral rates to those of (n=15,930) nonparticipants. To create a control group of nonparticipants, for every PCP in the test group, we identified 30 similar providers based on specialty, state, urban/rural, claim volume, who did not complete RAPID and averaged figures to create 1 control group subject.

Results: There was a significant increase in short-term learning at the time of participation through pre/post test results. We identified 531 participants with sufficient claims data covering a period of 4 months (mo) pre-participation and 4 mo post-participation. Of 531 CME participants identified in the claims database, pre-educational measurement showed that of the 1183 patients that were diagnosed with RA, 443 had an office visit with a rheumatologist within the next 4 mo, a referral rate of 37.4%. In the 4 mo post-educational intervention, the same providers' "referral rates" increased to 41.8%. There were no changes in the RA pt referral rates in the control group 18.1% to 18.0%.

Conclusions: This is the first study to examine the impact of an educational program on referral of RA pts by PCPs to rheumatologists.

Administrative claims data can be employed successfully to measure the impact of a CME program on changes in clinical practice. A program focused on PCP education concerning RA resulted in increased referrals to rheumatologists to provide optimal pt care. This emphasizes the continuing importance of PCP education to improve outcomes for RA pts.

Information Sources for Rheumatoid Arthritis: More Than Just the Rheumatologist. Katie Garneau[1], Maura Iversen[4], Saira Jan[3], Hsun Tsao[1], Daniel Hal Solomon[2] and Kavita Parmar[3]. [1]Brigham and Women's Hospital, [2]Brigham and Womens Hospital, Boston, MA, [3]Horizon Blue Cross Blue Shield, [4]Northeastern University, Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background: Studies show that patients who make high quality medical decisions are more likely to have better health outcomes. One defining characteristic of what constitutes a high quality decision is a well-informed patient. However, there has been little research studying patient behaviors regarding how they seek information about treatments for RA.

Methods: We surveyed beneficiaries of Horizon Blue Cross Blue Shield of New Jersey from 2009–2010, who were over age 18 and had 2 or more visits coded with RA (ICD 9 714.x). 101 (13%) of 799 invited subjects agreed to and completed interviews. Subjects answered a questionnaire consisting of items regarding sources of RA treatment information (provider and non-provider) and their usefulness, sociodemographic items, as well as 10 validated scales shown in table 1. Provider sources of information included primary care physician, rheumatologist, nurse practitioner or physician's assistant, and occupational or physical therapist. Non-provider sources included the Arthritis Foundation, books or magazines, friends or family, advertisements, health insurance, and the World Wide Web. Outcomes of interest include the average number of sources described (range 0 – 10) and the rating of usefulness for each source (1 = not useful and 4 = extremely useful).

Results: Most subjects (95%) reported at least 2 years of disease and had a mean age of 59 years. 76% of respondents were female, 71% had completed at least some college, and 43% reported earning over $100,000 in the past year. Methotrexate was the most widely used medication reported (85%). The average number of sources utilized was 5.0 (SD 2.1). Participants rated the information they utilized with an average score of 2.5 (SD 0.8). We found no strong patient correlates of these outcomes when comparing with the aforementioned domains, however positive correlations were noted between number of sources and social supports as well as usefulness of sources and trust in physician (see Table). 87% of the 98% of the total sample that used a Rheumatologist for information gave that source a 4 out of 4. The internet was the most frequently used non-provider source, with 63% of subjects reporting use, and an average usefulness rating of 3.0 (SD 1.03).

Conclusion: Participants, on average, use 5 sources of information regarding treatment decisions for RA. Participants rated these sources as useful, with Rheumatologists rated extremely useful. Strategies to enhance care and appropriate use of DMARDs should take this information into consideration.

Table 1. Correlations between patient characteristics and information sources for RA treatment decision making

	# of sources		Usefulness of sources	
	Correlation coefficient (r)	p-value	Correlation coefficient (r)	p-value
Trust in Physician	0.12	0.23	0.21	0.03
Self-Efficacy	0.43	0.67	0.16	0.11
Beliefs In Medicines	0.22	0.03	−0.11	0.26
Social Support	0.20	0.04	0.06	0.57
Brief Illness Perception*	0.12	0.24	−0.02	0.87
Social Norms	0.00	1.00	0.46	0.65

* Higher scores indicate a higher perception of illness, all other high scores denote more of the measured attribute.

Knee and Shoulder Cadaver Teaching Improves Internal Medicine Residents' Self-Reported Anatomy, Exam and Injection Skills. Jessica Berman[2], Michael H. Pillinger[3], Bradley Jensen[2], Jennifer Hammann[2] and Stephen A. Paget[1]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]NYU-Manhattan VA Med Hospital, New York, NY

Purpose: Medicine residents need to gain confidence and ability in basic musculoskeletal skills such as the joint exam, anatomy knowledge and joint injections. However, opportunities to develop these skills are frequently limited. Possible impediments include inadequate hands-on experience and the ineffectiveness of lectures and simulation models. To address these limitations, we have developed a series of innovative modules that focus on instruction in knee and shoulder anatomy, examination and injection teaching in the cadaver lab.

Methods: Rheumatology knee and shoulder teaching modules were designed for 3–4 second-year medicine residents each month, with over forty completing the program in the past year. Residents were surveyed (9-point Likert scale) before and after the rotation for their self-assessed ability to perform joint examination and aspiration. Modules were taught by an experienced rheumatologist and consisted of twice-monthly participation in interactive lectures with demonstrations of the relevant anatomy and injection classes employing cadaveric models. Examination skills relevant to the area discussed were also emphasized. Ample opportunity was given to practice injections using different approaches on the cadaver knee and shoulder joints.

Results: Before and after completing the above curriculum, second-year residents surveyed rated their abilities (1=poor to 9=very good) in specific musculoskeletal tasks as follows:

	Pre-lab (N=43)*	Post-lab (N=24)*
Injection knee	2.42	6.12
Injection shoulder	1.56	5.54
Examination of knee	4.23	6.76
Examination of shoulder	3.93	6.40
Anatomy of knee	4.09	6.44
Anatomy of shoulder	4.05	6.28

*$p<0.001$ for all comparisons

The average number of joints injected by each resident prior to the rotation was 0.88. By the end of the rotation this had risen only to 2.08.

Conclusion: Even in the setting of only limited opportunity to perform actual joint procedures, a rheumatology curriculum that includes an integrated, intense, hands-on exposure to musculoskeletal anatomy and injection teaching in the cadaver lab can improve residents' perceptions of their abilities and confidence in the anatomy, examination and injection of the knee and shoulder. This teaching approach may be a valuable alternative for programs wishing to improve musculoskeletal procedure skills, particularly in settings where actual experience may be limited.

Medical Student Education in the Electronic Age: A Web-Based Virtual Teaching Tool. Ernesto J. Rodriguez[1], Abie Alias[1], Aasim Rehman[1], Vanessa Osting[1], Tanisha Battle[2], Lara Westphal[2], Ashley G. Sterrett[3], Helen Bateman[3], John D. Carter[1] and Joanne Valeriano-Marcet[3]. [1]University of South Florida, Tampa, FL, [2]University of South Florida, [3]USF/JAHVA, Tampa, FL

Objective: Musculoskeletal (MSK) complaints have a high prevalence in primary care practice, yet many physicians continue to identify themselves as deficient in MSK medicine. Recognizing joint pattern involvement in rheumatic diseases is integral to establishing a differential diagnosis. Therefore there is an impetus to improve the quality and consistency of MSK teaching

in medical schools. This qualitative study was conducted to assess the effectiveness and satisfaction of 4th year medical students with "Arthur" (shown below).

Methods: "Arthur" is a web-based virtual education program that teaches joint pattern recognition of MSK disorders. Thirty cases highlight different joint pattern presentations (ie. Symmetric polyarthritis illustrated in above case). "Arthur" was developed by the University of South Florida Rheumatology and Education Departments. All fourth year medical students had access to "Arthur" and the accompanying survey. This survey contained open-ended questions designed to gather feedback on the students' experience, as well as the program's utility and possible areas of improvement.

Results: A total of 64 out of 107 (59.8%) fourth year medical students completed "Arthur" and the follow up survey. In response to the question regarding the strengths of "Arthur": 35 % of the respondents identified the program to be a useful tool for learning joint pattern recognition, 42.4% stated it was helpful in learning differential diagnoses of rheumatic diseases, and 20.3 % reported "Arthur" to be useful as a visual aid. In response to the question regarding areas for improvement: 48.4% identified the need for addition of explanations for each differential diagnosis, 10.9% reported the need for additional history, and 9.3% felt that "Arthur" did not need any improvement.

Conclusions: The "Arthur" virtual interactive teaching program was found to be most helpful in determining differential diagnoses, joint pattern recognition, and as a visual aid for learning. Based on this data, the most recent version of "Arthur" includes detailed explanations of the differential diagnoses for each case.

Rheumatology Fellowship Curricular Rotation in Musculoskeletal Ultrasound. Dimitrios A. Pappas[2], Marzouq A. Qubti[2], Clifton O. Bingham III[2] and Allan C. Gelber[1]. [1]Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD

Background: Within the American rheumatology community, musculoskeletal ultrasound (MSK-US) has over the last decade gained substantial support as a valuable diagnostic tool to evaluate swollen joints, bursae and tendons. Notwithstanding ongoing efforts to integrate MSK-US training into fellowship training, there remains a paucity of information detailing the experience of individual rheumatology programs at furnishing MSK-US training in their respective curricula.

Methods: We describe our new curricular rotation with MSK-US at a single academic medical center in the United States. In the 2009–2010 academic year, a new clinic was implemented wherein patients referred in consultation for acute sites of musculoskeletal swelling could be scheduled and evaluated within 72 hours of referral receipt. The attending rheumatologist was previously trained in musculoskeletal ultrasound. At this clinic, faculty-mentored, ultrasound-focused rheumatologic evaluations were conducted one afternoon each week over the course of 11 consecutive months.

Results: Between July, 2009 and May, 2010, there were 100 consecutive patients evaluated in tandem by a rheumatology fellow and faculty preceptor at this acute musculoskeletal clinic. These ultrasound-focused evaluations were conducted across a broad spectrum of patients with arthritis and rheumatic disorders, including osteoarthritis (n=20), rheumatoid arthritis (n=14), trochanteric bursitis (n=10), unspecified arthritis (n=9), gout (n=9), spondyloarthropathy (n=8), shoulder tendinitis/bursitis (n=7), pseudogout (n=5), tendinopathies (n=5), and other miscellaneous diagnoses (n=13). Ultrasound guidance was used to evaluate a knee (n=27), shoulder/rotator cuff (n=13), wrist (n=11), hip (n=10), elbow (n=5), ankle (n=5), interphalangeal joint (n=10), and other miscellaneous sites (n=19). Among these patients, a subset of 75 underwent an ultrasound-guided procedure, consisting of 52 patients who underwent ultrasound-guided joint, bursal or tendinous injections; 15 additional patients who underwent aspiration & injection, and 8 who underwent an aspiration procedure alone.

Conclusions: In the context of this new fellowship curricular offering, a single rheumatology trainee, working in unison with a single faculty preceptor, was able to achieve considerable exposure across a broad range of rheumatic disorders. Substantial proficiency was attained at use of ultrasonography, to identify and localize sites of joint, tendinous and bursal swelling, and to guide aspiration and/or injection procedures. Moreover, completion of 100 ultrasound-guided evaluations is a recognized target for an intermediate level of knowledge and skills for performing MSK-US [*J Clin Rheum* 2010;16:113).

Team-Based Learning in Rheumatology Resident Education: Two-Year Results on Receptiveness and Attitudes of Residents towards Collaborative Learning and Teamwork. Karina Marianne D. Torralba[2], Beatrice A. Boateng[1], Ron Ben-Ari[4] and Francisco P. Quismorio[3]. [1]Arkansas Children's Hospital-University of Arkansas for Medical Sciences, [2]University of Southern California-Los Angeles County Medical Center, Pasadena, CA, [3]University of Southern California-Los Angeles County Medical Center, Los Angeles, CA, [4]University of Southern California-Los Angeles County Medical Center

Objective: Team-based learning (TBL) is a structured small group learning approach that is well-recognized in medical education. It encourages accountability, teamwork and has been demonstrated to improve board scores and patient care. Since 2008, TBL has been utilized for Internal Medicine core curriculum learning sessions (CCLSs) in Rheumatology. Two of the aims of this study are to determine the level of satisfaction or receptiveness by residents of the strategy in improving their overall learning experience, and to determine their attitudes towards teamwork in learning and professional success.

Methods: Seven TBL modules had been developed on various topics including Rheumatoid arthritis, Osteoarthritis. Over 2 years, 13 modified-TBL sessions have been conducted. Learning materials provided a week before are reviewed briefly at start of class. Residents undergo individual readiness assessment test (IRAT), followed by group-RAT (GRAT) and case application done in teams of 3–4 members. Class discussion is supervised by the instructor. To assess receptiveness, a 5-point Likert scale evaluationa survey with two open-ended questions was anonymously filled out by residents at end of each session. To evaluate perception of collaborative learning, Value of Teams Survey (VOTS) was filled out yearly at the end of the CCLS series. In-training and board exam scores were tracked to determine effectiveness of TBL (results in separate abstract). Descriptive statistics and t-tests were used.

Results: Of 240 residents over a two year period (60 per year, including graduated residents and new PGY1s), 220 have gone through TBL-CCLSs. Over two years a sustained majority (80–100%) agreed-strongly agreed that TBL was conducive for CCLSs due to organization of activities, quality of learning and teammate and instructor interactions. Most commonly cited themes: 1) as to what was they liked best was that it was a fun and interactive format, it allowed them to learn from co-residents, it allowed them to review materials they already knew and to also advance their knowledge by using critical thinking; 2) as to what they liked least was the time constraint. For VOTS, a sustained majority (85–100%) agreed that utilizing teamwork is an effective way of learning, and is a necessary and valuable skill to learn, and is needed for better decision-making. At least 80% felt teamwork is necessary for professional success in their careers.

Conclusion: There is sustained acceptance and satisfaction by medical residents of TBL as a teaching strategy for CCLSs from year 1 to year 2 of implementation. Collaborative learning through teamwork is a recognized effective way of learning and a valuable skill to acquire.

The First Pediatric Rheumatology Objective Structured Clinical Examination: Providing Clinical Skills Feedback for Fellows and Program Directors. Megan L. Curran[1] and David D. Sherry[2]. [1]Children's Memorial Hospital, Northwestern University's Feinberg School of Medicine, Chicago, IL, [2]The Children's Hospital of Philadelphia, Philadelphia, PA

Background: Since objective data is often lacking, it is difficult for fellowship program directors (PDs) to provide meaningful feedback regarding fellows' communication and professionalism skills. To reliably assess these non-knowledge based competencies we conducted an OSCE for pediatric rheumatology fellows to measure pre-test expectations and actual scores in communication and professionalism skills and overall performance rank.

Methods: 22 fellows from 13 training programs were tested in 7 unique scenarios. The 21 evaluators were pediatric rheumatologists mostly from participating programs. Before the OSCE, fellows and PDs used 100 mm visual analog scales (VAS) to indicate expected performance in communication and professionalism. Evaluators scored fellows using identical VAS during scenarios. Scenario scores were averaged to give final scores in these areas. Before the OSCE, fellows and PDs estimated overall performance (upper, middle or lower third) compared to others. After all 7 fellows finished an evaluator's station, their performances were ranked from 1 (best) to 7 (worst). Rankings were averaged to determine each fellow's overall performance score. Scores were ordered numerically and divided into upper, middle and lower thirds.

Results: The 22 fellows' pre-test communication VAS estimates ranged 22–80 (56, 57, and 49 were the mean, median and mode). Post-test communication VAS scores ranged 26–89 (78, 80, 86). Fellows' pre-test professionalism VAS estimates ranged 39–98 (60, 60, 50). Post-test professionalism VAS scores ranged 26–90 (84, 88, 88). Upper, middle and lower third overall performance rank averages ranged respectively from 1.25 to 3.33 (n=8), 3.43 to 4.29 (n=7) and 4.43 to 5.83 (n=7). The following statistics show the number of fellows who estimated their performance ranking to fall into the specified third with the number actually achieving upper, middle, and lower third rankings listed in parentheses. 2 fellows estimated their performance as upper third (1, 0, 1), 12 as middle third (6, 4, 2) and 8 as lower third (1, 3, 4). 1st year fellows estimated their performance ranking to be lower than 2nd year fellows, whose estimates were lower than estimates of 3rd year fellows. PDs estimated 10 of their fellows' performances as upper third (4, 3, 3) and 4 as middle third (1, 2 and 1). No program director thought that their fellow would rank in the lower third. With few exceptions, attendings expected 1st year fellows to rank in the middle third and 2nd & 3rd year fellows to rank in the top third.

Conclusions: Our pediatric rheumatology OSCE was the first of its kind. Fellows tended to underestimate their communication skills, professionalism skills and overall performance ranking. PDs overestimated performances. Limitations of our study include inter-rater reliability of evaluators and comparison of fellows from different training levels. However, the pediatric rheumatology OSCE provided innovative feedback for program directors about their fellows' communication and professionalism skills. This OSCE provides the first opportunity to compare the clinical skills of pediatric rheumatology fellows from programs nationwide.

Utilization of Ambulatory Medical Clinic for Rheumatology Education. James M. Ross Lehigh Valley Health Network, Macungie, PA

Purpose: Development and assessment of a model of rheumatology education using medical residents own clinic patients with direct supervision of rheumatic cases by an academic rheumatologist.

Methods: An education model was developed utilizing an academic rheumatologist for direct supervision and education concerning rheumatic cases seen during internal medicine resident's clinic. The rheumatologist attended each resident's clinic monthly and saw scheduled patients specifically for rheumatology and non-scheduled rheumatic cases. The diagnoses, residents involved and any procedure performed were recorded. Assessment of this educational experience included testing of general rheumatology knowledge with multiple-choice questions, an annual assessment of overall resident impression and assessment of utility of the experience using a 5 point scale. This assessment was performed at baseline and yearly.

Results: Patient visits: There were 90 sessions attended by the rheumatologist over 24 months. 253 patients including 193 scheduled patients with rheumatology issues were seen. Due to initiation of EMR there was a transient decline in patients seen in the past year. 35% of the cases were followed over time giving residents experience of continuity of care of rheumatic disorders. Cases encompassed all aspects of rheumatology with the most common diagnoses being rheumatoid arthritis, osteoarthritis and soft tissue rheumatism with need for injections. Waiting time for patient seen with this program was 0– 40 days. Sixty different residents were supervised in this model including 40 without previous rheumatology rotation experience.

Educational assessment: At baseline the majorities of the first and second year groups of residents were not comfortable with rheumatic patients and scored poorly on basic rheumatology questions. As a group the third year residents were less than moderately comfortable in seeing rheumatology patients. On repeat assessment each of the resident groups demonstrated improvement in basic knowledge including those residents without a previous rheumatology rotation experience. They also reported an improvement in their level of comfort in dealing with rheumatic patients and performing arthrocentesis. The overall resident impression was that this model provided a useful clinical and educational experience.

Conclusions: This medical clinic educational model provides several additional benefits in addition to or combined with a standard rheumatology rotation. Benefits include residents having more responsibility for the care of these cases plus an increase in comfort level. This model provides an increased and earlier exposure to rheumatology that may interest residents into considering this field, in addition to improved medical clinic patient access to care and quality of care.

A Novel Baseline Biomarker of Acute-Phase Serum Amyloid A (A-SAA) and Serum Interleukin–2 Receptor alpha (sIL-2Rα) Predicted Long-Term (18 to 35 Yrs) Mortality of Incident Rheumatoid Arthritis (RA) and Matched Non-RA Cohort Controls (CN). Alfonse T. Masi[2], Jean C. Aldag[2] and Jean D. Sipe[1]. [1]Center for Scientific Review, NIH, Bethesda, MD, [2]University of Illinois College of Medicine at Peoria, Peoria, IL

Purpose: Research on biomarkers of mortality has high priority, especially for cardiovascular causes. Serum markers have predicted such mortality but not over decades-long intervals. This prospective study aimed to identify baseline, long-term biomarker predictors of mortality outcomes of incident RA and matched non-RA cohort CN.

Design: In 1974, 54 subjects had enrolled into a community-based cohort (n = 21,061 adults) who later had onset of ACR-positive RA, after 3 to 20 (mean 12) years (1977 – 1994). Each RA case was matched by age, gender, and race (all Caucasian) at baseline with 4 cohort non-RA CN. Baseline stored (-70°C) sera were assayed (ELISA) blindly for biomarkers. High sensitivity CRP (hsCRP) and A-SAA were assayed (Hemagen kits) at Boston University (sensitivity 0.1 μg/ml for hsCRP and 1 μg/ml for A-SAA). Three cytokines (IL-1β, IL-6, and TNF-α) and 3 cytokine receptors/antagonists (sIL-2Rα, sTNF-R1, and IL-1ra) were assayed (R & D Systems, high sensitivity kits) at Specialty Laboratories, Santa Monica, CA. Two baseline (1974) biomarkers correlated with mortality of all subjects from 1992–2009, i.e., A-SAA, p = 0.001 and sIL-2Rα (CD25), p = 0.036 (but not CRP, p = 0.125). Sex- and age-specific upper quartile values of A-SAA and sIL-2Rα were determined and a gradient score of their combined results was formulated: 1 = all negative tests (single only or both assayed); 2 = one test negative and other positive (or neither test assayed), and 3 = all positive tests (single only or both assayed). All cause, primary cardiovascular (ICD-9, 390–459 & ICD-10, 00–99), and all other combined mortality was monitored from 1992 thru 2009, excluding 12 pre-1992 deaths. Percentages of deaths by the biomarker gradient were determined. Hazard ratios (HR) of the biomarker gradient for mortality were estimated by Cox regression models.

Results: Deaths from all causes occurred in 27 (50%) of 54 RA vs 63 (31%) of 204 non-RA, OR = 2.24, 95% CI 1.22 – 4.12, p = 0.010. For all causes, HRs of the biomarker gradient were significant for deaths in RA (p = 0.026), non-RA (p = 0.002), and total (p < 0.001) subjects. For circulatory mortality, HRs of the biomarker gradient were significant for deaths in total (p < 0.001) and non-RA (p = 0.001) subjects, and nearly in RA (p = 0.072). For non-circulatory deaths, the biomarker only weakly predicted deaths in total subjects, p = 0.049 (Table):

Causes of Deaths and the Biomarker Gradient	Rheumatoid Arthritis (N=54) N (%) of Deaths	Non-Rheumatoid Arthritis (N=204) N (%) of Deaths	Total Cohort Subjects (N=258) N (%) of Deaths
All Causes of Deaths:			
Negative Only	8 (34.8%) of 23	22 (22.2%) of 99	30 (24.6%) of 122
No Assays or Neg & Pos	13 (56.5%) of 23	31 (36.0%) of 86	44 (40.4%) of 109
Positive Only	6 (75.0%) of 8	10 (52.6%) of 19	16 (59.3%) of 27
Total Mortality	27 (50.0%) of 54	63 (30.9%) of 204	90 (34.9%) of 258
Cox Regression Model: HR (95% CI) of Biomarker Gradient for Mortality (p Values)	1.80 (1.07–3.03) (p = 0.026)	1.78 (1.24–2.55) (p = 0.002)	1.83 (1.36–2.46) (p < 0.001)
Circulatory Deaths:			
Negative Only	1 (4.3%) of 23	6 (6.1%) of 99	7 (5.7%) of 122
No Assays or Neg & Pos	4 (17.4%) of 23	14 (16.3%) of 86	18 (16.5%) of 109
Positive Only	2 (25.0%) of 8	6 (31.6%) of 19	8 (29.6%) of 27
Total Mortality	7 (13.0%) of 54	26 (12.7%) of 204	33 (12.8%) of 258
Cox Regression Model: HR (95% CI) of Biomarker Gradient for Mortality (p Values)	2.57 (0.92–7.19) (p = 0.072)	2.62 (1.51–4.54) (p = 0.001)	2.62 (1.61–4.25) (p < 0.001)
Non-Circulatory Deaths:			
Negative Only	7 (30.4%) of 23	16 (16.2%) of 99	23 (19.9%) of 122
No Assays or Neg & Pos	9 (39.1%) of 23	17 (19.8%) of 86	26 (23.9%) of 109
Positive Only	4 (50.0%) of 8	4 (21.1%) of 19	8 (29.6%) of 27
Total Mortality	20 (37.0%) of 54	37 (18.1%) of 204	57 (22.1%) of 258
Cox Regression Model: HR (95% CI) of Biomarker Gradient for Mortality (p Values)	1.59 (0.87–2.92) (p = 0.134)	1.33 (0.82–2.17) (p = 0.253)	1.47 (1.00–2.16) (p = 0.049)

Conclusions: Baseline (1974) upper quartile values of serum A-SAA and sIL-2Rα predicted long-term (18 to 35 yrs) mortality (p < 0.001), mainly attributable to circulatory (p < 0.001), than other (p = 0.049), causes of death. This novel biomarker deserves further testing as a long-term predictor of cardiovascular mortality.

A Prediction Score To Differentiate Rheumatoid Arthritis from Undifferentiated Arthritis in an Early Arthritis Cohort. Christian Waimann[2], Fernando DalPra[2], Jimena Hogrefe[2], Josefina Marcos[2], Soledad Retamozo[2], Francisco Caeiro[2], Luciana Casalla[2], Mariana Benegas[2], Oscar Rillo[2], Horacio Berman[2], Alberto Berman[2], Rodrigo García Salinas[2], Antonio Catalán Pellet[2], Federico Ceccato[2], Sergio Paira[2], Juan Carlos Marcos[2], José Maldonado Cocco[2], Luis Cattogio[2], Enrique Soriano[2] and Gustavo Citera[1]. [1]CONAART, Buenos Aires, Argentina, [2]CONAART, Argentina

Objective: to identify predictor factors for progression into rheumatoid arthritis (RA) in patients with undifferentiated arthritis (UA).

Methods: A prediction score was developed using data from CONAART (Argentine Consortium for Early Arthritis), the first early arthritis cohort in Argentina (n=714). Patients with at least one swollen joint and less than 2 years of symptoms duration were followed for 6 months. The clinical characteristics associated with RA in univariate analysis were later selected using a logistic regression model. A weighted score was set according to strength of association (odds ratio: OR) of main variables as follows (OR 1 to 2=1 point, OR 2.1 to 4=2 points, OR 4.1 to 8=3 points and OR > 8=4 points), given a total score from 0 to 20. A prediction score of 7 variables (tender and swollen joint count, symmetric involvement, acute phase reactants, rheumatoid factor (RF) positivity and anti-CCP positivity) was obtained. Categorical variables were compared using chi square and Fisher exact test and continue variables using student T test and ANOVA. The discriminative ability of the score to differentiate RA from UA was evaluated using the area under the curve (AUC). Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for different cut-off points of the score were calculated.

Results: 619 patients were included (UA=312, RA=307), 515 (83.2%) were women, median age 47 years, median disease duration 6 months. Patients with RA had significantly higher disease activity (DAS28), and worse functional capacity and quality of life compared to UA patients. In the logistic regression analysis, the independent predictive variables for development of RA and their corresponding score were: more than 5 tender joints = 3 points, more than 4 swollen joints = 3 points, symmetric involvement = 2 points, ESR > 22.5 mm/h = 1 point, C-Reactive protein > 8.5 mg/L = 3 points, RF positive = 4 points, Anti CCP positive = 4 points. The AUC value of the score was 0.84 (95% CI: 0.80–0.87). A cut-off value of 9 had sensitivity of 80% and specificity of 81.4%, PPV of 82% and NPV of 81.4% to differentiate RA from UA. The validation of the van der Helm van Mil (A&R 2007;52:433–440) prediction rule in our population showed an AUC of 0.80 (95%CI 0.76–0.83).

Conclusion: The present score had an excellent ability to discriminate between RA and UA using simple variables obtained from daily practice.

Association of Patient Cost-Cutting Behaviors with Clinical Outcomes, Health Status, and Lost Work Productivity in Individuals with Rheumatoid Arthritis. Susan C. Bolge[1], Ahmad B. Naim[2], Chureen Carter[2], Marco DiBonaventura[3] and Mike Ingham[2]. [1]Centocor Ortho Biotech Services, LLC, Horsham, PA, [2]Centocor Ortho Biotech Services, LLC, [3]KantarHealth

Background: In an effort to reduce rising healthcare costs, there has been a trend in managed care toward greater patient cost sharing. However, in this time of economic recession, high costs may necessitate cost-cutting decisions by patients, especially those with multiple, costly, chronic conditions. This study seeks to quantify cost-cutting behaviors in patients with rheumatoid

arthritis (RA) and assess the association of these behaviors with patient-reported clinical outcomes, health status, and work productivity loss.

Methods: In August 2009, individuals aged ≥18 and reporting an RA diagnosis completed a cross-sectional, self-administered, Internet-based questionnaire. Cost-cutting behaviors were assessed for the prior six months. Differences in outcomes were compared between patients with identified cost-cutting behaviors and those without. Patient-reported clinical outcomes included the Health Assessment Questionnaire (HAQ) and severity of morning stiffness, fatigue, and pain, measured as 1=none experienced to 10=severe. Health status was assessed using the SF-36, and work productivity loss was assessed using the Work Productivity and Activity Impairment questionnaire. Patient demographics and comorbidities were adjusted using linear regression for clinical outcomes and health status and negative binomial regression for lost work productivity.

Results: Of 1580 patients, 41.6% (n=658) reported at least one cost-cutting behavior. The most frequently reported behaviors were delaying RA related physician visits (59.0%), taking RA prescription medication less often (25.7%), and reducing number of RA prescriptions filled (22.9%). After adjustment, cost-cutting behavior was associated with greater functional disability (HAQ: regression coefficient b=0.19, $P<0.001$); severity of morning stiffness (b=0.76, $P<0.001$), fatigue (b=0.80, $P<0.001$), and pain (b=0.84, $P<0.001$); and poorer health status (SF-36 physical component summary: b=-1.75, $P<0.001$ and mental component summary: b=-3.33, $P<0.001$). Among the employed, patient cost-cutting behaviors were associated with 1.39 times ($P<0.001$) the amount of overall work impairment compared to those without.

Conclusion: A substantial proportion of RA patients engage in cost-cutting behaviors which are associated with worsening patient-reported clinical outcomes, poorer health status, and decreased work productivity; however, due to the cross-sectional nature of the study, the direction of these associations cannot be determined. Further research is needed to investigate the potential impact of patient cost sharing on clinical effectiveness and disease progression markers.

Baseline Factors Related to Response to Conventional DMARD Treatments. Kimberly L. Sterling[1], Gebra Cuyun Carter[1], Susan Messing[6], George Reed[5], Rui Chen[6], Kimberly Kaukeinen[6], Xin Tu[6], David R. Nelson[2], Khaled Sarsour[3], Ronald A. Cantrell[3], Carlos I. Alatorre[3] and Jeffrey Greenberg[4]. [1]Eli Lilly and Co, Indianapolis, IN, [2]Eli Lilly and Co, [3]Eli Lilly and Co, Indianapolis, IN, [4]New York University School of Medicine, New York, NY, [5]University of Massachusetts, Amherst, MA, [6]University of Rochester, Rochester, NY

Background: Heterogeneity of treatment response exists in rheumatoid arthritis (RA), while there is a lack of understanding of genetic and non-genetic factors that predict treatment response. Identifying baseline factors associated with patient response to RA treatment will assist tailoring therapies for patients. This study aimed to determine non-genetic baseline factors associated with treatment response at one year among RA patients initiating conventional disease-modifying antirheumatic drugs (DMARD) therapy with no previous biologic use.

Methods: The study included RA patients previously naïve to biologic therapy who initiated a conventional DMARD and had at least one year of follow-up in the Consortium of Rheumatology Researchers of North America (CORRONA) registry. Treatment response was assessed using the Clinical Disease Activity Index (CDAI) at one year (±3 months), evaluated in both a continuous (change from baseline to endpoint) and categorical (endpoint score ≤19.6 and improvement from baseline > 4.3) manner. The registry allowed for exploration of a broad set of baseline factors including socio-demographics, clinical factors, patient reported measures (i.e. behaviors, comorbidities, function), and prior healthcare use. Multivariate stepwise regression using backward elimination was conducted to determine variables significantly associated ($p<0.05$) with improvement.

Summary of the Results: A total of 1,350 patients met the entry criteria, and 893 (66%) of those had complete data and were included in the multivariate analyses. Of those with complete data, the mean age was 59.7 years, 662 (74%) were female, 750 (84%) were white, and the mean initial CDAI score was 14.5. The following baseline factors were associated with greater CDAI improvement (continuous) ($R^2=0.39$): higher initial CDAI score (β=-0.598, $p<0.0001$), lower BMI (β=0.086, p=0.05), lower modified Health Assessment Questionnaire (mHAQ) score (β=3.738, $p<0.0001$), no history of infection (β=-1.336, p=0.03), no use of analgesics (β=1.303, p=0.04), and not being disabled (β=-3.839, p=0.0002). For the categorical CDAI improvement outcome, the odds of improvement in disease activity is greater for those at baseline with a higher initial CDAI score (odds ratio [OR]=1.101, $p<0.0001$), younger in age (OR=0.986, p=0.03), light to no alcohol consumption history (moderate/heavy vs none/light, OR=0.302, p=0.01), and are not disabled (yes vs no, OR=0.413, p=0.002) ($R^2=0.22$).

Conclusions: This study identified that higher baseline disease activity and not being disabled were consistently associated with treatment response (continuous and categorical CDAI). Additional exploration is needed to understand the predictive role of variables such as BMI, physical function, history of infections, and analgesic use, which were inconsistently associated with response; and differences in sets of risk factors between medication classes (e.g. conventional vs biologic DMARDs). With a broad set of predictors, clinicians will be able to tailor treatment based on baseline characteristics to improve patient outcomes.

Cerebrovascular and Venous Thromboembolic Events Predict Mortality in Rheumatoid Arthritis. A. Kirstin Bacani[2], Sherine E. Gabriel[2], Cynthia S. Crowson[1] and Eric L. Matteson[2]. [1]Rochester, MN, [2]Mayo Clinic, Rochester, MN

Purpose: While survival in patients with rheumatoid arthritis (RA) appears to have improved in recent years, RA patients still experience excess mortality compared to patients without RA. The purpose of our study was to examine the potential of cerebrovascular events, venous thromboembolic events, and peripheral arterial events as predictors of mortality in RA patients.

Methods: A population-based inception cohort of RA patients who fulfilled 1987 ACR criteria for RA between 1/1/1980 and 12/31/2007 was assembled and followed until death, migration, or the present. The occurrence of cerebrovascular events (hemorrhagic stroke, nonhemorrhagic stroke, transient ischemic attack or amaurosis fugax), venous thromboembolic events (deep venous thrombosis or pulmonary embolism), and peripheral arterial events (abdominal aortic aneurysm, renal artery stenosis, peripheral vascular disease, or arterial thromboembolism), was ascertained by review of the medical record. Cox proportional hazard models were used to examine these noncardiac vascular disease events as predictors of mortality after adjusting for risk factors.

Results: The study population included 814 RA patients (mean age [SD] 55.9 [15.7] years; 68% women). The average length of followup was 9.6 [6.9] years. In this cohort, 204 have died. After adjusting for age, sex, calendar year of RA incidence, smoking status, rheumatoid factor positivity, history of alcoholism, obesity, cardiovascular disease (including hospitalized or silent myocardial infarction, heart failure, revascularization, angina, or physician diagnosis of coronary artery disease), renal disease, liver disease, cancer, metastases, dementia, severe extra-articular manifestations (i.e. pleuritis, pericarditis, Felty's syndrome, RA vasculitis, scleritis, neuropathy or glomerulonephritis), and steroid use, we found cerebrovascular events (hazard ratio [HR]: 1.60, 95% confidence interval [CI]: 1.06, 2.43; p=0.026) and venous thromboembolic events (HR: 2.52; 95% CI: 1.61, 3.95; $p<0.001$) were independent predictors of mortality. Additional adjustment for RA therapies (methotrexate, hydroxychloroquine, other disease modifying antirheumatic drugs, and biologics) did not change these results.

Conclusion: Our findings suggest that cerebrovascular events and venous thromboembolic events are associated with increased mortality in RA patients. Further study is needed to understand the contribution of these events to the excess mortality in RA patients.

Changes in Corticosteroid Use after DMARD Initiation in Patients with Rheumatoid Arthritis. Vivian K. Kawai[5], Carlos Grijalva[6], Patrick Arbogast[6], Jeffrey R. Curtis[4], Daniel Hal Solomon[1], Elizabeth Delzell[3], Rita Ouellet-Hellstrom[2], Ed Mitchel[6], C. Michael Stein[5] and Marie R. Griffin[6]. [1]Brigham and Womens Hospital, Boston, MA, [2]FDA, [3]University of Alabama, [4]University of Alabama–Brimingham, Birmingham, AL, [5]Vanderbilt University, Nashville, TN, [6]Vanderbilt University

Background: Disease modifying anti-rheumatic drugs (DMARDs) and corticosteroids are both used to treat rheumatoid arthritis (RA). Corticosteroids have dose-related side effects, and therefore, clinicians strive to minimize their use. Biologic and non-biologic DMARD use reduces RA disease activity and thus would be expected to result in decreased use of corticosteroids. There is, however, little information about the effect of DMARD therapies on corticosteroid use. Thus, we examined the hypothesis that initiation of DMARD therapies decrease corticosteroid use.

Methods: We assembled 4 retrospective cohorts of patients with RA from 1998 to 2005 enrolled in Tennessee's Medicaid Program (TennCare), Kaiser Permanente Northern California (KPNC), Pennsylvania Pharmaceutical Assistance Contract for the Elderly (PACE), and multi-State Medicaid programs (MAX) and identified 5 mutually exclusive patient groups initiating DMARD regimens: new methotrexate (MTX) without (new MTX) or with (MTX) use of other non-biologic DMARDs in the previous year; new hydroxychloroquine and/or sulfasalazine with use of MTX in the previous year (HCQ/SSZ); new leflunomide with use of MTX in the previous year (LEF); and new TNF-α antagonists. We used McNemar's test to assess within-person differences in any use of oral corticosteroids (>= 1 prescription) during the 6 months before versus 6–12 months after starting one of the study DMARD regimens.

Results: We identified 32476 initiators of study DMARD regimens who had a full year of baseline and one follow-up year of data available: 13% from TennCare, 18% from KPNC, 7% from PACE and 62% from MAX. In all groups, the percentage of users of corticosteroids increased in the 0–6 months before new DMARD initiation compared to the previous 6 months, likely representing worsening of the disease that led to the new DMARD regimen. In most groups, the percentage of users of corticosteroid then decreased significantly by 6 to 12 months after DMARD initiation (Figure 1). Across the 4 datasets, the absolute decrease in % of RA patients using corticosteroids ranged from 8.0% to 10.9% in new MTX users and 9.3% to 12.1% in MTX users (all P<0.05). Absolute changes ranged from 7.1% to 11.5% in group HCQ/SSZ users, 4.0% to 6.9% in group LEF users, and 3.6% to 11.5% in TNF-α antagonists (all changes <0.05 except for PACE participants who had both the lowest % corticosteroid use at DMARD initiation and the lowest absolute change).

Conclusions: The percentage of patients with RA receiving corticosteroids increased in the 6 months prior to the initiation of a new DMARD regimen and then decreased 6–12 months after initiation. Decreased corticosteroid use may be due to DMARD effectiveness or other reasons for disease improvement.

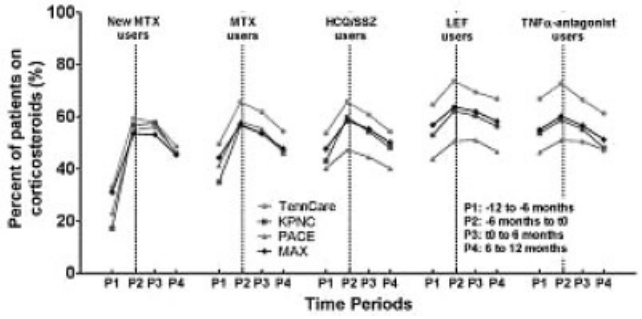

Figure 1. Changes in percent of users of corticosteroid after initiation of RA therapies.

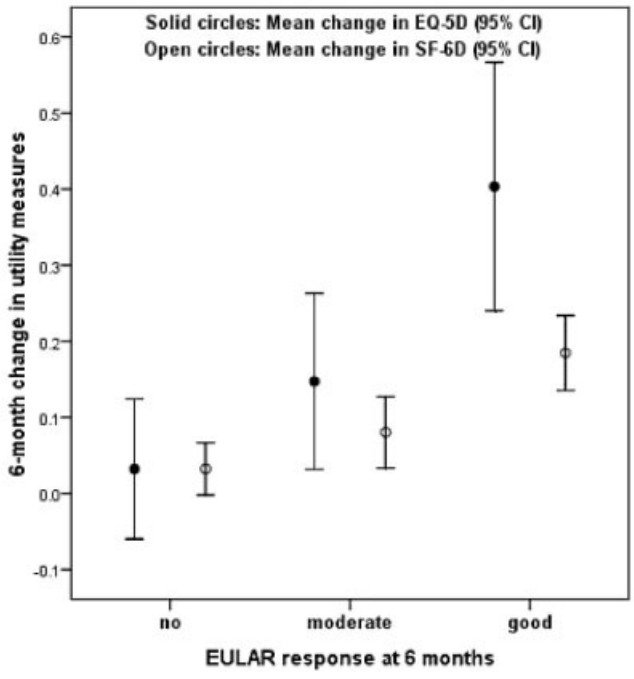
Changes in EQ-5D and SF-6D during Rituximab Treatment—Results from the CERERRA Collaboration. Elisabeth Lie[4], Katerina Chatzidionysiou[7], Evgeny Nasonov[9], Galina Lukina[9], Cem Gebay[12], Karel Pavelka[2], Dan Nordström[6], Matija Tomsic[13], Merete L. Hetland[3], Ulrik Tarp[1], Piet L. C. M. van Riel[10], Juan J. Gomez-Reino[11], Ronald Van Vollenhoven[8] and Tore K. Kvien[5]. [1]Aarhus University Hospital, Aarhus, Denmark, [2]Charles University, Prague, Czech Republic, [3]Copenhagen University Hospital at Glostrup/DANBIO Registry, Copenhagen, Denmark, [4]Diakonhjemmet Hospital, Oslo, Norway, [5]Diakonhjemmet Hospital, Oslo, Norway, [6]Helsinki University Central Hospital, Helsinki, Finland, [7]Karolinska University Hospital, Stockholm, Sweden, [8]Karolinska University Hospital, Stockholm, Sweden, [9]Moscow Institute of Rheumatology, Moscow, Russian Federation, [10]Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, [11]University Hospital of Santiago, Santiago, Spain, [12]University Hospitals of Geneva/SCQM Registry, Geneva, Switzerland, [13]University Medical Center of Ljubljana, Ljubljana, Slovenia

Background: Rituximab (RTX) has been shown to be efficacious in rheumatoid arthritis (RA) pts failing DMARDs or anti-TNF. However, biologic therapies are costly, raising an interest in the economics of treatment. Utility instruments (e.g EQ-5D, SF-6D) yield health state utility values for cost-utility analyses. The purpose of this study was to assess the 6-month utility gain across disease characteristics and levels of clinical response in pts treated with RTX, and to compare the performance of EQ-5D and SF-6D in patients in whom both measures had been recorded.

Methods: In a data set of patients treated with RTX (n=2265, from 10 European registries), EQ-5D and/or SF-36 had been recorded in a subset of Russian, Swiss and Norwegian pts. Mean ΔEQ-5D was compared across baseline characteristics and EULAR response categories by two samples t test and ANOVA. ΔEQ-5D and ΔSF-6D within patients were compared by paired samples t test & Wilcoxon's test.

Results: 192 pts (111 Russian, 75 Norwegian, 6 Swiss) had EQ-5D recorded at baseline and 6 months: These pts were younger than the other pts (51 vs 54 yrs, p=0.002) and more often treated with concomitant DMARDs (82% vs 74%, p=0.008). Other baseline characteristics were similar. 83% were female, 73% RF pos, 76% aCCP pos. Median(IQR) # of previous biologics/synthetic DMARDs was 1(0–2)/3(2–4); 41% were given RTX as the first biologic. Mean(SD) disease duration was 11.2(7.8) yrs, DAS28 5.9(1.3) and EQ-5D 0.29(0.34) [median(IQR) 0.52(-0.02–0.59)]. 21%/44%/35% achieved good/moderate/no EULAR response at 6 months, mean(SD) ΔDAS28 was −1.8(1.4) (both N.S. vs remaining pts) and ΔEQ-5D was 0.22(0.32) [median(IQR) 0.07(0.00–0.53)]. EQ-5D changes were not significantly different when comparing groups based on RF, gender, DMARD co-therapy, or # of previous biologics. There was a trend towards larger utility gain in aCCP pos vs neg pts (mean(SD) 0.21(0.32) vs 0.08(0.22), p=0.06), and mean ΔEQ-5D was larger in pts achieving EULAR response (mean(SD) 0.37(0.30)/0.24(0.32)/0.13(0.31) for good/moderate/no response, p=0.001; good vs no response post-hoc Bonferroni p=0.001). 68 pts had 6-month changes in both EQ-5D and SF-6D available. The two instruments yielded different results for change in utility values, figure shows change across clinical response. For patients achieving EULAR good response utility gain was significantly larger measured by EQ-5D vs SF-6D (mean/median 0.40/0.41 vs 0.18/0.22, paired t test p=0.002/Wilcoxon p=0.007). For individual pts the difference btw EQ-5D/SF-6D was 0.50–0.75 units.



Conclusion: This group of RA pts treated with RTX in a real life setting gained a mean of 0.22 units in EQ-5D during the first 6 months. Improvement in EQ-5D was associated with clinical response. The data also demonstrated that changes in EQ-5D and SF-6D can differ considerably, and thus the choice of instrument may substantially influence the cost-utility results.

Comparison of the Efficacy of Tocilizumab and TNFα-Inhibitors on the DAS28 in "Real Life" Conditions in Rheumatoid Arthritis (RA) Patients after DMARD Failure. Jörg Kaufmann[2], Eugen Feist[1], Hagen Schmidt[3], Anne-Eve Roske[4] and Adrian Kielhorn[4]. [1]Campus Charité Mitte, Med. Klinik Abt. Rheumatologie u. Klin. Immunologie, Berlin, Germany, [2]Praxis für Innere Medizin und Rheumatologie, Ludwigsfelde, Germany, [3]Praxis für Innere Medizin und Rheumatologie, Berlin, Germany, [4]Roche Pharma AG, Grenzach-Whylen, Germany

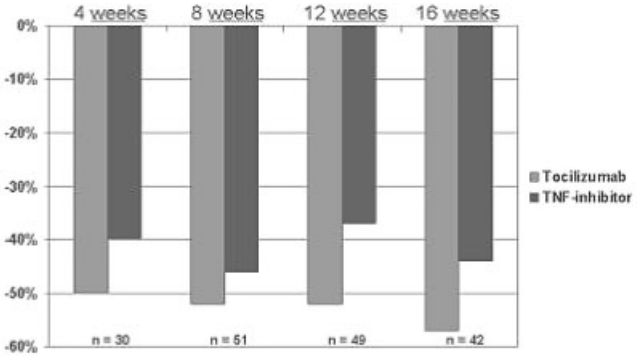
Clinical trials for a direct comparison of efficiency data between TNFα-inhibitors and tocilizumab are not available yet. Meta analysis could demonstrate no differences at least for various TNFα-inhibitors.

Objectives: The aim of this study was to compare the efficacy of TNFα-inhibitors and tocilizumab on the Disease Activity Score (DAS28) in patients with an inadequate response to DMARDs.

Methods: Retrospective, pseudonymous data from RA patients who received their first biologic, were documented. Two cohorts were formed: patients who received a first biologic TNFα-inhibitor (TNF cohort) or tocilizumab (TCZ cohort). Each center documented pseudonymous data of at least 3, maximum of 5 patients per cohort. From each of these groups each center selected the two best patients with justification. DAS28 data at baseline and either 4, 8, 12 or 16 weeks were documented.

Results: Data of 298 patients from 47 centres have been documented. The patients in both cohorts have similar clinical characteristics and can be considered to be representative of RA patients in accordance with the German Registry RABBIT

After 12 weeks the DAS28 in the TCZ cohort had fallen by 52%, which corresponds to a reduction of 2.6 points. In the cohort of TNF, DAS28 decreased by 38% and an absolute value of 1.8 points. For each of the observation dates was a greater reduction in DAS28 of TCZ cohort compared with the TNF cohort found (see figure).



Summary: In RA patients after failure or inadequate response to a DMARD therapy was a greater improvement in DAS28 with a tocilizumab therapy in comparison with a TNFα-inhibitor therapy during the observation period of 16 weeks.

Demyelinating Events in Seniors with Rheumatoid Arthritis (RA): A Population-Based Study. Jessica Widdifield[7], Sasha R. Bernatsky[2], J. Michael Paterson[1], Nadia Gunraj[1], Janet E. Pope[5], J. Carter Thorne[4], Alfred A. Cividino[3] and Claire Bombardier[6]. [1]Institute for Clinical Evaluative Science, [2]McGill UHC/RVH, Montreal, QC, Canada, [3]McMaster University, Hamilton, ON, Canada, [4]Southlake Regional Health Care, Newmarket, ON, Canada, [5]St Joseph Health Care London, London, ON, Canada, [6]University of Toronto, Toronto, ON, Canada, [7]University of Toronto

Background: Up until recently, multiple sclerosis and other demyelinating syndromes were reported only rarely in rheumatoid arthritis (RA). However, since the introduction of RA therapies targeting tumour necrosis factor (TNF), numerous case reports have arisen in the literature. Currently there are very few cohort-based assessments of the incidence of demyelinating events in RA, and/or the possible influence of drug exposures. The Ontario Biologics Research Initiative (OBRI) is an innovative undertaking to promote real-world rheumatic drug surveillance. Some of the OBRI analyses make use of Ontario's administrative healthcare databases. Since universal drug coverage occurs comprehensively for Ontario residents aged $\geq$ 65 years, we were able to assess the risk for developing demyelinating events in seniors with RA, and explore for potential drug effects in this sample.

Methods: An RA cohort was assembled from Ontario billing and hospitalization data, 1992–2009. Analyses were limited to subjects aged $>$ 65 with a diagnosis of RA, who filled at least 1 prescription for an oral glucocorticoid, disease-modifying agent (DMARD) or biologic. We excluded any individuals with a diagnosis of a demyelinating event, prior to their entry into the RA cohort. Then, over 1998–2009, we identified all new cases of demyelinating events occurring within this cohort. Our case definition of a demyelinating event was based on one or more hospitalization diagnoses, or at least 2 billing claims diagnoses (at least 8 weeks apart, but within 2 years). Identified cases were matched (on age, sex, and date of cohort entry) to up to 5 controls from the same RA cohort. We calculated the incidence rate of demyelinating events in the cohort of seniors with RA, and described medication use in relationship to these events.

Results: In 85,458 seniors with RA (over 614,915.5 person-years), 51 demyelinating events occurred. This provides an event rate of 8.3 events/100,000 person-years, which is comparable to recent figures for demyelinating events for seniors in the Canadian general population. Biologic exposures were rare in our cohort, and none of the cases of demyelinating events in our RA cohort had been exposed to an anti-TNF agent at the time of the event, or within the 12 months preceding the event. In both cases and controls, the most common medication exposures were NSAIDs/COXIBs, glucocorticosteroids, hydroxychloroquine, and methotrexate.

Conclusions: We provide novel data on the incidence of demyelinating events in a cohort of seniors with RA. The incidence rate of 8.3 new demyelinating events/100,000 patient-years is comparable to recent rates for Canadian seniors. None of these events appeared to have been triggered by anti-TNF drug exposures. Estimating the risk for demyelinating events due to these agents was problematic in our sample, given relatively low drug exposure rates.

Descriptive Epidemiology of Adult Rheumatoid Arthritis in an Insurance Claims Database. Martin M. Crane[1], Maneesh Juneja[3], Fayaz A. Aziz[3], Regina H. Kurrasch[2], Myron E. Chu[2], Emilia Quattrocchi[3], Stephanie Manson[4] and David J. Chang[2]. [1]GlaxoSmithKline R&D, Research Triangle, NC, [2]GlaxoSmithKline R&D, King of Prussia, PA, [3]GlaxoSmithKline R&D, [4]United Biosource

Background: Our goal was to estimate the incidence and prevalence of rheumatoid arthritis (RA) in a US administrative medical claims database. Databases such as this one contain the majority of encounters and prescriptions for any disease that can be defined using an ICD9 code in an insured US population ("real-world" practice); however, the major disadvantages are lack of any clinical information, left-censoring (incom-

plete medical history)and right-censoring (truncated follow-up) of data, and under-representation of the elderly due to Medicare coverage at age 65 years.

Methods: The study population was defined as all patients ≥ 18 years having medical information for the entire 4.75-year period of 1-Jan-2004 to 30 Sept-2008 (N=4.65 million) in a health claims database (IMS LifeLink: Health Plan Claims Database, PharMetrics, Inc, Watertown, WA.) Prevalent RA was defined as having at least one occurrence of a code (ICD9 7140–7142) prior to 2006, and one occurrence during 2006, with the two occurrences at least 30 days apart. Incident RA was defined as no RA codes prior to 2006, and two codes at least 30 days apart during the interval 1-Jan-2006 to 31-March 2007. Polyarthritis or undifferentiated arthritis (7149) was not part of the algorithm; however, an "aggressive" incident subset was defined based on having >8 RA physician visits in the 12 months post diagnosis and no prior 7149 code.

Summary: Prevalence was 0.65% overall (0.92% in females and 0.36% in males) and incidence was 0.07% (0.10% female; 0.04% male). Median age at the occurrence of the first RA code was 57.0 in the incident and 55.0 years in the prevalent patients and, prior to 2006, 47.8% of the latter had received at least one prescription for methotrexate. Other connective tissue diagnoses (based on two occurrences 30 days apart) were present in 7.9% and 9.7% of the incident and prevalent patients respectively. In the 12 months after the first RA visit, 64.0% of incident and 55.1% of prevalent patients were prescribed a non-biologic DMARD and 20.4% and 22.1% were prescribed an anti-TNF. The "aggressive" subset was approximately 11% of all incident patients.

Conclusions: Prevalence rate (0.65%) was lower than in other cohorts (Mayo Clinic – 0.72%; UK Norfolk– ~0.80%) that used ACR diagnostic criteria and fully captured RA in the aged. Incidence (0.07%) was greater than reported in either prior cohort (0.04% and ~0.025% respectively for Mayo Clinic, US and Norfolk, UK). Claims databases probably underestimate the true prevalence of RA but may better reflect the proportion of patients actively seeking care; incidence is likely to be overestimated due to left-censoring.

Disclosure: M. M. Crane: None; **M. Juneja:** None; **F. A. Aziz:** None; **R. H. Kurrasch:** None; **M. E. Chu:** None; **E. Quattrocchi:** None; **S. Manson:** None; **D. J. Chang:** None.

Different Factors Are Important for RA Patients and Rheumatologists Regarding DMARD Escalation. Laura van Hulst[2], Wietske Kievit[1], Piet van Riel[2] and Liana Fraenkel[3]. [1]Radboud University Nijmegen Medical Centre, Department of Rheumatology, Nijmegen, The Netherlands, [2]Radboud University Nijmegen Medical Centre, Department of Rheumatology, [3]Yale University School of Medicine, Department of Medicine, VA Connecticut Healthcare System, Section of Rheumatology

Background: Studies showed that treatment is not always escalated in RA patients with active disease which might by explained by differences in how rheumatologists and patients prioritize the factors relevant to the decision to escalate DMARDs.We determined which factors are most important to patients and rheumatologists in deciding whether or not to escalate DMARDs and if the importance that patients and rheumatologists assign to these factors differs.

Methods: We administered a Maximum Difference Scaling survey to 106 Dutch rheumatologists and 93 RA patients. The survey was composed out of 58 factors related to DMARD escalation. Respondents were presented with 24 choice tasks. For each choice, composed out of 5 items, respondents were asked to indicate the factor that was most important to them in their decision whether or not to escalate DMARDs. The design of the survey was determined by the Sawtooth Software ®. Data were analyzed using Hierarchical Bayes modelling resulting into individual item importance scores (IS) ranging from 0 to 100. Independent sample t-tests were performed to compare the importance scores of the top 5 reasons amongst rheumatologists and patients.

Results: Patients' mean age was 60.2 (sd: 12.6) years, mean disease duration was 12.3 (sd: 12.6) years, and 66% were female. Rheumatologists' mean age was 47.2 (sd: 9.3) years, 51% were male, The 5 most important reasons to escalate DMARDs for rheumatologists were: number of swollen joints (mean IS: 5.2; sd: 0.4), DAS28 (mean IS: 5.2; sd: 0.5), their global assessment of RA disease activity (mean IS: 5.2; sd: 0.6), worsening of patient's erosions (mean IS: 5.2; sd: 0.6) and RA disease activity now compared to 3 months ago (mean IS: 5.1; sd: 0.6). For patients, the top 5 was: current level of physical functioning (mean IS: 4.2; sd: 1.2), trust in their rheumatologist (mean IS: 4.0; sd: 1.2), number of painful joints (mean IS: 3.5; sd: 1.2), satisfaction with current DMARDs (mean IS: 3.4; sd: 1.4) and overall general health (mean IS: 3.3; sd: 1.5). Figure 1 shows that these 5 items are approximately twice as important for rheumatologists compared to patients (all statistically significant; p<0.001).

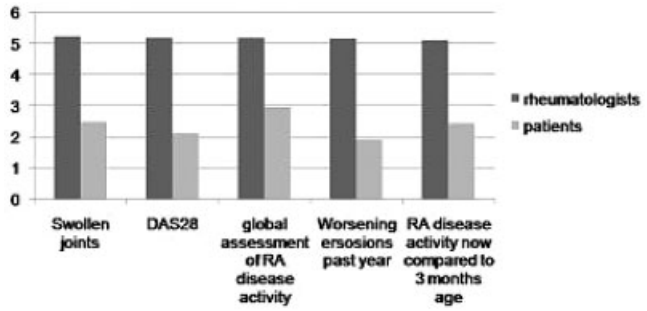

Figure 1. Most important factors that are considered by rheumatologists regarding DMARD escalation. A comparison with patients' importance scores.

A comparison of the 5 most important factors for patients vs rheumatologist showed that patient's trust in the rheumatologist (4.0 vs 0.4), number of painful joints (3.5 vs 3.0) and satisfaction with current DMARDs (3.4 vs 2.3) were statistically more important for patients than for rheumatologists, respectively (p<0.001). Physical functioning (4.2 vs 4.4) and current general health (3.3 vs 3.1) were equally important.

Conclusions: Different factors are important for patients and rheumatologists regarding DMARD escalation. Improved communication between physicians and patients regarding the factors influencing decision making might increase the number of RA patients receiving treatment concordant with published guidelines.

DMARD Use for Rheumatoid Arthritis as Reported in the National Ambulatory Medical Care Survey, 1996–2007. Daniel Hal Solomon[4], John Ayanian[3], M. Alan Brookhart[6], Sebastian Schneeweiss[2], Tamara Shaykevich[2], Edward H. Yelin[5] and Jeffrey N. Katz[1]. [1]Brigham & Womens Hosp, Boston, MA, [2]Brigham and Women's Hospital, [3]Brigham and Women's Hospital, Harvard Medical School, [4]Brigham and Womens Hospital, Boston, MA, [5]University of California, San Francisco, CA, [6]University of North Caroline

Background: There is broad agreement on the value of disease modifying anti-rheumatic drug (DMARD) treatment for rheumatoid arthritis (RA). In fact, a DMARD prescription for patients with RA has become a quality measure for various US-based health insurance programs. There are few population-based estimates of the rates of DMARD use for RA. We studied correlates of DMARD use in a large nationally representative US sample.

Methods: The study database consisted of visits in the US National Ambulatory Medical Care Survey (NAMCS), 1996–2007. Visits for RA were defined based on diagnosis codes reported by the providers.

Providers list all medications, up to 8, used by the patient. Medication lists were checked for DMARDs, synthetic or biologic. Unadjusted and adjusted risk ratios were calculated to assess associations between patient and provider characteristics and receipt of any DMARD, as well as a biologic DMARD. All models accounted for the sampling design of NAMCS, using Rlogist in SUDAAN.

Results: From the 317,416 visits recorded in NAMCS over the study period, we identified 859 (0.3%) visits associated with an RA diagnosis. 404 (47%) of these visits had a DMARD noted in the medication list—273 of 377 (72%) visits to rheumatologists and 131 of 482 (27%) to non-rheumatologists. Nine percent of RA visits had a biologic DMARD noted. There was no significant trend towards improved DMARD use rates over the 12 year study period. In adjusted models, black race was associated with reduced DMARD use and use of more medications was associated with increased DMARD use (see Table). Visits to non-rheumatologists were associated with a 60% reduction in DMARD use and a 50% reduction for biologic DMARDs.

Table: Risk Ratios for DMARD use in the National Ambulatory Medical Care Survey, 1996–2007

	Any DMARD* use, risk ratio (95% CI)			Biologic DMARD use, risk ratio (95% CI)		
	Model 1	Model 2	Model 3	Model 1	Model 2	Model 3

3+		1.9 (1.4–2.7)	1.8 (1.4–2.4)		1.8 (1.2–2.5)	1.7 (1.3–2.3)
Rheumatologist						
Yes			1.00			1.00
No			0.4 (0.3–0.5)			0.5 (0.4–0.6)

*Any DMARD includes methotrexate, sulfasalazine, hydroxychloroquine, leflunomide, cyclosporine, gold preparations, D-penicillamine, azathioprine, etanercept, adalienumab, infliximab, rituximab, abatacept, anakinra. Model 1 only includes race/ethnicity and calendar year of NAMCS visit. Model 2 also includes age, gender, and number of drugs. Model 3 includes all of Model 2 variables and rheumatologist.

Conclusions: While there is likely misclassification of some visits, the use rate for DMARDs for RA was sub-optimal as reported in NAMCS over the 12-year study period. A visit to a rheumatologist was the most important correlate of DMARD use. Race/ethnicity remained associated with DMARD use after full adjustment. Interventions to improve DMARD use should target improving access to rheumatic disease specialists and identifying and overcoming barriers to DMARD use faced by Black patients.

Early Life Socioeconomic Factors and Rheumatoid Arthritis (RA) in Adulthood. Christine G. Parks[2], Aimee A. D'Aloisio[1], Lisa A. DeRoo[1], Huiber Kirstin[3] and Dale P. Sandler. [1]National Institute of Environmental Health Science, Research Triangle Park, NC, [2]National Institute of Environmental Health Science, Research Triangle Park, NC, [3]UNC, School of Public Health, Chapel Hil NC

Objective: To determine whether early life socioeconomic environment is related to prevalence of rheumatoid arthritis (RA) in adult women.

Methods: The study sample included the first 32,017 women (ages 35 to 74; median age 55 years;91% non-Hispanic white, 4% black, 5% other) participating in the Sister Study, a national cohort study of environmental factors and health. Data were obtained from baseline questionnaires. Cases were defined as women reporting doctor-diagnosed RA, with current or past use of disease modifying anti-rheumatic drugs (DMARDs) or steroids for RA, and history of bilateral joint swelling lasting 6 weeks or longer. Early life factors included childhood food insecurity, relative household income, highest household education, and parental ages at participants' birth. Odds Ratios (OR) and 95% Confidence Intervals (CI) were estimated by logistic regression, adjusting for age. Fully-adjusted models also included multiple early life factors and race/ethnicity.

Results: We identified 233 (0.7%) women reporting RA diagnosed after age 16 (median age 46 years at diagnosis) who also reported DMARD use or steroids for RA and bilateral joint swelling. Compared to 30,951 women without reported RA, cases were more likely to report childhood food insecurity (13% vs. 8%), younger maternal age (under age 21; 13% vs. 7%), and lower household income and education (chi-squared p-values <0.01). After adjusting for age, significant associations were seen for food insecurity (OR=1.8; 95%CI 1.2, 2.7), low household education (OR=1.7; 95%CI 1.0, 2.9; less than high school versus college degree) and young maternal age (OR=1.8; 95%CI 1.2, 2.9; ages <21 vs. ≥ 32 years at birth). Non-significantly elevated ORs were also seen for low household income and younger paternal age. In mutually-adjusted models, significant associations persisted for food insecurity (OR=1.7) and young maternal age (OR=1.8), and were not confounded by race/ethnicity.

Conclusions: These results suggest lower socioeconomic status in childhood may be related to DMARD-treated RA in women. Few studies have addressed early life factors in RA, but research across a broad spectrum of other diseases supports an important role of early life influences on the immune system in both humans and experimental models. The etiologic pathway linking childhood socioeconomic factors and RA may include maternal and childhood characteristics and environmental exposures, as well as adult socioeconomic status and exposures. Disease severity, reporting, and survival may impact case identification, so these preliminary findings need to be confirmed in incident cases.

Effect of Disease-Modifying Anti-Rheumatic Drug (DMARD) Exposure on Head and Neck Cancer in a National Cohort of Veterans with Rheumatoid Arthritis. Christopher R. Phillips[2], Angelique L. Zeringue[3], Jay R. McDonald[1], Seth A. Eisen[3], Liron Caplan[4] and Prabha Ranganathan[5]. [1]Division of Infectious Disease, St. Louis Veterans Affairs Medical Center, [2]Division of Rheumatology, Washington University School of Medicine, Paducah, KY, [3]St. Louis Veterans Affairs Medical Center, [4]Univ of CO–Denver Med Sc, Aurora, CO, [5]Washington University School of Medicine, St. Louis, MO

Purpose: A role for virus-induced malignant transformation has been postulated for primary squamous cell carcinoma of the head and neck (HNC). Previous studies have examined the effect of disease-modifying ant-rheumatic drug (DMARD) exposure on the risk of overall malignancy in patients with rheumatoid arthritis (RA). The effect of tumor necrosis factor (TNF) antagonists on the natural history of HNC in RA, which may be detrimental, given the possible viral etiology of these cancers, has not been explored. Our aim was to determine the effect of exposure to TNF antagonists on HNC in terms of incidence, recurrence, and death from HNC in a national cohort of veterans with RA.

Methods: We examined a retrospective cohort of 49,539 patients with an International Classification of Disease, Version 9, (ICD-9) diagnosis of RA and at least one DMARD prescription from the Department of Veterans' Affairs (VA) national administrative data-

bases enrolled between October 1, 1998 and September 30, 2008. Pharmacy data was obtained from national VA databases. Subjects with an ICD-9 code for HNC after entry into the cohort underwent medical record review to confirm the diagnosis of HNC and RA. Details on HNC diagnosis, recurrence, treatment, HNC-related death, and comorbidities were abstracted.

Results: Of 807 patients with an ICD-9 diagnosis of RA and HNC, 255 patients had both RA and HNC after validation by medical record review. Demographic and clinical characteristics of these patients are presented in Table 1. Of these, 65 patients received a TNF antagonist, and 190 received only non-biologic DMARDs. Of the 65 patients exposed to TNF antagonists, 43 were exposed prior to diagnosis of HNC, 20 had continued exposure after diagnosis, and 20 received TNF antagonists only after HNC diagnosis. Of the 255 patients, 201 had HNC remission, 42 had a recurrence or developed a second HNC (at a different site), and 60 had HNC-related death. Of the 40 patients exposed to a TNF antagonist post-HNC diagnosis for whom information was available, 7 developed a recurrence, and 5 had a HNC-related death. The incidence of HNC recurrence and HNC-related death was 27.3 and 18.8 per 1000 patient-years in patients exposed to TNF antagonists after HNC diagnosis compared to 29.3 and 30.3 per 1000 patient-years in patients exposed only to non-biologic DMARDs.

Conclusion: Exposure to TNF antagonists does not appear to increase the risk of HNC recurrence or HNC-related death in patients with RA compared to exposure to non-biologic DMARDs. The use of TNF antagonists may be safe in patients with RA and head and neck cancer with careful monitoring.

	Exposed only to non-biologic DMARDs	Exposed to TNF antagonists
Number	190	65
Age (std dev)	62.9 (9.1)	64.7 (9.2)
Male gender (%)	188 (99.0%)	64 (98.5%)
White race (%)	57 (87.7%)	171 (90.0%)
Smoker (%)	180 (94.7%)	59 (90.8%)
Alcohol Abuse (%)	132 (69.5%)	51 (78.5%)
Other Cancers (%)	13 (6.8%)	2 (3.1%)

Elaboration and Validation of a Questionnaire To Assess the Impact of Rheumatoid Arthritis (RA) on Sexuality, with Patient Involvement: QUALISEX. Laure Gossec[2], Catherine Solano[4], Simon Paternotte[2], Catherine Beauvais[3], Christelle Sordet[6], Philippe Gaudin[1] and Aleth Perdriger[5]. [1]Grenoble University Hospital, France, [2]Paris Cochin University Hospital, France, [3]Paris Saint Antoine University Hospital, France, [4]Paris, France, [5]Rennes University Hospital, France, [6]Strasbourg University Hospital, France

Background: RA may have consequences on sexual life either through physical or psychological aspects. These consequences are not evaluated, because current questionnaires do not assess the impact of RA on sexuality. A new questionnaire is needed with a particular attention to face validity and phrasing to avoid missing data in this sensitive field of research.

Objective: To develop a questionnaire assessing the impact of RA on sexuality (QUALISEX) then to assess the psychometric properties of this questionnaire.

Methods: Four-step process. (1) A steering group of 6 patients (5 women, 1 man) with RA, 2 rheumatologists and 1 sexologist elaborated during a one-day focus-group type meeting, an exhaustive list of issues relating to impact of RA on sexuality. Relative weights by importance were obtained for each item. (2) A preliminary questionnaire was developed with input from these patients, with particular attention for phrasing so as to avoid missing data. (3) The questionnaire was assessed by 5 external reviewers (2 physicians, 1sexologist, 2 allied health professionals), then pre-tested in fact-to-face meetings with 10 patients. (4) The questionnaire was tested for psychometric properties in a longitudinal multi center study (missing data, correlations with other disease aspects, reliability).

Results: The list of aspects related to impact on sexuality included 32 aspects, categorised into general aspects (5), psychological issues/ self-esteem (9), couple/relationship issues (7), partner/spouse issues (4) and physical issues (7). The list was brought down to 10 items according to the relative weights of the items. A 10-question questionnaire was constructed, with assessment by numeric rating scales (NRS) from 0 (no impact of RA) to 10 (full impact of RA). Preliminary validation was obtained on 53 patients (44 women, mean age 50.7 years; mean disease duration 15.5 years, mean DAS: 3.5). The Qualisex mean score was 3.3 ± 2.5, missing data was acceptable (7 patients, 13%, had more than one missing question). Qualisex results were correlated with RAID ($R=0.65$), DAS28 ($R=0.55$), fatigue ($R=0.55$), pain (0.54) and mHAQ ($R=0.50$), ($p < 0.001$); but not with demographics, depression or coping. Qualisex was reliable in 40 patients: the intra-class correlation coefficient was 0.83 (95% CI: 0.70–0.91).

Conclusion: A simple (10 NRS) and valid tool investigating impact of RA on sexuality has been developed with the involvement of patients. This tool could be useful to assess the efficacy of oriented interventions or of biologics.

Geographical Variation of Rheumatoid Arthritis in Stockholm County, Sweden. Henrik Källberg[4], Veronica M. Vieira[2], Jamie E. Hart[1], Karen H. Costenbader[3], Marie Holmqvist[5], Lars Klareskog[6], Lars Alfredsson[5] and Elizabeth W. Karlson[3]. [1]Channing Laboratory, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston Massachusetts, Department of Epidemiology, Harvard School of Public Health, Boston Massachusetts, [2]Department of Environmental Health, Boston University School of Public Health, Boston, MA, [3]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital and Harvard Medical School, Boston Massachusetts, [4]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [5]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [6]Rheumatology Unit, Department of Medicine, Karolinska Institutet/Karolinska Hospital, Stockholm, Sweden

Background: Past studies have displayed geographical variation in RA incidence, suggesting the influence of environmental factors on RA etiology. We aimed to investigate geographical distribution of risk of developing RA within Stockholm County, Sweden.

Methods: We studied spatial variation in incident RA among 1095 incident cases and 1251 controls participating in a Swedish case-control study. The Swedish RA study is a population-based case-control study that has collected information from almost all newly diagnosed RA cases in Stockholm County. Analyses were limited to those subjects living in Stockholm County prior to RA diagnosis for cases and prior to matched date for controls and having geocoded addresses. We used Generalized Additive Models (GAM) to create a risk surface, calculate odds ratios and adjust for potential confounding by smoking and socioeconomic status defined through occupation held at the time of diagnosis. We performed a stratified analysis based on presence/absence of antibodies to citrullinated peptides (ACPA).

Results: We found significant spatial variation regarding risk of developing RA in adjusted models ($p < 0.05$, Figure 1.). The spatial variation decreased for some areas but remained significant after adjusting for potential confounding from smoking and socioeconomic status. The stratified analysis for ACPA positive RA cases ($n = 700$) showed similar results as for the non-stratified analysis. We did not manage to estimate valid odds ratios for the RA subgroup without ACPA because of few cases ($n = 395$) in that subgroup.

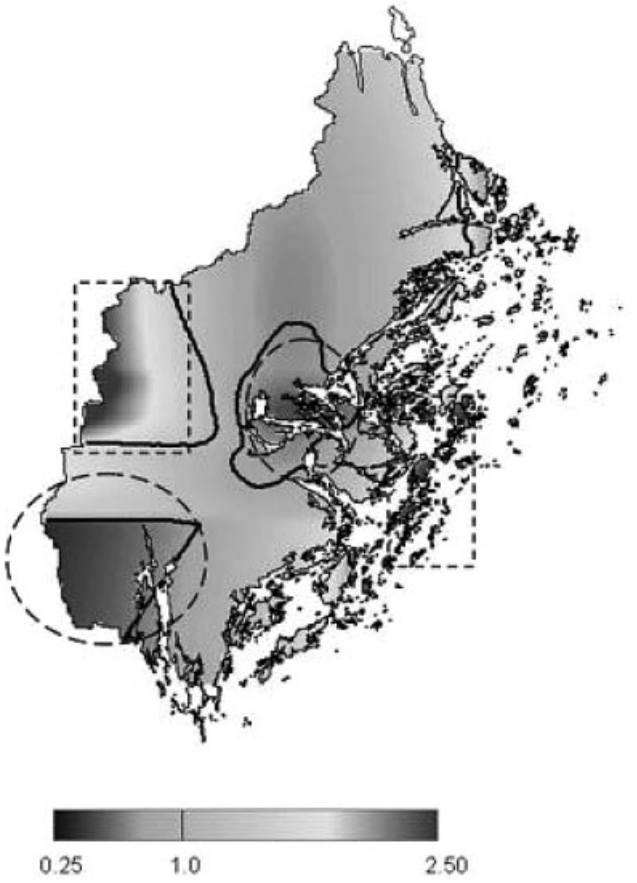

Figure 1. Spatial variation regarding odds ratios of developing RA in Stockholm County. Yellow-Red indicate areas (Dotted squares) associated with increased odds ratios for RA and Blue indicate areas (Dotted circles) with associated with decreased risks of developing RA.

Conclusions: Our analysis indicates that there is geographical variation within Stockholm County regarding risk of developing RA. This variation is not explained by smoking or current socioeconomic status according to occupational status. Therefore we suggest further studies in order to investigate potential sociodemographic or environmental factors to explain this variation.

H2607—Country of Residence Affects the Ability of Patients with Rheumatoid Arthritis (RA) To Achieve a Favorable Employment Status. Ronald van Vollenhoven[2], Mary Cifaldi[1], Annelies Boonen[4], Sanjoy Roy[1], Naijun Chen[1] and Vibeke Strand[3]. [1]Abbott Laboratories, Abbott Park, IL, [2]Karolinska University Hospital and Karolinska Institute, Stockholm, Sweden, [3]Stanford University, Palo Alto, CA, [4]University Hospital Maastricht, Maastricht, The Netherlands

Background: Clinical trials are conducted in many countries with varying social systems; country of residence may influence access to employment, disability benefits, and attitudes toward missing work for patients (pts) enrolling in RA trials. We examined differences in pts' probabilities of achieving favorable employment status (FES) in the PREMIER Health Economic Companion Study (DE032), based on country of residence.

Methods: PREMIER was a 2-year, randomized controlled trial of adalimumab (ADA), methotrexate (MTX), and ADA+MTX in pts with early RA (<3 years). DE032 was conducted in parallel with PREMIER and collected work productivity data for a large subset of pts. Countries were included if they had >25 employed pts at baseline. FES was defined as retaining baseline employment or gaining employment during the trial. Multivariate logistic regression models were used to evaluate association between FES at the end of the study for pts in each country vs. the other countries as a group. Adjustments were made for age, sex, Health Assessment Questionnaire Disability Index (HAQ DI), total Sharp score (TSS), treatment, and time on treatment. Baseline work-related outcomes were compared by country, including self-reported employed/homemaker status, missed work, % unfit for work at home, hours of missed work, and work productivity measured on a visual analog scale.

Results: Four countries enrolled >25 working pts at baseline: Germany, Australia, the United States (US), and Canada. Approximately half of the pts were employed at baseline in Germany and Canada vs. about two-thirds in Australia and the US. Pts in Germany tended to miss work more often and for more days than pts in other countries. Germany had fewer homemakers vs. other countries. Impacts of RA on performance at work and at home were similar across countries. Multivariate regressions comparing the odds ratios (ORs) for FES by country relative to all other countries showed that residing in the US (OR=2.3, $p<0.0001$) had an independent effect on FES. Age, male sex, HAQ DI, and TSS were predictors for FES. ADA+MTX vs. MTX alone was a predictor of FES in every country studied, whereas ADA monotherapy was not.

Independent Effect of Country of Residence on Favorable Employment Status

	Employed Workers			Homemakers		Favorable Employment Status		
	N	% at Baseline	% Missed Work	% at Baseline	% Unfit for Work	OR	95% CI	P-value
Australia	28	70	46	42	53	1.5	0.7–3.2	NS
Canada	37	49	38	37	43	0.9	0.5–16	NS
Germany	42	52	50	15	50	0.7	0.4–1.2	NS
United States	130	68	33	40	55	2.3	1.5–3.4	<0.0001

Conclusions: Employment status and % missing work, which are driven by health and social policies, differed more than performance at work or at home. Residents of the US were more likely to achieve favorable employment status, perhaps because of greater access to employment, a tendency for employees to miss less work, and greater financial pressure to return to remunerative employment. These results are important in consideration of transferability of data between countries. Patients who received ADA+MTX (vs. MTX) were more likely to achieve favorable employment status in all countries, regardless of health care and social system differences.

HLA Class II Associations Differ in Indian (Asian) Patients Suffering from RA: Regional Population (Urban and Rural) Surveys Using COPCORD Bhigwan Model. Anuradha Venugopalan[2], Arvind Chopra[3] and Renu Bharadwaj[1]. [1]BJ Medical College, Pune, India, [2]Center for Rheumatic Diseases, Pune, India, [3]Center for Rheumatic Diseases

The prevalence of RA and its association with HLA Class II alleles has varied considerably in different ethnic groups and populations. The data from Indian (Asian) studies, largely hospital based, is limited and supports association with HLA DRB1*04. We reported a striking prevalence (0.55%) of RA (ACR) in Bhigwan rural community but association with HLA DRB1*04 alleles was negligible (Chopra. Arthritis Rheum 2000: 7(Suppl)S71). Later, we completed 8150 population survey (house-house) in neighboring urban Pune using a similar COPCORD (Community oriented program for control of Rheumatic Diseases) Bhigwan model and found an unusually low prevalence (0.3%) of RA (Chopra. J Rheumatol 2009; 36:614). Seropositive RF (nephlometry, cut off 40 IU/ml) and anti-CCP (second generation ELISA, cut off 5 RU/ml) was 45% and 59% in Bhigwan: corresponding 57% and 89% in Pune. There were several other differences found in the results from the surveys. We decided to determine HLA associations of RA in Pune and Bhigwan population based cohorts which included post survey incident cases. After ethic committee approval, consent-

ing patients were bled. 101 rural and 54 urban subjects, ethnically matched and unrelated, were selected as healthy controls. HLA Class II typing for DRB1 (34), DQ (A1=10, B1=21) and DP (A1=5, B1=21) region alleles was performed by Polymerase Chain Reaction using sequence specific primers: number of alleles tested shown in parenthesis.

Results: Table 1 shows significant OR of alleles and shared epitope (SE) genotype; 95% confidence interval (CI) is shown in parenthesis.

	RURAL Bhigwan (n=55)	URBAN Pune (n=37)
Allele		
DRB1*1001	3.92 (1.57, 9.78)*	1.19 (0.41, 3.47)
DQA1*0103	3.72 (2.09, 6.62)*	3.07 (1.33, 7.07)*
DQB1*0303	4.15 (1.89, 9.10)*	1.04 (0.27, 3.95)
DPB1*0201	2.29 (1.03, 5.07)*	0.80 (0.24, 2.61)
DPB1*0401	0.68 (0.34, 1.33)	3.55 (1.56, 8.08)*
SE Genotype		
SE+/x	1.96 (0.86, 4.44)	1.10 (0.87, 5.25)
QKRAA/x	5.91 (0.24, 147.71)	4.74 (0.25, 115.14)
QRRAA/x	0.10 (0.01, 1.85)	1.58 (0.51, 14.94)
RRRAA/x	3.20 (1.14, 8.97)*	0.74 (0.49, 3.79)
SE+/SE+	1.96 (0.12, 32.0)	8.13 (0.39, 152.97)

*P<0.05

DRB1*04 and *01 were conspicuous by their absence/low frequency. Though not significant, HLA-DQA1*0101 and HLA-DQB1*0601 was more frequent in seropositive (RF) RA patients. None of the alleles tested showed significant association with anti-CCP antibody or articular deformities. None of the haplotype chosen showed significant association with RA or its selected features.

Conclusions: This COPCORD study demonstrated HLA Class II including SE associations of RA in an ethnically distinct Indian (Asian) community. To an extent, our small RA sample size is offset by the community study design and population sampling frame.Our results differ from several Caucasian and other ethnic studies and support the complex gene-environment interactions in the etiology of RA.

Hospitalizations Following Heart Failure Diagnosis in Rheumatoid Arthritis Patients. Cynthia S. Crowson, John M. Davis III, Veronique L. Roger, Eric L. Matteson, Terry M. Therneau and Sherine E. Gabriel. Mayo Clinic, Rochester, MN

Purpose: Patients with rheumatoid arthritis (RA) suffer from an excess burden of cardiovascular disease, especially heart failure (HF). In addition, RA patients have a higher mortality rate following HF diagnosis compared to patients without RA. Hospitalizations in patients with HF are a major public health problem. The purpose of our study was to compare the rate of hospitalizations and length of stay after HF diagnosis in patients with and without RA.

Methods: A population-based inception cohort of RA subjects who fulfilled 1987 ACR criteria for RA and subsequently developed HF (Framingham diagnostic criteria) between 1-1-1987 and 7-1-2008 was assembled and compared to an age, sex and calendar year matched (3:1) sample of HF patients without RA from the same population. Patients in both groups were followed until death, migration, or 1-1-2010 and all hospital admission and discharge dates were obtained. Person-year methods were used to estimate hospitalization rates. Andersen-Gill models, a modification of Cox models accounting for multiple hospitalizations per patient, were used to compare hospital admission rates between the groups.

Results: The study included 548 HF patients (137 with RA and 411 non-RA). Both groups had mean age of 77 (s.d. 10) years with 64% women. The RA patients were followed up for a mean of 3.9 years (528 person-years) after which the majority (83%) were deceased; similarly for the non-RA patients the mean follow-up was 4.8 years (1991 person-years)and 72% died. During this time RA patients experienced a higher rate of hospitalization (1.09 hospitalizations per year compared to 0.88 per year for non-RA; p<0.001). Thus, RA patients experienced 20% more hospitalizations (hazard ratio: 1.2; 95% confidence interval: 1.01, 1.5; p=0.038) compared to non-RA patients In addition the length of stay per hospitalization was on average 0.66 days longer for the RA patients compared to the non-RA patients (p=0.025). Significant independent predictors of hospitalization among patients with RA and HF include male gender, duration of RA, ischemic heart disease, diabetes, comorbidities (cerebrovascular disease, ulcers, renal disease, and cancer). In addition, steroid users were more likely to be hospitalized, even after adjusting for all other significant predictors (hazard ratio: 1.4; 95% CI: 1.03, 1.8; p=0.03).

Conclusion: Patients with RA and HF have a higher rate of hospitalization than HF patients without RA and they experience longer hospital stays. A complex constellation of comorbidities and other factors, including steroid use, are associated with the risk of hospitalization for RA patients with HF. More research is needed to improve the outcomes for RA patients with HF.

Importance of Changes in People/Patient Reported Outcomes in Rheumatoid Arthritis Patients Treated with Anti-TNF Therapies. The Example of the RAID (Rheumatoid Arthritis Impact Disease) Score after Etanercept Therapy. Maxime Dougados[2], Mahaut Ripert[4], Pascal Hilliquin[1], Patrice Fardellone[5], Olivier Brocq[3] and Isabelle Logeart[4]. [1]CH sud Francilien, Corbeil-Essonnes, France, [2]Hôpital Cochin and University of Paris, Paris, France, [3]Hopital Princesse Grace de Monaco, Monaco, [4]Pfizer France, la Défense, France, [5]University Hospital Amiens, Amiens, France

Purpose: OMERACT has emphasized the role of People/Patient Reported Outcomes (PROs) in the evaluation of rheumatic disorders. Under the umbrella of EULAR, a preliminary new score, a patient-derived composite response index, has been elaborated to assess the impact of rheumatoid arthritis (RA), the Rheumatoid Arthritis Impact Disease (RAID) score. The objective was to evaluate the importance of changes in the RAID score in RA patients treated with etanercept.

Methods: *Study design*: Open-label, 12-week duration. *Study treatment*: etanercept 50 mg once a week. *Patients*: adult (>18 years old) with active rheumatoid arthritis (DAS >3.2 and 4 clinical synovitis or CRP >10 mg/l or ESR >28 mm/h). *Outcome measures*: Apart from the RAID score composite index including the 7 following domains: pain, functional disability, fatigue, sleep disturbances, coping and overall assessment of physical and psychological well being, and the DAS, at week 12, the patients were asked whether their condition was acceptable using the PASS (Patient Acceptable Symptom State) question. *Statistical analysis*: Standardized Response Mean (mean change/SD of change) and its 95% confidence interval (Bootstrap method) were calculated to evaluate the magnitude of changes (a SRM over 0.60 is usually considered as clinically relevant). Moreover, the changes in RAID were compared in the groups of patients who achieved or not a PASS at week 12.

Results: Of the 87 screened patients, 81 (female: 72%, age: 54±13 years old, disease duration: 8.4±7.1 years) were enrolled. At baseline, patients had active disease (DAS: 5.5±0.8, CRP: 18.9±33.5 mg/l, painful joints: 10.5±5.6 and swollen joints: 8.5±4.1). During the 12 weeks of the study, 9 patients discontinued the treatment. At week 12, 49% the patients had a DAS below or equal to 3.2 (LDA), and 67% considered their condition as acceptable (PASS).

After etanercept therapy, both the RAID score and its different components improved significantly (table). Moreover, the changes in RAID were of much higher magnitude in the group of patients who achieved (*versus* those who did not) a PASS condition at week 12 (-3.6±1.8 *versus* −0.9±1.8, $p<0.001$).

	Improvement from baseline	
Outcomes	**Mean**	**SD**
DAS 28	−2.1	1.0
	SRM	95% CI
EULAR RAID	1.44	[1.13–1.88]

Function*	1.25	[0.96–1.68]
Fatigue*	1.16	[0.92–1.47]
Sleep*	0.96	[0.73–1.26]
Physical well being*	1.39	[1.11–1.76]
Emotional well being*	1.16	[0.90–1.51]
Coping*	0.95	[0.65–1.36]

* These domains have been evaluated using a single question and a 0–10 Numerical Rating Scale for the answer.

Conclusion: This study 1) confirms the symptomatic efficacy of etanercept in rheumatoid arthritis; 2) demonstrates the clinically relevant sensitivity of change of both the different domains and the composite index (*e.g.* RAID score) of the PROs' perceived as important for the patients.

This study was sponsored by Wyeth Pharmaceuticals France (Wyeth has been acquired by Pfizer in October 2009)

Inadequate Treatment of Rheumatoid Arthritis (RA). K. Andrew Crighton[3], Elliot D. Rosenstein[4], Jared S. Young[5], Yukiko Kimura[2] and Victor S. Sloan[1]. [1]Celgene Corporation, Summit, NJ, [2]Hackensack Univ Medical Ctr, Hackensack, NJ, [3]Prudential Financial, Newark, NJ, [4]Saint Barnabas Medical Center, Livingston, Far Hills, NJ, [5]Thomson Reuters, Ann Arbor, MI

Objective: Assess the adequacy of pharmacologic treatment of patients with RA.

Background: Treatment guidelines recommend DMARDs for all RA patients unless contraindicated. We recently assessed DMARD utilization in a large database and determined that RA patients were receiving suboptimal treatment.

Methods: The initial study used a database of Medical and Pharmacy claims for Prudential's employee and dependent population (PD) (~87,000 lives). Additional data were obtained from Thomson Reuters MarketScan Commercial Database (TRD), which assesses ~ 18 million lives. Not only is TRD substantially larger than PD, but it has a geographic breakdown reflecting a broader experience outside the northeastern US.

There were 849 (PD) and 99,687 (TRD) RA pts defined as:

- ≥18 yrs old as of 2007
- Treated for RA in 2007-8, with claims having these ICD9 codes: 714.0, 714.1, 714.2, 714.3, 714.31, 714.32, 714.33, 714.4, 714.81
- Continuously enrolled in a medical and pharmacy plan in 2007-8

DMARDs included small-molecule and biologic, identified by National Drug Code (Pharmacy Claims) and by Health Care Common Procedure Coding System (Medical Claims).

Subgroups were defined as:

- Non-compliant (NC): 0 days DMARD supply and 0 office procedures for DMARD administration (infusion) in 1 yr.
- Partially compliant (PC): 1 – 269 days DMARD supply or 1 – 11 office DMARD administration in 1 yr.
- Fully compliant (FC): ≥ 270 days DMARD supply or ≥ 12 office DMARD administration in 1 yr.

Subgroups were analyzed by demographic factors (age group, geography, job grade and whether subject was seen by a rheumatologist).

Results: <40% of patients received adequate DMARD therapy, as defined by being FC, and >40% were not on any DMARD (NC). There was no clear relation between adequacy of treatment and age (PD & TRD). Slight geographic differences were observed, with better results in the South and Midwest (TRD). Based on earning level, cost did not appear to be a factor in adequacy of treatment. (PD)

57% were seen by a rheumatologist and were more likely to receive adequate treatment, but 25% were still not on a DMARD. (PD) The most commonly prescribed traditional, self-administered biologic and IV biologic (adjusted to reflect standard dosing intervals) DMARDs were methotrexate, etanercept, and infliximab respectively. (PD)

Limitations: This is a retrospective, observational study based on administrative data. The diagnosis of RA was not independently adjudicated, but the prevalence is consistent with that observed in the US population (~1%). The consistency of the findings in the 2 databases support our initial findings.

Conclusions: Despite the proven benefits of DMARD therapy and recommended guidelines, most RA patients receive inadequate treatment. Adequacy of treatment does not appear to be influenced by age, income, or geography. As in other studies, RA patients in this population are more likely to receive adequate treatment from a rheumatologist, yet even specialist care remains deficient. Our findings warrant further investigation to determine those factors which impede effective treatment of RA patients.

Increased Risk of Total Mortality with Anti-Cyclic Citrullinated Peptide (Anti-CCP) Positivity among Postmenopausal Women Reporting RA. Rachel H. Mackey[5], Lewis H. Kuller[5], Michael Holers[4], Kevin Deane[4], Brian Walitt[2], Bill Robinson[3], Yuefang Chang[5], Charles Eaton[1], Iulia Grillo[1], Monica Bertoia[1] and Larry W. Moreland[5]. [1]Brown University, [2]Georgetown University, [3]Stanford University, [4]University of Colorado, [5]University of Pittsburgh

Background: The objective of this report is to evaluate the relationship between rheumatoid arthritis (RA) and total mortality among postmenopausal women from the Women's Health Initiative (WHI). Among the 161,808 postmenopausal women aged 50–79 years who enrolled in the Women's Health Initiative (WHI) at baseline and who have been followed up for ~ ten years, we evaluated total mortality risk for women who reported rheumatoid arthritis (RA) at baseline or followup (n= 16,461 (10.2%) compared with women with no reported RA (n=125,372). A study in 2 WHI centers documented that ~15% of self-reported RA was probable clinical RA, and that self-reported use of disease-modifying anti-rheumatic drugs (DMARDS) improved the positive predictive value of the self-report RA to 62%. To further improved classification we measured anti-cyclic citrullinated peptide (anti-CCP), a sensitive and specific marker of RA.

Methods: We sampled n=9,988 (66%) of the white, black, or Hispanic WHI participants who reported RA at baseline or followup and who had adequate stored serum specimens, and measured anti-CCP via 2nd generation ELISA. Cox proportional hazards regression was used to model the relationships of self-reported RA, DMARD use and anti-CCP positivity to total mortality using followup data through April 2009.

Results: At baseline, mean(SD) age was 64(7) years, 24.5% were African-American and 10% were Hispanic. The overall prevalence of anti-CCP positivity was 8.13% (n=812), but was much higher (~51%) among women reporting both RA at baseline and DMARD use (Table.)

Table: Anti-CCP positivity and age-adjusted mortality rates by self-reported RA and DMARD use

Reported RA	DMARD*	Anti-CCP	N	%	Total Mortality rate/1000 Person Years
At BL (or BL & followup					
	No	−	4650	95.8%	14.16 (12.50, 16.06)
	n=4855	+	205	4.2%	22.38 (15.12, 33.34)
	Yes	−	395	49.3%	18.35 (10.84, 32.34)
	n=802	+	407	50.7%	25.74 (17.01, 39.23)
At followup only					
	No	−	3852	96.5%	10.45 (8.91, 12.26)
	n=3992	+	140	3.5%	18.70 (10.65, 33.49)
	Yes	−	279	82.3%	23.14 (10.40, 51.50)
	n=339	+	60	17.7%	32.05 (8.02, 128.14)
Never	n/a	n/a	128,758	-	8.39 (8.15, 8.64)

Age-adjusted all-cause mortality rates were strikingly higher among anti-CCP positive women, regardless of reported DMARD use. Compared with women in WHI who never reported RA, total mortality was also substantially elevated among women who reported RA but did not report DMARD use and who were negative for anti-CCP.(Table) Among those who reported RA at baseline (excluding women with CVD or cancer at baseline), the hazard ratio (HR)(95% CI) for total mortality was 1.74 (1.33, 2.27) for anti-CCP positivity and 1.90 (1.42, 2.53) for reported DMARD use, in Cox models adjusted for age, white blood cell count (WBC), ethnicity, smoking, waist circumference, hypertension, diabetes, education and hormone therapy. Age, smoking, diabetes and WBC were also significant predictors.

Conclusions: Among postmenopausal women in WHI, anti-CCP positivity was associated with a substantial excess in total mortality compared with women who reported RA but were anti-CCP negative (regardless of self-reported DMARD use), or with women who did not report RA. Evaluation of additional risk markers is in progress to understand the reasons for this anti-CCP -associated excess mortality in older women.

Independent Impact of Statin Discontinuation on Mortality in Patients with Rheumatoid Arthritis: A Population-Based Study. Mary A. De Vera[1], Hyon K. Choi[3], Michal Abrahamowicz[2], Jacek Kopec[1] and Diane V. Lacaille[1]. [1]Arthritis Research Centre of Canada, Vancouver, BC, Canada, [2]McGill University, Montreal, QC, Canada, [3]Univ of British Columbia, Vancouver, BC, Canada

Purpose: Discontinuation of statin therapy is common and associated with increased risk of mortality in the general population, but no corresponding data are available among individuals with rheumatoid arthritis (RA). Since cardiovascular diseases (CVD) are the primary cause of excess mortality in RA, RA-specific data are highly relevant to clinical care of RA. Our objective was to evaluate the impact of statin discontinuation on risk of mortality in individuals with RA.

Methods: We conducted a population-based cohort study of RA patients with incident statin use followed from May 1996 to March 2006 with administrative health data. Exposure was statin discontinuation for ≥3 months at any time during follow-up, measured both as a categorical (y/n) and continuous (time since discontinuation) variable. Primary outcome was death due to all CVD and secondary outcome was death due to all causes. We used Cox's proportional hazards analyses, modeling statin discontinuation as a time-dependent dichotomous variable updated every month and in separate analyses, as a continuous time-dependent variable that increased with every month since discontinuation. Factors known to influence statin discontinuation, CVD, or mortality were considered as covariates, including age, gender, comorbidities (acute myocardial infarction, cerebrovascular accidents, malignancy, infections, chronic obstructive pulmonary disease, gastrointestinal diseases, renal failure, angina, use of diabetes, hypertension, and congestive heart failure medications), and use of medications known to influence cardiac risk (hormone replacement therapy, anticoagulants), all measured at baseline. As well, markers of RA severity (RA medication use [DMARDs, glucocorticosteroids, NSAIDs, methotrexate] and rate of RA-related medical visits) were included as time-dependent covariates. Established risk factors for mortality in RA (e.g., AMI, malignancy) were forced into multivariable models and for putative risk factors, a forward selection procedure with $p \leq 0.20$ criterion for entry, was used.

Results: The cohort of RA patients with incident statin use included 4,102 individuals with 16,144 person-years of follow-up (60% females; mean age 66 years). We documented 467 deaths overall with 198 due to CVD. Statin discontinuation was associated with a 60% increased risk of CVD mortality (adjusted hazard ratio [HR]=1.60 [95%CI=1.15–2.23]). When we modeled statin discontinuation as a continuous time-dependent variable, we found that with each additional month of discontinuation, the risk of CVD mortality was increased by 0.4% (adjusted HR=1.004 [95%CI=1.001–1.016]). We found similar increased risks associated with statin discontinuation in analyses of all cause mortality outcomes (adjusted HR [statin discontinuation as a dichotomous variable]: 1.79 [95%CI=1.46–2.20]; adjusted HR [statin discontinuation as continuous variable]: 1.010; 95%CI=1.002–1.015]).

Conclusion: These population-based data indicate that RA patients who discontinue statins have a higher risk of death from cardiovascular diseases and from all causes. Findings emphasize the importance of compliance with statin therapy in RA.

Joint Damage Progresses in DAS28 Remission and Is Driven by Residual Joint Swelling. Daniel Aletaha and Josef S. Smolen. Medical University of Vienna, Austria

Background: Remission is usually defined as a state of no (or minimal) residual clinical disease activity and ideally should go along with maximal reduction of physical disability and halt of progression of joint damage. The Disease Activity Score employing 28 joint counts (DAS28) is frequently used to assess remission (DAS28<2.6), however, there is often residual disease activity in this state[1]. It is currently not known to which extent joint damage is retarded in DAS28 remission.

Methods: We evaluated data from methotrexate (MTX) monotherapy arms of recent trials (ASPIRE, ERA, Leflunomide, PREMIER, TEMPO). We pooled patients with complete clinical data at baseline, 6, 9 and 12 months and X-ray data at baseline and 12 months (n=865). We identified patients who attained persistent DAS28 remission, defined as an average DAS28 from 6 to 12 months ($DAS28_{6-12}$) <2.6. For each of these patients, we calculated mean SJC for the 6–12 month period and then divided the patients into those without ($SJC_{6-12}<2$) and with ($SJC_{6-12}\geq 2$) joint swelling. We assessed the radiographic progression of TSS between these two groups. We compared the proportion of patients progressing radiographically (increase of TSS score of $>0.5^2$) by Chi^2 statistics.

Results: 115 patients (13.3%) achieved DAS28<2.6; 22 of them (19%) had a mean $SJC_{6-12}\geq 2$. DAS28 remitters without residual joint swelling showed a 1 year radiographic progression of 0.56±4.17, while those with residual swelling progressed by 2.16±4.22 TTS points. The proportion of patients with a TSS progression >0.5 was significantly higher in patients with residual joint swelling (50.0%) compared to those without (23.9%; p=0.015). Residual SJC were decisive for damage progression in DAS28 remission, since neither DAS28 levels nor tender joint count or ESR influenced it in DAS28 remission (not shown). We then compared DAS28 remission data with those in remission by the simplified and clinical disease activity indices: in SDAI (≤3.3) and CDAI (≤2.8) remission no patient had SJC>2 and damage progressed only by 0.5±5.9 and 0.6±5.3, almost identical as in DAS28 remitters who had no residual SJC. Interestingly, there were also significant differences in physical function: while HAQ was low in DAS28 remission (0.21±0.35), it was even lower in SDAI (0.09±0.18; p=0.0023) and CDAI remission (0.12±0.26; p=0.057).

Conclusions: A large proportion of patients in DAS28 remission not only have significant residual swollen joint count but also significant progression of damage, indicating that more stringent criteria for remission are needed. SDAI and CDAI criteria were more stringent regarding progression of joint damage and residual disability.

Large Discrepancy between Expected and Observed Ratios of Biologic Treated Rheumatoid Arthritis Patients Also Compliant on DMARDs. Denis Choquette[2], Mark Arundine[1] and Oliver Thomas[1]. [1]Mississauga, ON, Canada, [2]Institut de Rhumatologie de Montréal, Montreal, QC, Canada

Objective: It is common for most Canadian Rheumatologists to prescribe a biologic in combination with one or more DMARDS to 80–90% of their RA patients. Despite this practise, databases linked to drug plans indicate that RA patients receiving biologics do not fulfill DMARD scripts, and especially methotrexate at the same level as is prescribed by physicians. This study, examines this discrepancy more closely and suggests potential causal etiologies.

Methods: Biologic and DMARD concomitant therapy based on actual patient purchases was examined by tracking 6,744 anonymous patient records from public and private drug plans in Quebec and Ontario through a licensed 3rd party. A treatment algorithm criterion was applied to isolate RA patients. All patients who purchased a biologic for the treatment of RA over a 1 month period were monitored to determine if they filled prescriptions for DMARDS within a period of 90 days before and 90 days after they purchased their biologic. The month of September 2009 was randomly selected and deemed as a typical representative month. Each patient was linked in the public or private system with a unique identifier so that their acquisition of all drugs through their drug plan could be monitored over time to determine the relative prevalence of biologic monotherapy vs. combination therapy with a DMARD based on drug purchases.

Results: Among patients on their first biologic for more than 6 months, 45% did not purchase a DMARD. Likewise, 41% of patients who were on biologic therapy for more than 24 months did not purchase a DMARD. For patients on their 2nd biologic, rates of patients who did not purchase a DMARD ranged from 36% to 38% over the same time period. Furthermore, the proportion of patients on their first biologic who did not purchase methotrexate ranged from 58% for those on biologic therapy for more than 6 months to 54% for those on therapy for more than 24 months.

Conclusion: Despite what is prescribed by physicians, the data suggests that many RA biologic patients do not comply with taking DMARDs as

directed. This is especially evident for those patients prescribed methotrexate. These findings also suggest that approximately half of RA biologic patient's studied in this cohort failed to adhere to expected treatment regimes. This rate is inconsistent with the majority of physician's intended treatment regimens. Reasons for this discrepancy include efficacy and safety elements. Closer examination of actual combination therapy, compliance rates and therapy discontinuation at the patient level warrants further investigation.

Leflunomide and the Risk of Hepatotoxicity: A Review of Post-Marketing Data. Jane L. Gilbert[1], Kate Gelperin[2], Joann Lee[2], Poonam Mishra[2], Lauren Choi[2], Allen Brinker[2], David Graham[2], Robert Boucher[2], Mark Avigan[2] and John Senior[2]. [1]FDA, Washington, DC, [2]FDA

Background: This abstract summarizes a review undertaken by FDA to evaluate the risk of hepatotoxicity in patients receiving leflunomide (LEF). LEF is an oral, disease-modifying, antirheumatic drug (DMARD), approved in the US for the treatment of rheumatoid arthritis (RA) in 1998. ACR guidelines (2008) recommend "leflunomide monotherapy for [RA] patients with all disease durations and for all degrees of disease activity. . . ." Combination therapy with methotrexate (MTX) is "recommended for patients with intermediate or longer disease duration. . . as long as disease activity [is] high." The potential for LEF hepatotoxicity was noted at the time of product approval and a bolded warning describing severe liver injury with LEF as well as a recommendation to monitor serum transaminase levels every 6–8 weeks was added to the U.S. label in 2003.

Methods: Using pre-specified criteria, a comprehensive search of FDA's Adverse Event Reporting System (AERS) database was undertaken to identify post-marketing cases (US and foreign) of serious liver injury and acute liver failure (ALF) from 8/25/2002 through 5/1/2009. Additional cases reported to the Drug-Induced Liver Injury Network (DILIN), a multicentre network established to assess liver injury due to medications, were also retrieved. A multidisciplinary group of experts from the FDA, including hepatologists, adjudicated these cases based on DILIN criteria. Cases involving death and ALF were further analyzed for common features.

Results: A total of 111 reports were identified (106 from AERS and 5 from DILIN). Many of these reports (62) were either duplicates, had insufficient information or were clearly unrelated to LEF. The remaining 49 reports (including 27 describing ALF) met criteria for the DILIN definition of severe liver injury, formed the case series, and were adjudicated. Based upon DILIN causality criteria, adjudicators classified all 27 cases of ALF (including 12 deaths and 5 liver transplants) as at least possibly associated with leflunomide. Case series analysis revealed that LEF hepatotoxicity may be rapid in onset and progress to ALF. This contrasts with MTX hepatotoxicity which usually involves chronic fibrosis or cirrhosis. Among the cases resulting in death or transplant, 88% (15 of 17) of patients were using concomitant hepatotoxic medications such as MTX, TNF inhibitors or statins. In the same group, 24% (4 of 17) had evidence of hepatitis B (active or chronic) or previous hepatitis A.

Conclusion: Leflunomide is approved in the US (for RA) and Europe (RA and psoriatic arthritis). It is recommended by the ACR for mono- or combination therapy. Our review shows a LEF risk for hepatoxicity which may present with rapid onset. The review further points to specific risk factors: concomitant hepatotoxic medication and pre-existing liver disease. Appropriate patient selection and careful monitoring may mitigate this risk.

Meta-Analysis and Biologics—Comparing Apples to Apples: An Example Using Radiographic Outcomes in Rheumatoid Arthritis. Mike Ingham[1] and Chureen Carter[2]. [1]Centocor Ortho Biotech Services, LLC, Horsham, PA, [2]Centocor Ortho Biotech Services, LLC

Background: Many meta-analyses exist for biologics in rheumatoid arthritis (RA). Most have focused on signs and symptoms. Few have attempted to look at radiographic outcomes of disease progression.

Methods: This study used meta-analytic techniques to compare adalimumab (ADA), certolizumab (CER), etanercept (ETA) and infliximab (IFX). Randomized controlled trials (RCTs) of biologics in active RA, added to methotrexate, reporting 1 year radiographic outcomes, Erosion scores (ES), Joint Space Narrowing scores (JSNS) and modifications of Total Sharp scores (mTSS) were included. Sources for trials were drawn from recent Cochrane and Agency for Health Care Research and Quality publications. Moderator variables related to outcome were created from trial baseline patient population results, with dichotomization of continuous variables to allow for simplified stratification of trials. Trial data were split into higher or lower dose intensity, based on trial arms. Primary outcomes included differences in mean change scores from baseline of mTSS between active and control groups (MD). Due to varying versions of mTSS used in trials, standardized mean differences (SMD) were also analyzed (standardized by change scores' standard deviation). Negative results favor the biologic.

Results: Four trials met inclusion criteria (one for each product). For higher dose intensity, mTSS MD [95% confidence limits] were ADA: −2.60 [−3.82 to −1.38]; CER: −2.60 [−2.74 to −2.46]; ETA: −3.34 [−3.46 to −3.22]; IFX: −6.80 [−9.26 to −4.34]. SMD were: −0.44; −3.10; −5.24; −0.92 respectively. Simultaneous inclusion of all four trials however was complicated by observed differences in baseline moderator variables, confirmed by an I^2 heterogeneity score of 99.5 out of 100. Stratifying the ADA/IFX separately from the ETA/CER trials optimized reduction in the I^2 statistic vs. all four trials together. Within these strata, for SMD comparisons, IFX demonstrated twice the effect size of ADA, while ETA was 1.7 times that of CER.

Conclusion: Meta-analytic comparisons that do not consider more in depth RCT inclusion criteria risk ignoring important baseline population differences that might mask clinically meaningful results or lead to inaccurate conclusions. In the absence of access to patient level data, this type of stratification may prove useful for reducing heterogeneity. Confirmation using other outcomes and larger numbers of trials, while keeping treatment constant, is warranted.

Baseline moderator variable dichotomization of RCTs in active RA for radiographic outcomes (DMARD=Disease Modifying Anti-Rheumatic Drug, MTX=Methotrexate, CRP=c-Reactive protein, EU=European union, NA=North America)

Multiple Serum Cytokines/Chemokines Are Associated with RA-Related Autoantibodies in First-Degree Relatives without Rheumatoid Arthritis (RA): Studies of the Etiology of Rheumatoid Arthritis (SERA). Jan M. Hughes-Austin[8], Kevin D. Deane[9], Lezlie Derber[8], Jason R. Kolfenbach[10], Michael Weisman[2], Jane Buckner[12], James R. O'Dell[6], Ted R. Mikuls[11], Peter K. Gregersen[3], Richard M. Keating[1], William Robinson[4], V. Michael Holers[5] and Jill Norris[7]. [1]Oak Park, IL, [2]Cedars Sinai Medical Center, [3]N Shore Univ Hosp Rsch Ctr, Manhasset, NY, [4]Stanford Univ School of Med, Stanford, CA, [5]Univ of Colorado School of Med, Aurora, CO, [6]University of Nebraska Medical Center, Omaha, NE, [7]University of Colorado Denver, Aurora, CO, [8]University of Colorado Denver, [9]University of Colorado School of Med, Aurora, CO, [10]University of Colorado School of Medicine, Aurora, CO, [11]University of Nebraska Medical Center, Omaha, NE, [12]Virginia Mason Research Center

Background: Studies have shown that serum cytokine levels are higher in people with RA prior to the onset of their disease. We explored the relationship between RA-related autoantibodies and serum cytokine/chemokine levels in a population without RA but at an elevated risk for future development of RA due to family history of disease.

Methods: A cohort of RA-free first-degree relatives (FDRs) is being prospectively followed with serial epidemiologic questionnaires, joint exam-

inations and blood testing to investigate the relationships of genetic and environmental factors to RA-related autoimmunity. From this cohort, we selected 113 FDRs who had been positive for any of 5 RA-associated autoantibodies (Ab): rheumatoid factor (RF), RF isotypes—IgM, IgG, or IgA, or anti-cyclic citrullinated peptide (anti-CCP) on at least one of their visits. Additionally, we selected 100 FDRs (frequency-matched on age, sex, and ethnicity) who had never been autoantibody positive. The study population had a mean age of 50 years, was 75% female, and 83% non-Hispanic white. A panel of 27 cytokines/chemokines was measured using a bead-based assay in serum obtained from 397 visits of these FDRs. HeteroBlock™ was used to minimize effects of RF in these samples. For analyses, cytokine/chemokine levels were log transformed, and the relationship between cytokine/chemokine levels (as continuous variables) and autoantibody positivity (dichotomous, either RF alone or combination of RF isotypes with or without anti-CCP positivity) was calculated using a non-linear mixed model [SAS PROC NLMIXED]. Results are reported as odds ratios (OR), which were calculated to indicate change in risk of RA-related autoimmunity for every 1 standard deviation increase in cytokine/chemokine levels.

Results: Of 397 visits, 73 were positive for RF, and 50 were positive for the high-risk autoantibody profile. Eleven cytokines/chemokines were significantly associated with either RF or the high-risk autoantibody profile or both in RA-free FDRs, as summarized in Table 1. For example, for each standard deviation increase in IL-6 levels, there is an ~3-fold increased risk of RF and a 67% increased risk of the high-risk autoantibody profile. Cytokines/chemokines that were not associated with autoantibody positivity in this dataset include: PDGF, IL -1β, -1rα, -7, -8, -13, -15, -17, FGF-basic, G-CSF, MCP-1-MCAF, MIP-1α, -1β, RANTES, TNF-α, and VEGF.

Table 1. Summary of Significant Odds Ratios (OR) for Positivity for Either Rheumatoid Factor or the High-risk Autoantibody Profile (Bold ORs indicate $p<0.05$)

	Rheumatoid Factor			*High-risk Autoantibody Profile* (2 or more RF isotypes and/or Anti-CCP)*		
	OR	***95% CI***		***OR***	***95% CI***	
IL-2	1.20	0.67	2.16	**1.62**	**1.06**	**2.49**

* This autoantibody profile has been shown in prior work using pre-clinical RA samples to be >96% specific for future RA

Conclusion: Increases in multiple cytokines are associated with RA-related autoantibody positivity in FDRs, suggesting that autoantibodies are associated with evidence for circulating inflammation in subjects without clinically apparent RA. Further longitudinal study is needed to determine the significance of these findings in relationship to the natural history of RA-related autoimmunity and RA.

Noncardiac Vascular Disease in Rheumatoid Arthritis (RA): Increase in Venous Thromboembolic Events? A. Kirstin Bacani, Sherine E. Gabriel, Cynthia S. Crowson and Eric L. Matteson. Mayo Clinic, Rochester, MN

Purpose: Patients with rheumatoid arthritis (RA) suffer from an excess burden of cardiovascular disease, but little is known about the incidence of noncardiac vascular disease in RA patients. The purpose of our study was to examine whether the incidence of venous thromboembolic events and other noncardiac vascular disease events has changed in recent years among RA patients and to compare the incidence to that in a non-RA cohort.

Methods: A population-based inception cohort of RA patients who fulfilled 1987 ACR criteria for RA between 1/1/1980 and 12/31/2007 and a cohort of non-RA subjects from the same underlying population were assembled and followed until death, migration, or the present. The occurrence of venous thromboembolic events (deep venous thrombosis or pulmonary embolism), cerebrovascular events (hemorrhagic stroke, nonhemorrhagic stroke, transient ischemic attack or amaurosis fugax), and peripheral arterial events (abdominal aortic aneurysm, renal artery stenosis, peripheral vascular disease, or arterial thromboembolism), was ascertained by review of the medical record. Cox proportional hazard models were used to compare development of noncardiac vascular disease in RA subjects diagnosed in 1980–1994 to those diagnosed in 1995–2007 and to compare RA patients diagnosed in 1995–2007 to the non-RA comparison cohort.

Results: The study included 814 RA patients (mean age [SD] 55.9 [15.7] years; 68% women). The average length of follow-up was 9.6 years [SD 6.9] and 66% were rheumatoid factor positive. Among RA patients, the incidence of venous thromboembolic events was more than 3-fold higher in the 1995–2007 time period compared to the 1980–1994 time period (cumulative incidence [$\pm$SE] 7.6 $\pm$ 1.9 vs 2.4 $\pm$ 0.9, respectively; $p=0.004$). The incidence of cerebrovascular events was similar in the 1995–2007 time period compared to the 1980–1994 time period (cumulative incidence [$\pm$SE] 4.4 $\pm$ 1.3 vs 3.3 $\pm$1.0, respectively; $p=0.52$), as was the incidence of peripheral arterial events (cumulative incidence [$\pm$SE] 3.5 $\pm$ 1.1 vs 3.7 $\pm$ 1.1, respectively; $p=0.81$).

Patients diagnosed with RA in 1995–2007 were compared to non-RA subjects of similar age and sex (mean age [SD] 55.6 [15.5] years; 69% women). RA patients had a higher incidence of venous thromboembolic events compared to non-RA subjects (cumulative incidence [$\pm$SE] 7.6 $\pm$ 1.9 vs 3.1 $\pm$ 1.2, respectively; $p=0.003$). The incidence of cerebrovascular events was similar between RA patients and non-RA subjects (cumulative incidence [$\pm$SE] 4.4 $\pm$ 1.3 vs 4.6 $\pm$ 1.6, respectively; $p=0.38$), as was the incidence of peripheral arterial events (cumulative incidence [$\pm$SE] 3.5 $\pm$ 1.1 vs 4.1 $\pm$ 1.6, respectively; $p=0.54$).

Conclusion: The incidence of venous thromboembolic events appears to have increased over time among RA patients and is increased in RA patients compared to non-RA subjects. The incidence of cerebrovascular events and peripheral disease events was similar over time among RA patients and was similar in RA patients compared to non-RA subjects. Further investigation is needed to explore the reasons for the increased incidence of venous thromboembolic events among RA patients.

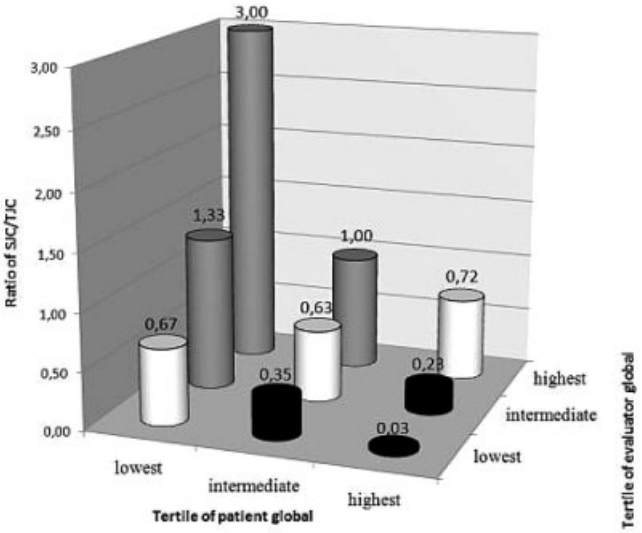
Perception of RA Disease Activity by Patients and Physicians: Reasons for and Estimators of Discrepancies. Paul Studenic, Josef S. Smolen and Daniel Aletaha. Medical University of Vienna, Austria

Background: In clinical practice, the perception of disease activity in rheumatoid arthritis (RA) often differs between physicians and patients. These discrepancies may impact the patient-physician relationship. It is not completely clear in what proportion of patients the perception is different, and why. We aimed to investigate this discordant perception in more detail.

Methods: We identified RA patients from an observational, prospective RA outpatient database, and obtained visual analogue scores (VAS) for global disease activity perception by the patients (PGA) and evaluators (EGA). Patients were divided into tertiles by PGA and by EGA, and the groups were then cross-tabulated. We explored the other RA core set variables in patient groups, formed according to concordant (tertile of PGA equivalent to tertile of EGA) or discordant tertiles (differing tertiles: PGA>EGA or EGA>PGA). For statistical comparisons, Mann-Whitney-U-Test was performed.

Results: Of the 302 RA patients (81% women, 61% rheumatoid factor positive, mean disease duration: 10.1 years), 49.3% fell into concordant PGA and EGA tertiles; 25.5% were discordant with higher tertile by PGA, and 25.2% were discordant with higher tertile by EGA. Those falling into higher EGA than PGA tertiles, had significantly higher swollen joint counts (SJC), but lower pain scores, and lower HAQ-scores, suggesting that EGA is primarily influenced by SJC and PGA by pain.

Given the impact of swelling for EGA and pain for PGA, we calculated the SJC/TJC ratio as an estimate for this discrepancy, finding good correlation with the additional variable "EGA minus PGA" ($r=0.399$, $p=0.0001$, Spearman-rho) and association with the respective tertiles (Figure). A SJC/TJC ratio of 0.6–0.7 appears associated with a balanced perception by patients and evaluators, irrespective of disease activity (Figure).



White: concordant groups; black: group PGA>EGA; gray: group PGA<EGA

Figure 1. SJC/TJC ratio of PGA/EGA tertiled groups.

Conclusion: The evaluator's perception of disease activity is strongly driven by the SJC, while the patient's perception is driven by pain and functional disability. A SJC/TJC ratio of ~0.65 seems associated with a balanced perception. For the rheumatologist, a ratio of >1.0 may serve as an indicator for the need of more detailed explanation of treatment changes, while a ratio of <0.4 may indicate a need for more intensified pain management to better comply with the patient's perception.

Permanent Working Disability Caused by Rheumatoid Arthritis Is Declining, Partly Due to Use of TNF-Inhibitors—Results from a Nationwide Finnish Register in 2000–2007. Vappu Rantalaiho[6], Hannu Kautiainen[1], Salme Järvenpää[3], Lauri Virta[5], Timo Pohjolainen[4], Markku Korpela[6], Timo Möttönen[7] and Kari Puolakka[2]. [1]Jyväskylä Central Hospital, Finland, [2]Lappeenranta Central Hospital, Finland, [3]Medcare Foundation, Finland, [4]Orton Rehabilitation Unit, Finland, [5]Social Incurance Institution, Finland, [6]Tampere University Hospital, Finland, [7]Turku University Hospital, Finland

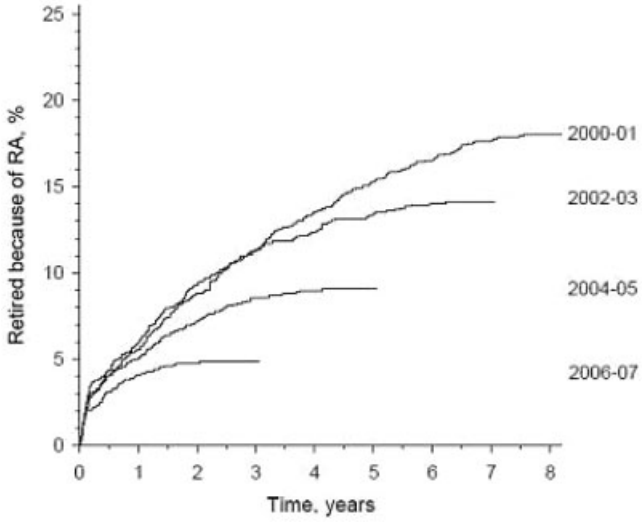
Background: Rheumatoid arthritis (RA) often leads to premature retirement. Globally, the treatment of RA has intensified, but whether this active strategy helps preserving the patients' working ability, is unclear.

Methods: From a nationwide register maintained by The Finnish Social Insurance Institution (SII) we collected information on sex, age, and date of medicine reimbursement decisions indicating the date of diagnosis (index date), of all new, not-retired, RA patients during the time period from 1 Jan 2000 to 31 Dec 2007. Patient cohorts were analyzed in 2-year time periods (2000-01, 2002-03, 2004-05, 2006-07) and work disability pensions due to RA up to 31 Dec 2008 were identified. Initial disease modifying antirheumatic drugs (DMARDs) during the first 3 months after the index day, as well as the initiation of etanercept or adalimumab at any time point were elucidated.

Results: A total of 7 909 (73% female, 61% RF-positive) patients were identified. During the first 2 years after the index day, the incidence of RA related work disability pensions were 8.8 %, 9.3 %, 7.2 %, and 4.7 % in the year cohorts 2000-01, 2002-03, 2004-05, and 2006-07, respectively (age, sex, and RF adjusted $p<0.001$ for linearity) (Figure). In a Cox multivariate analysis for the 8-year follow up, the year cohort (HR 0.67, 95 % CI 0.64 to 0.72), higher age (HR 1.06, 95 % CI 1.05 to 1.07), male gender (HR 1.53, 95 % CI 1.33 to 1.75), and the presence of RF (HR 1.17, 95 % CI 1.01 to 1.34) were related to premature retirements.

Throughout the follow-up, the use of single-DMARD treatment during the first 3 months decreased from 57 to 35 %, and that of combination-DMARDs increased from 36 to 61 %. The use of methotrexate, either alone or in combinations, increased from 31 to 67 %. However, presumably due to the confounding effect of indication, in seronegative patients, the ones with more active initial treatments (methotrexate, combination-DMARDs) had a higher risk of disability pensions than the ones with less active treatments (non-methotrexate single DMARD, no DMARDs); in seropositive patients the initial treatment had no effect on consequent pensions (data not shown).

During the follow-up, etanercept or adalimumab were prescribed to 278 patients while still available to workforce. Of these patients, 11.0 % (95 % CI: 6.9 to 17.3) became prematurely retired, whilst altogether 14.4 % (95 % CI: 13.4 to 15.5) of the patients without TNF-inhibitors did so during the 8-year follow-up ($p = 0.024$, adjusted for age, sex, RF presence, initial treatment strategy, and diagnosis cohort).



Conclusions: During the present millennium, parallel to increasingly active treatment strategies, the frequency of disability pensions in early RA has declined. Even though we failed to confirm any protective effect of aggressive initial DMARD treatment, the commencement of adalimumab or etanercept seemed to help preserve the patients' working capacity.

Prescription Patterns in Pregnant Women with Rheumatoid Arthritis. Bindee Kuriya[3], Sonia Hernandez-Diaz[4], Jun Liu[2], Gregory Daniel[5] and Daniel Hal Solomon[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, [3]Harvard School of Public Health, Brookline, MA, [4]Harvard School of Public Health, [5]HealthCore Inc., Wilmington, DE

Background: Little is known about how pregnant women with RA are treated in routine clinical practice. Our aim was to characterize the frequency and type of therapy prescribed during pregnancy to women with RA.

Methods: We conducted a cohort study using data from a U.S. commercial insurance plan from 2002–2008. We included women aged 18–45 years with RA (≥ 2 ICD-9 diagnoses) who had pregnancies ending in delivery (1° analysis) or abortion, identified by diagnostic/procedural codes. The estimated date of conception (EDC) was calculated as date of delivery - 270 days. We examined the use of therapeutic drug classes, including NSAID/coxibs, glucocorticoids (GCs), non-biologic DMARD and biologic DMARD during 90-day pregnancy trimesters and two 90-day periods prior to pregnancy. Drugs were categorized by the U.S. FDA pregnancy risk system. We defined exposure as the first filling of a drug from each class during each of the 90-day periods. We analyzed the distribution of drugs used for RA in the peri-partum period. Differences in the distribution between periods, and between women with deliveries compared to abortions, were determined by chi-square tests. Annual exposure, by year of EDC, for deliveries, to each therapeutic class was also calculated. Drug use was evaluated in the 180 days prior to abortion date due to risk of misclassification.

Results: 393 pregnancies were identified among 34,169 women. The mean age for women with deliveries was 32.8 ± 4.8 years and for abortions was 33.7 ± 5.3 years. More than 1/3 of women used ≥ 1 DMARD in the pre-conception period (Table). During pregnancy, 64 women were dispensed ≥ 1 DMARD and the proportion of use significantly declined from the first to third trimester (p=0.03). More women were prescribed GCs during pregnancy than before pregnancy. In contrast, use of NSAID/coxibs, any DMARD, combined use of DMARD or exposure to category D/X medications was significantly lower compared to pre-pregnancy use (p<0.05). Use of biologics occurred in ~ 13% of women during pregnancy. GCs were the most prescribed therapy in each of the study years, and the pattern of exposure to other classes remained relatively constant over time. Women who experienced abortions were more frequently exposed to each therapeutic class in the 180 days before abortion, compared to deliveries, except for GCs or biologics (p<0.05). Dispensing of category D/X medications was also higher in women with abortions compared to deliveries, and primarily involved methotrexate (p<0.01).

Table. Therapeutic class and drug-specific exposure (N and %) among women with deliveries (N=281).

	91-180 Days Prior to EDC	0-90 Days Prior to EDC	During Pregnancy
NSAID/coxibs	54 (19.2)	37 (13.2)	31 (11.0)[1]
Glucorticoids (GCs)	88* (31.3)	92* (32.7)	156* (55.5)[2]
Combination of NSAID/Coxibs and GCs	24 (8.5)	21 (7.5)	23 (8.2)
Any DMARD (≥1)	97 (34.5)	90 (32.0)	64 (22.8)[2]
Combination of ≥ 2 DMARD	32 (11.4)	24 (8.5)	16 (5.7)[1]
Non-Biologic DMARD (Category A, B or C)	47* (16.7)	40* (14.2)	32* (11.4)
Chloroquine	---	1 (0.4)	---
Cyclosporine	1 (0.4)	1 (0.4)	---
Gold	1 (0.4)	---	1 (0.4)
Hydroxychloroquine	34 (12.1)	30 (10.7)	25 (8.9)
Sulfasalazine	17 (6.1)	15 (5.3)	11 (3.9)
Non-Biologic DMARD (Category D or X)	36* (12.8)	23* (8.2)	11* (3.9)[2]
Azathioprine	1 (0.4)	1 (0.4)	1 (0.4)
Leflunomide	5 (1.8)	4 (1.4)	3 (1.1)
Methotrexate	32 (11.4)	19 (6.8)	8 (2.9)
Biologic DMARD (Category A, B or C)	42* (14.9)	47* (16.7)	35* (12.5)
Adalimumab	9 (3.2)	10 (3.6)	7 (2.5)
Anakinra	---	---	1 (0.4)
Etanercept	25 (8.9)	28 (9.9)	23 (8.2)
Infliximab	9 (3.2)	9 (3.2)	6 (2.1)
Rituximab	1 (0.4)	1 (0.4)	---

[1] χ^2 test p-value <0.05 comparing overall pregnancy to 91-180 days prior to EDC
[2] χ^2 test p-value <0.05 comparing overall pregnancy to 0-90 days prior to EDC
*Category totals may be smaller than sum of individual drugs due to use of combination therapy

Conclusion: Approximately 1/3 of women used a DMARD in the 180 days before conception. This proportion dropped during pregnancy. Exposure to category D/X drugs during pregnancy was 3.9%; the use of GCs was 55.5% Our results suggest that continued efforts directed at counseling women and their physicians about the potential risks/benefits of GCs and DMARD use during pregnancy are warranted.

Relative Importance of Patient's Opinion and Physician's Criteria of Disease Activity Versus Information of Disease Duration and Rheumatologist Type of Exercise for Treatment Decision in Rheumatoid Arthritis: DUO Study. Maxime Dougados[2], Henri Nataf[1], Ghislaine Steinberg[4], Géraldine Martineau[4], Stéphanie Rouanet[4] and Bruno Falissard[3]. [1]Centre Hospitalier François Quesnay, Mantes-La-Jolie, France, [2]Hospital Cochin, Paris, France, [3]INSERM U669, PSIGIAM, Paris, France, [4]Roche, Neuilly-sur-Seine, France

Background: The decision to initiative/intensify a DMARD therapy in rheumatoid arthritis (RA) is based on the evaluation of the activity of the disease. Such evaluation is performed using both subjective (patient's opinion) and objective (e.g. physical exam.) information. The composite index DAS (Disease Activity Score) elaborated in the 90's based on such treatment decision is emphasizing the role of the patient's perspective.

Objectives: To assess the respective weight of subjective and objective information in DMARDs changes in RA patients in 2009 as well as the information related to both the other disease and rheumatologist characteristics.

Methods: *Study design*: Prospective, non interventional, cross-sectional epidemiological study. *Patients*: Consecutive RA adult patients. *Rheumatologists*: Randomly selected to be representative of the French rheumatologist population. *Outcome measures*: Dependent variable: changes (initiation/intensification) of DMARD at the end of the outpatient visit. Independent variables: physicians characteristics (age, gender, type of practice, region), disease duration (DD), information provided by both the patient (RAID, HAQ, visual analogue scale [VAS] patient global assessment [PGA], Patient Acceptable/Non Acceptable Symptom State [PASS]) and the physician (swollen joint count [SJC], tender joint count [TJC], ESR/CRP). *Analysis*: Uni and multivariate analysis, adjusted attributable risk fraction [1].

Results: The 200 participating rheumatologists were practicing either in a full time community office (37%), hospital (28%) or mixed (35%).

The 1107 evaluable (1115 enrolled) patients (female: 76%, age: 58±13 years) were suffering from RA with the following characteristics: median (range) DD: 6.2 (0–60) years, SJC 1 (0–24), TJC 2 (0–28), ESR 15 (1–126) mm, mean DAS 28-ESR 3.5±1.4 and HAQ 1.1±0.6.

Factors (OR[95%CI]) influencing such DMARD changes were hospital based rheumatologist (versus community office and mixed) (2.5[1.4; 4.3]), physicians age<40 years (2.5[1.2; 5.1], DD <5 years (2.4[1.5; 3.7]), SJC >3 (2.1[1.3; 3.4]), TJC >3 (1.9[1.1; 3.2]), VAS PGA >40 mm (3.0[1.7; 5.2]) and non acceptable PASS (2.1[1.2; 3.6]). Using the adjusted attributable risk fraction, physicians characteristics weight (type of practice and age) was 47%, DD weight was 38%, physician global disease activity weight (SJC and TJC) was 42%, and patient global disease activity weight was 61% (VAS PGA and PASS) for treatment intensification decision.

According to DAS 28 and PASS questionnaire, the intensification was proposed to 24% of the patients with DAS 28 > 3.2 and to 39% of the patients with a non acceptable PASS and DAS 28 > 3.2.

Conclusion: This study showed that: 1/ despite the current EULAR recommendations, the majority of patients with DAS 28 > 3.2 had no treatment intensification of their RA treatment 2/ treatment intensification decision was mainly based on the patient's disease activity evaluation compared to the physician's one 3/ a part from disease activity, treatment intensification decision was also based on other dimensions such as DD and mode of practice of rheumatologists

Respiratory Cause Mortality Was Greater in 54 Incident Rheumatoid Arthritis (RA) Patients Than 204 Community-Based, Non-RA Matched Cohort Controls (CN). Alfonse T. Masi and Jean C. Aldag. University of Illinois College of Medicine at Peoria, Peoria, IL

Purpose: Mortality from interstitial lung disease (ILD) is known to be increased in RA (Bongartz T et al. A&R 2010; 62: 1583-91). This study aimed to analyze non-malignant respiratory cause mortality in incident RA cases from a prospective, community-based cohort, and as compared to matched non-RA CN.

Design: The 54 cases studied had onset of ACR-positive RA, 3 to 20 (mean 12) years, after entry into the cohort (n = 21,061 adults) in 1974. RAs were matched by age, gender, and race (all Caucasian) at baseline with 204 cohort non-RA CN. All study subjects (n=258) had baseline (1974) data on: demographic variables; cigarette smoking, and immunological testing on stored (−70°C) sera. A novel baseline biomarker predicted cohort mortality (data separately submitted), consisting of upper quartile values of acute-phase serum amyloid A (A-SAA) or serum interleukin-2 receptor alpha (sIL-2Rα). Each RA was also grouped in 1995 by the sole community rheumatologist into 3 course-wide *therapy responses*: 1 = *full*; 2 = *moderate*, and 3 = *limited*, (data separately submitted). Deaths from primary non-malignant respiratory causes (ICD-9, 460–519 & ICD-10, J00-J99) were analyzed, over 1992–2009. Hazard ratio (HR) for respiratory cause mortality was estimated using Cox regression models, adjusting for covariates.

Results: Deaths from non-malignant respiratory causes occurred in 8 (15%) of 54 RA vs 10 (5%) of 204 non-RA, OR = 3.37 (95% CI 1.30 – 8.79), p = 0.017. None of the 8 RA had deceased from chronic airway disease (ICD-9 496 or ICD-10 J44.9) or pulmonary edema (ICD-9 518.4 or ICD-10 J81), unlike 5 of the 10 respiratory deaths in non-RA CN (p = 0.036). Respiratory deaths occurred in 4 (22%) of 18 male RA, and 4 (11%) of 36 female RA. Three of the 4 males who had respiratory deaths were treated in 1995 with oral methotrexate (MTX) doses of 20+ mg weekly and with predisone (Pred) doses of 10+ mg daily vs only 1 of the remaining 14 male RA (p = 0.019). Only 2 of 4 female RA respiratory deaths had received low-dose MTX (7.5 mg/wk) and prednisone (5 mg/d) therapy, similar to the other 32 female RA. Respiratory cause mortality was greater in RA than non-RA (HR=2.88, 95% CI 1.06–7.82), after adjusting for cohort entry age (p = 0.027), baseline heavy cigarette (30+ daily) smoking (p = 0.018), limited therapy responses (p = 0.033), and the biomarker (p = 0.056). Mean (± 1 SE) features of the 8 RA deceased from respiratory causes vs the other 46 RA are shown (Table):

8 Respiratory Deaths vs 46 Other RA Cases	Age at RA Onset (X ± SE)	Age in 1995 (X ± SE)	Last Age At Follow (X ± SE)	Baseline Cigs/Day (X ± SE)	1995 Pred mg/d (X ± SE)	1995 MTX mg/wk (X ± SE)
18 Male RA						
4 Respiratory	52.0 ± 4.9	57.8 ± 5.2	70.0 ± 5.3	18.8 ± 7.2	13.1 ± 2.8	18.1 ± 3.7
14 Other RA	55.1 ± 2.7	64.0 ± 2.2	74.5 ± 2.0	20.3 ± 6.0	3.0 ± 1.7	8.0 ± 3.5
36 Female RA						
4 Respiratory	51.8 ± 2.4	64.5 ± 3.3	71.6 ± 1.9	11.3 ± 7.2	2.5 ± 1.4	3.8 ± 2.2
32 Other RA	56.1 ± 2.4	64.8 ± 2.3	74.7 ± 1.9	10.4 ± 2.3	3.8 ± 0.7	5.5 ± 1.1

Conclusions: Respiratory deaths were greater ($p = 0.036$) in incident RA (15%) than non-RA (5%), especially after excluding chronic airway disease and pulmonary edema ($p = 0.001$). Respiratory mortality was increased in RA after adjusting for multiple relevant covariates. Respiratory cause mortality of RA patients deserves further prospective study.

Disclosure: A. T. Masi: None; **J. C. Aldag:** None.

84

Rheumatoid Arthritis (RA) Is the Only One of 8 Diseases for Which a Patient History and Physical Examination (Versus Laboratory Tests and Ancillary Studies) Were Rated as Most Important for Clinical Decisions by >50% in a Physician Survey. Lauren McCollum[4], Sangmo Park[4], Tuulikki Sokka[2], Hasan Yazici[1] and Theodore Pincus[3]. [1]Cerrahpasa Medical Faculty, Istanbul, Turkey, [2]Jyvaskyla Central Hospital, Jyvaskyla, Finland, [3]New York University Hospital for Joint Disease, Hastings-on-Hudson, NY, [4]NYU Hospital for Joint Diseases

Purpose: To survey physicians concerning the relative importance of 5 sources of information in the clinical encounter—vital signs, patient history, physical examination, laboratory tests, and ancillary studies—in diagnosis and management of 8 chronic diseases: congestive heart failure (CHF), diabetes mellitus, hypercholesterolemia (HC), hypertension (HTN), lymphoma, pulmonary fibrosis (PF), rheumatoid arthritis (RA), and ulcerative colitis (UC).

Methods: An Internet survey using Survey Monkey™ was sent to about 6,636 rheumatologists and 6,964 non-rheumatologists, with the following query: "Please indicate the relative importance of 5 sources of information in diagnosis of CHF, diabetes, HC, lymphoma, HTN, PF, RA, and UC." A second query with identical language addressed management decisions in the 8 diseases. Response options were 0–20%, 21–40%, 41–60%, 61–80%, and 81–100%. The proportions of physicians who estimated each element as most important (or tied for most important) in diagnosis or management of each disease was computed.

Results: The survey was completed by 588 physicians (5% response rate), including 329 rheumatologists and 254 non-rheumatologists (5 unknown specialty), and 313 U.S. and 187 non-U.S. physicians (88 unknown country). Substantial differences were seen in the physicians' estimates of the most important element in diagnosis and management of the 8 diseases (Table 1): vital signs for HTN (82–83%), physical examination for RA (70–72%), laboratory tests for diabetes (96–96%) and HC (97–99%), and ancillary studies for lymphoma (75–77%), PF (75–93%) and UC (67–92%). One-third or more of respondents rated patient history as most prominent (or tied) in CHF (39–49%), RA (57–59%) and management of PF (40%) and UC (55%). RA was the only disease for which history and physical examination were rated as most important by >50%, including rheumatologists and non-rheumatologists.

Table 1. Highest ranked source of information in clinical encounter estimated in survey by 329 rheumatologists (Rh) and 254 non-rheumatologists; sources selected by >50% are shaded.

		Vital signs		Patient history		Physical examination		Laboratory tests		Ancillary studies	
		Rh	Non-Rh	Rh	Non-Rh	Rh	Non-Rh	Rh	Non-Rh	Rh	Non-Rh
Congestive heart failure	Diagnosis	21%	22%	35%	45%	61%	64%	8%	14%	69%	56%
	Management	38%	39%	44%	55%	63%	61%	10%	15%	54%	39%
Diabetes mellitus	Diagnosis	2%	4%	10%	15%	3%	6%	97%	95%	3%	4%
	Management	2%	9%	8%	24%	6%	12%	97%	94%	6%	7%
Hyperchol-esterolemia	Diagnosis	2%	2%	3%	4%	2%	2%	99%	98%	2%	5%
	Management	3%	4%	6%	11%	4%	6%	97%	97%	7%	7%
Hypertension	Diagnosis	84%	84%	8%	9%	24%	24%	3%	5%	4%	4%
	Management	82%	82%	6%	19%	22%	23%	6%	13%	8%	9%
Lymphoma	Diagnosis	2%	4%	10%	16%	23%	26%	33%	50%	85%	67%
	Management	4%	11%	12%	30%	20%	24%	40%	51%	78%	69%
Pulmonary fibrosis	Diagnosis	5%	8%	14%	19%	15%	23%	8%	9%	95%	91%
	Management	15%	26%	32%	50%	23%	35%	10%	16%	82%	65%
Rheumatoid arthritis	Diagnosis	2%	5%	54%	63%	85%	57%	17%	43%	10%	18%
	Management	3%	7%	52%	69%	83%	53%	16%	35%	21%	20%
Ulcerative colitis	Diagnosis	2%	4%	19%	32%	2%	6%	3%	8%	95%	89%
	Management	3%	11%	50%	63%	11%	16%	13%	16%	69%	62%

Conclusion: A patient history and physical examination are estimate by physicians to provide a larger proportion of the information for clinical decisions in diagnosis and management of RA than for 7 other chronic diseases. The patient history and physical examination may be regarded as "clinician-intensive," compared to vital signs, laboratory tests, and ancillary studies. This greater physician effort might be recognized in policies for scheduling, reimbursement, and allocation of physician resources by planners, regulators, and payers.

Similar Performance of New and Old Criteria for Rheumatoid Arthritis in an Early Arthritis Cohort in Amsterdam. Karin Britsemmer, Jennie Ursum and Dirkjan van Schaardenburg. Jan van Breemen Institute Amsterdam

Background: The 1987 RA classification criteria of the American College of Rheumatology (ACR) were developed using patients with established RA. At least partly for this reason, the usefulness of these criteria in early RA, when criteria are most needed, is low. Recently an ACR/EULAR taskforce presented a revised set of criteria for RA. The aim of the present study was to validate the diagnostic capacity of the ACR/EULAR RA classification criteria for the diagnosis of early RA compared to the 1987 ACR criteria in an independent EAC, and to evaluate the capacity of the new criteria to identify erosive disease.

Methods: Data were used of those patients from the EAC at the Jan van Breemen Institute in Amsterdam who were included from 2000 onwards. The inclusion criteria of this EAC are age >=18 years, symptom duration <= 2 years, at least 2 swollen joints, no prior DMARD treatment. Exclusion criteria are osteoarthritis, crystal arthropathy, connective tissue diseases and infectious arthritis. Thus the study population consists of patients with oligo- or polyarthritis, who would formerly be classified as having RA or undifferentiated arthritis. The gold standard for the diagnosis of RA was methotrexate (MTX) treatment at 6 and/or 12 months. The classification criteria were applied as proposed by the ACR/EULAR task force. 3-year radiographic progression was assessed with the Sharp/Van der Heijde Score (SHS) in patients with available scores at the time of data collection.

Results: 383 patients were included (mean age 52 [SD13] years, 69% female, median symptom duration 4 months, median swollen and tender joint count 5 [IQR 2–9] and 4 [IQR 2–8], respectively, mean DAS28 4.63 ±1.34, anti-CCP 55%, RF 41%). 305 patients had RA according to the gold standard. Sensitivity and specificity of the new criteria for RA were 77% and 69%, respectively, the positive and negative predictive values were 91% and 44%, respectively. The corresponding values of the 1987 ACR criteria for RA were 75%, 64%, 89% and 40%, respectively. The Area Under the Curve of the Receiver Operating Characteristics curve shows good discrimination between patients who did and did not use MTX at 6 or 12 months (0.79, $p<0.0001$)

Radiographic scores were available of 156 patients, of whom 121 fulfilled the new criteria at baseline. The median SHS progression was 0 (IQR 0-0) and 0 (IQR 0–4) in patients with and without RA according to the new classification, respectively (P 0.008). 71% of "non-RA" patients according to the new criteria used MTX in the first year. A similar difference in radiographic progression was observed between the groups of patients with and without RA according to the 1987 ACR criteria (data not shown).

Conclusion: The performance of the new ACR/EULAR RA classification criteria in this EAC was similar compared to the ACR 1987 RA criteria. Patients with RA according to the ACR/EULAR criteria had significantly higher median radiographic progression rates versus those without RA, which supports the aim of the new criteria to identify patients who are at high risk of joint damage. However, the low radiographic progression in the group of "non-RA" patients may be more a consequence of a high rate of MTX use than of a good prognosis per se.

The Impact of Health Beliefs on Therapeutic Adherence in Patients with Rheumatoid Arthritis (RA). Tara J. Rizvi[1], John Gomez[1], Sofia de Achaval[2], Michael A. Kallen[2], Vanessa L. Cox[2], Marsha N. Richardson[2], Bernard Ng[1], John D. Reveille[3] and Maria E. Suarez-Almazor[4]. [1]Baylor College of Medicine, Houston, TX, [2]The University of Texas M. D. Anderson Cancer Center, Houston, TX, [3]Univ Texas Health Sci Ctr, Houston, TX, [4]University of Texas, MD Anderson Cancer Center, Houston, TX

Objective: To determine whether the health beliefs of persons with RA influence their adherence to planned treatment.

Methods: We ascertained a cohort of patients with RA followed at publicly funded hospitals in Houston, TX. Eighteen specific components of the health belief model (HBM), including perceived severity and susceptibility, perception of self efficacy, benefits and risks of treatment, and barriers to treatment were measured using a self-report questionnaire. Treatment adherence was assessed with a previously validated questionnaire used in patients with rheumatic disease: de Klerk's Compliance Questionnaire Rheumatology (CQR). Pearson correlations between HBM components at baseline and CQR at baseline and 24 months were calculated. Stepwise linear regression modeling to predict adherence was then conducted, using HBM components that were statistically significantly ($p<.05$) correlated with adherence; select demographic and clinical patient characteristics such as age, gender, education level, and disease duration, were included in the modeling.

Results: 201 patients with RA were included: 75% were female; mean age was 51 years; 172 patients completed the 24 month follow-up. Ten of 18 HBM components ascertained were significantly related to treatment adherence at baseline and/or 24 months (Table 1). HBM components with a negative impact on treatment adherence were: belief in natural remedies, barriers in access to care, barriers due to beliefs about medication side effects, and beliefs about therapeutic lack of efficacy of RA therapies. Positive correlations with treatment adherence were observed with the following HBM components: belief in treatment benefits, belief in traditional medical treatment benefits, and positive attitudes towards risks of treatment. In the multi-variable regression analysis, belief in benefits of traditional treatment, willingness to take more risk, and longer disease duration were independent predictors of increased baseline treatment adherence, while higher levels of forgetting, financial barriers, and side effects were independent predictors of decreased adherence.

Table 1. Pearson Correlations of HBM Components with de Klerk Adherence (CQR)

HBM Component	CQR Baseline	CQR 24 Months
Perceived Severity/Susceptibility	.20*	0.14
Perceived Threat	0.11	.21*
Self Efficacy-Pain	−.15*	−0.09
Self Efficacy-Function	0.01	0.04
Self Efficacy-Symptoms	−0.03	0.03
Self Efficacy-Optimism	.20*	.17*
Health Beliefs & Attitudes	0.1	.18*
Risk Items	.34*	.24*
Benefits Traditional Remedies	.35*	.21*
Benefits of Treatment	.26*	.26*
Natural Remedies	−.19*	−.18*
Barriers Scheduling	−.22*	−0.13
Barriers Transportation	−.21*	−0.13
Barriers Clinic	−0.13	−.19*
Barriers Financial	−.29*	−.20*
Barriers Forget	−.46*	−.37*
Barriers Side Effects	−.33*	−.41*
Barriers Inefficacy	−.30*	−.30*

* $p < .05$.

Conclusion: A number of patient perceptions and beliefs impact therapeutic adherence in patients with RA. Based on our findings, strategies to improve adherence may include interventions to positively modify patients' beliefs regarding treatment benefits and side effects, and to limit modifiable barriers leading to non-adherence.

TNF and Natural Atheroprotective Antibodies Against Phosphorylcholine: Implications for Biologics in RA. Sofia Ajeganova, Roland Fiskesund, Ingiäld Hafström and Johan Frostegård. Karolinska Institutet, Sweden

Background: We have recently determined that natural antibodies against phosphorylcholine (anti-PC) are protection factors for cardiovasculardisease (CVD), where low levels of anti-PC independent of other risk factors increase the risk of CVD. Further, anti-PC is anti-inflammatory, inhibiting proinflammatory effects of inflammatory phospholipids. Levels of IgM anti-PC are low in individuals living a traditional life-style in New Guinea (where CVD and rheumatic diseases are very uncommon) as compared to a western population. We have hypothesized that an immune deficient state – low levels of anti-PC –predispose to chronic inflammatory diseases. TNF is of major importance not only in rheumatic disease but also in CVD, atherosclerosis and metabolic syndrome. We here determine the role of TNF and TNF-inhibition on anti-PC levels and anti-PC production. We compared effects by TNF-inhibitors with rituximab.

Methods: In vitro anti-PC production by B-cells isolated from peripheral blood was determined by ELISA after 6 days of cell culture. Two hundred fifteen RA patients, aged 57.9 ± 12.4 years with a mean disease duration of 8.5 (5–15) years were investigated with a one year follow up. Of these patients, 60 were treated with etanercept, 60 with infliximab and 42 with adalimumab as the first biologic, furthermore, 53 patients were treated with rituximab. The patients were followed and blood sampled at 0, 3, 6 and 12 months.

Results: TNF at 1 ng/ml was shown to drastically (more than tenfold) decrease anti-PC production in vitro ($p<0.0001$) without inducing apoptosis. Anti-TNF treatment induced a 26% increase in anti-PC after 12 months of treatment (28%, 27.8% and 22% on etanercept, infliximab and adalimumab respectively), $p<0.0001$, while rituximab decreased anti-PC levels by 14%, $p=0.023$. Non-responders had lower anti-PC levels at baseline than responders in both anti-TNF, $p=0.007$, and Rituximab-treated subjects, $p=0.041$.

Conclusion: TNF was demonstrated to inhibit anti-PC production, a finding which suggest a novel mechanism by which anti-PC IgM could be decreased. Anti-TNF treatment may decrease risk of CVD by raising anti-PC levels. The adverse effect of rituximab on anti-PC levels may influence CVD-risk negatively. If treatment with anti-PC could have a role in some patients with RA including non-responders to biologics deserves further investigations.

TNF Therapy Reduces the Odds of Worsening Disability Trajectories in Rheumatoid Arthritis over at Least 2 Years—Data from the NDB-Portugal Cohort. Sofia Pedro[1], Elizabeth Benito-Garcia[1], Joana Vasconcelos[1], Irina Chaves[1], Rita Marques[1], Andreia Rodrigues[1], Kaleb Michaud[3] and Fred Wolfe[2]. [1]Bioepi Clinical and Translational Research Center, Oeiras, Portugal, [2]National Databank for Rheumatic Diseases, Kansas, [3]University of Nebraska Medical Center, NE

Background: The trajectories of the health assessment questionnaire (HAQ) disability scores among rheumatoid arthritis (RA) patients are known to have different courses. Wolfe et al. (2000) characterized them as being non linear, chaotic and non-time determined. It is suggested that HAQ be measured between clinic visits to monitor disability and the effect of therapy. Many studies have defined the predictors of HAQ, but few have evaluated the predictors of HAQ trends among RA patients.

Objective: To investigate the predictors of worsening disability trends compared to improving, no change or other patterns of disability trajectories among RA patients over at least 2 years.

Methods: 646 RA patients from the ongoing biannual NDB-Portugal cohort (started in 2003) with at least four consecutive HAQ scores per patient during their follow-up were used in this analysis. Questionnaires included socio-demographics, disease characteristics, function, etc.

The proportion defined by the number of 6-month positive increments in HAQ scores (worsening function) divided by the total number of differences was computed per patient and used to define patients' trajectories. The outcome was then defined as the presence of a trend of worsening disability (when the proportion was > 0.5). Univariate (UV) and multivariate (MV) generalized estimating equations (GEE) were used to study the predictors of a worsening disability trend. Age, educational level, disease duration, paid form of work, retirement, number of total major comorbidities, SF-36 mental component (MCS) (0–100, 0 is worse), RADAI (0–10, 10 is worse), the VAS scales of sleep, fatigue and pain (VAS 0–10, 10 is worse), the use of current TNF (with or without concomitant DMARDs) vs. traditional DMARD therapy and corticosteroids, were used as possible predictors.

Results: 168 patients of 646 (26%) had worsening disability trends. The UV analyses showed that all of the following factors were statistically relevant: age, educational level, number of major comorbidities, sleep disturbances and fatigue, RADAI and the use of TNF therapy. The final MV model included pain (OR: 1.003 (95%CI: (1.000; 1.005))), age (OR: 1.02 (1.01; 1.02)) and the use of TNF (OR: 0.94 (0.91; 0.97)).

Conclusions: In our study, we showed that older age and more pain predicted worsening HAQ disability trends. The use of TNF therapy (with or without concomitant DMARDs) when compared with traditional DMARD was the only factor that decreased the odds of having a worsening HAQ trajectory.

TNF-alpha Blocking Therapy Lowers Cardiovascular Risk in Rheumatoid Arthritis. Ingrid M. Visman[1], Alper M. van Sijl[3], Mike J. L. Peters[5], Carlo J. J. van Dongen[1], Ben A. C. Dijkmans[4] and Michael T. Nurmohamed[2]. [1]Jan van Breemen Institute, [2]Jan van Breemen Institute and VU Medical Centre, Amsterdam, The Netherlands, [3]Jan van Breemen Institute and VU Medical Centre, [4]VU Medical Centre, Amsterdam, The Netherlands, [5]VU Medical Centre

Background: Patients with rheumatoid arthritis (RA) have an increased risk of developing cardiovascular (CV) disease and the underlying chronic inflammatory process appears to play a pivotal role. As tumor-necrosis factor (TNF)-alpha blocking agents have powerful anti-inflammatory effects it is conceivable that these agents will lower CV risk in RA. The objective of this study was to compare the CV disease incidence rate in RA patients receiving TNF-alpha blocking therapy with RA patients not receiving these drugs.

Methods: Two prospective cohort studies of individuals with RA (the CARRÉ study and the Biologicals-cohort of the Jan van Breemen institute in Amsterdam, the Netherlands) were followed for several years. The CARRÉ study is a prospective cohort of individuals with RA, most of whom did not use biologic agents at inclusion. Patients who did use biologicals were excluded from further analysis. The Biologicals-cohort is a prospective cohort of adult RA patients starting therapy with TNF-alpha blocking agents. Data was collected regarding traditional cardiovascular risk factors, RA related factors, cardiovascular morbidity and mortality. Cardiovascular events were defined as objectified myocardial infarction, cerebrovascular accident, transient ischaemic attack, peripheral arterial reconstruction, or coronary stent- or by-pass procedure. Cox proportional hazard model was used to evaluate the difference in cardiovascular incidence between both groups and models were adjusted for age, sex and previous cardiovascular disease.

Results: 377 and 322 individuals, with and without TNF-alpha blocking therapy, respectively, were followed for a mean duration of 2.1 and 2.7 years, resulting in 793 and 888 patient years, respectively. Cardiovascular incidence was 10.1/1000 patient years and 24.8/1000 patient years, respectively. Cox proportional hazard model showed a statistically significantly decreased cardiovascular incidence in individuals using TNF-alpha blocking therapy, hazard ratio (95%-confidence interval): 0.42 (0.18–0.97). After adjustment for age, gender and previous CVD there was still a 30% lower cardiovascular risk in RA patients treated with TNF-blockers, but this was not longer statistically significant (hazard ratio (95%-confidence interval): 0.71 (0.29–1.72).)

Table 1. Incidence of cardiovascular risk factors and cardiovascular events

	Carre cohort (n=322)		Biologicals cohort (n=377)	
	Cases	Incidence rate per 1000 patient years	Cases	Incidence rate per 1000 patient years
All cause mortality	10	11.3	3	4.1
All CV-events	22	24.8	8	10.1
IHD	13	14.6	2	2.7
CVA/TIA	5	5.6	4	5.5
PAD	3	3.4	2	2.7

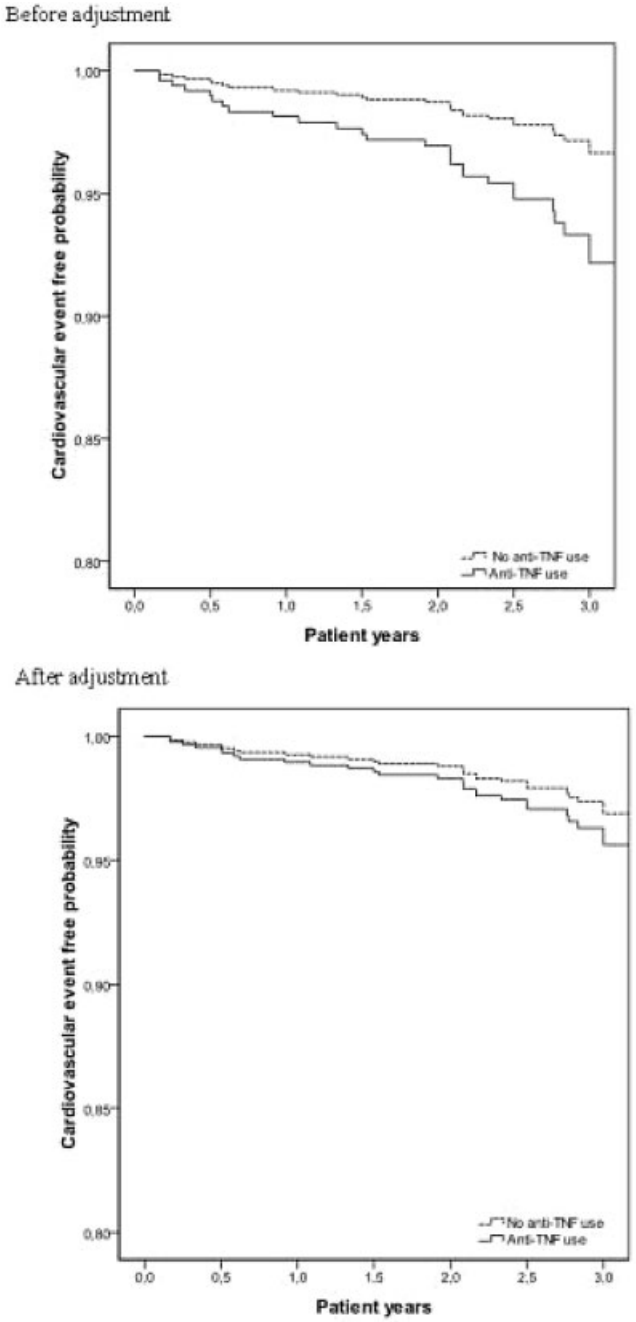

Figure 1. Cox-regression analyis of cardiovascular event free probability for patients with and without TNF-blocking therapy, corrected for age, gender and previous CVD.

Conclusions: This investigation strongly suggests that TNF-blocking agents indeed lowers the cardiovascular risk in RA. However, confirmatory investigations are still required.

Validation of the Work Performance Visual Analog Scale: Measuring Work and Household Productivity of Patients with Early, Aggressive Rheumatoid Arthritis. Dennis Revicki[2], Sanjoy Roy[1], Miriam Kimel[2], Chris Thompson[2] and Mary Cifaldi[1]. [1]Abbott Laboratories, Abbott Park, IL, [2]United Biosource Corporation, Bethesda, MD

Background and Purpose: Visual analog scales (VASs) have been used in clinical and observational studies to assess the impact of rheumatoid arthritis (RA) on work performance for employed patients and homemakers. To date, however, the psychometric properties of these scales have not been described. To assess the appropriateness for use in clinical trials, we evaluated the psychometric properties of a work performance VAS in both employed workers and homemakers with RA.

Methods: Data from PREMIER and DE032 (health economic companion study of PREMIER), clinical trials of adalimumab (ADA) with or without methotrexate (MTX) in patients with early RA, were analyzed. The VAS measured the impact of RA on work performance on a scale of 0 to 100, in which 0=not affected at all and 100=completely affected. Data were pooled across treatment groups (ADA alone, MTX alone, and ADA+MTX) and analyzed separately for employed patients and homemakers. Psychometric assessments of the VAS included test-retest reliability, convergent validity, known-groups validity, and responsiveness based on minimum clinically important difference (MCID) criteria.

Results: This analysis included 664 patients from PREMIER who participated in the health economic companion study. Test-retest reliability for performance in employment-related and household work was evaluated for patients with no change in clinical status based on Health Assessment Questionnaire (HAQ) and Patient Global Assessment of Disease Activity (PaGA) scores from Weeks 4 to 8 and Weeks 8 to 12 (intraclass correlation coefficients of 0.78–0.85). Convergent validity for employed work performance was demonstrated through moderate to large correlations (0.40–0.72, absolute values; all $p<0.0001$) with the HAQ, 28-joint Disease Activity Score (DAS28), Functional Assessment of Chronic Illness Therapy-Fatigue scale, PaGA, Health Utilities Index Mark 3, Short Form 36 Health Survey, and tender joint counts. Similar findings were observed for household work performance (correlation coefficients ranged from 0.47 to 0.84, absolute values; all $p<0.0001$). Mean VAS scores for both employment-related and household work performance varied significantly across different levels of physical function and disease severity based on HAQ and DAS28 scores; patients with better clinical status had better work performance scores, demonstrating good known-groups validity. From anchor-based methods using American College of Rheumatology response criteria, MCID estimates for VAS scores ranged from 8.6 to 13.2 points for employment-related work performance, and the MCID estimate for household work performance was 13.1 points for all. Based on DAS28 remission status, MCID estimates for VAS scores ranged from 10.7 to 17.0 points for employment-related work performance and from 19.8 to 23.4 points for household work performance.

Conclusions: Results suggest that the work performance VAS scores for employment-related and household work possess acceptable reliability and validity, making them appropriate for use in clinical research to evaluate the impact of RA and treatment on work performance.

ACR Poster Session A
Fibromyalgia and Soft Tissue Disorders Poster I
Monday, November 8, 2010, 9:00 AM–6:00 PM

92

Candidate Gene Studies of Fibromyalgia: A Systematic Review and Meta-Analysis. Young Ho Lee, Sung Jae Choi, Jong Dae Ji and Gwan Gyu Song. KUMC, Seoul, Korea, Republic of

Objectives: The aim of this study was to explore whether the candidate gene polymorphisms contribute to fibromyalgia susceptibility.

Methods: The authors conducted a meta-analysis on associations between serotonin transporter (5-HTT) gene-linked polymorphic region (5-HTTLPR) S/L allele, Catechol-O-methltransferase (COMT) Val158Met, and serotonin 2A (5-HT2A) receptor 102T/C polymorphisms and fibromyalgia susceptibility as determined using 1) allele contrast, 2) recessive, 3) dominant models, and 4) contrast of homozygotes. We also performed a systematic review with available data of the candidate genes.

Results: A total of 21 separate comparisons were considered in this systematic review and meta-analysis. Seventeen candidate genes and over 35 different polymorphisms were identified in studies on fibromyalgia susceptibility. Meta-analysis of the 5-HTTLPR S/L allele and COMT val158Met failed to reveal any association with fibromyalgia. However, meta-analysis of the C allele, CC+CT genotype, and CC vs. TT genotype of the 5-HT2A receptor 102T/C polymorphism showed significant association with fibromyalgia. The overall OR of the association between the C allele and fibromyalgia was 1.333 (95% CI = 1.053 – 1.688, p = 0.017). The ORs for the CC+CT genotype, and CC vs. TT genotype showed the same pattern as that observed for the C allele (OR = 1.541, 95% CI = 1.032 – 2.303, p = 0.035; OR = 1.838, 95% CI = 1.151 – 2.936, p = 0.011).

Conclusions: This meta-analysis demonstrates that the 5-HT2A receptor 102T/C polymorphism confers susceptibility to fibromyalgia. In contrast, no association was found between the 5-HTTLPR S/L allele, COMT val158Met and susceptibility to fibromyalgia.

Clinical Determinants of Physical Activity in Fibromyalgia Patients. Dennis Ang[1], Anthony Kaleth[3], Silvia Bigatti[2], Steven Mazzuca[2], Chandan Saha[2] and Robert Bandy[2]. [1]Indiana University, Indianapolis, IN, [2]Indiana University, [3]Indiana University-Purdue University Indianapolis

Background: The standard of care for fibromyalgia (FM) includes recommendations for increased physical activity (PA) and exercise. Unfortunately, while most FM patients have no medical contraindications to begin a physically active lifestyle, many remain sedentary. In this report, we sought to determine modifiable clinical correlates of physical activity (PA).

Methods: This was an analysis of cross-sectional data from a randomized clinical trial of motivational interviewing (MI) to improve exercise adherence for patients with FM. Subjects (n=216) completed web-based assessments and wore an ActiGraph monitor around the waist for ≥10 waking hours/day for 4–7 days. Logistic regression was used to identify clinical factors associated with exhibiting median or greater PA in two respects: ≥3,722 steps/day and ≥77 minutes/week in moderately intense PA.

Results: Most of the FM patients were female (95.8%), white (88.4%), married (61.1%) and employed (53.7%). Baseline means for demographic and clinical variables and bivariate associations with PA indicators ($P \leq 0.15$) are tabled below.

Dependent Variable	Predictor	Mean ± SD	Odds Ratio*	95% CI
≥3,722 steps/day	Employed vs. unemployed		2.28	1.29–4.02
	# of co-morbidities	1.0 ± 1.0	0.62	0.45–0.84
	BMI, kg/m^2	31.4 ± 7.2	0.63	0.47–0.85
	Total FIQ	67.0 ± 12.7	0.65	0.47–0.89
	PHQ-8 depression severity	12.5 ± 4.9	0.71	0.54–0.94
	Age, years	45.8 ± 11.3	0.71	0.54–0.94
	FM duration, years	9.0 ± 7.0	0.74	0.56–0.98
	# of medications	3.0 ± 1.6	0.78	0.59–1.03
BPI pain intensity		6.0 ± 1.3	0.80	0.61–1.06
Moderate PA ≥77 minutes/week				
	BMI, kg/m^2	31.4 ± 7.2	0.63	0.47–0.85
	PHQ-8 depression severity	12.5 ± 4.9	0.64	0.48–0.85
	# of co-morbidities	1.0 ± 1.0	0.76	0.57–1.02
	Total FIQ	67.0 ± 12.7	0.76	0.56–1.03
	# of medications	3.0 ± 1.6	0.80	0.61–1.05

* Change in odds of being above median, relative to below, associated with a 1-SD increment in the predictor variable except for total FIQ where a 14% change is considered clinically meaningful.

In the multivariate analysis, being relatively active (≥3,722 steps/day) was associated with lower BMI (OR: 0.62, 0.45–0.86), fewer co-morbidities (OR: 0.71, 0.51–0.99), shorter disease duration (OR: 0.72, 0.52–1.0) and lower Total FIQ (OR: 0.61, 0.43–0.88). Alternatively, time spend in PA of moderate or greater intensity (≥77 min/wk) was limited by greater BMI (OR: 0.64, 0.48–0.86) and increased depressive symptomatology (OR: 0.74, 0.56–0.99).

Conclusions/Implications: Active lifestyles were rare in this sample of FM patients. Employed patients were more active than unemployed ones. While several associations with clinical variables may be bidirectional, sedentary patients tended to be more obese and have greater duration and severity of FM and more numerous co-morbidities. Clinicians may take these associations as evidence supporting the encouragement of PA early in the disease process. However, attainment of appreciable levels of moderate intensity of PA may be difficult without attention to weight loss and mood, when indicated.

Development of Responder Definitions for Fibromyalgia Clinical Trials. Lesley M. Arnold[8], Philip J. Mease[6], David A. Williams[7], Susan A. Martin[5], Fujun Wang[2], Birol Emir[4], Chinglin Lai[3] and Rong Zablocki[1]. [1]Cypress Bioscience, Inc., [2]Eli Lilly and Company, [3]Jazz Pharmaceuticals, [4]Pfizer, Inc., [5]RTI-Health Solutions, [6]Seattle Rheumatology Associate, Seattle, WA, [7]Univ of MI Hlth System-Lobby M, Ann Arbor, MI, [8]University of Cincinnati College of Medicine, Cincinnati, OH

Background: Previous analyses of fibromyalgia (FM) clinical trial databases found patient perceptions of global improvement relied not only on improvements in pain but also on improvements in accompanying symptoms such as fatigue, sleep problems, physical functioning, and mood. These symptom and functional domains may form the components of a responder definition for FM clinical trials. The objective of this study was to develop and test responder definitions for FM clinical trials using key symptom and functional domains.

Methods: Informed by existing responder definitions for other rheumatologic disorders, 8 candidate responder definitions were developed by expert consensus. These 8 definitions were evaluated in the context of randomized placebo-controlled clinical trials of 4 medications for FM between baseline and 3 months. For each of the proposed definitions, treatment effects of the medication compared with placebo were analyzed using the Cochran-Mantel-Haenszel test. A meta-analysis of the pooled results for the 4 medications established risk ratios so as to determine the definitions that best favored medication over placebo.

Results: Two definitions performed best in the analyses and shared common features. Both definitions included ≥ 30% reduction in pain and both included ≥ 10% improvement in physical function. They differed in that one (FM 30 short version) included ≥ 30% improvement in sleep or fatigue, and the other (FM 30 long version) required ≥ 30% improvement in 2 of the following symptoms: sleep, fatigue, depression, anxiety, or cognition. In the analysis of both versions, the response rate was about 20% or greater for each medication and was significantly greater than placebo. The risk ratio (95% CI) in the pooled analysis of the FM 30 short version was 1.69 (1.04, 2.72), $P=0.03$; the risk ratio (95% CI) for the FM 30 long version was 1.60 (1.31, 1.96), $P=<0.00001$.

Conclusion: Among the 8 responder definitions tested, 2 were identified as most sensitive in identifying response to treatment. The identification of responder definitions for FM clinical trials that include assessments of key symptom and function domains will hopefully improve the sensitivity of clinical trials to identify meaningful improvements, leading ultimately to improved management of FM.

Does Obesity in Patients with Fibromyalgia Modify Response to Tai Chi Therapy: Analysis of a Randomized Controlled Trial. Chenchen Wang[1], Christopher H. Schmid[2], Yoojin Lee[2] and Timothy McAlindon[1]. [1]Tufts Medical Center, Boston, MA, [2]Tufts Medical Center

Purpose: Fibromyalgia (FM) is a chronic pain disorder of complex etiology. Recent evidence about the association between obesity and FM suggests that this might obfuscate therapy. We evaluated the association of obesity and changes in FM severity, sleep quality and health related quality of life in a randomized controlled trial of FM patients.

Methods: We studied a sample of 66 eligible individuals (age 21 or older and fulfilled the American College of Rheumatology 1990 diagnostic criteria for FM) who participated in a single-blind, randomized controlled trial. Using computer-generated numbers, we randomly assigned participants to Tai Chi mind-body exercise (Classical Yang style, n=33) or attention control (stretching and wellness education n=33) in three cycles of 22 patients each. The 60-minute group sessions occurred twice-weekly for 12 weeks. We defined obesity as body mass index (BMI) ≥30.00 kg/m2. Study endpoints included changes from baseline to 12 weeks in FM Impact Questionnaire (FIQ) score (range, 0 to 100; higher scores indicate more severe symptoms), Pittsburgh Sleep Quality Index (range, 0–21, higher scores indicate worse sleep quality), and Physical Component Summary and Mental Component Summary of the Short Form-36 (SF-36) to assess quality of life (range 0–100; lower scores indicate worse health status). We estimated the relationship between obesity and the treatment effect by the interaction of treatment and obesity in linear regression using each of the three study endpoints.

Results: The 66 participants had mean age 50y (SD 11.1), mean disease duration 11 y (SD 7.1), mean BMI 33 kg/m^2 (SD 8.2), and were mainly female (86%) and white (56%). Thirty-six patients were obese (BMI≥30) and 29 patients were not obese (< 30.00) and 1 had missing BMI. The proportion of obese BMI remained stable in both Tai Chi and control groups. Obese patients assigned to Tai Chi group exhibited significantly greater improvement in FIQ total score (between-group difference −17.5, 95% CI, [−34.1 to −1.0]; P=0.04)

than the non-obese group. The SF-36 Physical Component Summary and Mental Component Summary tests also favored obese group but did not reach statistical significance. Both groups improved their sleep quality (Pittsburgh Sleep Quality Index) equally **(Table)**.

Table. Changes in FM severity, sleep quality and health status by BMI group at Week 12*

Variables/ BMI level	Groups	Baseline Mean (SD)	At 12 week Mean Change (95% CI)	Mean change between Tai Chi vs. control (95% CI) and P-value	Mean change between obese vs. non-obese (95% CI) and P-value
BMI ≥30 (n=36)	Tai Chi	38.7 ± (6.9)	−0.1 (−0.5, 0.4)	0.1 (−0.6, 0.8)	−0.3 (−1.3, 0.8),
	Control	38.2 (5.4)	−0.2 (−0.7, 0.4)	P=0.79	P=0.62
BMI <30 (n=29)	Tai Chi	24.7 (3.5)	0.2 (−0.4, 0.8)	0.4 (−0.4, 1.1)	
	Control	25.9 (2.5)	−0.2 (−0.6, 0.3)	P=0.37	
FIQ (0-100)	Tai Chi	66.8 (14.4)	−32.9 (−40.0, −25.8)	−26.3 (−37.2, −15.4)	−17.5 (−34.1, −1.0),
BMI ≥30 (n=36)	Control	71.5 (10.3)	−6.6 (−14.9, 1.8)	**P<0.0001**	P=0.04
FIQ (0-100)	Tai Chi	56.6 (16.2)	−20.6 (−30.2, −10.8)	−8.8 (−21.2, 3.6)	
BMI <30 (n=29)	Control	65.1 (11.0)	−11.8 (−19.4, −4.2)	P=0.17	
SF-36:PCS (0-100)	Tai Chi	26.4 (7.2)	10.1 (6.7, 13.5)	9.0 (3.7, 14.3)	4.5 (−3.5, 12.5),
BMI ≥30 (n=36)	Control	26.0 (7.4)	1.1 (−2.9, 5.2)	P=0.001	P=0.27
SF-36:PCS (0-100)	Tai Chi	31.8 (9.7)	6.1 (1.4, 10.8)	4.5 (−1.5, 10.5)	
BMI < 30 (n=29)	Control	29.6 (8.0)	1.6 (−2.1, 5.2)	P=0.14	
SF-36:MCS (0-100)	Tai Chi	42.0 (13.3)	9.0 (4.3, 13.7)	8.7 (1.4, 16.0)	5.4 (−5.6, 16.4),
BMI ≥30 (n=36)	Control	35.6 (7.3)	0.3 (−5.3, 5.9)	P=0.02	P=0.34
SF-36:MCS (0-100)	Tai Chi	43.5 (11.1)	6.0 (−0.5, 12.5)	3.3 (−4.9, 11.6)	
BMI < 30 (n=29)	Control	39.1 (12.5)	2.7 (−2.4, 7.8)	P=0.43	
PSQI (0-21)	Tai Chi	14.0 (3.0)	−3.5 (−5.0, −2.1)	−3.3 (−5.5, −1.0)	−0.2 (−3.6, 3.2),
BMI ≥ 30 (n=36)	Control	14.7 (3.7)	−0.3 (−2.0, 1.5)	**P=0.005**	P=0.91
PSQI (0-21)	Tai Chi	13.9 (3.7)	−4.2 (−6.2, −2.2)	−3.1 (−5.6, −0.5)	
BMI < 30 (n=29)	Control	12.4 (3.4)	−1.1 (−2.7, 0.5)	**P=0.02**	

* N=33 for Tai Chi and Control each group. FIQ = Fibromyalgia Impact Questionnaire. PSQI=Pittsburgh Sleep Quality Index. SF-36: PCS and MCS = Short Form-36 Physical Component Score and Mental Health Summary

Conclusion: Despite no weight loss in either group, obese patients with FM improved more in their symptoms and quality of life with Tai Chi than with attention control. Tai Chi mind-body exercise may be a particularly beneficial treatment for obese patients with FM. BMI should be considered in future behavioral intervention design.

Dorsal Root Ganglia/Sympathetic Ganglia Sodium Channels Gene Polymorphisms in Fibromyalgia. Gilberto Vargas-Alarcon, Edith Alvarez-Leon, Jose-Manuel Fragoso, Angelica Vargas, Aline Martinez, Maite Vallejo and Manuel Martinez-Lavin. National Institute of Cardiology, Mexico

Background: A consistent line of investigation suggests that autonomic dysfunction may explain the multi-system features of fibromyalgia (FM), and that FM is a sympathetically maintained neuropathic pain syndrome. Dorsal root ganglia (DRG) are potential sympathetic-nociceptive short-circuit sites. Sodium channels located in DRG (particularly Nav1.7) act as molecular gatekeepers for pain detection. Nav1.7 is encoded in gene SCN9A of chromosome 2q24.3 and is predominantly expressed in the DRG pain-sensing neurons and sympathetic ganglia neurons. Several SCN9A sodium channelopathies have been recently recognized as the cause of rare painful-dysautonomic syndromes such as paroxysmal extreme pain disorder and primary erythermalgia (Ann N Y Acad Sci. 2010;1184:196, Med Hypotheses. 2009;72:64). SCN9A polymorphisms (particularly rs6746030) have been linked to altered pain perception (Proc Natl Acad Sci USA 2010;107:5148).

Objective: To identify associations between fibromyalgia and several Nav1:7 polymorphisms encoded in gene SCN9A.

Methods: We studied 73 Mexican women with FM according to the 1990 ACR criteria and 48 Mexican women who considered themselves healthy. All participants filled out the Fibromyalgia Impact Questionnaire (FIQ). Genomic DNA from whole blood containing EDTA was extracted by standard techniques. The following SCN9A single-nucleotide polymorphisms (SNPs) were studied: rs4371369, rs4387806, rs4453709, rs4597545, rs6746030, rs6754031, rs7607967, rs12620053, rs12994338, and rs13017637. SNPs were analyzed by 5-exonuclease TaqMan assays on a 7900HT fast real-time PCR system.

Results: Are summarized in table 1. Rs6754031 nucleotide distribution was significantly different in both groups (p = 0.036) mostly due to an absence of GG genotype in controls. Interestingly, patients with this rs6754031 GG genotype had higher total FIQ scores, than patients with the other two rs6754031 genotypes (p = 0.039). Table 2.

Table 1. Nucleotide distribution.

Rs-6754031	Patients	Controls	P value
n	73	48	
Age (mean ± SD)	44.7 ± 12.8	42.8 ± 12.3	ns
Genotype	n (%)	n (%)	
GG	8 (11)	0 (0)	
GT	24 (33)	15 (31)	0.036
TT	41 (56)	33 (69)	

Table 2. Total FIQ score in patients with Rs-6754031

	FIQ score			
Rs-6754031 Genotype	Percentile 25	Median	Percentile 75	P value
GG	69.74	80.38	88.74	0.039
GT	58.55	63.29	77.53	
TT	64.23	71.25	77	

Conclusions: In this ethnic group, a disabling form of FM was associated to a particular SCN9A gene variant. These preliminary results raise the possibility that patients with severe FM may have a sodium channelopathy.

Durability of Response in a 38-Week Open-Label Study of Sodium Oxybate in Patients with Fibromyalgia. Michael Spaeth[5], I. Jon Russell[7], Serge Perrot[6], Sarah Alvarez-Horine[3], Diane R. Guinta[1], Y. Grace Wang[2] and Robert M. Bennett[4]. [1]Jazz Pharmaceuticals Inc., Palo Alto, CA, [2]Jazz Pharmaceuticals Inc., [3]Jazz Pharmaceuticals, Inc., [4]Oregon Health and Science Univ, Portland, OR, [5]Rheumatologische Schwerpunktpraxis, [6]Service de Medecine Interne et Centre de la Douleur, Hôtel-Dieu, [7]University of Texas Health Science Center, San Antonio, TX

Background: Two pivotal phase 3 clinical trials demonstrated the efficacy and tolerability of sodium oxybate (SXB) for the treatment of fibromyalgia (FM). Fibromyalgia is a chronic disorder characterized by widespread musculoskeletal pain, fatigue, sleep disturbances, and functional impairment. The current report describes the durability of response of SXB in a FM population.

Methods: Patients with FM who completed a 14-week, placebo-controlled, phase 3 study of SXB were eligible to enroll in this international, open-label extension within 7 days after completing the previous study. Eligible subjects received open-label treatment for up to an additional 38 weeks. SXB was initiated at 4.5 g/night (administered in equally divided doses 2.5 to 4 hours apart), and increases were permitted in increments of 1.5 g/night, at intervals of at least 1 week, up to 9 g/night. Dose reductions were permitted in increments of 1.5 g/night to a minimum of 4.5 g/night; subjects unable to tolerate this dose were discontinued. Efficacy was evaluated based on reductions in pain and fatigue, recorded daily on a 100 mm Visual Analogue Scale (VAS), and improvement in function assessed using the Fibromyalgia Impact Questionnaire (FIQ) at each study visit. Study endpoint was defined as the last available data, whether obtained at study completion or early discontinuation.

Results: Of 560 subjects who were treated (mean age, 46.9 years; 91.1% female), 366 subjects (65.4%) received study drug for at least 24 weeks and 269 subjects (48.0%) received study drug at least 38 weeks. Mean dose was 6.28 g/night at last dose for all subjects. Improvements seen on multiple measures in the previous trials were maintained. At study endpoint, the mean change from prior study baseline in pain VAS for all treated patients was –35.84 mm, with 68.8% and 53.0% achieving a ≥30% and ≥50% pain reduction, respectively. At study endpoint, the mean change from baseline in fatigue VAS was –37.15 mm. At endpoint, 69.7% of patients had achieved ≥30% reduction from baseline in total FIQ score. The incidence of AEs was 88.9% overall. AEs were generally mild or moderate in severity. Twenty-three percent of subjects discontinued due to AEs. The most common AEs (≥5% in any treatment group) were nausea, headache, dizziness, nasopharyngitis, vomiting, sinusitis, diarrhea, anxiety, insomnia, influenza, somnolence, upper respiratory tract infection, muscle spasms, urinary tract infection, and viral gastroenteritis.

Conclusions: This open-label study demonstrated the long-term durability of effect of SXB for the treatment of FM over a dose range of 4.5 to 9 g/night for 38 weeks. Treatment effects were substantial across multiple fibromyalgia symptoms, including pain, fatigue, and impairments in daily living and physical functioning. SXB was generally well-tolerated over the 38 weeks of treatment.

Effects of Milnacipran Added to Pregabalin on Cognition and Mental Clarity in Fibromyalgia Patients. Robert S. Katz[4], Robert H. Palmer[2], Yong Wang[3] and R. Michael Gendreau[1]. [1]Cypress Bioscience, Inc, San Diego, CA, [2]Forest Research Institute, Jersey City, NJ, [3]Forest Research Institute, [4]Rush University Medical Center, Chicago, IL

Purpose: Fibromyalgia (FM) is characterized by chronic widespread pain accompanied by a host of symptoms that include perceived cognitive dysfunction, which is also known as fibrofog. Cognitive impairments associated with fibrofog include problems with attention, mental confusion, and short-term memory loss. A recent clinical trial evaluating the efficacy of milnacipran when added to pregabalin utilized the Mental Clutter Scale, a new 16-item measure of fibrofog, to assess improvements in cognitive disability in FM patients.

Methods: The Mental Clutter Scale is composed of 2 subscales that measure cognition and mental clarity; each subscale consists of 8 items. This randomized, open-label, controlled study evaluated the efficacy and tolerability of milnacipran 50 mg BID when added to pregabalin 150 mg BID or 225 mg BID in FM patients who had an incomplete response to pregabalin during a 4- to 12-week open-label run-in phase. Pregabalin incomplete responders (defined as patients with weekly recall VAS pain score ≥40 and ≤90 [0 to 100 scale], Patient Global Impression of Severity score ≥4 [moderately ill to extremely ill], and Patient Global Impression of Change [PGIC] score ≥3 [minimally improved to very much worse]) were randomized to either pregabalin alone (n=180) or milnacipran added to pregabalin (n=184) for 11 weeks. Least squares mean changes from baseline in Mental Clutter Scale subscale and item scores were analyzed at endpoint using an LOCF approach.

Results: Patients treated with milnacipran added to pregabalin demonstrated significant improvements compared to pregabalin alone in the Mental Clutter Scale full scale score ($P<.001$) as well as the Cognition and Mental Clarity subscale scores ($P\leq.001$). All item scores of the Cognition subscale were significantly improved in the milnacipran added to pregabalin group compared with pregabalin alone except for memory assessment ($P=.052$). Scores for concentration ($P=.043$), staying focused ($P=.008$), multitasking ($P=.009$), expressing self ($P=.004$), thinking clearly ($P<.001$), perceptual clarity ($P=.002$), and mental speed ($P=.001$) were all significantly improved in the milnacipran added to pregabalin group compared with pregabalin alone. In addition, significant improvements were demonstrated on all items of the Mental Clarity subscale: spaciness ($P<.001$), haziness ($P<.001$), confusion ($P<.001$), cluttered thinking ($P=.005$), fogginess ($P=.009$), rushing thoughts ($P=.002$), fuzzy headedness ($P=.007$), and information overload ($P=.002$).

Conclusions: When added to pregabalin, milnacipran resulted in significant improvements in the cognitive impairments perceived by FM patients, as measured by a new self-report tool intended to measure cognition and mental clarity.

99

Fatigue in Fibromyalgia Patients: A Qualitative Study Exploring a Conceptual Framework. Philip J. Mease[4], Lisa D'Ambrosio[3], Asha Hareendran[6], Maureen Mohyde[2], Robin Pokrzywinski[6], Kristin Seymour[5] and Steven Blum[1]. [1]Forest Research Institute, [2]Outcome Sciences, [3]Outcome Sciences and MIT AgeLab, [4]Seattle Rheumatology Associate, Seattle, WA, [5]Seattle Rheumatology Associates, [6]United BioSource Corporation

Purpose: In addition to pain, fatigue is a common and important symptom of fibromyalgia (FM) and has been included in the OMERACT (Outcome Measures in Rheumatology Clinical Trials) core domain set1 and the 2010 ACR Preliminary Diagnostic Criteria for FM.2 The FDA Guidance on Patient-Reported Outcome (PRO) Measures recommends input from patients in development or modification of PRO instruments. This study was conducted to further explore FM patients' experience of fatigue and to provide insight into how it can be measured in a way that captures concepts that are most relevant to patients with FM.

Methods: Two focus group discussions among clinically diagnosed FM patients were conducted (n=18). All patients were female and were recruited from a single clinical practice site. The focus groups were conducted using a semi-structured interview guide. Initial discussions began with open-ended questions about challenges of living with FM, effects of FM on daily life, interactions with others and experience with fatigue. Patients were then further probed about their experience with fatigue due to FM. Audio recordings were transcribed and analyzed using a researcher developed coding book and atlas.ti software.

Results: The data support existing frameworks for FM but offers additional insights in the experience of fatigue among patients with FM. The data suggest that fatigue in FM varies within a week and even within a single day. FM patients perceive the severity of their fatigue in terms of its implications for daily function, impacts on sleep, cognition, motivation and emotions. When discussing the impact of fatigue on functioning, patients described activities they are no longer able to participate in, such as personal care, housework, work productivity, cooking, making or keeping plans, and losing spontaneity. Although sleep disturbances were reported by patients, many perceived being fatigued and tired as separate concepts. Fatigue was not necessarily improved by sleep. Fatigue and cognitive dysfunction were closely intertwined, such as being in a 'fibro fog', not being able to concentrate, forgetting things, difficulty making decisions, and feeling like there is a mental curtain or veil. Lack of motivation as a result of fatigue was exemplified by having to push to start or complete activities, lacking initiative, and feeling depleted. The emotional impact of fatigue stemmed from feeling frustrated with not being able to do things they wanted and not being able to remember things. Patients also expressed feeling embarrassment or guilt for not being able to do things, especially with family and friends. Patients perceived physical experiences of fatigue as if being weighted down, such as wearing heavy clothing made of cement.

Conclusion: This qualitative work has provided additional insights for a framework for evaluating fatigue in FM. It is important to evaluate more than the frequency and severity of being tired. The variability of patients' experience of fatigue in FM suggests the need for more frequent assessment as well as a broader set of concepts to be evaluated when measuring fatigue in FM.

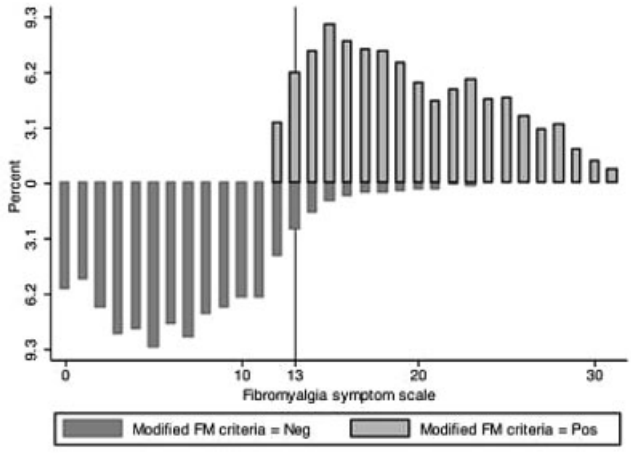
Fibromyalgia Criteria and Severity Scales for Clinical and Epidemiological Studies: A Modification of the ACR Preliminary Diagnostic Criteria for Fibromyalgia. Frederick Wolfe[2], Daniel J. Clauw[7], Mary Ann Fitzcharles[1], Don L. Goldenberg[3], Winfried Häuser[6], Robert S. Katz[4], Philip J. Mease[5], Anthony S. Russell[8], I. Jon Russell[10] and John B. Winfield[9]. [1]Montreal West, QC, Canada, [2]National Data Bank for Rheumatic Diseases, Wichita, KS, [3]Newton-Wellesley Hosp, Newton, MA, [4]Rheumatology Associates, Chicago, IL, [5]Seattle Rheumatology Associate, Seattle, WA, [6]Technische Universität München, Munich, Germany, [7]UM/Chronic Pain & Fatigue Res, Ann Arbor, MI, [8]University of Alberta, Edmonton, AB, Canada, [9]University of North Carolina, Chapel Hill, NC, [10]University of Texas HSC, San Antonio, TX

Purpose: To develop a FM survey questionnaire for epidemiologic and clinical studies using a modification of the 2010 ACR Preliminary Diagnostic Criteria for Fibromyalgia (ACR2010). We also created a new FM symptom scale to further characterize fibromyalgia [FM] severity.

Methods: The ACR2010 consists of two scales, the Widespread Pain Index (WPI) and the Symptom Severity (SS) scale. We modified these ACR2010 criteria by eliminating the physician's estimate of the extent of somatic symptoms and substituting the sum of 3 specific self-reported symptoms. The 3 specific symptoms score was sum of the number of the following symptoms occurring during the previous 6 months: headaches, abdominal pain, and depression. We made this change because the physician's estimate of the extent of somatic symptoms was an evaluative measure that could be not performed in a survey. The 3 new symptoms tapped into the same domain of symptom reporting. We also created a 0–31 FM Symptom scale (FS), also known as the Fibromyalgianess scale, by summing the WPI and the modified SS scale. We administered the questionnaire to 729 patients previously diagnosed with fibromyalgia, 845 with osteoarthritis or with other non-inflammatory rheumatic conditions (OA), 439 with lupus, and 5,210 with RA.

Results: The modified ACR2010 criteria were satisfied by 60% with a prior diagnosis of fibromyalgia, 21.1% with RA, 16.8% with OA, and 36.7% with SLE. The criteria properly identified diagnostic groups according to FM severity variables. An FS score ≥13 best separated criteria (+) and criteria (-) patients, classifying 93.0% correctly, with a sensitivity of 96.6% and a specificity of 91.8% in the study population, as shown in Figure 1.



Characteristics of patients according to entry and criteria status demonstrated appropriate classification.

Fibromyalgia-related Characteristics According Entry and Diagnostic Criteria

Variable	*FM (+) Criteria +*	*FM (+) Criteria −*	*FM (−) Criteria +*	*FM (+) Criteria −*
	Mean or %	Mean or %	Mean or %	Mean or %
Widespread pain index (0–19)	12.9	5.6	11.7	3.6
4-item Modified SS score (0–12)	8.0	4.0	7.4	2.8
Fibromyalgia symptom scale (0–31)	20.9	9.6	19.0	6.5
Fatigue (0–10)	7.2	4.2	7.1	3.1
Sleep disturbance (0–10)	6.5	3.8	6.1	3.0
VAS Pain (0–10)	6.3	3.8	5.9	2.7
Mood (0–10)	4.0	2.6	3.8	2.0
Muscle tenderness (%)	89.7	63.0	65.7	18.6
Symptom count (0–37)	16.1	8.8	14.5	5.7

FM (+) and FM (−) refer to clinical diagnosis at time of data bank entry. Criteria + and Criteria − refer to results of the modified ACR 2010 diagnostic criteria.

Conclusions: A slight modification to the ACR2010 will allow their use in epidemiologic and clinical studies without the requirement for an examiner. The modified criteria can also be used to determine widespread pain according to the 1990 ACR classification criteria. The modified criteria are simple to use and administer, but they are not to be used for self-diagnosis. The FS may have wide utility beyond the bounds of FM, including substitution for widespread pain in epidemiological studies and measurement of FM severity.

Fibromyalgia Is Associated with a Disruption of Emotional Modulation of Pain, but Not Emotional Modulation of Spinal Nociception. Jennifer L. DelVentura[1], Ellen L. Terry[2], Emily J. Bartley[2], Ashley Vincent[2], Ewa Olech[3] and Jamie L. Rhudy[2]. [1]The University of Tulsa, Tulsa, OK, [2]The University of Tulsa, [3]University of Oklahoma, Health Sciences Center

Background: Fibromyalgia syndrome (FM) is a disorder of unknown etiology that is characterized by chronic, widespread musculoskeletal pain and hyperalgesia. Recent functional imaging research has shown that FM patients exhibit differing patterns of brain activation during anticipation of and experience of experimental pain, as compared with rheumatoid arthritis (RA) patients and healthy controls (HC). Therefore, FM-related hyperalgesia may be due to an amplification of the nociceptive signal via cognitive-emotional mechanisms at the supraspinal level. Indeed, individuals with FM tend to report increased negative affect and reduced positive affect; a finding consistent with their higher rates of anxiety and depressive disorders. Given that emotion modulates pain and nociception, such that negative emotions augment pain and positive emotions inhibit it, and that FM patients exhibit hyperalgesia and greater negative affect, the present study examined whether FM patients would show disrupted emotional modulation of pain and nociception relative to RA and HC.

Methods: Patients with physician-verified diagnoses of FM or RA, and HCs with no chronic pain were recruited (N=33; FM=11, RA=8, HC=14). Participants were shown pictures that varied in emotional content (mutilation, neutral, erotica). To elicit pain and the nociceptive flexion reflex (NFR, a physiological correlate of spinal nociception), suprathreshold electrocutaneous stimuli were delivered to the left ankle over the sural nerve pseudorandomly, during and in between pictures.

Results: Pain and NFR during different picture contents were analyzed using a linear mixed model analysis. Results suggested that all groups exhibited emotional modulation of the NFR—unpleasant pictures augmented NFR and pleasant pictures inhibited NFR. Conversely, emotional modulation of pain ratings was exhibited in the RA and HC groups, but not in the FM group. Average pain ratings were not significantly different between groups (p=.28).

Conclusions: Thus, only FM patients exhibited abnormal emotional modulation of pain, while cerebrospinal modulation of the NFR was similar across groups. These data support prior research indicating disrupted supraspinal processing of the pain signal in FM. This study was funded by NIAMS (grant number: 5R03AR054571).

Fibromyalgia with and without Comorbid Positional Cervical Cord Compression (PC3): An Iron-Clad Difference. Patrick B. Wood[2], Tobias Schmidt-Wilcke[3] and Andrew J. Holman[1]. [1]Pacific Rheumatology Assoc, Renton, WA, [2]Pacific Rheumatology Associates, Renton, WA, [3]University of Michigan

Fibromyalgia (FM) is associated with abnormalities of dopaminergic neurotransmission. Because iron is an important cofactor for dopamine

metabolism, we investigated whether FM symptom severity might correlate with iron stores as indicated by serum ferritin level (FE). Positional cervical cord compression (PC3) has also been recently identified as a common abnormality among FM patients (*J Pain 2008;9:613-22*). We therefore investigated whether FM patients with (FM/PC3+) or without (FM/PC3-) this cervical abnormality might differ with regard to symptom severity or their potential relationship to FE.

Methods: A convenience sample of 150 patients referred to a community-based FM specialty clinic was analyzed. All subjects met ACR 1990 diagnostic criteria for FM. Among these, 50% (n=75) were randomly selected from a pool of patients with: (1) a clinical history of cervical trauma and/or exacerbation of symptoms on cervical extension; and (2) PC3 on dynamic magnetic resonance imaging (dMRI). The other 50% (n=75) were randomly selected from among patients who either (1) denied a history of cervical trauma and had no exacerbation of symptoms on cervical extension, or (2) had undergone cervical dMRI and had no evidence of cord compromise. FE was drawn on all patients at intake and processed at the same clinical reference laboratory. All patients completed a comprehensive series of medical questionnaires, including a scaled review of systems and Adult ADHD Self-Report Scale (ASRS). Categorical indices of symptom severity were derived by summation of scaled symptoms from the intake review of systems (0–5 scale: 0 = none; 1 = minimal; 2 = mild; 3 = moderate; 4 = severe; 5 = extreme). Student's t-test for non-paired samples was used to compare FE and symptom severity between groups. Pearson's correlation was used to evaluate potential correlations between FE and symptom severity within each group.

Results: There were no significant differences between groups concerning FE (FM/PC3- vs. FM/PC3+, mean ± SD: 49.4 ± 33.8 ng/ml vs. 56.4 ± 35.9 ng/ml, p =.22) or the severity of any clinical index. However, among FM/PC3- significant negative correlations were found between FE and the severity of several measures, including ASRS score (rho = −.377, p =.001), dyscognition (rho = −.488, p <.001), dys-coordination (rho = −.392, p =.001), affective disturbance (rho = −.384, p =.001), and clinical pain (rho = −.231, p =.047). Conversely, among FM/PC3+, no significant correlations were found between FE and the severity of any symptoms.

Discussion: Among FM patients without comorbid PC3, negative correlations exist between FE and the severity of symptoms ostensibly linked to dopaminergic neurotransmission, including dyscognition, dys-coordination, affective disturbance, and clinical pain. These remarkable differences among FM patients suggest distinct pathophysiological subtypes within the greater 'FM construct'. Further research is needed to determine whether FM might be associated with abnormal iron metabolism and to evaluate for potential correlations between FE and objective measures of dopaminergic neurotransmission.

Flt3-L Is a Novel Biomarker Increased in Cerebrospinal Fluid of Patients with Primary Fibromyalgia and Sjogren Syndrome. Jan L. Bjersing, Mats Dehlin, Henrik Zetterberg, Anette Larsson, Malin Erlandsson, Kaisa Mannerkorpi and Maria Bokarewa. Dept Rheumatology, Gothenburg University, Sweden

Primary fibromyalgia syndrome (FM) is a non-inflammatory condition, characterised by chronic generalized pain with allodynia. Primary Sjogren syndrome (pSS) is an autoimmune inflammation of exocrine glands. Fms-like tyrosine kinase 3 (Flt3-L) is a growth factor expressed in brain microglia and regulating differentiation and recruitment of monocytes into dendritic and glial cells. Both FM and pSS are commonly associated with fatigue and non-restorative sleep, and occasionally with depression and cognitive dysfunction. The aim of the study was to compare inflammatory and axonal biomarkers in cerebrospinal fluid (CSF) of pSS and FM patients.

Paired samples of CSF and serum from female patients with pSS (age 48±12 years, disease duration 10±8 years) and FM (age 49±8 years, symptom duration 12±5 years) were evaluated for the levels of Flt3-L and related to inflammatory (IL-6, IL-8) and axonal (NFL, Tau, phosphorylated Tau, GFAP) biomarkers.

Flt3-L in CSF was significantly higher in FM patients compared to pSS patients (table 1). The proportion of phosphorylated Tau (pTau) to total Tau (tTau) was significantly higher in FM compared to SS. However, total levels of tTau and pTau were not different between the groups. Flt3-L in CSF correlated with levels of tTau and pTau, in both pSS (r=0.68, r=0.65) and FM (r=0.38, r=0.45). In FM, Flt3-L was also associated with neurofilament light chain (NFL, r=0.41) and astrocyte marker glial fibrillary acidic protein (GFAP, r=0.58). Flt3-L in CSF correlated with Flt3-L in serum of patients with pSS (r=0.53) but not in FM. IL-6 in CSF was significantly higher in pSS patients compared to FM (table 1). No correlation was found between Flt3-L and IL-6. Serum levels of IL-6, IL-8 or Flt3-L were not significantly different between pSS and FM patients.

Table 1. Levels of biomarkers in cerebrospinal fluid in primary fibromyalgia (FM) and primary Sjögren syndrome (pSS)

	Flt3-L pg/ml	IL6 pg/ml	IL8 pg/ml	tTau/pTau	NFL ng/L	GFAP ng/L
pSS	53	2.3	41	4.7	500	420
n = 15	[28; 76]	[0.7; 4.5]	[54; 25]	[3.8; 5.3]	[240; 1780]	[170; 860]
FM	$64.5^{p<0.003}$	$1.5^{p<0.003}$	$33^{p<0.02}$	$4.1^{p<0.02}$	500	510
n = 34	[46; 95]	[0; 3.3]	[20; 51]	[0; 5.2]	[250; 1550]	[230; 2320]

Values are presented as median [min, max]. Mann-Whitney U-test was used.

Flt3-L is a novel biomarker in CSF, distinguishing patients with FM and pSS. Levels of Flt3-L are positively related with axonal products, suggesting potential clinical impact of Flt3-L in fatigue and pain of patients with FM and pSS.

Hysterectomy Status and Fibromyalgia Symptom Severity. Mary O. Whipple, Ann Vincent, Terry H. Oh, Connie A. Luedtke and Tanya L. Hoskin. Mayo Clinic, Rochester, MN

Background: Clinical observation and preliminary studies suggest that gynecological surgeries impact symptom severity in fibromyalgia. However, the literature is deficient in published studies assessing this relationship. Our objective was to compare differences in Fibromyalgia Impact Questionnaire (FIQ) scores in women with fibromyalgia who had a hysterectomy and/or oophorectomy and those who did not.

Methods: We conducted a retrospective chart review of 889 women with fibromyalgia, seen in the Fibromyalgia Treatment Program at a tertiary medical center between 2001 and 2004. Patients completed the FIQ at the time of their initial evaluation and data on age, race, duration of fibromyalgia symptoms, hysterectomy status, oophorectomy status and use of hormone therapy was abstracted from the clinical record. Linear regression analysis was used to compare FIQ scores between women who had a hysterectomy and those who did not.

Results: Of the women included in our review, 43.4% had a hysterectomy, 29.7% had a bilateral oophorectomy and 4.3% had a unilateral oophorectomy. After adjusting for age, duration of fibromyalgia symptoms and use of hormone therapy, total FIQ scores of women who had a hysterectomy were significantly higher than those who did not (p=.0013). Similarly, FIQ subscales of physical impairment (p=.0405), pain (p=.0001), stiffness (p=.0397) and depression (p=.0079) were also higher in women who had a hysterectomy than in those who did not. Though not statistically significant, trends were also observed in subscales of fatigue (p=.0979) and anxiety (p=.0517). These associations were independent of oophorectomy status and the timing of the hysterectomy.

Conclusions: Our results indicate that presence of hysterectomy influences symptom severity in women with fibromyalgia. The prevalence of hysterectomy is also higher than the rate of approximately 33% by age 60 reported in general population. To our knowledge, this is the first retrospective review assessing this relationship. Since, our retrospective review was limited by incomplete information on duration of hormone therapy use in relationship to timing of hysterectomy, we are unable to speculate on the influence of surgical menopause on FIQ scores. A prospective study with longitudinal follow-up will better characterize this influence.

Improvement in Multiple Dimensions of Fatigue in Fibromyalgia Patients Treated with Duloxetine. Lesley M. Arnold[2], Fujun Wang[1], Jonna Ahl[1], Paula Gaynor[1] and Madelaine Wohlreich[1]. [1]Lilly USA LLC, Indianapolis, IN, [2]Women's Health Research Program, Department of Psychiatry, University of Cincinnati College of Medicine, Cincinnati, OH

Background: In addition to widespread pain, fatigue is one of the most common and disabling symptoms of fibromyalgia. Fatigue was assessed as a secondary objective in this 2-phase 24-week trial of duloxetine in patients with ACR-defined fibromyalgia.

Methods: Outpatients 18–65 years of age, with Brief Pain Inventory average pain ≥4 were randomized to duloxetine 60–120 mg/d (N=263) or placebo (N=267) for the 12-week acute phase. At Week 12, all patients in the placebo group were switched to double-blind treatment with duloxetine for the 12-week extension phase. Fatigue was assessed at baseline and every 4 weeks by the Multidimensional Fatigue Inventory (MFI), which is comprised of the following subscales: General Fatigue (GF), Physical Fatigue (PF), Mental Fatigue (MF), Reduced Activity (RA), and Reduced Motivation (RM). The frequency of treatment-emergent adverse events (TEAE) that might be associated with fatigue, such as fatigue, insomnia and somnolence, was also assessed. Changes from baseline in MFI subscale scores during the acute phase, and from Week 12 during the extension phase were analyzed by mixed-effects model repeated measures analysis. For the acute phase, the model included baseline value, acute phase treatment, investigator, visit, treatment-by-visit, and baseline-by-visit interactions; for the extension phase, the model included: investigator, visit, Week 12 baseline score and baseline-by-visit interaction (the model was fitted separately for patients randomized to duloxetine and patients randomized to placebo then switched to duloxetine in the extension phase).

Results: At the end of the acute phase, patients who received duloxetine versus placebo had significantly reduced scores on each MFI subscale (all $p<.05$) indicating improvement (Arnold et al). In the extension phase, mean MFI subscale scores indicated that improvement was maintained for patients who received duloxetine for up to 24 weeks (n=176). For placebo-treated patients who were switched to duloxetine (n=187), significant within-group improvement in MFI subscale scores was observed at Weeks 16, 20 and 24 for PF, Weeks 20 and24 for GF, Week 20 for MF, and Weeks 20 and 24 for RA. Individual subscale scores after switching to duloxetine were similar to those for patients who received duloxetine for 24 weeks. This suggests that patients treated with duloxetine for 6 months maintained improvement in several dimensions of fatigue assessed by the MFI, and that placebo patients switched to duloxetine quickly reached the level of improvement in fatigue observed in the active treatment group. In the acute phase, TEAE rates of fatigue, somnolence and insomnia were: 9.5%, 5.7% and 9.1% for duloxetine; 7.1%, 3.4%, and 7.1% for placebo. In the extension phase, overall rates for these TEAEs were: fatigue 4.1%; somnolence, 2.5%; and insomnia, 3.6%.

Conclusion: Treatment with duloxetine significantly improved multiple dimensions of fatigue in patients with fibromyalgia, and improvement was maintained with duloxetine treatment up to 24 weeks.

Novel Treatment of Tendinopathies with a Sulfated Disaccharide of Hyaluronic Acid-Promising *In Vitro* Results. Anna Torrent[1], Ramon Ruhí[1], Carlos Aláez[1], Constanze Buhrmann[2] and Mehdi Shakibaei[3]. [1]BIO-IBERICA S.A., Palafolls, Barcelona, Spain, [2]Ludwig-Maximilians-University, Munich, Germany, [3]Ludwig-Maximilians-University Munich, Munich, Germany

Purpose: As tendons regenerate slowly and inefficiently after trauma, tendinopathies pose a serious musculoskeletal problem. Recent studies indicate that initiators of tendinopathy include a number of pro-inflammatory cytokines such as Interleukin-1β (IL-1β), which are known to enhance and support inflammation and promote apoptosis through the production of cyclooxygenase-2 (Cox-2), metalloproteinases (MMPs) and activation of caspase-3. The aim of this study was to evaluate the potential prophylactic and/or regenerative effects of a sulphated disaccharide of hyaluronic acid (methyl 2-acetamido-2-deoxi-3-O-(β-D-glucopyranosyluronic acid)-4,6-di-sulfo-α-D-glucopyranoside, trisodium salt), BIS014, on suppression of catabolic, inflammatory and apoptotic pathways in IL-1β stimulated human tenocytes *in vitro*.

Method: Monolayer cultures of primary human tenocyes were pre-stimulated with BIS014 followed by co-treatment with IL-1β and BIS014 and evaluated with electron microscopy and western blotting. Control cultures were left untreated or treated with IL-1β or BIS014. Cell viability, adhesion, proliferation and production of extracellular matrix (ECM) were analysed with light microscopy and transmission electron microscopy. Immunofluorescence was used to evaluate production of type I collagen, the main extracellular matrix protein synthesized by tenocytes. Immunoblotting was performed to determine expression of type I collagen, β-1 integrins, caspase-3, Cox-2 and MMP-1, -9 and -13.

Results: Ultrastructural evaluation with electron microscopy demonstrated that BIS014 exerts a potent stimulatory effect on human tenocyte proliferation and was able to suppress catabolic, apoptotic and inflammatory effects induced by IL-1β. Suppression of IL-1β-induced up-regulation of activated caspase-3, Cox-2 and MMP-1, -9 and -13 by western blotting further confirmed these results.

Conclusion: These results demonstrate that the synthetic disaccharide of hyaluronic acid BIS014 may have therapeutic utility for the healing, regeneration and repair of tendons.

Outcome for a Prospective Cohort of Fibromyalgia Patients Receiving Tailored Treatments in a Multidisciplinary Pain Center. Mary-Ann Fitzcharles, Pantelis Panopalis, Ann Gamsa, Mark Ware and Yoram Shir. McGill University

Background: The ideal management of fibromyalgia (FM) is still under debate. There is increasing appreciation of the importance of the various core component symptoms in FM patients, contributing to the complexity of management. Expert opinion suggests that multimodal treatment including non pharmacologic and pharmacologic interventions are desirable. In view of the complexity of combining various treatment strategies, observational studies in real life clinical settings should provide helpful information regarding outcome. We have examined the outcome in FM patients being followed in a multidisciplinary setting with treatments tailored to individual patient needs.

Methods: Patients newly referred to a multidisciplinary pain clinic with a primary diagnosis of FM were entered into a prospective cohort study. All patients were evaluated by a physician and a psychologist, a treatment plan was developed and patients had access to nursing or physiotherapy consultation when deemed necessary. Treatments were individually based taking into consideration previous treatments and severity of core symptoms. Demographic, disease and psychosocial variables included the following: Fibromyalgia Impact Questionnaire (FIQ), visual analogue scale (VAS) for patient global status and pain scores, McGill Pain Questionnaire (MPQ), Arthritis Impact Measurement Scale, anxiety and depression (AIMS), pain catastrophizing scale (PCS), and pain disability index (PDI). All patients were advised to participate in a regular physical activity program of their choice, and were asked to identify outcome and functional goals. At follow-up, patients were queried about overall change in symptoms, and were categorized into one of two groups: improved or same/worse. Univariate comparisons were made between the two groups using Student's t-tests for continuous variables and chi-squared tests for categorical variables. Logistic regression was used to model the association between selected variables.

Results: Of the 184 patients entered in the cohort, 114 had at least one follow-up assessment at least one year after entry and were included in the analysis. The average age of the study sample was 49.0 (SD 10.0) and 92.1% were female. Improvement was reported in 80 patients (70%) whereas 34 patients (30%) reported symptoms as same or worse. Improvement was associated with improvement in measurements of the following disease parameters: FIQ ($p= 0.001$), global VAS score (0.02), pain VAS score ($p=0.004$), PDI ($p<0.001$), AIMS (depression) ($p<0.001$) and PCS ($p=0.002$). MPQ scores and AIMS (anxiety) were not associated with improved global outcome. A logistic regression model including all significant univariate associations found that only reduced AIMS (depression) was associated with improved global outcome (OR 1.4, 95% CI 1.1–2.0).

Conclusion: More than two thirds of FM patients, receiving tailored multidisciplinary treatment, had a favourable outcome. This was observed even in the setting of longstanding symptoms, and for patients seen in a tertiary care centre, likely representative of those with disease at the severe end of the spectrum. Targeting depression may improve outcome for FM patients.

Predictors of Clinical Outcome in Fibromyalgia: Single Center Experience of a Brief Interdisciplinary Fibromyalgia Treatment Program. Terry H. Oh[1], Tanya L. Hoskin[1], Connie L. Luedtke[2], Toby N. Weingarten[2], Ann Vincent[2] and Jeffrey M. Thompson[2]. [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic

Purpose: To determine which patient characteristics are associated with a positive response to a brief interdisciplinary fibromyalgia treatment program.

Methods: Prospectively designed follow-up questionnaire study among patients who underwent the Fibromyalgia treatment program at a tertiary medical center. Patients with confirmed fibromyalgia, underwent a one and half day interdisciplinary fibromyalgia treatment program, and completed the Fibromyalgia Impact Questionnaire (FIQ) at baseline and again 6–12 months after treatment were studied (n=536). Minimally clinically important difference (MCID) in fibromyalgia derived from FIQ changes was reported to be 14%. Therefore, we defined responders as participants who reported an improvement of ≥14% in the FIQ total score from baseline to 6–12 months after treatment, and non responders as participants who either worsened or improved < 14 % in the FIQ total score 6–12 months after treatment.

Predictor variables included demographic variables, baseline FIQ depression score, psychosocial variables, numeric rating scale (NRS) pain scores and number of fibromyalgia tender points. Univariate associations with responder status were assessed using two-sample t-tests and chi-square tests. Multivariate analysis used logistic regression; these results are reported with odds ratios (OR) and 95% confidence intervals (CI)

Results: Mean (SD) age of participants was 50.3 (13.0) years; 515 (96%) women and 23 (4%) men. Two hundred forty-eight patients (46%) were responders. In univariate analysis, responders were younger (p=0.008), achieved a higher level of education (p=0.02), had fewer tender points (p=0.048) and higher FIQ depression subscores (p=0.02) when compared to non responders. Positive abuse history did not reach statistical significance but showed a trend (p=0.05).

In multivariate analysis, these factors remained statistically significant. In addition, positive abuse history became significant (p=0.03). Younger age (OR:1.03, 95% CI: 1.01 to 1.05 per 1 year decrease), having a college or graduate degree (OR: 1.59, 95% CI: 1.07 to 2.36) and higher baseline FIQ depression score (OR:1.11, 95% CI: 1.05 to 1.20 per 1 unit increase) were associated with increased odds of being a responder, while increasing number of tender points (OR:0.91, 95% CI: 0.83 to 1.0 per 1 point increase), and abuse history (OR:0.62, 95% CI: 0.40 to 0.96) were associated with decreasing odds of being a responder. Gender, duration of symptoms, marital, employment, or smoking status, geographical location and 3 NRS scores were not statistically different between the responders and non responders.

Conclusions: Younger age, college or graduate degree, higher baseline FIQ depression score, lower tender point count and absent history of abuse were all associated with increased odds of treatment response.

Should Rheumatologists Retain Ownership of Fibromyalgia? A Survey of Ontario Rheumatologists. Sassan Ghazan-Shahi, Tanveer E. Towheed and Wilma Hopman. Queen's University, Kingston, ON, Canada

Background: Fibromyalgia is a controversial widespread chronic pain disorder that includes a wide constellation of somatic and emotional symptoms. This study surveyed the opinion of Ontario Rheumatologists with respect to their beliefs about the nature and management of fibromyalgia. A key objective was to ascertain if Rheumatologists should continue to be the main care providers for these patients.

Methods: A survey questionnaire comprising 13 questions was sent electronically to all 150 Ontario Rheumatologists. The questionnaire was designed to obtain demographic data as well as opinions regarding different aspects of fibromyalgia. Data were analyzed descriptively and comparisons were made using chi-square tests.

Results: A total of 80 respondents (58% male) completed our survey for a completion rate of 53%. The majority had completed their training in Canada (85%) and had been practising for more than 15 years (50%). 55% worked in University hospitals and 45% worked in the Community. Key findings were: (1) 71% believe that Rheumatologists should not retain ownership of fibromyalgia, (2) 55% believe that fibromyalgia is primarily a psychosomatic illness as opposed to a physical illness, (3) 60% are accepting new referrals for fibromyalgia, (4) 60% are managing patients with fibromyalgia, (5) 89% believe that the family physician should be the main care provider for these patients, (6) 31% usually consider psychiatric referral for these patients, (7) 79% recommend behavioural treatment methods, (8) 58% consider severe fibromyalgia to be a potentially disabling condition that warrants financial compensation through disability, (9) Rheumatologists who consider fibromyalgia to be a physical illness were also significantly more likely to believe that Rheumatologists should retain ownership of this disease (p=0.023). They were also more likely to accept new referrals for this disease (p=0.044), and also more likely to continue managing these patients in their practice (p=0.011).

Conclusions: The majority of Ontario Rheumatologists do not wish to retain ownership of fibromyalgia. However, most of them continue to accept new referrals and continue to manage these patients, even though they believe that the family physicians should be the main care provider for patients with fibromyalgia. Rheumatologists may be providing care to these patients primarily because this care is not available to them from their primary care physicians.

Disclosure: S. Ghazan-Shahi: None; **T. E. Towheed:** None; **W. Hopman:** None.

The Course of Fibromyalgia—A Long-Term Longitudinal Cohort Study. Brian Walitt[5], Winfried Häuser[3], Afton Hassett[4], Robert S. Katz[2] and Frederick Wolfe[1]. [1]National Databank for Rheumatic Diseases, [2]Rush University, [3]Technische Universität München, [4]University of Michigan Medical School, [5]Washington Hospital Center, Washington, DC

Purpose: Fibromyalgia (FM) is a chronic condition in which treatment is of limited effectiveness. However, the ACR 2010 criteria study reported that 25% of FM patients improved sufficiently so that they did not meet classification criteria at follow-up. Other studies have also reported various degrees of improvement. Much of the uncertainty about the course of FM can be attributed to selection bias and non-standardized measures of improvement. In this report, we followed 1,555 criteria positive FM patients for a mean of 4.0 years (range 1.0 to 11.5 years) to determine the symptomatic course.

Methods: Patients were participants in a longitudinal study of FM outcomes. They were assessed semi-annually in 11,006 observations (6,251 pt-years). Assessments included the Widespread Pain Index, fatigue, sleep disturbance, functional status and a general measure of FM severity (the Fibromyalgianess Scale). Criteria status was assessed with a survey modification of the ACR 2010 diagnostic criteria. We used generalized estimating equations (GEE) to assess the rate of change of study variables over time and Cox regression to assess incidence of loss and regain of FM diagnostic status.

Results: Patients switched between criteria positive and negative states. 716 patients became criteria negative during the study (44.0%), for an incident rate of 16.9 (15.7, 18.2) per 100 pt-years; and 378 patients (24.3%) who satisfied FM criteria at entry no longer satisfied criteria at the study close, an incident rate 6.0 (5.5, 6.6) per 100 pt-years. All FM related variables predicted the transition between positive and negative states. The strongest predictor was the 0–31 fibromyalgianess scale, which decreased by −.36 (0.32, 0.40) units annually. Other study variables also decreased during the study. Figure 1 shows fibromyalgianess in patients remaining criteria positive (23.8 ±4.5) and those who became criteria negative (12.9 ±4.2).

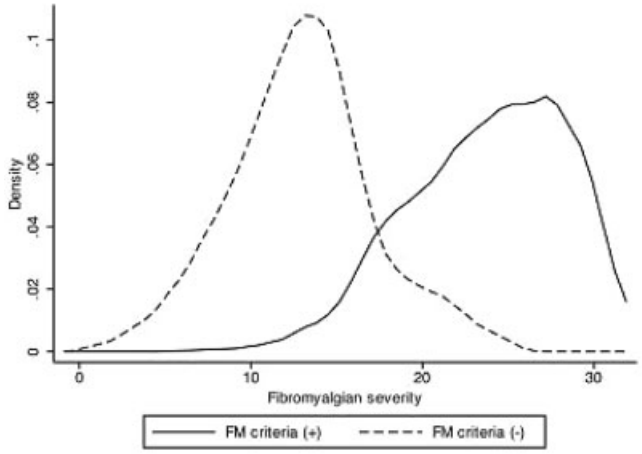

Figure 2 demonstrates minimum and maximum pain, symptom count, fatigue, and mood scores during follow-up.

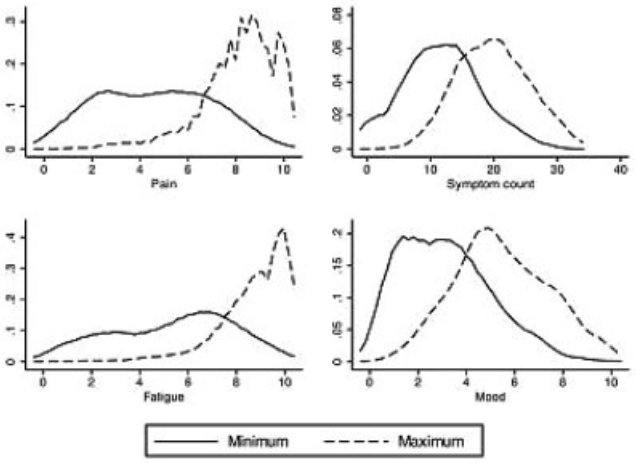

Conclusions: FM patients often switch between criteria positive and negative states and have a wide variation in symptoms. These data indicate limitations in the usefulness of the discrete diagnosis of FM. Symptom severity, as opposed to diagnosis, appears to be more clinically reliable and relevant. The fluctuating nature of FM diagnosis has important implications for clinical care and treatment indications.

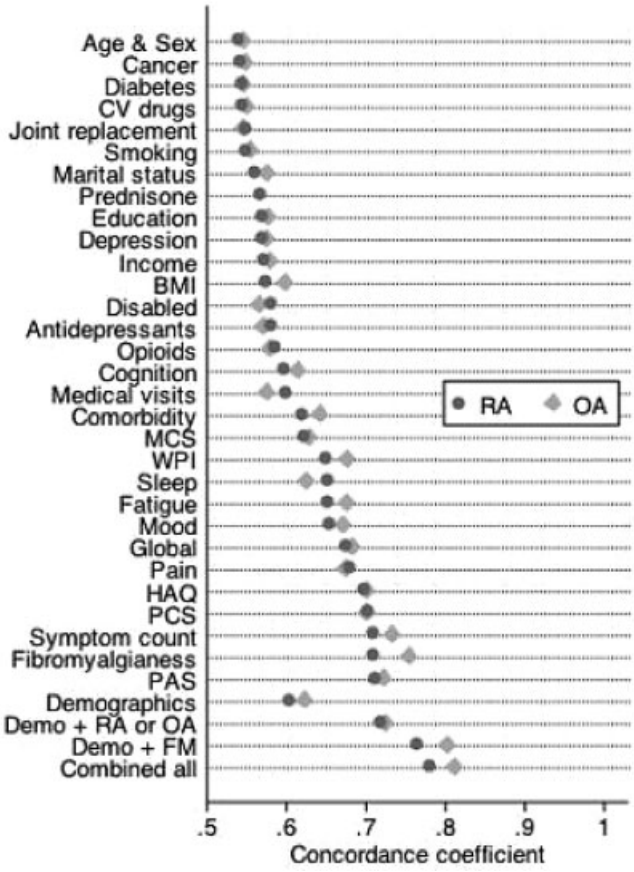
The Development of Fibromyalgia: Examination of Rates and Predictors in Patients with Osteoarthritis (OA). Frederick Wolfe[1] and Winfried Häuser[2]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Technische Universität München, Munich, Germany

Purpose: Using modified ACR 2010 fibromyalgia (FM) criteria, we have reported that in 9,739 rheumatoid arthritis (RA) patients without FM, a series of demographic, RA, FM, and psychological variables predict FM development. However, it is possible that RA damaged joints or systemic illness may interfere with FM measurements and predictors, and prediction and predictive strength might be different in RA compared with regional rheumatic disorders such as osteoarthritis (OA). To examine this possibility, to compare FM in RA and OA, and to confirm our prediction models, we analyzed predictors of FM in OA.

Methods: After excluding patients with FM and those with high levels of FM symptoms (fibromyalgianess score >10), we studied the FM development in 1,888 OA patients during 6,892 patient-years of follow-up over a mean follow-up time of 4.3 (SD 3.5) years (range, 5 to 11). We defined FM using a modification of the ACR 2010 FM diagnostic criteria. We used Cox regression to predict future FM, and examined the discriminatory power and accuracy of predictions using Harrell's C concordance coefficient.

Results: At the last observation, 6.0% of OA compared with 7.4% of RA patients satisfied FM criteria, although 18.8% of OA and 19.8% with RA did so at some point during follow-up, for an OA FM incidence rate of 5.0 (95% CI 4.2, 5.3) and an RA rate of 5.3 (5.1, 5.6) per 100 pt-years. The rate in women was 5.5 (4.9, 6.2) and was 3.5, (4.7, 5.5) in men. Among those satisfying criteria, half of follow-up time after diagnosis was FM criteria (+), and was associated with markedly abnormal OA and FM variable scores. C-statistics, adjusted for age and sex, are shown in Figure 1.



The discriminatory power of variables was similar in OA and RA, except that FM variables were slightly more predictive in OA than RA. In multivariable analyses, demographics were weak predictors of FM (OA C = 0.623, RA C=0.604). Stronger predictors were demographics plus OA (C = 0.725) compared with demographics plus RA variables (C= 0.720), and demographic plus FM variables (OA C = 0.803, RA C = 0.765), and all predictors (OA C = 0.812) (RA C= 0.782) in the multivariable model shown below.

Variable	*H.R (95% CI)*	*z*	*P*-value
Widespread pain index (0–19)	1.28 (1.21, 1.36)	8.41	<0.001
HAQ (0–10)	2.06 (1.67, 2.54)	6.81	<0.001
Symptom count (0–34)	1.10 (1.07, 1.13)	6.45	<0.001
Fatigue (0–10)	1.26 (1.17, 1.35)	6.40	<0.001
Mood (0–10)	1.11 (1.02, 1.21)	2.50	0.013
Opioid use	1.29 (0.99, 1.67)	1.87	0.062
Comorbidity			
None			
1	1.34 (0.97, 1.84)	1.8	0.072
2	1.72 (1.25, 2.37)	3.35	0.001
3	1.70 (1.15, 2.49)	2.69	0.007
4–9	1.35 (0.86, 2.12)	1.29	0.196

Clinically important HRs were noted for cognition, depression, comorbidity and high levels of OA and FM continuous variables.

Conclusions: FM is predicted similarly in patients with OA and RA. Multiple factors contribute to FM development, including socio-demographic disadvantage, comorbidity, psychological distress, drug and service utilization, FM symptoms (particularly somatic symptom reporting), and functional status; but there is little evidence of the effect of underlying causes.

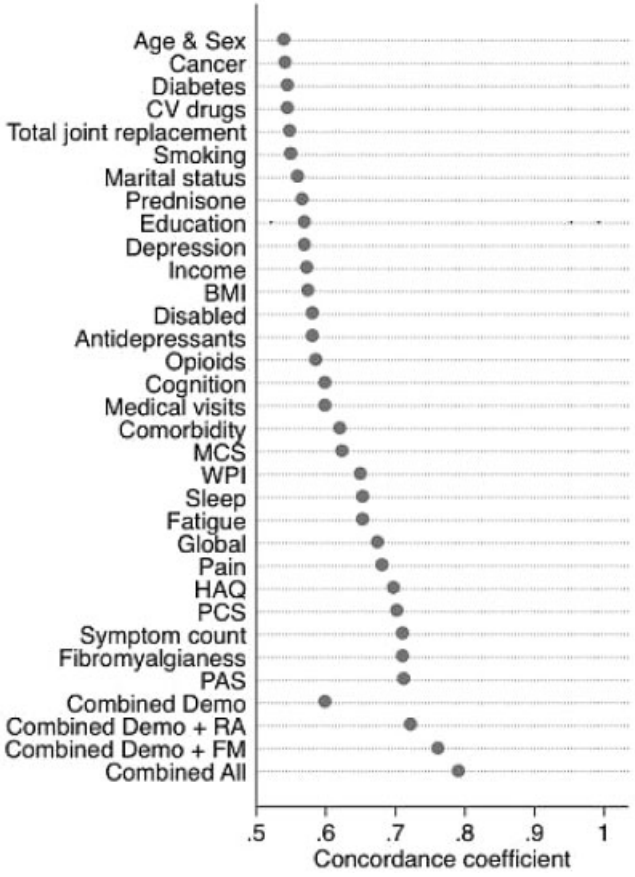
The Development of Fibromyalgia: Examination of Rates and Predictors in Patients with Rheumatoid Arthritis (RA). Frederick Wolfe[1], Winfried Häuser[3], Afton L. Hassett[4], Robert S. Katz[2] and Brian T. Walitt[5]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Rush University Medical Center, Chicago, IL, [3]Technische Universität München, [4]University of Michigan Medical School, [5]Washington Hospital Center, Washington, DC

Purpose: There are no prospective studies of the development of criteria-based fibromyalgia (FM) that consider multiple risk factors. The purpose of the study was to determine rates and predictors of future development of FM in patients with rheumatoid arthritis (RA). We studied FM in RA because of its intrinsic interest and because RA patients provided a substrate of patients that were unselected, particularly with respect to FM characteristics. In addition an extensive set of demographic and severity covariates were available.

Methods: After excluding patients with FM and those with high levels of FM symptoms (fibromyalgianess score >10), we studied the development of FM in 9,739 RA patients during 42,591 patient-years of follow-up. We defined FM using a modification of the ACR 2010 FM diagnostic criteria. We used Cox regression to predict future FM, and examined the discriminatory power and accuracy of predictions using Harrell's C concordance coefficient.

Results: At the last observation, 7.4 % of patients satisfied criteria, although 19.8% satisfied criteria at some point during follow-up, for an incidence rate of 5.3 (95% CI 5.1, 5.6) per 100 patients-years, and at rates that were similar in men (7.0%) and women (8.1%). Among those satisfying criteria, during 11,363 years of follow-up from the time of first fibromyalgia diagnosis, approximately half of follow-up time was fibromyalgia+ and was associated with markedly abnormal RA variable and FM variable scores. C-statistics for individual variables, adjusted for age and sex, are shown in the Figure.



In multivariable analyses, demographic factors were weak predictors of fibromyalgia (C=0.604). Stronger predictors were demographic plus RA variables (C= 0.720) and demographic plus fibromyalgia variables (C= 0.765), and all predictors (C= 0.782). Clinically important hazard ratios were noted for cognition, depression, comorbidity and high levels of RA and FM continuous variables. Using a z score of ≥5 as a cut point, the most important independent predictors for the multivariable prediction of FM were antidepressant use, HAQ, fatigue, widespread pain index and the symptom count.

Conclusions: FM can be predicted with clinically available variables. Multiple correlated factors contribute to the development of fibromyalgia. These factors include socio-demographic disadvantage, comorbidity, psychological distress, drug and service utilization, fibromyalgia symptoms (particularly somatic symptom reporting), and functional status; but there is little evidence of the effect of underlying causes. After diagnosis, patients move in both directions across the diagnostic criteria cut point.

The Effect of Duloxetine on Cognition in Patients with Fibromyalgia. Philip J. Mease[3], Lesley Arnold[4], Fujun Wang[1], Jonna Ahl[1], Richard Mohs[1], Paula Gaynor[1] and Madelaine Wohlreich[2]. [1]Eli Lilly and Company, [2]Lilly USA, LLC, [3]Seattle Rheumatology Associate, Seattle, WA, [4]Women's Health Research Program, Department of Psychiatry, University of Cincinnati College of Medicine, Cincinnati, OH

Background: Cognitive difficulties are common complaints among patients with fibromyalgia and include perceived deficits in attention, concentration and memory. Cognitive testing was conducted in a subset of patients participating in a randomized, double-blind, placebo-controlled trial of duloxetine in fibromyalgia.

Methods: At selected sites, patients eligible for the main study were asked if they would like to participate in the cognitive testing and provided separate informed consent for this testing. Patients were ≥18 years of age, met ACR criteria for fibromyalgia, and ≥4 score on the Brief Pain Inventory (BPI) 24-h average pain severity item. Patients who consented to cognitive testing were randomized to duloxetine (n=80) or placebo (n=76) for 24 weeks of double-blind treatment. The primary endpoint was at Week 12, after which placebo patients were switched to double-blind treatment with duloxetine. The results presented here are for the first 12 weeks. Verbal learning and memory was tested using the 15 word Verbal Learning and Recall Test (VLRT); speed of processing, visual attention and executive function were tested using the Symbol Digit Substitution Test (SDST), the Two Digit Cancellation Test (2DCT), and the Trailmaking Test (Trails A and B). Change from baseline to endpoint (last-observation-carried-forward) was analyzed by an analysis of covariance model, which included baseline, treatment, investigator and treatment-by-investigator interaction.

Results: Most of the patients (N=156) were Caucasian (89%) women (92%), ranging in age from 21 to 88 years, 23% had comorbid major depressive disorder (MDD), and 8% had comorbid generalized anxiety disorder (GAD). Cognitive test scores at baseline were close to published scores[1–4] for the general population indicating no impairment. Baseline-to-endpoint changes in cognitive scores did not differ significantly between treatment groups.

Conclusion: Impairment in cognitive function in patients with fibromyalgia was not evident on VLRT, SDST, 2DCT, or Trails A and B. Overall, treatment with duloxetine did not have a positive or negative effect on cognition when measured with these tests.

The Effectiveness of Botulinum Toxin Type-A and Prilocaine Injections in Myofascial Pain Syndrome. Mehmet Zeki Kiralp, Baki Ozdemir, Engin Cakar, Oguz Durmus, Levent Tekin and Umit Dincer. Gülhane Military Medical Academy, Haydarpasa Training Hospital, Department of Physical Medicine and Rehabilitation, Istanbul, Turkey

Objective: The objective of this study was to compare the effectiveness of botulinum toxin-A (Btx-A) and prilocaine injections in the treatment of myofascial pain syndrome (MAS).

Methods: Forty-six eligible patients who had diagnosed as MAS were recruited and were randomized into two treatment groups namely Btx group

(n=23) and prilocaine group (n=23). The injections were made to most painful maximum three trigger points of the patients. 10 IU of Btx-A in Btx group and 2ml prilocaine in the prilocaine group were injected to each points. All of the patients were trained about the stretching exercises and instructed to do at home regularly. Clinical assessment parameters were visual analog scale (VAS) for pain during function, pain score (PS) during digital pressure, short form-36 (SF-36) for quality of life and Beck depression inventory (BDI) for general well-being. The assessments were performed at baseline and at 2nd and 6th weeks after the injections.

Results: There were no statistical differences between the groups at baseline. The study was finished with 38 patients (19 patients in each group). Both of the groups' VAS, PS, BDI scores at 2nd and 6th weeks and all of the subscale scores of SF-36 at 6th week improved according to baseline. In inter-group comparison it was seen that the VAS score at 2nd and 6th weeks and PS at 6th week improved statistically better in Btx group than prilocaine group ($p<0.05$). In addition, all of the subscale scores of SF-36 except physical functioning were statistically better in Btx-A group ($p<0.05$) at 2nd and 6th weeks.

Table 1. The intra-group and inter-group comparisons of the treatment effects of Btx-A and prilocaine

	Baseline		2nd week		6th week	
	mean ± SD	p**	mean ± SD	p**	mean ± SD	p**
VAS						
Prilocaine	**8.95 ± 1.13**		4.26 ± 1.41		3.74 ± 1.66	
%			−52		−58	
p*		0.16	<0.0001	0.012	<0.0001	0.001
Btx-A	**8.37 ± 1.38**		3.21 ± 1.03		2 ± 0.88	
%			−62		−76	
p*			<0.0001		<0.0001	
PS						
Prilocaine	**2.89 ± 0.32**		1.68 ± 0.58		1.42 ± 0.61	
%			−42		−51	
p*		0.11	<0.0001	0.16	<0.0001	0.01
Btx-A	**2.68 ± 0.48**		1.42 ± 0.51		1 ± 0.33	
%			−47		−63	
p*			<0.0001		<0.0001	

* : p score of intra-group changes according to baseline
** : p score of inter-group changes
% : the percentage of change according to baseline

Conclusions: Both Btx-A and prilocaine injections combined with appropriate exercise program were beneficial treatment choices in MAS management. It was also seen that Btx-A injections have better effects especially in regard to pain and health quality in short to medium term. It was noticeable that there was no difference between the groups at 2nd week in regard to PS, but Btx group's PS scores were statistically better at 6th week control. This might be interpreted as the progressive cumulative effect of Btx-A.

These outcomes were the preliminary results of an ongoing follow-up study. Further studies are needed for the clarification of the long term effects of Btx-A injections in MAS management.

The Patient Specific Functional Scale Outperforms the Fibromyalgia Impact Questionnaire Physical Function Scale. Chad S. Boomershine[1], Kim A. Edwards[2], Jennifer Y. Hong[2] and Kenneth A. Wallston[2]. [1]Vanderbilt University, Nashville, TN, [2]Vanderbilt University

Background: Fibromyalgia (FM) is a disease defined by chronic widespread pain and tenderness that causes functional impairment in many patients. The FM impact questionnaire physical function scale (FIQPFS) has been the standard used by rheumatologists to measure functional impairment in FM patients. However, its clinical utility is limited due to its length (11 questions), complex scoring, and assessment of rarely performed activities. The patient specific functional scale (PSFS) is a brief (3 question) functional impairment measure that assesses difficulty with patient-selected activities on an easily scored 0 to 10 numeric rating scale (NRS) commonly used by physical therapists. We hypothesized that the PSFS is a more clinically useful functional measure than the FIQPFS due to its brevity, ease of scoring and patient-specific nature. However, performance of the PSFS has never been compared to the FIQPFS. We compared baseline psychometric properties of the PSFS and the FIQPFS and the ability of both scales to measure global change in patients treated with physical therapy (PT).

Methods: Patients (N=340) sent for PT treatment were assessed at baseline and after treatment for 1 month. Baseline and follow-up evaluations included demographics, a pain NRS, regional pain scale (RPS), fatigue problem scale (FPS), disease-neutral FIQPFS, PSFS, and patient global impression of change (PGIC). Baseline pain NRS scores ≥4 identified pain patients. FM survey criteria (RPS ≥8 and FPS ≥6) at baseline identified FM patients. Spearman rank correlations were used to compare questionnaire scores. Statistical methods were performed using PASW Statistics 17.

Results: At baseline, the PSFS had lower floor effects for all patients (n=340) compared to the FIQPFS (0.9% vs 17.3%, respectively). In patients with pain (n=249), the PSFS also had lower floor effects compared to the FIQPFS (1.2% vs 8.8%, respectively). In FM patients (N=82), the PSFS had no floor effects whereas the FIQPFS had 7.3%. Ceiling effects were negligible for both scales in all patient groups (<1%). PSFS scores were normally distributed for all patient groups, while FIQPFS scores were not normally distributed for any group. At follow-up, PGIC scores significantly correlated with change in PSFS scores for all patients ($\rho=0.52$, $p<0.001$), pain patients ($\rho=0.52$, $p<0.001$) and FM patients ($\rho=0.91$, $p<0.001$).

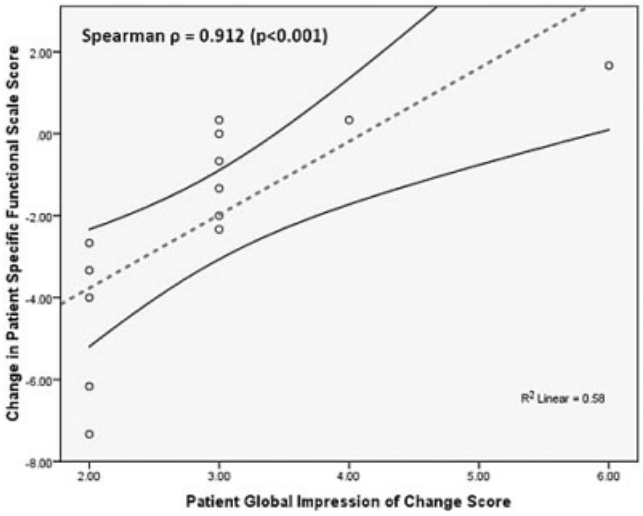

Figure 1. Patient global impression of change score correlates with change in patient specific functional scale score in fibromyalgia patients.

PGIC scores did not correlate significantly with change in FIQPFS scores for any patient group [all patients ($\rho=0.13$, $p=.314$), pain patients ($\rho=0.09$, $p=0.548$), or FM patients ($\rho=0.272$, $p=.347$)].

Conclusions: The PSFS has superior psychometric properties compared to the FIQPFS and significantly correlates with PGIC scores in patients treated with PT. Our results indicate the PSFS may be a better questionnaire to evaluate functional impairment and response to therapy than the FIQPFS in many patient groups including FM patients.

Disclosure: C. S. Boomershine: Eli Lilly and Company, 8, Forest Pharmaceuticals, Inc, 8, NIH, 2, Pfizer Inc, 2, 8; **K. A. Edwards:** None; **J. Y. Hong:** None; **K. A. Wallston:** None.

The Revised Version of the Fibromyalgia Impact Questionnaire: Association with Physical Function and Quality of Life. Seong-Rye Seo[1], Sung-Ji Lee[3], Tae-Jong Kim[3], Yong-Wook Park[3] and Shin-Seok Lee[2]. [1]Chonnam Natl Univ Med School, Gwangju, Republic of Korea, [2]Chonnam Natl Univ Med School, Gwangju, Korea, Republic of, [3]Chonnam Natl Univ Med School

Purpose: Despite its shortcomings, the Fibromyalgia Impact Questionnaire (FIQ) is widely used to assess clinical symptoms and measure therapeutic changes in patients with fibromyalgia (FM). Recently, the updated version (FIQR) was released. In this study, we validated the Korean version of the FIQR and evaluated whether the revised version is superior to the original one in reflecting the physical function and quality of life of these patients.

Methods: After translating the FIQR into Korean, the FIQR was administered to 50 FM patients to assess its comprehensibility. Next, 76 patients who met the American College of Rheumatology (ACR) criteria for

FM were invited to complete a questionnaire that included the original FIQ, FIQR, Multidimensional Health Assessment Questionnaire (MDHAQ), Rheumatology Attitudes Index (RAI), and Medical Outcome Study Short-Form 36 (SF-36) and were examined for tender points using thumb palpation.

Results: The test-retest reliability was assessed in 53 patients after 1 week, and the correlation coefficients were between 0.604 and 0.825 (Cronbach's alpha = 0.961). The total score on the FIQR was closely correlated with that on the original FIQ ($r = 0.869$, $p < 0.001$), and each of the three FIQR domains was also significantly correlated with the three related FIQ domains (all $p < 0.001$). The FIQR was significantly correlated with tender point counts and scores, pain visual analogue scale (VAS), fatigue VAS, RAI, MDHAQ, and the physical and mental component summary scores of the SF-36 (all $p < 0.001$). The FIQR was more strongly associated with the MDHAQ and SF-36 than with the original FIQ.

Table. Comparison of FIQR and FIQ with symptoms, physical function, and quality of life.

				SF-36	
	Pain	Fatigue	MDHAQ	Physical component	Mental component
FIQR					
1) Function	0.634***	0.635***	0.789***	−0.527***	−0.462***
2) Impact	0.666***	0.637***	0.656***	−0.563***	−0.418***
3) Symptom	0.665***	0.733***	0.568***	−0.385***	−0.501***
Total scores	0.724***	0.755***	0.736***	−0.523***	−0.502***
FIQ					
1) Function	0.457***	0.420***	0.611***	−0.488***	−0.168***
2) Impact	0.677***	0.608***	0.613***	−0.534***	−0.410***
3) Symptom	0.646***	0.676***	0.515***	−0.282***	−0.517***
total scores	0.713***	0.714***	0.612***	−0.426***	−0.498***

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

Conclusion: Our study showed that the updated FIQR is a reliable, valid instrument for assessing FM patients and performs better at predicting physical function and health status than does the original FIQ.

Treatment with FDA Approved Therapies in Patients with Fibromyalgia. Brian T. Walitt[3], Robert S. Katz[2] and Frederick Wolfe[1]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Rheumatology Associates, Chicago, IL, [3]Washington Hospital Center, Washington, DC

Purpose: Usual treatment for fibromyalgia (FM) is generally considered to be unsatisfactory. Recently, the US Food and Drug Administration approved several drugs specifically for treatment of FM based on controlled clinical trials that showed modest improvement compared to placebo. These treatments include pregabalin, duloxitine, and milnacipram. The treatments are now widely advertised and available in the US. However, whether such treatments are superior to prior conventional FM therapy, as used in the community, is not known. In this study we compare the new therapies to usual therapy to determine the degree to which they improve patients with FM.

Methods: We compared clinical status in patients who received at least one of the 3 therapies when they were receiving the treatments compared with when they were not receiving any of the treatments. Patients were assessed longitudinally at 6 month intervals. We assessed 611 patients during 4,415 observations, 1,895 of which (42.9%) were on treatment and 2,520 (57.1%) were not. To assess treatment effect we used generalized estimating equations (GEE), controlling for age, sex and baseline fibromyalgia severity. The study outcome variables included visual analog scales for pain, fatigue and global, HAQ, SF-36 PCS, MCS and mood, and fibromyalgia severity—using a severity measure from the American College of Rheumatology 2010 fibromyalgia criteria.

Results: The mean age (SD) of treated patients was 56.5 (10.7), and 97% were women. Table 1 shows the adjusted means by treatment category.

Variable	Treatment	Mean (95% CI)	P-value
FM severity	Off Rx	19.9 (19.5, 20.2)	< 0.001
	On Rx	19.2 (18.9, 19.6)	
Pain	Off Rx	6.4 (6.2, 6.5)	0.002
	On Rx	6.2 (6.0, 6.3)	
Fatigue	Off Rx	6.8 (6.7, 7.0)	0.203
	On Rx	6.7 (6.6, 6.9)	
Global	Off Rx	5.4 (5.2, 5.6)	0.403
	On Rx	5.5 (5.3, 5.6)	
Mood	Off Rx	3.9 (3.7, 4.0)	0.152
	On Rx	3.9 (3.8, 4.1)	
HAQ	Off Rx	1.3 (1.2, 1.3)	0.146
	On Rx	1.3 (1.2, 1.3)	
MCS	Off Rx	30.7 (30.1, 31.3)	0.216
	On Rx	31.0 (30.4, 31.6)	
PCS	Off Rx	40.8 (40.0, 41.7)	0.441
	On Rx	40.6 (39.7, 41.5)	

As shown in the table, most variables were not significantly different by treatment class. The 0–10 pain scale was minimally improved by 0.22 units and the 0–31 fibromyalgia severity scale by 0.63 units. We also analyzed the effect of each drug separately. In none of the separate analyses was a significant treatment effect detected.

Discussion: Each of the treatments studied has been shown to be superior to placebo in randomized controlled trials. While our data cannot address treatment effect versus placebo, because there is no true placebo in clinic care, the data does not suggest that treatment is superior to conventional treatments used by fibromyalgia patients. The new treatments are expensive and heavily promoted. But patients in this study did not appear to have additional benefits benefit from the therapies.

A Novel Tool for Fully Automatic Quantification of MRI Synovitis in Rheumatoid Arthritis Is More Sensitive to Change Than the Current Standard Semi-Quantitative Assessment. Michael A. Bowes[1], Jane E. Freeston[4], Edward J. Vital[4], Graham Vincent[2], Gwenael Guillard[2], Paul Bird[5], Paul Emery[3] and Philip G. Conaghan[4]. [1]Imorphics Ltd, Manchester, United Kingdom, [2]Imorphics Ltd, [3]rrrpe@leeds.ac.uk, [4]Section of Musculoskeletal Disease, University of Leeds, UK, [5]University of NSW, Sydney, Australia

Background: Current MRI evaluation in rheumatoid arthritis (RA) employs a semi-quantitative tool (OMERACT RAMRIS). Fully automated quantification of change in MRI pathology remains a highly desirable outcome for clinical trials and practice. 3D statistical appearance models have been used in osteoarthritis to detect very small physical changes in bone, cartilage and soft tissue.

Objectives: To determine the responsiveness of a novel 3D automated measurement of MRI synovitis in the MCP and wrist joints of RA subjects in an open label study and to compare this with the RAMRIS synovitis assessment.

Methods: 3T VIBE MR images pre- and post-contrast of 47 established RA patients who had recently commenced the same biological therapy were evaluated. Subjects were imaged at baseline and regular intervals after 6 months. 3D models or 'masks' of the joints assessed by RAMRIS were created from a separate dataset of RA images. Masks were created for the MCP joints, the radio-carpal joint, the radio-ulnar joint, and a mask for the carpal bones. These masks were fitted to each pre-contrast image and then subtraction images were created using a shuffle transform method. Synovitis volume (in mm^3) was calculated automatically from the enhancing voxels within each mask. RAMRIS scoring was performed by a single experienced reader, blinded to time point.

Results: Mean age of patients was 54.7 years, 88% women, 88.9% RF positive, mean number of previous DMARDs 2.88, 22/55 patients had received previous anti-TNF [10 1TNF, 9 2TNFs, 3 3TNFs] therapy. The numbers of patients with scans available at each time point were: 46 (6 months), 35, 15, 21, and 14 (14 months). At the group level, significant

changes in automated synovitis volume were demonstrated at all time points except 10 months (where the size of the cohort was 15 individuals). RAMRIS scoring showed a similar pattern of change but with no significant change at any time point (Figure 1).

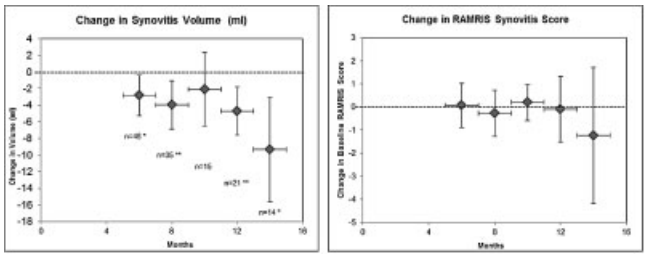

Figure 1. Change in synovitis volume (ml) and RAMRIS scores from baseline, with 95% confidence limits. Cohort size at each time point is shown on left hand graph. RAMRIS synovitis change scores did not achieve statistical significance at any time point. * = $p<0.05$, ** = $p<0.005$.

Conclusions: Fully automated quantitative synovitis measurement is now feasible and practical, and in this observational study proved to be more responsive than semi-quantitative scores. This method could also be applied to clinical practice as well as clinical trials, as synovial volume is measured at the individual joint level.

Application of High-Resolution Peripheral Quantitative Computed Tomography (HR-pQCT) To Quantify Bony Damage in Rheumatoid Arthritis. Cheryl C. M. Barnabe[1], Liam Martin[1], Steven K. Boyd[2] and Susan G. Barr[1]. [1]University of Calgary, Calgary, AB, Canada, [2]University of Calgary

Background: High-resolution peripheral quantitative computed tomography (HR-pQCT) (isotropic voxel size of 82 μm) provides three-dimensional information on bone microarchitecture. We investigated the ability of HR-pQCT to provide quantitative assessments of features of RA bony damage, and diagnostic performance.

Methods: Fifteen patients with established RA and damage of the MCP or PIP joints and 15 age- and sex-matched control patients were recruited and scanned by HR-pQCT (XtremeCT; Scanco Medical, Switzerland). A semi-automated segmentation method identified bone mineral based on changes in the gray-scale, with manual correction of any errors made by the program. These images were used to create a three-dimensional reconstruction of the joint. The minimum joint space width was calculated by counting the number of voxels between articular surfaces (Image Processing Language). The number and location of erosions were assessed visually from the two-dimensional images. Quantitative measures of bone density were obtained for the 2nd, 3rd and 4th MCP joints. Diagnostic test performance for HR-pQCT compared to the clinical diagnosis of RA was calculated. Reproducibility was assessed by re-contouring a subset of the images.

Results: Joint space narrowing was detected in RA patients compared to controls (Table 1). In RA, the majority of erosions occurred at the proximal bone surface (mean 23.6 (SD 17.6)). Some controls were found to have erosions, mainly in the IP and PIP joints. Quantitative assessment of bone density parameters did not reveal significant differences between RA patients and controls (Table 2). The best test performance for the clinical diagnosis of RA was determination of an erosion in MCP2 (sensitivity 76.9%, specificity 93.3%, ROC area 0.851, positive likelihood ratio 11.5 (95%CI 1.7–78.4)). Reproducibility was good for bone density parameters (all root square mean coefficients of variance were under 1%), but less so for joint space measurements (17%), perhaps related to difficulties in contouring angulated joints.

Table 1. Relative (and standard deviation) joint space of controls compared to RA patients (positive value indicates the control has a wider joint space).

	PIP 2	PIP 3	PIP 4	PIP 5	MCP 2	MCP 3	MCP 4	MCP 5
Difference (μm)	71 (171)	167 (247)	−68 (181)	44 (196)	131 (535)	262 (502)	106 (406)	145 (287)

Table 2. Relative (and standard deviation) bone density parameters of controls compared to RA patients (positive value indicates that the parameters is higher in controls).

Parameter	MCP 2	MCP 3	MCP 4
Whole bone density (mg/cm^3)	.07 (66)	−8.91 (46)	−24.6 (96)
Cortical density (mg/cm^3)	21.05 (60)	14.21 (53)	−19.55 (90)
Trabecular density (mg/cm^3)	6.13 (48.6)	−1.19 (33.8)	−18.34 (67.3)
Average cortical thickness (mm)	.007 (.047)	−.004 (.037)	−.015 (.046)
Average trabecular number (mm^{-1})	−.04 (.20)	−.01 (.21)	−.36 (1.16)
Average trabecular thickness (mm)	−.004 (.03)	−.002 (.03)	−.010 (.02)
Average trabecular spacing (mm)	.003 (.07)	−.014 (.06)	.006 (.06)

Conclusions: We have developed methods to provide quantitative measurements of bony damage in established RA using HR-pQCT. Differences in joint space width are most pronounced at the MCP joints. Erosions at MCP2 are highly specific for RA, but erosions were detected in controls unrelated to clinical disease. A larger sample size may reveal detectable differences in bone density parameters between subjects with active inflammatory arthritis and those without. In this preliminary study, HR-pQCT demonstrated good performance characteristics for RA diagnosis.

Baseline CRP Predicts Early Improvement in Synovitis, Osteitis, and Erosion on MRI in RA Patients Treated with Tocilizumab: Results from the ACT-RAY MRI Substudy. Orrin M. Troum[6], Charles G. Peterfy[4], Jeffrey L. Kaine[3], Carol Chung[1], Andrew Anisfeld[1], Ewa Olech[2] and Philip G. Conaghan[5]. [1]Genentech, a Member of the Roche Group, South San Francisco, CA, [2]Oklahoma University Health Sciences Center, Oklahoma City, OK, [3]Sarasota Arthritis Research Center, Sarasota, FL, [4]Spire Sciences and Synarc, San Francisco, Kentfield, CA, [5]University of Leeds, Leeds, United Kingdom, [6]University of Southern California, Santa Monica, CA, Santa Monica, CA

Purpose: IL-6R inhibition with tocilizumab (TCZ) inhibits progression of radiographic joint damage in patients (pts) with RA within 6 months. However, clinical and biochemical markers of disease activity, including CRP, and bone and cartilage turnover markers show improvement 2–4 weeks after TCZ initiation. Synovitis (SYN), particularly osteitis (OST), on magnetic resonance imaging (MRI) and elevated CRP levels have been shown to be strong predictors of radiographic progression of joint damage in patients with RA. This analysis examined early effects of TCZ on SYN, OST, and erosion (ERO) in pts with erosive RA who were inadequate responders to methotrexate (MTX-IR).

Methods: As part of a randomized, double-blind, phase 3b study (ACT-RAY) in MTX-IR pts, 63 RA pts on stable MTX were randomly assigned to continue stable MTX or to receive placebo, both in combination with TCZ 8 mg/kg IV every 4 weeks. In this substudy, 0.2T extremity MRI of one hand (metacarpophalangeal joints [MCP] 1–5) and wrist was acquired at baseline and at weeks 2 and 12. MR images were quality controlled and scored by two radiologists using a RAMRIS method blinded to visit order. In this interim analysis, blinded data from both TCZ arms were pooled and analyzed. CRP values were measured at baseline and every 4 weeks.

Results: By week 2, SYN scores improved in 44% of pts and improved ≥ smallest detectable change (SDC) in 7% of pts. By week 12, SYN and OST scores improved ≥SDC in 32% and 28% of patients, respectively. Median ERO score did not change at either time point, but 10 pts showed ERO score change ≥SDC (7 regressed [12%], 3 progressed [5%]) at week 12. Baseline CRP levels were variable, with a mean of 1.2 mg/dL (range 0.1–10.3); 93% of patients achieved normal CRP levels by week 12. Exploratory analysis stratifying MRI RAMRIS subscores by baseline CRP levels revealed that mean baseline SYN, OST, and ERO scores were numerically higher in patients with baseline CRP ≥1.0 than in those with CRP ≤0.3, or 0.3–1.0. Pts with high baseline CRP (≥1.0) were 1.7-, 7.2-, and 3.2-fold more likely to achieve improvements ≥SDC in SYN, OST, and ERO, respectively, at week 12 than were pts with normal baseline CRP levels (≤0.3) (Table).

Conclusions: TCZ reduced synovitis in only 2 weeks and pre-erosive OST within 12 weeks of treatment initiation. Pts with baseline CRP levels ≥1.0 mg/dL were more likely than pts with baseline CRP levels <1 mg/dL to achieve improvements in MRI measures of inflammation and erosive activity, indicating that CRP may have the potential to predict which pts will

experience the greatest MRI improvements after treatment with TCZ. Analysis of the upcoming 52-week visit from this study will offer an opportunity to confirm this observation. MRI evidence of early improvement with TCZ is in line with prior demonstration of inhibition of X-ray joint damage at 1 year and the observation that baseline CRP predicts radiographic progression.

		Baseline CRP, mg/dL			
		≤0.3	>0.3−<1.0	≥1.0	Total
Mean baseline RAMRIS score	n	19	22	22	63
	SYN	6.6	6.5	9.4	7.5
	OST	3.9	5.3	16.2	8.7
	ERO	13.6	20.4	22.3	19.0
Pts with week-12 improvement ≥ SDC, %	n	16	20	21	57
	SYN	25[a]	25	43[a]	32
	OST	6[b]	30	43[b]	28
	ERO	6[c]	10	19[c]	12

SDC: SYN = 1.7, OST = 3.0, ERO = 2.2.
[a] 43 is 1.7-fold greater than 25, [b]43 is 7.2-fold greater than 6. [c]19 is 3.2-fold greater than 6.

Bone Density Measurement in Osteoarthritis Using Digital Radiographic Procedures. M. B. Kinds[2], L. W. Bartels[1], A. C. A. Marijnissen[3], K. L. Vincken[1], H. W.A.M. de Jong[1], M. A. Viergever[1] and F. P. J. G. Lafeber[3]. [1]Image Sciences Institute, University Medical Center Utrecht, The Netherlands, [2]Rheumatology & Clinical Immunology, Image Sciences Institute, University Medical Utrecht, The Netherlands, Utrecht, The Netherlands, [3]Rheumatology & Clinical Immunology, University Medical Center Utrecht, The Netherlands

Background: Dual energy X-ray Absorptiometry (DXA) is the method of choice for quantifying bone density (BD). In clinical practice however, BD is commonly subjectively assessed on standard radiographs for the evaluation of bone changes (sclerosis) in osteoarthritis (OA). The transition from conventional radiography to digital radiography needs reevaluation whether BD can be quantified on radiographs. The objective of this study was to evaluate whether actual BD (hydroxylapatite in g/cm^2) can be reliably related to grey value in digital radiographs, and to study whether an aluminum step wedge can be used as a reference for BD (in mm aluminum equivalent: mmAl) to make the measurement independently of radiographic settings.

Methods: A bone density standard (BDS) was created consisting of predefined amounts of hydroxylapatite (eight cups ranging from 0 to 5.75 g/cm^2). The BDS was validated by use of DXA (R^2=0.99). Digital radiographs of the BDS were acquired (Philips Digital Diagnost) with different settings. Peak voltage (kVp), milliampere seconds (mAs), position of the BDS in the radiographic field, and filtration were varied. Also the default clinical post-processing module, which is introduced with the development of digital radiography, was compared with post-processing switched off. In all cases a human (cadaver) knee joint was added to simulate clinical conditions. For analysis of BD an aluminum step wedge (40×200mm) consisting of 20 steps with increasing thickness of 2mm was added in all radiographs as a reference. A modified version of Knee Images Digital Analysis (KIDA)[1] was used to express the grey values in the BDS in mmAl by comparison with the grey values in the step wedge. The grey values in the step wedge were represented by a linear or a third order polynomial function. The relation between actual BD (g/cm^2) and BD in mmAl was evaluated with linear regression analysis. The effects of the different radiographic settings were evaluated as well.

Results: The relation between actual BD and BD in mmAl was most importantly influenced by regular clinical post-processing settings. Specifically switching off the post-processing module during acquisition improved the linear relation from R^2=0.82 to R^2=0.93. When a third order polynomial representation of the step wedge was used, the relation improved to R^2=0.95 with clinical post-processing and to R^2=0.98 when post-processing was off. Variation in the other radiographic settings (kVp, mAs, position, and filter) moderately influenced the linearity: R^2=0.71–0.87.

Conclusion: Bone density evaluation on digital radiographs is hampered by the default post-processing as used in clinical practice. By use of an aluminum reference step wedge and by using a third order polynomial function in KIDA, BD on digital radiographs can be reliably expressed in mmAl equivalents.

Bone Marrow Lesion (BML) Size in Osteoarthritic Knees Correlates with Extent of Cartilage Damage and Predicts Longitudinal Cartilage Loss. Jeffrey B. Driban[3], Grace H. Lo[1], Ji Yeon Lee[2], Robert J. Ward[3], Eric Miller[5] and Timothy E. McAlindon[4]. [1]Tufts Medical Center, Houston, TX, [2]Tufts Medical Center, Brookline, MA, [3]Tufts Medical Center, Boston, MA, [4]Tufts Medical Center Box 406, Boston, MA, [5]Tufts University

Purpose: Although BMLs appear to be associated with cartilage damage in knee osteoarthritis (OA), the nature of the relationship is unclear. Prior studies have used semi-quantitative BML scales which limit analyses of longitudinal relationships and measurements of BML change. Therefore, our aim was to evaluate the cross-sectional and longitudinal relationships between BML size and the extent of cartilage damage using quantitative 3-dimensional measurements (BML size; cartilage volume, thickness and area of denudation).

Methods: The sample comprised 44 knees (baseline Kellgren Lawrence score ≥ 2) from participants in a clinical trial who had sagittal and coronal intermediate-weighted fat-suppressed (IW FS) and DESS MRIs at baseline and 2 years (Siemens Magnetom Avanto 1.5T). Knees were selected that had areas of full thickness cartilage loss. We defined BMLs as regions of high-signal intensity on IW FS images located within 1.0 cm of hyaline cartilage and present on ≥ 2 sagittal or coronal images and classified them within 2 regions: index femur or tibia. Two rheumatologists defined the index compartment as the compartment (medial or lateral) with greater pathology based on radiograph and MRI findings. We measured the maximal anterior-posterior, medial-lateral, and vertical dimensions of each BML. Their product represented the volume of each BML (intra-tester ICC =.96). When multiple BMLs were present in a region their volumes were summed to calculate regional volume. Cartilage measurements were determined by manual segmentation of registered DESS images using Analyze© (intra-tester ICC >.99).

Results: Participants were 65 ± 9 years of age (m ± sd), 52% female, and body mass index of 29.8 ± 5.8 kg/m2. Among femurs, 91% had full thickness cartilage loss at baseline (baseline = 11.0 ± 10.4% of subchondral bone; 2 incident knees; change = 1.5 ± 1.8% of subchondral bone) and 91% had baseline BMLs (baseline = 15.3 ± 16.0 cm3; 1 incident knee; change = 1.6 ± 12.4 cm3). Among tibias, 66% had full thickness cartilage loss at baseline (baseline = 16.3 ± 18.6% of subchondral bone; 3 incident knees; change = 2.1 ± 4.2% of subchondral bone) and 85% had BMLs (baseline = 30.7 ± 31.5 cm3; 2 incident knees; change = 3.9 ± 14.8 cm3).

Table 1 demonstrates intra-region correlations among BML and cartilage. Baseline BML volume had direct associations to area of full thickness cartilage loss (baseline and change). There was also a direct association between tibia BML volume change and tibia cartilage volume change (r =.32, p =.047, n = 39). There were no other correlations between BML volume change and cartilage parameters (baseline or change).

Table 1. Spearman Coefficients among Baseline BML and Cartilage Parameters

	Femur BML Volume: Baseline (n = 40)	Tibia BML Volume: Baseline (n = 37)
Cartilage Volume: Baseline	−.06	−.31*
Cartilage Thickness: Baseline	.02	−.37*
Area of Full Thickness Cartilage Loss: Baseline	.33*	.63**
Cartilage Volume: Change	.03	.16
Cartilage Thickness: Change	−.11	−.13
Area of Full Thickness Cartilage Loss: Change	.48**	.43**

* significant findings ($p \leq .05$)
** significant finding after Bonferroni corrections (18 multiple comparisons; $p < .003$)

Conclusion: In knees with cartilage denudation, BML size indicates the level of risk for further full thickness cartilage loss.

Decreased Incidence of Synovitis, Osteitis, and Erosion in Early RA Patients Treated with Adalimumab Plus Methotrexate Compared to Those with Methotrexate Alone: High-Field MRI Analysis from OPTIMA. Charles Peterfy[4], Boulos Haraoui[5], Patrick Durez[3], Kaushik Patra[2] and Hartmut Kupper[1]. [1]Abbott GmbH & Co. KG, Ludwigshafen, Germany, [2]Abbott Laboratories, Abbott Park, IL, [3]Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Brussels, Belgium, [4]Spire Sciences, San Francisco, CA, [5]University of Montreal Hospital Centre, Hopital Notre Dame, Montreal, QC, Canada

Background: Combination therapy with adalimumab (ADA) and methotrexate (MTX) has been shown to reduce X-ray progression of joint damage in rheumatoid arthritis (RA). Magnetic resonance imaging (MRI) is more sensitive than X-ray for bone erosion and also visualizes pre-erosive synovitis and osteitis.

Objective: To determine the proportion of early RA patients showing progression or improvement in synovitis, bone erosion, and osteitis on high-field MRI after 26 weeks of therapy with ADA+MTX or MTX monotherapy in a substudy of OPTIMA (**O**ptimal **P**rotocol for **T**reatment **I**nitiation With **M**ethotrexate and **A**dalimumab Combination Therapy in Patients With Early Rheumatoid Arthritis).

Methods: OPTIMA is an ongoing 78-wk study with 26- and 52-wk periods including MTX-naive patients with RA <1 year, DAS28>3.2, ≥6 SJC, ≥8 TJC, ESR ≥28 mm/h or CRP ≥1.5 mg/dL, and ≥1 of the following: >1 joint erosion, RF+, or anti-CCP+. Patients were randomized to ADA (40 mg every other wk)+MTX (titrated to 20 mg/wk by wk 8) or placebo (PBO)+MTX. Fifty-nine patients had 1.5-Tesla MRI of metacarpophalangeal and wrist joints before and after i.v. gadodiamide. Of these, 23 patients had baseline MRI after the first dose of study drug; 19 (83%) within 7 days of dosing. This analysis reports results at baseline and wk 26. Synovitis, erosions, and osteitis were scored by 2 independent blinded readers using the OMERACT-RAMRIS scoring system. Progression or improvement of MRI scores were defined as positive or negative change from baseline ≥ smallest detectable change (SDC)[1], respectively.

Results: Mean (SD) baseline MRI scores for PBO+MTX (N=32) and ADA+MTX (N=27) were comparable for synovitis: 6.8 (4.33) and 6.2 (4.18), P=0.63; for erosions: 4.1 (5.85) and 6.1 (7.43), P=0.26; and for osteitis: 3.3 (4.74) and 5.4 (7.93), P=0.25. Subjects in the PBO+MTX and ADA+MTX groups, respectively, had mean changes in synovitis of −2.0 and −3.6 (P=0.003), in erosion of 1.4 and −0.8 (P=0.004), and in osteitis of 0.0 and −4.0 (P=0.006), indicating that joint inflammation and damage were significantly alleviated by ADA+MTX. Clinical responses to treatment (ACR20/50/70 and DAS28) were correspondingly greater in the ADA+MTX group. The SDC values for synovitis, erosion, and osteitis were 1.8, 1.2, and 3.8, respectively. Subjects receiving ADA+MTX were more likely to exhibit improvements in synovitis, erosion, and osteitis ≥SDC; only one subject in the ADA+MTX group showed progression of bone erosion ≥SDC, compared with 12 subjects in the PBO+MTX group (Table). A similar pattern was seen among the 36 patients who received MRI prior to the first dose of study drug (data not shown).

Table. Proportion of subjects demonstrating progression or improvement ≥SDC in 26 weeks

n (%) subjects	PBO+MTX (N = 32)	ADA+MTX (N = 27)	P value[a]
Progression			
Synovitis	2 (6%)	0	0.50
Erosion	12 (38%)	1 (4%)	0.002
Osteitis	4 (13%)	0	0.12
Improvement			
Synovitis	14 (44%)	20 (74%)	0.03
Erosion	3 (9%)	6 (22%)	0.28
Osteitis	3 (9%)	8 (30%)	0.09

[a] for comparison between treatment groups, based on Fisher's exact test

Conclusion: Treatment of early RA with ADA+MTX for 26 weeks yielded better MRI profiles than did treatment with MTX alone; the improvements in joint inflammation and damage corresponded with enhanced clinical outcomes.

Detection of Radiographic Progression in Early Knee Osteoarthritis (CHECK): Sensitivity to Change of Knee Images Digital Analysis Compared to Altman Grading. M. B. Kinds[3], S. M. A. Bierma-Zeinstra[1], A. C. A. Marijnissen[5], M. A. Viergever[2], J. W. J. Bijlsma[5], P. M. J. Welsing[4] and F. P. J. G. Lafeber[5]. [1]General Practice, Erasmus University Rotterdam, the Netherlands, [2]Image Sciences Institute, University Medical Center Utrecht, The Netherlands, [3]Rheumatology & Clinical Immunology, Image Sciences Institute, University Medical Center Utrecht, The Netherlands, [4]Rheumatology & Clinical Immunology, Julius Center for Health Sciences & Primary Care, University Medical Center Utrecht, The Netherlands, [5]Rheumatology & Clinical Immunology, University Medical Center Utrecht, The Netherlands

Background: In the detection of radiographic progression in osteoarthritis, semi-quantitative measurement commonly results in low sensitivity to change. Quantitative measurement of separate radiographic OA features using Knee Images Digital Analysis (KIDA)[1] theoretically enables more precise measurement and greater sensitivity to change. In the longitudinal Cohort Hip & Cohort Knee (CHECK) radiographic progression is evaluated early in OA. The objective of this study was to determine whether the sensitivity to change of separate radiographic features of OA can be improved by using digital analysis (KIDA).

Methods: Knee radiographs (PA semiflexed) were evaluated for the OA parameters: joint space narrowing (JSN; lateral and medial), osteophytes (lateral and medial femur, lateral and medial tibia), and bone density (BD; lateral femur and medial tibia) by quantitative measurement with KIDA and by semi-quantitative grading according to the Altman atlas[2]. For KIDA measurement sensitivity to change was determined by calculation of the smallest detectable difference (SDD), which accounts for the variability of the radiographic procedure and digital analysis. SDD was determined in a subset of unchanged knees from baseline to 2 year follow-up based on an Altman grade of 0 for all parameters at both time points (313, 303, and 213 pairs of knee radiographs for JSN, osteophyte area, and BD parameters respectively). Next, of all 1002 participants in CHECK available baseline and follow-up knee radiographs were evaluated. The percentage of knees changing on the radiographic parameters was determined for KIDA, defined as a change larger than the SDD, and for the Altman atlas defined as a change of at least one grade. Further, for each parameter knees with a change on KIDA and/or Altman were evaluated for agreement using cross-tabulations.

Results: The SDD for the OA parameters in the different compartments ranged from 0.96 to 2.63mm for JSN, 1.30–4.89mm^2 for osteophyte area, and 10.92–12.96mmAl equivalents for BD. Using KIDA, OA progression was found in 2.4–10.2% (JSN), 6.0–9.2% (osteophyte), and 2.2–4.8% (BD) of knees. Using Altman, OA progression was found in 4.1–11.0% (JSN), 3.3–10.6% (osteophyte), and 0.9–1.3% (BD) of knees. According to both KIDA and Altman, in two years of follow-up only in a limited number of knees radiographic progression occurred: e.g. 3% for JSN medial, and 2% for osteophytes at medial tibia. In 82% and 84% of knees no change occurred. In 15% of cases disagreement existed between knees changing according to KIDA measurement and the Altman atlas.

Conclusion: Sensitivity to change for the detection of radiographic progression in early OA is not improved by using KIDA. Quality of acquisition of radiographs seems to be at least as important as quality of analysis.

Background: We previously showed that different combinations of bones and joints in the hand and wrist varied in their ability to discriminate significant change in synovitis, osteitis and erosion with MRI in patients wtih RA in a multicenter clinical trial[1]. In this study, we corroborated these findings using pooled data from 4 multisite clinical trials.

Methods: A total of 522 RA patients from 4 clinical trials were included in the analysis. Three of these studies (459 patients) included 1.5T MRI, and 2 studies (118 patients) included 0.2T MRI. All scans used a hand frame to ensure reproducible positioning, and were read by the same 2 radiologists. Metacarpophalangeal joints (MCP) 1–5 and all bones and joints in the wrist were scored using the RAMRIS scale[2] for erosion and osteitis in all 4 trials and synovitis in all but one of the 1.5T trials. Six combinations (RAMRIS, 23 bones and 7 joints in original RAMRIS; RAMRIS+, RAMRIS + MCP1; V-Sharp, MCP1–5 + 6 wrist bones in van der Heijde-Sharp X-ray score; G-Sharp, MCP1–5 + 5 wrist bones in Genant-Sharp X-ray score [V-Sharp – lunate]; MCPs, MCP1–5; Wrist, 15 bones and 3 joints in RAMRIS) were compared for percentages of patients changing (increase or decrease) ≥ smallest detectable change (SDC)[3] at week 12 or 24.

Results: Frequency of involvement at baseline varied by location (Fig.1), but showed a similar pattern in all 4 studies and between patients with early (<2y) RA and those with established (>10y) RA (data not shown). Inter-reader agreement, expressed as intraclass correlation coefficient (ICC), also varied among locations (median = 0.84, 0.88 and 0.81, for erosion, osteitis and synovitis, respectively.) Percent of patients changing ≥SDC at 12 or 24 weeks varied among the different combinations (Fig. 2). Adding MCP-1 to RAMRIS (RAMRIS+) increased discrimination for erosion and synovitis. G-Sharp showed the highest discrimination for osteitis and synovitis, and was equivalent to RAMRIS for erosion. Excluding all wrist locations (leaving only MCPs) actually increased discrimination for erosion over that with RAMRIS, but decreased discrimination for osteitis or synovitis.

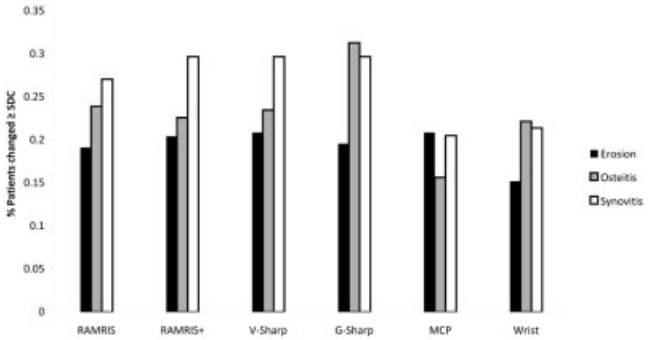

Figure 1. Frequency of involvement of different bones and joints of MCPs and wrist with erosion, osteitis and synovitis (RAD, radius; ULN, ulna; SCAP, scaphoid; TRIQ, triquetrum; PIS, pisiform; TPM, trapezium; TPD, trapezoid; CAP, capitate; HAM, hamate; PMC, proximal metacarpal; DMC, distal metacarpal; PP, proximal phalanx; DRU, distal radioulnar joint; RC, radiocarpal joint; ICMC, intercarpal and carpometacarpal 2-5.)

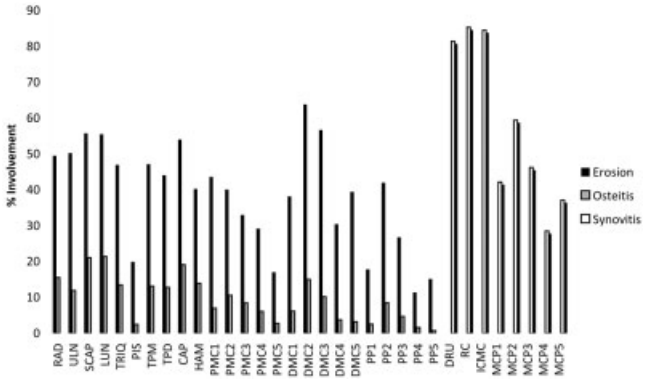

Figure 2. Proportion of patients showing change (increase or decrease) from baseline in erosion, osteitis or synovitis scores ≥ ±SDC for different combinations.

Conclusions: Filtering out noisy and infrequently involved bones and joints may improve discriminative power of RAMRIS. Determining the combination that optimally balances functional relevance with reading reliability requires further investigation.

Giant Cell Arteritis and MRI Evaluation of the Cranial Arteries. Marie I. Clements-Baker[1], Samir Patel[4], Ryan Rebello[2], George Ionnadis[5] and Nader Khalidi[3]. [1]St Joseph's Healthcare Hamilton Ontario, Canada McMaster University, Hamilton, ON, Canada, [2]St Joseph's Healthcare Hamilton, Mcmaster University, Hamilton, ON, Canada, [3]St. Joseph's Healthcare Hamilton, McMaster University, Hamilton, ON, Canada, [4]St. Joseph's Healthcare Hamilton, Mcmaster University, [5]St. Joseph's Healthcare Hamilton. McMaster University

Objective(s): To evaluate whether high field Magnetic Resonance Imaging (MRI) can demonstrate mural edema and inflammation within the superficial temporal artery and other intra- and extracranial arteries and how it compares to temporal artery biopsy results in patients who meet American College of Rheumatology (ACR) criteria for giant cell arteritis (GCA).

Method(s): 49 patients meeting ACR criteria for GCA, and 6 patients otherwise suspicious of GCA were examined by 3T MRI using a head coil. The MRI protocol matured over the course of the study but, in general, high-resolution fluid-sensitive and Gadolinium enhanced images of the clinically-affected STA were obtained, in addition to larger field of view sequences to visualize the other scalp arteries. The images were graded according to protocols reported in recently published studies. All patients except 1 underwent temporal artery biopsy. Images and biopsy were obtained as soon as possible after initiating corticosteroid therapy.

Result(s): Overall 23/55 patients had postive scalp artery MRI findings and 8/55 patients had positive biospy findings. Of these positive biopsies, MRI was reported as positive in 7 with evidence of STA inflammation present in 6 and the seventh patient demonstrating only cavernous carotid artery inflammation. One false negative occured but an inadvertent protocol deviation had occurred with suboptimal image resolution obtained for that patient. The average biopsy length was 2.79 cm. The average number of days from corticosteroid to MRI was 3.9 days and the average number of days to biopsy was 8.98 days.

Other important MRI findings in patients who had negative artery inflammation included 1 case ipsilateral pachymeningitis, 1 cortical infarct, 1 bone lesion questionable for metastatic disease, 1 ipsilateral pansinusitis and 1 case of multiple meningiomas requiring neurosurgical referral.

Conclusion: In patients meeting ACR criteria for GCA, MRI demonstrates evidence of STA inflammation in 43% of patients. This appears superior to our biopsy positive rate of 13%. These results support previous studies and suggest that MRI could replace or complement biopsy as an effective and non-invasive way to diagnose GCA. The MRI protocol and image resolution are crucial components in MRI evaluation of scalp artery

inflammation. MRI is clearly useful in diagnosing other pathologies that may clinically mimic giant cell arteritis.

High-Field MRI and Powerdoppler Sonography—Supplementary Imaging Techniques in Assesing Disease Activity in Patients with Psoriasis Arthritis (PsA) and Rheumatoid Arthritis (RA) in Sustained Clinical Remission. Maria Hoehle Rheumatologic Practice, Hamburg, Germany

Background: Patients with rheumatoid arthritis (RA) and psoriatic arthritis (PsA) responding to anti-TNF therapy show a rapid decrease in inflammatory parameters as well as sustained improvement of clinical signs and symptoms. However inflammatory activity, e.g. synovitis, tenosynovitis, edema still can persist at the joints in patients with clinical remission. These rheumatic processes can be monitored using modern imaging techniques such as high-field MRI and powerdoppler sonography (PD-US).

Objectives: To evaluate whether MRI and US are helpful to stratify patients in clinical and imaging remission for discontinuation of anti-TNF treatment, 41 patiens were followed-up for six years.

Methods: 41 patients (30 women) with RA (35) and PsA (6) starting therapy with adalimumab in 2004 were followed-up for six years. Every six months patients were monitored by standard routine diagnostics as well as by high-field MRI and PD-US. Thereby, the clinically dominant joint was evaluated using RAMRIS and semiquantitative PD-US-score (0–3). Clinical remission was defined as DAS28<2,6. Imaging remission was defined as no detectable synovitis at the clinically dominant joint using MRI and PD-US (RAMRIS synovitis = 0, PD-US synovitis score = 0) (Ref 1,2).

Results: In sixteen patients (16) with early RA (disease duration < 2 years, mean DAS28 = 3,9, mean RAMRIS synovitis = 2,8, mean PD-US synovitis score 2,9) responding to anti-TNF therapy with adalimumab in combination with methotrexat by showing sustained clinical remission (mean DAS28 = 1,5) and imaging remission of at least 12 months adalimumab was discontinued. Clinical and imaging remission persisted in the follow-up period.

In twenty-five patients (25) with established inflammatory rheumatic disease (RA (19), PsA (6), disease duration > 2 years, mean DAS28 = 3,8, mean RAMRIS synovitis = 2,9, mean PD-US synovitis score 2,7) responding to anti-TNF therapy with adalimumab in combination with methotrexat by showing sustained clinical remission (mean DAS28 = 1,4) subclinical synovitis persisted (mean RAMRIS synovitis = 2,1, mean PD-US synovitis score 2,1). Combination therapy was continued in the follow-up period.

In both groups flares of disease activity, erosive progression at hands, severe infections e.g. tuberculosis infections, reactivation of tuberculosis infections or malignoma were not observed since 2004.

Conclusion: According to current evidence patients with RA and PsA should be monitored clinically (DAS28) as well as by modern imaging modalities in a tight and continuous fashion. Early use of adalimumab in the course of the rheumatic disease may allow discontinuation of anti-TNF treatment in true responders as both clinical and imaging remission persisted for five years in the early treatment group. MRI and PD-US seem helpful to stratify patients for discontinuation of biologics.

Inflammatory Osteophyte Formation Is Different from Degenerative Osteophyte Formation. Stephanie Finzel, Christian Ernet, Christian Stach, Klaus Engelke, Matthias Englbrecht and Georg Schett. University of Erlangen-Nuremberg

Objectives: To investigate the differences in the pattern of periarticular oteophyte formation in patients with psoriatic arthritis and hand osteoarthritis by a high-resolution micro-computed tomography scanner (μCT) designed to visualize bone architecture. Both psoriatic arthritis (PSA) and osteoarthrits (OA) lead to joint destruction via deforming osteophytic proliferation but may differ substantially in their periarticular bone changes.

Methods: 24 patients with PSA and 24 patients age- and sex-matched with OA received a micro- computed tomography scan of the dominantly affected hand to compare structural bone changes in the metacarpophalangeal joints. Number, size and distribution of osteophytes were recorded.

Results: Number and size of osteophytes in PSA were comparable to OA. However osteophytes in OA were exclusively found at the palmar and dorsal sites of the MCP-joints. Moreover, in OA patients the metacarpal heads were by far more affected than the phalangeal bases. In contrast, osteophyte formation in PSA did also involve skeletal sites which are normally spared in OA patients, such as the radial and ulnar sites, usually leading to affection of the entire circumference of the periarticular bone surface ("bony corona"). Also significant affection of the phalangeal bases was observed in PSA in contrast to OA.

Conclusions: High-resolution μCT imaging shows profound differences in periarticular bone changes between PSA and HFE. The differential pattern of osteophyte formation between PSA and OA patient suggest different mechanisms to be involved in bone spur formation in consequence of inflammatory and degenerative arthritis of the finger joints. In particular the wide spread corona- shaped osteophyte formation in PSA suggests a profound involvement of the insertion sides of the tendons which is also supported by a far more severe affection of the phalangeal bases. Theses data suggest that it is possible to differentiate between inflammatory and degenerative osteophyte formation by advanced imaging technology.

Magnetic Resonance Elastography for the Evaluation of Liver Fibrosis in Patients with Rheumatoid Arthritis Receiving Methotrexate. Deana D. Hoganson[1], Jun Chen[2], Richard L. Ehman[2], Jayant A. Talwalkar[2], Clement J. Michet[1], Meng Yin and Eric L. Matteson[1]. [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic

Background: Hepatic magnetic resonance elastography (MRE) allows for noninvasive assessment of liver fibrosis. The purpose of this study was to evaluate the usefulness of MRE in detecting and quantifying liver fibrosis in patients with rheumatoid arthritis (RA) who have received methotrexate (MTX).

Methods: Patients receiving MTX for > 5 years or with an abnormal serum AST value in the two years preceding the study onset were evaluated with MRE. Logistic regression and linear regression models with and without adjustment were used to assess the association between mean liver stiffness value as determined by MRE and variables of interest. Prior analyses have shown that a diagnostic cut-off value of 2.9 kilopascals (kPa) can predict all stages of liver fibrosis when compared to normal liver with a sensitivity and specificity of 98% and 99%, respectively. Study participants with an abnormal liver stiffness were subsequently offered evaluation in the hepatology clinic and the decision for a liver biopsy was made based on clinical judgment.

Results: Sixty-five RA patients were enrolled. Mean liver stiffness value by MRE was abnormal in 7 patients, suggestive of hepatic injury. As a result of findings from the MRE, biopsies were performed in 5 patients and all correlated with elevated liver stiffness values (Table). The biopsies revealed chronic inflammation in all subjects; 4 individuals had evidence of fibrosis. There was a significant association between elevated mean liver stiffness and abnormal AST values ever and in the preceding 2 years prior to the scan ($p=0.035$ and $p=0.031$, respectively). Elevated mean liver stiffness values were associated with body mass index (BMI) (OR= 1.18 per 1 kg/m^2; 95% CI: 1.03, 1.36; $p=0.017$), and this remained significant following adjustment for MTX dose, MTX treatment duration, diabetes mellitus, hyperlipidemia, and impaired fasting blood glucose. Neither the total MTX dose nor the duration of MTX treatment was associated with mean liver stiffness value ($p=0.51$ and $P=0.20$, respectively). Eleven patients reported using alcohol more than once a month. Alcohol use was not associated with abnormal mean liver stiffness values ($p=0.96$).

Conclusions: MRE provides a reliable, non-invasive assessment of liver fibrosis in patients with RA receiving MTX. Patients with RA receiving MTX who have an elevated BMI may be at increased risk for chronic hepatic injury, regardless of MTX cumulative dose or duration of treatment.

Table. Abnormal Hepatic Magnetic Resonance Elastography (MRE) Scans in Patients receiving Methotrexate for Treatment of Rheumatoid Arthritis.

Patient	Age (years)	Sex	BMI (kg/m^2)	Total MTX dose (mg)	Frequency abnormal AST 2 years prior to MRE	Mean liver stiffness value (kPa)	Liver biopsy findings
1	71	F	31.1	14235	4/9	3.36	Mildly active (grade 1 of 3) steatohepatitis with focal pericellular fibrosis and mild portal fibrosis (stage 1 of 4)
2	65	F	37.9	2950	1/13	3.46	Mild reactive hepatitis with mild portal fibrosis (stage 1 of 4)
3	57	F	42.1	11880	0/15	3.23	Mildly active steatohepatitis without fibrosis.
4	46	F	44.9	6875	5/7	2.92	Moderately active steatohepatitis, grade 2 (of 3) with portal, periportal, and pericellular fibrosis, stage 2 (of 4).
5	65	F	27.4	6340	1/8	3.26	Not pursued; repeat MRE showed results within a normal range

Magnetic Resonance Imaging (MRI) of the Spine May Be Useful in Patients with Non-Radiographic Axial Spondyloarthritis (NRASpA) without Active Sacroiliitis on MRI. Guillaume Direz[1], Manuel Couchot[2], Philippe Cotty[1], Denis Mulleman[3] and Philippe M. Goupille[1]. [1]University Hospital, Tours, Tours, France, [2]University Hospital, Tours, Tours, France, [3]University Hospital, Tours, Tours, France

Background: MRI of the sacroiliac joints (SIJ) is useful for the diagnosis of axial spondyloarthritis (SpA) in patients who don't fulfil the modified New York criteria (1). However, about 25 to 30 % of patients with NRASpA have no active sacroiliitis on MRI, according to ASAS/OMERACT criteria (2). MRI of the spine may show lesions such as Romanus and fatty Romanus which, when multiple or severe, may be highly suggestive of the diagnosis of axial SpA.

Objective: To assess, in a NRASpA cohort without active sacroiliitis on MRI, the prevalence of spine lesions on MRI highly suggestive of axial SpA.

Methods: Retrospective analysis of the MRI of SIJ and of the thoracic and lumbar spine, performed between 2005 and 2009, in patients with NRASpA. Blind analysis was performed by two independent radiologists (SIJ and spine were independently assessed). Active sacroiliitis on MRI was defined according to ASAS/OMERACT criteria, and a positive spinal MRI was defined according to the presence of highly suggestive lesions (Romanus, fatty Romanus, Andersson spondylitis, inflammatory posterior lesions) and the experience of the two radiologists (study performed before the definition of a positive spinal MRI by the ASAS group).

Results: MRI of 93 NRASpA patients were analysed. Mean age was 39.4 years, mean disase duration was 4.5 years; 39% of the patients were HLA B27 positive, all patients fulfilled ASAS criteria or Amor criteria of SpA and had a diagnosis of NRASpA by their rheumatologist. Thirty-eight of 93 patients (40.8%) had active sacroiliitis on MRI, 25/93 (26.8%) had sacroiliitis and spine lesion highly suggestive of SpA, 10/93 (10.7%) had a normal MRI of SIJ and spine, 10/93 (10.7%) had some inflammatory lesions of SIJ and/or spine not sufficient for the diagnosis of SpA.

Ten of 93 patients (10.7%) had spine lesion highly suggestive of SpA without active sacroiliitis on MRI (6/10 had other lesions of the SIJ (enthesitis, erosions, sclerosis) suggestive of inflammatory involvement). Eight of these 10 patients fulfilled the recently presented ASAS criteria of positive spinal MRI (3) because they had at least 3 Romanus lesions. Therefore, according to new ASAS criteria, 8/93 patients (8.6%) had a positive spinal MRI without active sacroiliitis. More interesting, on 30/93 patients without active sacroiliitis on MRI, 8/30 (26.6%) had at least 3 Romanus lesions on spinal MRI, leading to the diagnosis of axial SpA. There was no significant association between the presence of psoriasis, uveitis, disease duration, HLA B27 or increased CRP and isolated positive spinal MRI.

Conclusions: In NRASpA patients, only 10% had isolated positive spinal MRI. However, in case of suspicion of SpA without active sacroiliitis on MRI, spine MRI may allow the diagnosis of SpA in about 25% of patients.

Malalignment of the Knee Is Associated with an Increased Risk for Incident and Enlarging Subchondral Bone Marrow Lesions in the More Loaded Compartments: The MOST Study. Daichi Hayashi[3], Martin Englund[5], Frank Roemer[4], Jingbo Niu[1], Leena Sharma[6], Neil Segal[9], Cora Lewis[8], David T. Felson[2], Michael C. Nevitt[7] and Ali Guermazi[4]. [1]Boston University, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]Boston University School of Medicine, [5]Lund University, Sweden, [6]Northwestern University, Chicago, IL, [7]UCSF, San Francisco, CA, [8]University of Alabama at Birmingham, [9]University of Iowa

Purpose: Malalignment of the lower limb influences the load distribution across the articular surfaces of the knee joint. We hypothesized that subchondral bone marrow lesions (BML) result from increased mechanical loading. The aim of this study was to assess if malalignment is associated with incident and enlarging BML in the more loaded compartments of the tibiofemoral (TF) joint.

Methods: The Multicenter Osteoarthritis Study (MOST) is an NIH-funded longitudinal observational study of individuals who have or are at high risk for knee OA. Full limb radiographs of both legs were taken at baseline and hip-knee-ankle mechanical axis was measured (varus $<179°$, neutral 179–181° and valgus $>181°$). MRI was performed on a 1.0T extremity system. MR images were assessed semiquantitatively in known order using the WORMS system. BML was scored on a 0–3 scale at baseline and at 30 months in 5 TF regions of the medial and lateral compartment, respectively. Outcome was defined as any increase in BML score, including within-grade change not fulfilling the criteria of a full-grade change. Relative risk of an increase in BML score in the medial and lateral compartments in relation to malalignment was estimated using a log linear regression model with the Poisson assumption. Adjustments were made for age, sex, body mass index and physical activity level. We also combined analyses for the more loaded compartments (i.e. medial BML in varus + lateral BML in valgus knees). In secondary analyses results were stratified by ipsilateral meniscal and cartilage status at baseline (i.e. no meniscal or cartilage pathology; meniscal damage present; cartilage loss present; both meniscal and cartilage pathology present) and also by compartments with or without pre-existing BML (i.e. 'incident' if no BML at baseline or 'enlarging' if pre-existing BML).

Results: 1,782 knees from 1,338 subjects were included (62% women, mean age 62.2 ± 7.9 years, mean BMI 29.9 ± 4.8 kg/m^2). Compared to neutral alignment, baseline varus alignment was associated with increased BML scores in the medial compartment (adjusted RRs [95%CI] 1.8 [1.5–2.3]) and valgus alignment with BML score increases in the lateral compartment (2.4 [1.7–3.4]). Increase in BML score was more likely in the more loaded compartments (2.2 [1.8–2.6]) in malaligned knees compared to neutral knees. After stratification, this association remained in knees with ipsilateral meniscus damage (4.9 [1.1–22.6]), cartilage loss (1.4 [1.1–2.0]), or both (1.6 [1.2–2.0]) but not in knees without any ipsilateral meniscal or cartilage pathology (1.8 [0.9–3.4]). Both incident BML (1.8 [1.4–2.4]) and enlarging BML (1.8 [1.4–2.3]) were more likely to occur in the more loaded compartments in malaligned knees compared to neutral knees.

Conclusion: Knee malalignment is associated with increased risk of incident and enlarging BMLs in the more loaded compartments of the TF joint over 30 months. Further longitudinal studies are needed to explore whether malalignment is a primary trigger of structural damage or a secondary phenomenon due to underlying structural damage. BML may be a

marker of increased mechanical load experienced by overlying cartilage in a compartment-specific manner.

MRI and X-Ray Measured Changes in Joint Space Narrowing Are Closely Associated in Early RA Patients: A Pilot Study. Siri Lillegraven[2], Pernille Bøyesen[2], Mikkel Østergaard[3], Sølve Sesseng[2], Tore K. Kvien[1] and Espen A. Haavardsholm[2]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Hvidovre University Hospital, Hvidovre, Denmark

Background: Magnetic Resonance Imaging (MRI) is commonly used to assess erosions, synovitis, tenosynovitis and bone marrow edema in rheumatoid arthritis (RA) patients. During the development of the OMERACT RA MRI score (RAMRIS) joint space narrowing (JSN) was tested, but left out due to insufficient image resolution. However, MRI image quality has now improved, and a MRI JSN score with encouraging inter-reader reliability was presented at the 2010 OMERACT meeting.

Objectives: To investigate the intra- and inter-reader reilability of the OMERACT JSN score in a longitudinal setting, and to assess the association with X-ray changes.

Methods: 10 patients were selected from a cohort of early RA patients (disease duration less than one year at baseline) with 5-year follow-up. The patients were examined by X-ray of both hands and MRI of the dominant wrist (GE Signa 1.5 T MRI scanner). The 10 patients were chosen according to 5-year change of van der Heijde Sharp JSN score (hands only), with two patients selected from the two lowest quartiles, and three patients from each of the two highest quartiles. The MRI images were assessed on coronal T1-weighted sequences by two readers (PB and SL), both familiar with the RAMRIS score and with experience from previous JSN exercises. 18 joint sites in the wrist were scored 0 (no JSN) - 4 (ankylosis/total loss of joint space). The images were assessed twice on consecutive days, with anonymization and randomization between the readings. Intra-class correlation coefficients were calculated for intra-reader (single measures), inter-reader (average measures) reliability and association to X-ray (average measures).

Results: The median (25th percentile, 75th percentile) age was 54 (47, 67) years, disease duration 98 (48, 139) days, 8 were female and 4 were anti-ccp positive. 5-year change in van der Heijde Sharp JSN score ranged from 0 to 20, with a median of 4. Table 1 shows the intra-reader ICCs, inter-reader ICCs and comparison of MRI scorings and X-ray for each reader.

Table 1. Intra-reader ICCs, inter-reader ICCs and comparison of MRI and X-ray JSN score.

	Intra-reader ICC		Inter-reader	MRI vs. X-ray ICC	
	Reader 1	Reader 2	ICC	Reader 1	Reader 2
Baseline	0.60	0.75	0.67	0.68	0.40
5 year	0.87	0.91	0.95	0.85	0.82
Change	0.90	0.97	0.99	0.91	0.94

The figure shows an example patient with x-ray and MRI images.

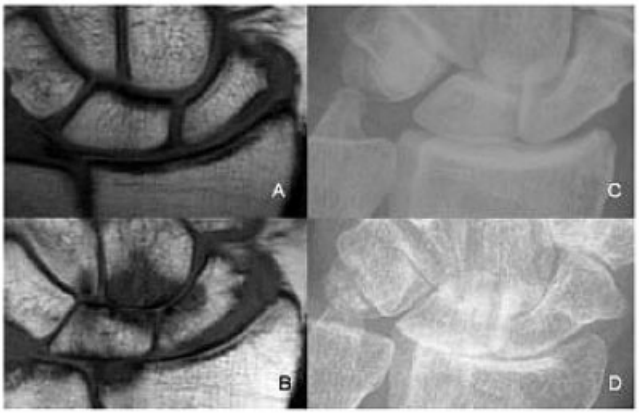

Figure. Patient example with development of JSN at several wrist joints: MRI images from baseline (A) and 5-year follow-up (B) left, X-ray images from baseline (C) and 5-year follow-up (D).

Few of the patients had much change in JSN assessed by MRI, with a median change (range)[25th percentile, 75th percentile] for scorer 1 of 0 (0–30) [0, 1.25] and for scorer 2 1.5 (0 – 28) [0.75, 3.5].

Conclusion: This small study shows promising results for the assessment of JSN on MRI, with strong association between change in JSN on MRI and X-ray. However, these results need to be confirmed in other cohorts, especially including patients with more JSN.

MRI Bone Edema Is an Independent Predictor of Development of Rheumatoid Arthritis in Patients with Early Undifferentiated Arthritis. Anne Duer-Jensen[7], Kim Hørslev-Petersen[10], Merete L. Hetland[1], Lene Bak[5], Bo J. Ejbjerg[9], Michael S. Hansen[6], Julia S. Johansen[3], Hanne M. Lindegaard[8], Henrik Vinterberg[11], Jakob M. Møller[4] and Mikkel Ostergaard[2]. [1]Copenhagen Univ Hosp Hvidovre and Glostrup, Hvidovre, Denmark, [2]Copenhagen University Hospitals at Hvidovre and Glostrup, Hvidovre, Denmark, [3]Dept of Oncology, Copenhagen University Hospital at Herlev, [4]Dept of Radiology, Copenhagen University Hospital at Herlev, [5]Dept of Radiology, Sygehus Lillebælt, Kolding, [6]Dept of Rheumatology, Copenhagen University Hospital at Gentofte, [7]Dept of Rheumatology, Copenhagen University Hospital at Glostrup and Hvidovre, Denmark, [8]Dept of Rheumatology, Odense University Hospital, [9]Dept of Rheumatology, Slagelse Hospital, [10]King Christian Xth Hospital for Rheumatic Diseases, Gråsten, [11]Rheumatology Clinic, Amagerbrogade, Copenhagen

Objectives: To study magnetic resonance imaging (MRI) as a tool for early diagnosis of rheumatoid arthritis (RA) in patients with early undifferentiated arthritis (UA).

Methods: 116 patients without a specific rheumatological diagnosis, but with ≥2 tender and/or swollen metacarpophalangeal, proximal interphalangeal, wrist or metatarsophalangeal (MTP) joints for >6 weeks but <24 months, underwent clinical, biochemical, conventional radiography and MRI examinations (qualitatively assessed for various pathologies and according to the OMERACT RAMRIS scoring method (CMC1 and MTP1 joints excluded)) and were followed for >12 months for final RA/non-RA diagnosis.

Based on univariate analyses, clinical, biochemical and imaging parameters were selected as explanatory variables in multiple logistic regression analysis with development of RA as dependent variable.

Results: 27 patients (23.3%) developed RA. The gender distribution and median age in the RA/non-RA groups were 81.5/76.4% women and 50 yrs (range 21–80)/47 yrs (19–82), respectively, and the symptom duration 4 mth (2–18)/7 mth (1.5–24). The final prediction model, consisting of presence of hand arthritis, positive rheumatoid factor (RF), morning stiffness >1 hour and OMERACT sum score of bone edema in MTP and wrist joints, correctly identified 82% of patients, who eventually developed RA or not RA (sensitivity/specificity: 81%/82%) (table, model 1). An alternative model (table, model 2), in which OMERACT sum score of bone edema in MTP and wrist joints was replaced by OMERACT sum score of bone edema in MTP, wrist and PIP joints, confirmed bone edema as independent predictor.

Table. Baseline predictors of development of rheumatoid arthritis (logistic regression analysis)

	Model 1			Model 2		
Variable	Coefficient	OR (CI)	p-value	Coefficient	OR (CI)	p-value
Arthritis of the hand	2.367	10.7 (2.9–39.7)	<0.001	2.309	10.1 (2.7–37.4)	0.001
Rheumatoid factor positive	0.881	6.6 (2.0–22.0)	0.001	1.889	6.6 (2.0–21.0)	0.002
> 1 hour of morning stiffness	1.997	7.4 (2.3–24.1)	0.001	1.944	7.0 (2.3–22.9)	0.001
OMERACT bone edema sum score in wrist+MTP joint areas (per unit)	0.365	1.4 (1.0–2.0)	0.035	—	—	—
OMERACT bone edema sum score in wrist+MTP+PIP joint areas (per unit)	—	—	—	0.348	1.4 (1.0–2.0)	0.046

Abbreviations: MTP=met at arsophalangeal, PIP=proximal interphalangeal, OR=Odds Ratio, CI=Confidence interval for OR.

Conclusion: MRI bone edema in MTP and wrist joints is an independent predictor of future RA in patients with early UA. A prediction model,

including clinical hand arthritis, morning stiffness, positive RF and MRI bone edema score in MTP and wrist joints correctly identified the development of RA or non-RA in 82% of patients.

Objectives: To investigate the relation between inflammation in the sacroiliac joints (SIJ) on magnetic resonance imaging (MRI) and biomarkers of inflammation (C-reactive protein (CRP), interleukin-6 (IL-6), YKL-40), angiogenesis (vascular endothelial growth factor (VEGF)), cartilage turnover (CTX-II, matrix metalloproteinase 3 (MMP3), total aggrecan, cartilage oligomeric matrix protein (COMP)) and bone turnover (CTX-I, total osteocalcin) in patients with axial spondyloarthritis (SpA) treated with TNFα inhibitors.

Methods: Forty-three patients (34 men, 9 women; median age 40 yrs (range 21–62); disease duration 14 yrs (1–45)) initiated treatment with TNFα inhibitors (infliximab (n=31), etanercept (n=9) and adalimumab (n=3)) and were followed for 46 weeks. MR images were evaluated according to the Berlin SIJ inflammation scoring method at baseline, week 22 and 46. Biomarker levels of the patients were compared to these scores and biomarker levels of healthy subjects.

Results: The patients had a pretreatment MRI SIJ score of median 5 (range: 0–23) and SIJ inflammation was seen in 33 (77%) patients. The SIJ scores correlated with CTX-II (rho=0.57, p<0.0001) and COMP (inversely, −0.36, p=0.02), whereas no correlations were seen with the other 8 biomarkers. Compared to patients without pretreatment SIJ inflammation, patients with SIJ inflammation (MRI score ≥1) had higher baseline urine CTX-II levels (median 490 ng/mmol (IQR: 396–766) vs. 245 (128–345), p=0.003), and higher time-integrated mean concentrations of CTX-II from baseline to week 22 (461 ng/mmol (313–665) vs. 311 (185–404), p=0.04) and to week 46 (418 ng/mmol (286–610) vs. 214 (175–306) p=0.009) and lower YKL-40 from baseline to week 46 (41 μg/l (25–62) vs. 69 (46–106), p=0.03). After 22 weeks of anti-TNFα therapy 17 (52%) patients with SIJ inflammation on baseline MRI decreased in score, whereas 16 (48%) patients were unchanged or increased in score. A decrease in SIJ scores after 22 weeks was associated with larger percentage decreases in CRP (-84% (−94;−67) vs. −45% (−65;−18), p=0.008) and IL-6 (−76% (−88;−73) vs. −43% (−84;15), p=0.03) but not with any other biomarker as compared to unchanged/increased SIJ score. CRP and IL-6 frequently normalized after 22 weeks (i.e. CRP ≤8 mg/l and IL-6 ≤3.3 ng/l) in patients with a decrease in SIJ score as compared to patients with unchanged/increased SIJ score (Table 1).

Table 1. Changes in biomarkers of inflammation (CRP and IL-6) versus change in Berlin MRI inflammation score

	SIJ Inflammation score		
Changes from baseline to week 0–22	**Decreased N=17**	**Unchanged/Persistent N=16**	**p-value**
CRP decreased to ≤8 mg/l	12 (71)	5 (29)	
CRP remained >8 mg/l	1 (0)	7 (100)	0.01†
CRP remained ≤8 mg/l	4 (50)	4 (50)	NS§
IL-6 decreased to ≤3.3 ng/l	15 (79)	4 (21)	
IL-6 remained >3.3 ng/l	1 (14)	6 (86)	0.005†
IL-6 remained ≤3.3 ng/l	1 (14)	6 (86)	0.005§

Number (%). Chi² test and Fisher's Exact test. †Normalization vs. persistently increased biomarker levels. §Normalization vs. normal levels at baseline

Conclusion: Inflammation in SIJ on baseline MRI was associated with higher urine levels of the cartilage degradation biomarker CTX-II. Decrease in MRI inflammation during treatment with TNFα inhibitors was associated with decrease in systemic inflammation.

Quantitative Characterization of Bone Marrow Edema in Patients with Rheumatoid Arthritis.

Xiaojuan Li[1], Daniel Kuo[2], Warapat Virayavanich[2], Thomas M. Link[2], Sarah B. Gratton[2], Jonathan Graf[2] and John Imboden[2]. [1]University of California, San Francisco, San Francisco, CA, [2]University of California, San Francisco

Objective: When assessed qualitatively or semi-quantitatively, bone marrow edema (BME) pattern, the hyperintense region within trabecular bone/bone marrow on T2-weighted fat-suppressed magnetic resonance imaging (MRI), predicts radiographic erosion progression in rheumatoid arthritis (RA). The goal of this study was to develop quantitative measures of BME, including volume, signal intensity and perfusion parameters, in the wrist using 3 Tesla (3T) MRI.

Methods and Materials: 10 patients (56.8 ± 12.9 years, 7 females) who fulfilled ACR classification criteria for RA and 3 healthy controls (36.2 ± 17.2 years, 2 females) were recruited. All patients were on disease-modifying anti-rheumatic drugs with (n=2) or without (n=8) biological agents. All MRI data were acquired with a 3T GE Signa scanner using an 8-channel wrist coil. Coronal T2-weighted fast spin-echo (FSE) images (TR/TE=3500/50ms, in plane resolution = 0.2 mm, slice thickness = 2 mm) were acquired using iterative decomposition of water and fat with echo asymmetry and least-squares estimation (IDEAL) sequences. Coronal 3D dynamic contrast enhanced images were acquired during Gd-DTPA injection (TR/TE = 6.4/2.1ms, in plane resolution = 0.4 mm, slice thickness = 3 mm, temporal resolution 12 s, 32 time points). A semi-automatic algorithm was developed to segment BME in T2-weighted IDEAL FSE images. Volume, and signal intensity change of BME compared to normal bone marrow (NBM), defined as (SIBME – SINBM)/SINBM, were calculated automatically. Perfusion parameters were calculated based on the signal-time curve obtained from DCE-MRI, including slope (S) = (SImax-SIbase)/(SIbase* Tmax) and maximum enhancement (E) = (SImax-SIbase)/SIbase. Two subjects were scanned twice and coefficients of variation (CV) of BME quantification were calculated for evaluating reproducibility. Spearman correlation coefficients between imaging measures and clinical evaluation (DAS28, ESR, and C-reactive protein, CRP) were calculated. Perfusion measures within BME were compared to outside BME using a paired t-test.

Results: The mean DAS28, ESR and CRP was 3.23 ± 1.43, 18 ± 17 mm/h, and 2.9 ± 2.3 mg/l, respectively. Nine patients had BME. The mean volume and signal intensity change of BME was 0.89 ± 1.05 cm3 and 6.09 ± 1.51, respectively. Quantification of BME volume showed good reproducibility (mean CV 6.9%). The maximum enhancement and slope were significantly higher in BME compared to normal bone marrow (1.5 ± 1.2 vs. 1.1 ± 0.6, p<0.001; 1.8 ± 0.5 vs. 0.9 ± 0.3, p<0.001), indicating increased perfusion in areas of BME. BME quantification did not correlate significantly with DAS28, ESR, or CRP. BME was detected in 3 of the 4 RA patients who had DAS28<2.6.

Conclusions and Discussion: BME quantification using IDEAL sequences was highly reproducible. In this preliminary study, there were discrepancies between BME burden and clinical measures of disease activity, with BME present in the majority of patients in remission by DAS28. Quantifying BME may provide a useful parameter to assess the adequacy of therapeutic response on the

individual patient level. Future work will examine the relationship between BME quantification and disease progression.

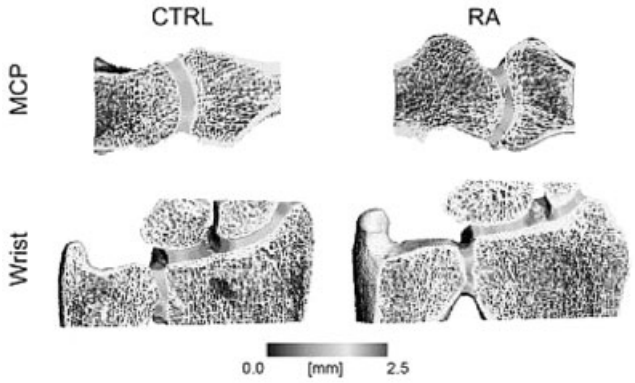
Quantitative In Vivo HR-pQCT Imaging of 3D Radiocarpal and Metacarpophalangeal Joint Space Distances in Rheumatoid Arthritis. Andrew J. Burghardt[2], Christina Kurhanewicz[3], John B. Imboden[1], Sharmila Majumdar[3], Thomas M. Link[3] and Xiaojuan Li[2]. [1]Department of Medicine, University of California, San Francisco and Division of Rheumatology, San Francisco General Hospital, [2]Musculoskeletal Quantitative Imaging Research Group, Department of Radiology and Biomedical Imaging, University of California, San Francisco, San Francisco, CA, [3]Musculoskeletal Quantitative Imaging Research Group, Department of Radiology and Biomedical Imaging, University of California, San Francisco

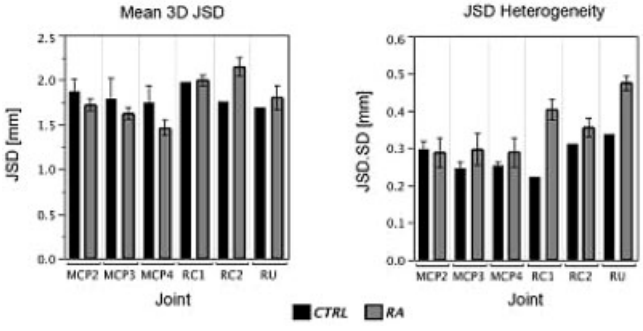
Purpose: In this technique development study, high-resolution peripheral quantitative computed tomography (HR-pQCT) was applied to non-invasively image the radioulnar (RU), radiocarpal (RC) and metacarpophalangeal (MCP) joints of patients with established rheumatoid arthritis (RA). Automated image processing methods were developed to quantify 3D MCP joint space morphology.

Methods: HR-pQCT imaging (82μm isotropic resolution) of the dominant hand was performed in patients with diagnosed rheumatoid arthritis (RA, N=7, age:54±14) and young healthy controls (CTRL, N=2, age:36±17). An automated segmentation technique was developed to individually segment the articulating joint space in the RU, two RC, and the 2nd to 4th MCP joints. The 3D distance transformation approach was applied to spatially map joint space distance and was summarized by the mean joint space distance (JSD) and standard deviation (JSD.SD) – a measure of joint space heterogeneity. The *in vivo* precision for each measure was characterized using root mean square coefficient of variation (RMSCV%) from repeat acquisitions performed on two RA patients.

Results: The *in vivo* reproducibility was high for JSD (RMSCV: 1.3%) and moderate for JSD.SD (RMSCV: 9.4%) despite one repeat measure with substantial motion artifacts. Qualitatively, the HR-pQCT images and JSD maps showed global joint space narrowing as well as focal defects in RA patients compared to CTRL (Fig 1).



In a modest number of subjects there was a general trend for decreased JSD at the MCP and comparable or greater JSD at the radial joints in RA subjects compared to CTRL. Joint space heterogeneity (JSD.SD) all tended to be greater in RA patients compared to CTRL (Fig 2).



Conclusions: This study has established the feasibility of *in vivo* quantification of 3D joint space morphology in RA using HR-pQCT. This technology has the potential to provide a highly resolved, longitudinal assessment of joint morphology, which could provide new insights into clinical research studies of early disease progression and the efficacy of therapeutic interventions.

Radiographic Severity of Knee Osteoarthritis Predicts Quantitative Bone Marrow Lesions on MRI. Svetlana Krasnokutsky[4], Ravinder Regatte[2], Jenny Bencardino[2], Leon Rybak[2], Ilana Belitskaya-Lévy[2], Jonathan Samuels[1], Mukundan Attur[3] and Steven B. Abramson[4]. [1]New York University Hospital for Joint Disease, New York, NY, [2]NYU Langone Medical Center, [3]NYU Langone Medical Center, NYU Hospital for Joint Diseases, [4]NYU Langone Medical Center, NYU Hospital for Joint Diseases, New York, NY

Objective: To evaluate the relationship of quantitative assessment of Bone Marrow Lesions (BML) with knee OA severity by radiographic findings.

Methods: 58 OA patients (mean age 62±10, mean BMI 27±3, 59% female) underwent standardized nonfluoroscopic fixed-flexion knee radiographs. Two radiologists read the X-rays for KL grade, joint space width (JSW), and, using the OARSI atlas, joint space narrowing (JSN) and osteophytes; inter-reader agreement was assessed using Kappas and concordance correlation coefficients. Linear and logistic regression analysis was performed to assess associations while controlling the effects of age, sex and BMI. 3T-MRI included sagittal T2-weighted fat saturated spin-echo images (TR/TE=4000ms/75ms, FOV=15cm, matrix=256×128, slice thickness=3.0mm, receiver bandwidth 130Hz/pixel) and in/out of phase of FLASH images. Compartment-wise (medial tibial, lateral tibial, medial femur, lateral femur) BML volumes were quantified with T2-weighted fat saturated images and in/out of phase images respectively. BML volumes were dichotomized for statistical analysis.

Results: KL score was a significant predictor of total BML volume (OR = 8.41, p = 0.0235). Medial tibial JSW, OARSI medial JSN, and medial tibial plateau osteophytes approached significance as predictors of BML volume at the medial tibia (OR = 0.71, p = 0.0551; OR = 2.16, p = 0.0597; and OR = 2.68, p = 0.0875, respectively). OARSI lateral JSN was a significant predictor of BML volume at the lateral tibia (OR = 3.62, p = 0.0169). Lateral tibial plateau osteophytes were predictors of total BML volume (OR = 4.58, p = 0.0299) and of BML volume at the lateral tibia (OR = 2.31, p = 0.0685). Lateral femoral condyle osteophytes approached significance as a predictor for BML at the lateral femur (OR = 2.25, p = 0.0651). Furthermore, quantitative BML volume strongly correlated with total quantitative synovial volume measured on MRI (β = 0.22, p = 0.0003).

Conclusions: Our data indicate that BML volume on MRI is a characteristic feature of progressive stages of OA, which not only correlates with JSN and osteophytes, but does so in a compartment-specific way. The data suggest that the altered mechanical forces that promote compartmental disease in OA lead to BML, JSN and osteophyte formation. Whether BML further contribute to cartilage loss, and are therefore targets of therapeutic intervention, remains to be determined.

REMISSION^{PLUS}: Multicenter Evaluation of Low-Field MRI for Monitoring Treatment Response in Rheumatoid Arthritis Patients. Ben Ostendorf[8], Sabine Kamp[8], Birthe Koerbl[2], Dorothea Reichelt[1], Klaus Strassburger[2], Axel Scherer[1], Sabine Blaschke[9], Edmund Edelmann[6], Ino Gao[7], Gernot Keyβer[11], Hans-Martin Lorenz[5], Ulf Müller-Ladner[10], Hans-Georg Pott[3], Marisa Walther[4] and Matthias Schneider[8]. [1]Department of Radiology, Heinrich-Heine-University Düsseldorf, Düsseldorf, NRW, Germany, [2]German Diabetes Center at the Heinrich-Heine-University Düsseldorf, Leibniz Center for Diabetes Research, Institute of Biometrics and Epidemiology, Düsseldorf, NRW, Germany, [3]Rheumatology Center, Hannover, Hannover, Germany, [4]Rheumatology Clinic, Berlin-Buch, Berlin, Germany, [5]Rheumatology Department, Heidelberg University Hospital, Heidelberg, Germany, [6]Rheumatology Office, Bad Aibling, Bad Aibling, Germany, [7]Rheumatology Office, Heidelberg, Heidelberg, Germany, [8]Rheumatology, Department of Endocrinology, Diabetology and Rheumatology, Rhine-Ruhr Rheumatology Center, Heinrich-Heine-University Düsseldorf, Düsseldorf, NRW, Germany, [9]Rheumatology, Göttingen University Hospital, Göttingen, Germany, [10]Rheumatology, Kerckhoff Clinic, Bad Nauheim, Germany, [11]Rheumatology, Martin Luther University, Halle-Wittenberg, Halle, Germany

Objective: Multicenter evaluation of low-field MRI as a tool for monitoring treatment response in patients with rheumatoid arthritis (RA) on the REMISSION PLUS pilot project.

Methods: RA patients initiating treatment with a DMARD or biologic at 9 sites throughout Germany underwent low-field MRI (C-scan, Esaote, 0.2 T) of the clinically dominant hand at time points T0 (baseline), T1 (3 months) and T2 (6 to 12 months). The images were evaluated semiquantitatively using the RAMRIS scoring system and correlated with clinical and lab chemistry markers.

Results: 206 RA patients (T0), 58 = m, 148 = f, age (years): (mean=55.87, min.19, max. 84), time since diagnosis: (median=20.32 months, min. 0.2 months, max. 45 years), DAS28 (mean = 4.83, 2.1 – 8), rheumatoid factor positive n = 118, CCP antibody positive n = 118, treatment naive: n = 64, switching treatments: n = 187; MRI follow-up at 3 months (T1) and at 6 to 12 months (T2); T0 and T2: n=96; T0, T1 and T2: n=55. RAMRIS (T0-T1-T2): 41.58-29.62-21.91; MCP: 13.31-8.76-6.38; wrist: 28.19-20.74-15.50; synovitis score (MCP): 5.11-3.06-1.60; wrist: 4.47-3.64-2.54; edema score (MCP): 2.85-1.74-0.91; wrist: 10.04-5.60-2.91; erosion score (MCP): 5.35-4.13-3.87; wrist: 13.68-11.49-10.06; SRM (standardized response mean (> 0.5 moderate potential to detect changes)) T0-T2 synovitis: 0.999 (MCP); 0.709 (wrist), edema: 0.702 (MCP); 0.792 (wrist); p-correlations T0-DAS28 for synovitis: 0.010 (MCP); 0.037 (wrist); for edema: 0.507 (MCP); 0.049 (wrist); T0-CRP for synovitis: 0.538 (MCP); 0.276 (wrist); for edema: 0.154 (MCP); 0.011 (wrist).

Conclusions: Low-field MRI is a sensitive imaging method and RAMRIS a practicable scoring system for morphological and semiquantitative evaluation of therapeutic response to real-life rheumatologic care in significant correlation to clinical and lab data. The added benefit of low-field MRI is that it provides in-depth information on the severity of synovitis, edema (significant reduction on treatment) and erosion during follow-up, hence enabling early identification of responders/non-responders and providing a basis for individual prediction of prognosis and optimal disease management.

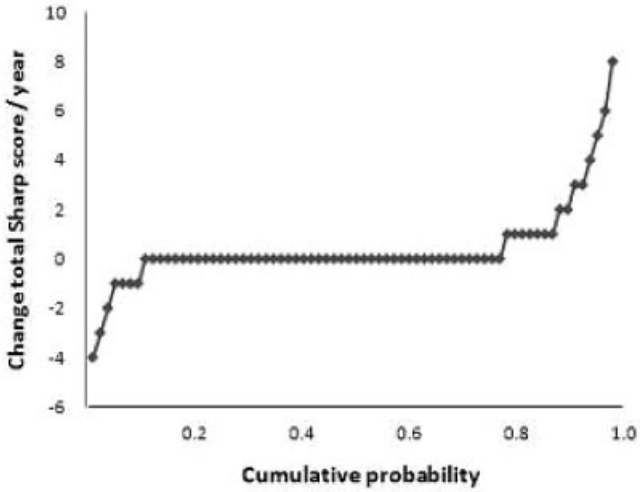
Repair of Bone Erosions in Patients Treated with TNF Antagonists in the Real World. Kaoru Takase[2], Kouji Kobayashi[3], Kayo Terauchi[3], Toshiyuki Watanabe[3], Reikou Watanabe[3], Maasa Hama[3], Rhusuke Yoshimi[3], Hiroshi Kobayashi[3], Atsushi Ihata[3], Atsuhisa Ueda[3], Mitsuhiro Takeno[3], Haruko Ideguchi[1], Shigeru Ohno[1] and Yoshiaki Ishigatsubo[2]. [1]Center for Rheumatic Diseases, Yokohama City University Medical Center, [2]Department of Internal Medicine and Clinical Immunology, Yokohama City University Graduate School of Medicine, Yokohama, Japan, [3]Department of Internal Medicine and Clinical Immunology, Yokohama City University Graduate School of Medicine

Objectives: A number of clinical studies have shown that TNF antagonists suppress not only clinical symptoms but also the progression of joint destructions in patients with RA. Moreover, the therapeutic effects are accompanied by repair of bone erosions in some patients, though the prevalence is uncertain in the real world. We have previously reported that repair of bone erosions was found in 10.7% of RA patients treated with nonbiologic DMARDs. This study investigated the frequency of repair in RA patients receiving TNF antagonists and characterized clinical features in the patients.

Methods: Seventy RA patients (63 female, 7 male; age range, 28–76 years) who fulfilled the 1987 ACR classification criteria and received TNF antagonists for longer than one year were enrolled in this study. Radiographs of hands and feet were evaluated before the initiation of the TNF antagonists including infliximab, etanercept, and adalimumab, and thereafter annually according to the van der Heijde modified Sharp score. Bone erosion was defined as a discrete interruption of the cortical surface, based on standard plain film radiograph criteria. Evaluators assessed the findings without clinical information and chronological orders of radiographs in the same patient. The patients who had repair of bone erosion in any joints were defined as the repaired group, while the others were into the non-repaired group.

Results: Mean yearly progression of total Sharp score was 0.39 in all subjects. The score was increased in 15, decreased in 7, and unchanged in 48 patients after one year.



Progression of bone erosions in any joints were observed in 10 patients, while 6 patients (8.6%) having repair were categorized into the repaired group. Representative images are shown.

Therapies in the repair group were as follows; etanercept + MTX + PSL 2, etanercept + MTX 1, etanercept + PSL 1, etanercept alone 1, and infliximab + MTX + PSL 1. Three of them were concurrently treated with MTX. There were no differences in Stage, Class, and DAS28 before the initiation of TNF antagonists. The repaired group showed more favorable clinical responses to TNF antagonist therapy compared with the non-repair group. Most patients had a good response according to EULAR criteria. DAS28 was statistically more reduced in the repaired group than that in non-repaired group during the first one year of TNF antagonist therapy ($P<0.05$).

Discussions: The present study showed that repair of bone erosion is associated with good response to treatment with TNF antagonists. Well controlled disease activity is a precondition for structural recovery, irrespective of therapeutic agents.

Responsiveness to Change and Reliability of Radiographic Joint Space Width in Osteoarthritis of the Knee: A Systematic Review. William M. Reichmann[2], Jean Francis Maillefert[4], David J. Hunter[5], Jeffrey N. Katz[1], Philip G. Conaghan[3] and Elena Losina[2]. [1]Brigham & Womens Hosp, Boston, MA, [2]Brigham and Womens Hospital, Boston, MA, [3]Chapel Allerton Hospital, Leeds, United Kingdom, [4]Dijon University Hospital, Dijon, France, [5]University of Sydney, Boston, MA

Introduction: The quest for disease modifying OA drugs is anchored on the availability of responsive and reliable methods of measuring structural progres-

sion. The goal of this systematic review was to report the responsiveness to change and reliability of joint space width (JSW) measured on conventional knee radiographs.

Methods: We searched the PubMed and Embase databases using the following search criteria: (osteoarthritis [MeSH]) AND (knee) AND (x-ray OR radiography OR diagnostic imaging OR radiology OR disease progression) AND (joint space OR JSW or disease progression). The search was not limited by publication date and the last search occurred in January 2009. We assessed responsiveness by calculating the standardized response mean (SRM), defined as the mean change in JSW divided by the standard deviation of change. An SRM that is greater than 0.4 is considered to have moderate responsiveness. We assessed reliability using intra- and inter-reader intra-class correlation (ICC; higher ICCs indicate more reliable estimates) and coefficient of variation (CV, calculated as standard deviation/mean; higher CVs indicate less reliable estimates). The I-squared statistic was used to assess heterogeneity of study estimates (0=no heterogeneity; 1= complete heterogeneity). Random-effects models were used to pool results from multiple studies. Results were stratified by technique for obtaining radiographs, measurement method, design, and study duration.

Results: 998 articles were identified using the search terms. Of these, 32 articles (43 estimates) reported data on responsiveness and 24 articles (50 estimates) reported data on reliability. For studies assessing responsiveness the I-squared statistic was 0.82, indicating substantial heterogeneity. The overall pooled SRM was 0.33 (95% CI: 0.26, 0.41). Responsiveness to change in JSW was substantially greater in studies of greater than 2 years duration (SRM=0.57; 95% CI: [0.39, 0.75]; see Table). The pooled intra-reader ICC was estimated at 0.97 (95% CI: 0.92, 1.00) and the intra-reader CV at 3.0% (95% CI: 2.0%, 4.0%). The pooled inter-reader ICC was estimated at 0.93 (95% CI: 0.86, 0.99) and the inter-reader CV at 3.4% (95% CI: 1.3%, 5.5%).

Table. Results of random-effects pooling for studies that reported estimates of responsiveness by different study characteristics

	Number of Estimates	Mean Sample Size	Pooled SRM (95% CI)
Overall	43	100	0.33 (0.26, 0.41)
Knee Flexion			
Extended	16	102	0.32 (0.26, 0.37)
Flexed	27	99	0.34 (0.22, 0.45)
Use of Fluoroscopy			
Fluoroscopy used	23	104	0.38 (0.27, 0.48)
Fluoroscopy not used	20	96	0.28 (0.17, 0.39)
Measurement Method			
Manual	18	97	0.38 (0.26, 0.50)
Computerized	24	104	0.31 (0.20, 0.41)
Study Type			
RCT	19	135	0.30 (0.20, 0.40)
Cohort	24	73	0.36 (0.24, 0.49)
Follow-up Time			
1-year or less	21	71	0.24 (0.15, 0.32)
1–2 years	10	144	0.25 (0.13, 0.37)
Greater than 2 years	12	115	0.57 (0.39, 0.75)

Conclusions: There was considerable heterogeneity in estimates of responsiveness to change of quantitative JSW measured on conventional radiographs. Studies of greater than 2 years duration provided the greatest responsiveness, while methods of obtaining and measuring radiographs did not have a large impact on responsiveness. Measurement of radiographic JSW is reliable. These data will be useful in planning RCTs that use change in minimum JSW as the outcome of interest.

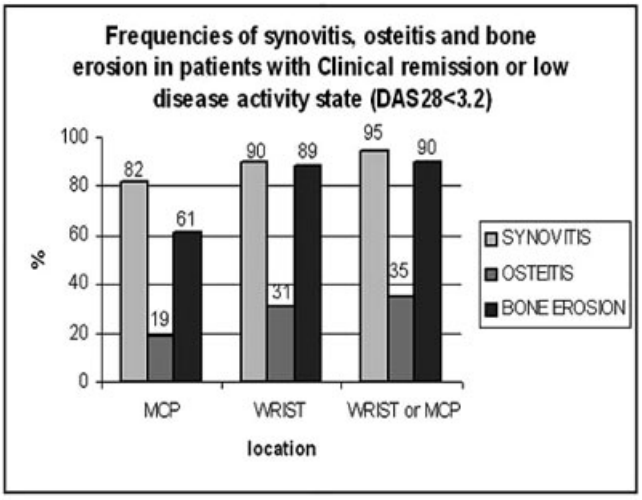
Synovitis and Osteitis Is Very Frequent in Rheumatoid Arthritis (RA) Patients in Clinical Remission: Results from a MRI Study of 300 RA Patients in Clinical Remission or Low Disease Activity State. Frederique Gandjbakhch[5], Philip G. Conaghan[12], Bo Ejbjerg[2], Espen Haavardsholm[3], Violaine Foltz[6], Andrew Brown[12], Uffe Moller Dohn[11], Marissa Lassere[9], Jane Freeston[12], Pernille Bøyesen[3], Paul Bird[4], Bruno Fautrel[6], Merete Lund Hetland[2], Paul Emery[1], Pierre Bourgeois[6], Kim Hørslev-Petersen[8], Tore Kvien[3], Fiona M. McQueen[10] and Mikkel Østergaard[7] [1]Chapel Allerton Hospital, Leeds, United Kingdom, [2]Copenhagen University Hospitals at Hvidovre and Glostrup, Denmark, [3]Diakonhjemmet Hospital, University of Oslo, Oslo, Norway, [4]Division of Medicine, University of NSW, Sydney Australia, [5]Hôpital Pitié-Salpétrière, Université PARIS VI - UPMC, Paris, France, [6]Hôpital Pitié-Salpétrière, Université PARIS VI-UPMC, Paris, France, [7]Hvidovre University Hospital, Hvidovre, Denmark, [8]King Christian X's Hospital for Rheumatic Diseases, University of Southern Denmark, [9]St. George Hospital, University of NSW, Sydney, Australia, [10]Univ of Auckland Sch of Med, Auckland, New Zealand, [11]University Hospitals at Hvidovre and Glostrup, Denmark, [12]University of Leeds, Leeds, UK

Background: The OMERACT rheumatoid arthritis magnetic resonance imaging score (RAMRIS) has been validated for RA monitoring and has been demonstrated to be reliable, sensitive to change and discriminative. Structural progression may occur despite clinical remission. However, remission and low disease activity (LDA) are defined on clinical criteria, and MRI may reveal subclinical inflammation.

Objective: To determine MRI characteristics of RA patients in clinical remission or LDA state.

Materials and Methods: Databases issued from 6 different cohorts were collected from 5 centres. RA patients in clinical remission or LDA state (defined as DAS28-CRP < 3.2) with available MRI data were included. MRIs were assessed according to RAMRIS. Data were analysed using SAS software, version 9.1.

Results: 300 patients in clinical remission (219 patients) or LDA state (81 patients) were included. Patient characteristics: 69% female, age: median 55(IQR 43–63) years, disease duration 2.4(0.7–5.1) years, DAS28-CRP 2.2(1.7–2.6), SDAI: 3.9(1.9–6.5), CDAI: 3.1(1.5– 5.8), RF/anti-CCP positivity: 56%/54%, presence of radiographic erosions: 67 %. Wrist and MCP-MRI data were available for 287 patients and 247 patients respectively. MRI inflammatory activity was observed in the majority of patients, as synovitis and bone edema (osteitis) were observed in wrist or MCP joints in 95 % and 35% of the patients, respectively (figure1). The median (IQR) RAMRIS score for synovitis was 6(3–9) and for osteitis was 0(0–2).



The occurrence of synovitis and bone edema was not significantly different between patients in DAS28-clinical remission (synovitis/osteitis 96%/35%) and patients in LDA but not remission (synovitis/osteitis 91%/36%)(p=0.15/0.87). A trend towards lower frequencies of synovitis and osteitis in patients fulfilling more stringent remission criteria (SDAI and CDAI) was observed (data not shown).

Conclusion: Subclinical inflammation was revealed by MRI in the majority of RA patients in clinical remission or LDA state. This may explain structural progression in such patients. It should be considered whether future remission criteria should include modern imaging.

142

The Intra- and Inter-Reader Reliability of the Oslo Hand Osteoarthritis (HOA) Magnetic Resonance Imaging (MRI) Score. Ida Kristin Haugen[2], Siri Lillegraven[2], Barbara Slatkowsky-Christensen[2], Espen Haavardsholm[2], Sølve Sesseng[2], Tore K. Kvien[1], Desiree M. Van Der Heijde[3] and Pernille Bøyesen[2]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Diakonhjemmet Hospital, [3]Leiden University Medical Center, Meerssen, The Netherlands

Background: HOA is increasingly recognized to involve the whole joint, incl. articular cartilage, subchondral bone, synovium, capsule and ligaments. MRI has a unique advantage to depict all joint components, and may be useful in evaluation of emerging treatments.

Objectives: To examine if pathological HOA features can be reliably assessed by testing the intra- and inter-reader reliability of the proposed Oslo HOA MRI score [1].

Methods: The exercise was performed using MRI scans from 10 patients (9 women) with mean (SD) age of 69.5 (6.1) years from the Oslo HOA cohort [2]. The patients were selected from quintiles of radiographic severity. The dominant hand was anchored in a cylindrical coil (diameter 100 mm), and the distal (DIP) and proximal interphalangeal (PIP) joints of the 2nd-5th fingers were examined using a high-field extremity MRI unit (1.0 T). Coronal, sagittal and axial T1w fat-suppressed pre-and postgadolinium images were reproduced from a 3D dual echo Dixon technique (TR 20 ms, TE 5 ms, 1 mm slice thickness), in addition to coronal and axial Short T1 Inversion Recovery (STIR) images (TR 2850/3150 ms, TE 16.3/21 ms, 2/3 mm slice thickness). A training session and two exercises were arranged prior to this study. The images were read by three assessors (IKH, SL, PB) in accordance to the proposed MRI score of the DIP and PIP joints in HOA: Synovitis (grade 0–3), flexor tenosynovitis (grade 0–3), erosions (grade 0–3), cysts (grade 0–1), osteophytes (OP) (grade 0–3), joint space narrowing (JSN) (grade 0–3), malalignment (grade 0–1 in frontal and sagittal plane), bone marrow lesions (BML) (grade 0–3) and collateral ligament (CL) presence (grade 0–1), and BML at CL insertion sites (grade 0–1). The readers were blinded for patient characteristics. The images were read twice with one week interval, and were anonymised and rearranged prior to the last scoring session. Mean scores for all features across the three readers were calculated. The intra- and inter-reader reliability of the individual subscales was assessed by intra-class correlation coefficients (ICCs) (two way mixed effect model, single and average measure).

Results: Table shows mean (min, max) scores and ICCs for intra- and inter-reader reliability. The range of each feature is reported in brackets. Inter-reader reliability was good to excellent for synovitis, tenosynovitis, erosions, OP, JSN, malalignment, BML and CL presence. The median intra-reader reliability was good to excellent for most features except synovitis, tenosynovitis and cysts.

Table

DIP and PIP joints	Mean (min, max)	Inter-reader AvmICC	Intra-reader SmICC median (min, max)
Synovitis [0–24]	11.6 (6.3–15.0)	0.84	0.48 (0.09–0.70)
Flexor tenosynovitis [0–24]	5.9 (1.7–10.3)	0.64	0.51 (0.49–0.65)
Erosions [0–48]	13.1 (2.3–29.0)	0.94	0.92 (0.91–0.96)
Cysts [0–16]	0.4 (0.0–2.0)	0.59	0.21 (0.00–0.57)
Osteophytes [0–48]	22.7 (7.3–34.0)	0.91	0.88 (0.86–0.89)
Joint space narrowing [0–24]	10.8 (0.7–15.3	0.99	0.97 (0.93–0.99)
Malalignment frontal [0–8]	0.9 (0.0–2.3)	0.95	0.79 (0.77–1.00)
Malalignment sagittal [0–8]	0.0 (0.0–0.3)	0.00	*
BMLs [0–48]	4.2 (0.3–9.7)	0.83	0.89 (0.65–0.89)
CL presence [0–16]	10.0 (3.0–14.3)	0.79	0.81 (0.61, 0.81)
BML at CL insertion sites [0–32]	2.4 (0.0–5.0)	0.42	0.81 (−0.07,0.82)

AvmICC=Average measure ICC, SmICC=single measure ICC, BMLs=bone marrow lesions, CL=collateral ligaments, *=no variance

Conclusion: The proposed Oslo HOA MRI score could reliably assess key features of HOA. Further validation of the system to clinical and radiological findings should be performed.

Validity and Responsiveness to Change of Radiograph-Based Joint Space Narrowing Metric Measurement: A Systematic Review. Delphine Chu Miow Lin[6], William M. Reichmann[2], Laure Gossec[4], Elena Losina[1], Philip G. Conaghan[5] and Jean-Francis Maillefert[3]. [1]Department of Orthopaedic Surgery, Brigham and Women's Hospital, Boston, MA, [2]Department of Orthopaedic Surgery, Brigham and Women's Hospital, Boston, MA and 3. Department of Biostatistics, Boston University School of Public Health, Boston, MA, [3]Department of Rheumatology, Dijon University Hospital, Dijon, F-21078, France, University of Burgundy, Dijon, F-21079, France, INSERM U887, Dijon, F-21079, France, [4]Paris Descartes University, Medicine Faculty; UPRES-EA 4058; APHP, Rheumatology B Department, Cochin Hospital, Paris France, [5]Section of Musculoskeletal Disease, University of Leeds & NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, [6]Tours Medicine Faculty; Department of Rheumatology, Tours University Hospital, Tours, France

Introduction: The quest for disease modifying Osteoarthritis (OA) drugs is anchored on the availability of responsive and reliable methods of measuring structural progression. The goal of this systematic review was to report the responsiveness to change and reliability of conventional hip radiographic joint space width (JSW). We performed a systematic analysis of the literature on the concurrent validity, predictive validity and responsiveness of radiographic metric measurement of coxo-femoral joint space in hip OA.

Method: We searched studies reporting any data on 1- hip OA patients in whom a metric measurement of the coxo-femoral JSW on X-rays was performed and 2- on correlations with clinical symptoms and/or with further symptomatic state, joint space loss or joint replacement, and/or JSW change over time. We searched the PubMed and Embase databases using the following search terms ((Osteoarthritis[MeSH] and (hip)) AND (x-ray OR radiography OR diagnostic imaging OR radiology OR disease progression) AND (joint space OR JSW OR disease progression). Pooled SRM were evaluated using data obtained in articles in which the SRM were available or could be calculated from the mean change and standard deviation of change. For randomized clinical trials (RCTs), only the placebo arms were entered. Pooled SRMs were obtained for minimum JSW metric measurement. Additional analyses restricted to cohorts and RCTs, to intention to treat (ITT) and completer analyses, to measurement of joint space performed with manual and computer-based methods, were performed.

Results: Twenty four studies were identified. Five suggested an association between JSW and symptoms in the general population. Two evaluated the correlations between the coxofemoral JSW and symptoms in hip OA patients, with heterogeneous results. Two suggested that joint symptoms are moderately correlated to further joint space loss. Five demonstrated that minimal JSW is predictive of further hip joint replacement. Responsiveness (11 studies, see table) was good, but tended to be lower in randomized clinical trials than in cohort studies, using an intention to treat rather than a completer analysis, and using computer-based rather than manual measurement.

Table. Summary of hip responsiveness from radiographs using random-effects pooling of the standardized response mean (SRM) of the minimum joint space narrowing.

Analysis	Number of Studies	Mean Sample Size	SRM	95% Confidence Interval
Overall	11	164	0.66	0.41–0.91
Study design				
RCT	4	111	0.35	0.12–0.57
Cohort	7	194	0.83	0.49–1.16
Analysis				
Completers	8	176	0.80	0.50–1.10
ITT	3	132	0.30	0.06–0.55
Measurement Technique				
Computer	4	40	1.12	0.64–1.59
Manual	7	234	0.47	0.31–0.62

RCT = randomized controlled trial, ITT = intention-to-treat

Conclusion: There is some evidence of a weak association with symptoms and evidence of at least moderate responsiveness of metric measurement of JSW and symptoms in hip OA.

A Single Cohort, Dose Escalation Phase 1 Study of Intravenous Infusion of Pegsiticase (Formerly Uricase-PEG 20), a Drug for Managing Hyperuricemia in Refractory Gout. Tony Fiorino[3], Alan J. Kivitz[1], Patricia Pardo[5], Rocelle Flores[2], Zhihua Zhang[2] and John S. Bomalaski[4]. [1]Altoona Arthritis & Osteo Ctr, Duncansville, PA, [2]EnzymeRx, [3]EnzymeRx, Paramus, NJ, [4]EnzymeRx, Wayne, PA, [5]Miami Research Associates, Miami, FL

Background: The enzyme uricase, found in most mammals but not humans, metabolizes uric acid into the highly soluble allantoin and represents a potential treatment for patients suffering from tophaceous and refractory gout. As a foreign protein, uricase is highly immunogenic and not suited for

chronic use. Pegsiticase is a pegylated recombinant uricase designed to have an extended half life and reduced that has been previously studied as a single intramuscular dose in a phase 1 study in gout patients. It has not yet been studied as an intravenous agent.

Methods: This was an open label, single dose escalation phase 1 study in healthy volunteers and gout patients. Subjects of age 40–75 with screening plasma uric acid ≥ 6 mg/dL for men and ≥5 mg/dL for women were eligible to participate. The study enrolled five cohorts (4 subjects per cohort) at doses of 0.05, 0.1, 0.2, 0.3, and 0.4 mg/kg, respectively. Pegsiticase was administered via intravenous infusion over one hour without premedication, and subjects were followed for 24 days. The primary endpoint was safety and tolerability and the secondary endpoints were pharmacodynamics (plasma uric acid), and pharmacokinetics (serum uricase activity). Adverse events were graded according to the Common Toxicity Criteria for Rheumatology, version 2.0.

Results: Pegsiticase was well tolerated in this study. No serious or grade 3 adverse events were observed, and no infusion or allergic reactions were observed in any subjects. The only observed grade 2 toxicities were gout flares. Plasma uric acid level decreased upon infusion of pegsiticase, with the rate of uric acid decrease exhibiting dose-dependence At 0.05 mg/kg, uric acid levels decreased from a baseline of 8.3 mg/dL to almost undetectable levels within 24 hours of the infusion, whereas at the highest dose (0.4 mg/dL), plasma uric acid decreased from a mean of 7.8 mg/dL to undetectable levels within 3 hours. All subjects responded to pegsiticase, and the duration of uric acid suppression below 2 mg/dL ranged from 7 to 24 days, in a dose-dependent manner. In the highest dose cohort, all four subjects maintained plasma uric acid at or near the limit of detection for the entire 24 day follow-up period.

Conclusions: A single intravenous infusion of pegsiticase was safe and well-tolerated in these 20 subjects, and was capable of profoundly suppressing uric acid levels for up to 24 days. Further study of intravenous pegsiticase as a chronic therapy in gout patients is warranted.

145

Canakinumab (ACZ885) Relieves Pain and Controls Inflammation Rapidly in Patients with Difficult-To-Treat Gouty Arthritis: Comparison with Triamcinolone Acetonide. A. So[6], M. De Meulemeester[4], A. Pikhlak[2], A. E. Yücel[1], U. Arulmani[3], D. Richard[3], V. Murphy[3], P. Sallstig[3] and N. Schlesinger[5]. [1]Baskent University, Ankara, Turkey, [2]Moscow State University of Medicine and Dentistry, Moscow, Russian Federation, [3]Novartis Pharma AG, Basel, Switzerland, [4]Private Practice, Gozée, Belgium, [5]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ, [6]University of Lausanne, Lausanne, Switzerland

Purpose: Monosodium urate (MSU) crystals stimulate the production of interleukin (IL)-1β, a potent inflammatory cytokine. Targeted IL-1β blockade with canakinumab, a fully human monoclonal anti-IL-1β antibody, is a novel treatment for gouty arthritis. Its effects on pain and inflammation in acute gouty arthritis flares were compared with triamcinolone acetonide (TA). TA has been shown to be effective in the treatment of acute gouty arthritis flares[1].

Methods: This was an 8-week, dose-ranging, multicenter, blinded, active-controlled trial. Patients ≥18 to ≤80 years with an acute gouty arthritis flare, refractory to or contraindicated to NSAIDs and/or colchicine were randomized to 1 subcutaneous dose of canakinumab (10, 25, 50, 90, or 150 mg; n=143) or 1 intramuscular dose of TA (40 mg; n=57). Primary outcome was pain intensity at 72 hours post dose on VAS scale (0–100 mm). Secondary outcomes included C-reactive protein (CRP), serum amyloid A (SAA), and physician's assessment of tenderness, swelling and erythema of target joint at 72 hours, 7 days, 4- and 8-weeks post dose.

Results: 191/200 patients completed the study. Canakinumab showed a statistically significant dose response at 72 hours. The 150 mg dose group reached superior pain relief compared to TA group starting from 24 hours as previously reported[2]. At 72 hours post dose, 78% of canakinumab 150 mg treated patients achieved ≥75% and 96% achieved ≥50% reduction in pain from baseline. In contrast, 45% and 61% of patients treated with TA achieved ≥75% and ≥50% pain reduction, respectively. Median CRP/SAA levels were normalized by Day 7 for all canakinumab doses above 10 mg and remained below the Upper Limit of Normal [(ULN): CRP 3.0 mg/L; SAA 6.7 mg/L)] for rest of the study. In TA group, median CRP levels remained above the ULN throughout the study while median SAA levels decreased below ULN only 28 days after first dose. At 72 hours post dose, canakinumab 150 mg group was 3.2 (95% CI, 1.27–7.89) times more likely to have less joint tenderness and 2.7 (95% CI, 1.09–6.5) times more likely to have less joint swelling than TA group ($p<0.05$). At 72 hours post dose, erythema disappeared in 74.1% of patients receiving canakinumab 150 mg and 69.6% of patients receiving TA. At 7 days post dose, erythema was absent in 96.3% of canakinumab 150 mg treated patients vs. 83.9% of patients receiving TA. The overall incidence of AEs was similar for canakinumab (41%) and triamcinolone acetonide (42%). Serious AEs (canakinumab treatment groups n=4, TA n=1) were not considered treatment related by investigators. No discontinuations occurred due to AEs.

Conclusions: Canakinumab 150 mg provided superior pain relief compared to TA for acute flares in difficult-to-treat gouty arthritis patients. Canakinumab provided rapid normalization of markers of inflammation accompanied by reduction of clinical signs and symptoms of inflammation.

Change in Uric Acid Level Is Associated with Change in Patient Reported Outcomes in the Context of a Clinical Trial for Chronic Gout. Will Taylor[1], Steve Hamburger[2], Lisa K. Stamp[5], Zebulun D. Horowitz[3] and Nicola Dalbeth[4]. [1]Department of Medicine, University of Otago Christchurch, New Zealand, [2]Savient Pharmaceuticals, Inc., E. Brunswick NJ, [3]Savient Pharmaceuticals, Inc., E. Brunswick NJ, Baskingridge, NJ, [4]Univ Auckland, Auckland, New Zealand, [5]University of Otago Christchurch, Christchurch, New Zealand

Background: Serum uric acid (SUA) is an important endpoint for clinical trials of gout therapy. It is strongly endorsed by rheumatologists as the most important indicator of response in the context of a clinical trial for chronic gout. It fulfils most of the OMERACT biomarker criteria as a biomarker for patient reported outcomes (PRO), except that change in SUA has never been shown to be independently associated with change in PRO.

Methods: Data from 2 replicate Phase 3 randomised controlled trials of pegloticase were analysed for the association between change in uric acid levels from baseline to final follow-up (6 months) and change in PRO scores (pain, patient global, HAQ-DI, SF-36 MCS and SF-36 PCS). In this study, plasma uric acid levels were measured (PUA). For each PRO, a linear regression model was developed that incorporated final value of PUA, age and sex and a separate model that incorporated the change in PUA, age and sex. Change and final value of PUA were not incorporated together in the same model because of collinearity (correlation - 0.815).

Results: Change in PUA and also final value of PUA was significantly associated with changes in all PRO except the mental health summary score of SF-36. The magnitude of the beta coefficients for change and final value in PUA were similar. The magnitude of the association is weak.

Table 1. Regression models for each PRO by change in PUA and final PUA (all models adjusted for age and sex)

	p-value	Beta coefficient	Overall model r^2
As a predictor of ΔHAQ-DI			
Change in PUA	0.012	0.201	0.055
6 month PUA	0.002	−0.25	0.074
As a predictor of Δpatient global			
Change in PUA	<0.001	−0.299	0.096
6 month PUA	<0.001	0.357	0.129
As a predictor of Δpain			
Change in PUA	0.041	0.164	0.027
6 month PUA	0.004	−0.233	0.051
As a predictor of ΔSF36-PCS			
Change in PUA	0.002	0.247	0.078
6 month PUA	0.003	−0.236	0.070
As a predictor of ΔSF36-MCS			
Change in PUA	0.921	0.008	0.055
6 month PUA	0.702	−0.031	0.056

Conclusion: Although weak, the association of changes in PUA with changes in PRO help confirm that uric acid is a valid biomarker for outcomes of direct relevance for people with chronic gout.

Chronologic Age, Renal Function, and Comorbid Conditions (Physiologic Age) of Patients with Gout Did Not Increase Likelihood of Adverse Events (AEs): AGREE Study Post Hoc Analyses. Daniel E. Furst[1], Paul Maranian[1], Matthew W. Davis[3], Suman Wason[3], Dinesh Khanna[1] and Robert Terkeltaub[2]. [1]University of California Los Angeles, Los Angeles, CA, [2]University of California San Diego, San Diego, CA, [3]URL Pharma, Inc, Philadelphia, PA

Background: Typical patients with gout have multiple comorbidities such as metabolic and cardiovascular (CV) disorders, hypertension, and kidney disease; concern for these conditions can make gout treatment conditions complex. This post hoc analysis was conducted to examine the relationship of age and comorbidities (renal, hepatic, CV function, and body mass index [BMI]) on the adverse event (AE) profile of patients with acute gout who were treated with colchicine.

Methods: A phase 3 multicenter, randomized placebo-controlled trial (AGREE) compared safety and tolerability of 2 different colchicine regimens, low dose (2 × 0.6 mg initially, then 0.6 mg 1 hr later to 1.8 mg/day total) and high dose (2 × 0.6 mg initially, then 0.6 mg/hr to 4.8 mg/day total) versus placebo in patients with gout (N = 185). Data were pooled for the low-dose and high-dose groups. For the present analyses, logistic regression was undertaken using presence or absence of AEs as the dependent variable and the following as independent variables: creatinine clearance (≥60 mL/min); alanine aminotransferase and aspartate aminotransferase ([ALT, AST] above upper limit of normal [ULN]); albumin (≤3.5 g/L); alkaline phosphatase (>ULN); gout duration (years); BMI (>30); age (years); and presence or absence of CV history (eg, myocardial infarction, CV or cerebrovascular illness). Odds ratios (OR) were reported and compared. A Pearson chi-square P value <0.05 was used as the measure of statistical significance.

Results: At baseline, patients had a mean age of 51.5 (standard deviation [SD] = 11.1) years, with a diagnosed gout duration of 10.5 (SD = 8.9) years, a BMI of 33.0 (SD = 5.7), and serum uric acid level of 8.8 (SD = 1.8) mg/dL, and had experienced ≥2 acute gout flares in the 12 months before enrollment. Across the study, 83 patients (~45%) experienced an AE; most of these were mild to moderate gastrointestinal AEs (~73%). Incidence of AEs in patients treated with colchicine was not significantly affected by any of the independent variables analyzed in this study (Table). Additional sensitivity analyses using cutoffs of 3 × ULN for AST (n = 0), ALT (n = 0), and alkaline phosphatase (n = 1), and 3.0 g/L for albumin (n = 0), were not performed because numbers of patients meeting these criteria were negligible.

Table

Independent baseline variables analyzed	Patients, n (%)	Odds ratio	95% Confidence interval	*P* value
Age (continuous)	185 (100.0)	1.00	0.97, 1.03	0.999
BMI >30	125 (67.6)	1.22	0.63, 2.37	0.548
Gout duration >8 years	91 (49.2)	1.24	0.68, 2.25	0.476
Cardiovascular history (yes/no)	107 (57.8)	1.13	0.60, 2.10	0.707
Creatinine clearance ≥60 mL/min	161 (87.0)	0.87	0.34, 2.22	0.778
AST > ULN	12 (6.5)	1.19	0.31, 4.61	0.805
ALT > ULN	31 (16.8)	0.57	0.23, 1.44	0.236
Albumin ≤3.5 g/L	0	—	—	—
Alkaline phosphatase > ULN	2 (1.1)	1.04	0.06, 19.01	0.976

Conclusions: In these regression analyses of 185 patients with gout in a randomized phase 3 study, there was no effect of chronologic age, gout duration, renal function (indicated by creatinine clearance), liver function (as assessed by AST, ALT, albumin, and alkaline phosphatase), presence of CV history, or obesity with the incidence of AEs following colchicine treatment (inclusive of all doses). Although additional studies would be needed to corroborate these results, these data offer reassurance regarding the safety of colchicine in patients with several comorbid conditions.

Colchicine Use Is Associated with Decreased Diagnosis of Myocardial Infarction (MI) and Trend toward Reduction of All-Cause Mortality and C-Reactive Protein (CRP) Levels: Insights from the NY VA Gout Cohort. Aaron Lehmann[5], Laura Schneck[5], Robert T. Keenan[2], William O'Brien[6], Daria B. Crittenden[6], Kristen Lee[6], Rekha Tadoori[6], Jeffrey D. Greenberg[1], Bruce N. Cronstein[3], Steven Sedlis[4] and Michael H. Pillinger[5]. [1]Millburn, NJ, [2]Duke University, Durham, NC, [3]New York Univ Med Ctr, New York, NY, [4]NYU Langone Medical Center, [5]NYU Langone Medical Center, NYU Hospital for Joint Diseases, New York, NY, [6]NYU Langone Medical Center, NYU Hospital for Joint Diseases

Statement of Purpose: Inflammatory mechanisms contribute to the pathogenesis of cardiovascular (CV) disease, and some drugs that reduce CV risk (ex, statins) also reduce inflammatory markers such as CRP. Patients with some chronic inflammatory diseases (ex, rheumatoid arthritis) have increased CV risk that may improve with immune modulation. Gout is a chronic/intermittent inflammatory condition driven by hyperuricemia and uric acid crystal formation, and associated in some studies with increased CV risk. Gout is frequently managed with colchicine, an agent that modulates inflammatory mechanisms of potential relevance to CV disease (leukocyte adhesion molecules expression, IL-1 expression, etc), including lowering CRP even in patients without gout. We tested whether colchicine use alters MI rate, all-cause mortality and CRP levels among patients with gout.

Methods: Using the electronic medical record system (EMR) of the New York Harbor Healthcare System (N=40,107), we identified all patients receiving an ICD-9 gout code at the Manhattan, Brooklyn and St Albans Veterans Affairs Hospitals in New York City between August 2007 and August 2008. Demographics, cardiovascular co-morbidities and endpoints were collected by chart review, including review of each patient's EMR problem list and note review as appropriate. Primary (MI) and secondary (all-cause mortality, CRP level) outcomes were analyzed based on presence/absence of colchicine use. Using ICD-9 codes, patients with osteoarthritis (OA) but no gout were identified to serve as controls for the first phase of the study.

Results: 1,288 gout patients were identified, and 1,288 patients with OA/no gout were randomly selected from among 3,300 to serve as controls. OA and Gout patients were similar in mean age (71 each group) and other demographics, but gout patients had more CV disease (23 vs 31%) and all-cause mortality (2 vs 4.5%), consistent with reports that gout conveys increased CV risk. Gout patients were then divided according to ever or never use of colchicine. Colchicine (N=576) and no colchicine (N=712) groups were similar in age, sex, race, BMI, HTN, blood pressure, smoking, diabetes, kidney disease, hyperlipidemia, peripheral vascular disease, stroke, and serum uric acid. Incidence of MI diagnosis was 2.6% in the no colchicine vs 1.2% in the colchicine group (p=0.04, Fisher's exact test). All-cause mortality rates were 5% (no colchicine) vs 3.9% (colchicine) (n.s.). CRP levels were 4.53 (no colchicine) vs 2.49 (colchicine) mg/dl (n.s.). Use of allopurinol was not associated with reduced MI in either group.

Conclusion: In this retrospective study, gout patients ever vs never treated with colchicine had similar rates of atherosclerosis and fixed cardiovascular disease. Nonetheless, gout patients treated with colchicine demonstrated decreased diagnosis of MI, and trends toward lower CRP levels and all-cause mortality. These data suggest a possible protective effect of colchicine on the incidence of acute coronary syndromes.

Effect of Multiple Doses of Febuxostat on the Pharmacokinetics of a Single Dose of Theophylline. Max Tsai, Jingtao Wu, Lhanoo Gunawardhana and Himanshu Naik. Takeda Global Research & Development Center, Inc., Deerfield, IL

Background: Theophylline is metabolized by cytochrome P-450 (CYP) to 1-methylxanthine, 3-methylxanthine, and 1, 3-dimethyluric acid. Further,

metabolism of 1-methylxanthine to 1-methyluric acid is mediated by xanthine oxidase (XO). Febuxostat is not expected to have any inhibitory effect on the CYP isozymes involved in metabolism of theophylline. However, since febuxostat is a nonpurine selective inhibitor of XO, it could affect the XO-mediated metabolism of theophylline and potentially alter the clearance of theophylline. Since theophylline is a low therapeutic index drug and coadministration with high doses of the XO inhibitor allopurinol results in decreased clearance of theophylline, this study was performed to evaluate the effect of febuxostat and its metabolites at steady-state on the pharmacokinetics of theophylline.

Methods: This was a Phase 1, double-blind, randomized, 2-period crossover study. Twenty-four subjects (12 male and 12 female) were enrolled in the study and were randomly assigned in a 1:1 ratio to receive febuxostat or matching placebo for 7 days. On Day 5 of each period, 400 mg of theophylline was administered followed by collection of plasma and urine pharmacokinetic samples until 72 hours postdose.

Results: Theophylline was absorbed with median T_{max} value of 6 hrs and eliminated with a mean $T_{1/2}$ of 9.69 hrs following oral administration of theophylline 400 mg with placebo or febuxostat. Mean theophylline C_{max} values were 4.14 and 4.39 μg/mL when subjects were coadministered placebo and febuxostat, respectively. Mean theophylline $AUC_{0\text{-}tlqc}$ values were 115 and 122 μg·hr/mL when subjects were coadministered placebo and febuxostat, respectively. Likewise, mean $AUC_{0\text{-}inf}$, $T_{1/2}$, CL/F, and V_z/F values were also comparable between regimens. The mean amount of theophylline excreted in the urine over a 72-hour interval was comparable between the 2 regimens. The mean amounts of 1,3-dimethyluric acid and 3-methylxanthine was also similar between the 2 treatment arms. In contrast, the amount of 1-methyluric acid decreased and 1-methylxanthine increased in subjects following administration of theophylline with febuxostat compared to placebo. The changes in the amounts of metabolites excreted in urine have little or no clinical significance, as neither of these metabolites has pharmacological activity.

The point estimate for the ratio of theophylline C_{max} central values following administration of theophylline with febuxostat or placebo, and corresponding 90% confidence intervals (CIs) were 1.03 and (0.917, 1.149), respectively. The point estimate for the ratio of theophylline $AUC_{0\text{-}tlqc}$ central values following administration of theophylline with febuxostat or placebo, and corresponding 90% CIs were 1.04 and (0.927, 1.156), respectively. Both 90% CIs fell within the *no-effect* range of 0.8 and 1.25.

Conclusions: Coadministration of febuxostat with theophylline has no effect on the pharmacokinetics of theophylline. No dose adjustment for theophylline is required when coadministered with febuxostat.

Effects of a Purine Nucleoside Phosphorylase Inhibitor, BCX4208, on the Serum Uric Acid Concentrations in Patients with Gout. David Fitz-Patrick[2], Waymon Drummond[4], John Pappas[3] and Alan S. Hollister[1]. [1]BioCryst Pharmaceuticals, Inc., Durham, NC, [2]East-West Medical Research Institute, Honolulu, HI, [3]Kentucky Medical Research Center, Lexington, KY, [4]Renaissance Clinical Research, Dallas, TX

Purine nucleoside phosphorylase inhibitors (PNPi) are a novel approach to lowering serum uric acid (sUA) in patients with gout. The specific PNPi, BCX4208, has a 0.52 nM K_i for human PNP. This compound was studied in a randomized, placebo-controlled, double blind three week trial using oral doses of 40, 80, and 120 mg daily in 60 gout patients whose sUA was >8 mg/dL at baseline. Eligible subjects were followed weekly for sUA, safety labs (including lymphocyte subsets), and adverse events during treatment and for 4 weeks of follow-up.

56 males and 4 females (39W, 6B, 5 Pacific Islander, 4 Asian, 6 Other) meeting the ARA criteria for the diagnosis of gout completed the study. Mean (SD) age was 51 (12) years; mean weight was 108 (25) kg. Trial endpoints were: absolute reduction in sUA at 3 weeks, proportion of subjects with sUA <6.0 mg/dL, frequency of gout flares, safety, tolerability, and abbreviated first dose BCX4208 pharmacokinetics.

After 3 weeks of therapy, sUA was reduced by −2.7, −3.3, and −3.4 mg/dL in the 40, 80, and 120 mg/d dose groups of BCX4208, respectively, compared to −0.4 mg/dL in the placebo group ($p<0.001$). No placebo-treated subject achieved a sUA <6.0 mg/dL, whereas 33%, 36%, and 31% of the subjects on BCX4208 at 40, 80, and 120 mg/d, respectively, met this goal at 3 weeks ($p<0.05$). 33%, 57%, and 56% of the BCX4208-treated subjects met this goal at least once during the 3 weeks of treatment ($p<0.001$), and 38%, 60%, and 100% of subjects with baseline sUA <10 mg/dL met this goal at least once during therapy with the 3 respective dose levels ($p<0.001$). One gout flare (1/16) occurred in a subject on 120 mg/d, and two gout flares (one placebo- and one 80 mg/d-treated subject) occurred during the 4 week follow-up period. Lymphocyte subsets (CD4+, CD8+, CD20+, and CD56+ cells) were reduced 30 to 70% by all doses of BCX4208, without a clear dose-response relationship. No subject met pre-defined stopping criteria for lymphocyte subset cell counts during the treatment period. All subjects completed the study and adverse events were evenly distributed in the BCX4208 and placebo arms. There were no serious adverse events. Abbreviated pharmacokinetics on the first day of treatment with BCX4208 showed a dose-proportional increase in C_{max} and AUC_{0-24}.

BCX4208 at 40, 80, and 120 mg/day produced a prompt reduction in sUA in gout patients and achieved the therapeutic goal of < 6.0 mg/dL in up to one-half of the patients during a 3 week trial. The drug produced moderate reductions in lymphocyte subsets, but was well tolerated. PNP inhibition may represent a novel approach to the treatment of gout.

Efficacy and Tolerability of Celecoxib in the Treatment of Moderate to Extreme Pain Associated with Acute Gouty Arthritis: A Randomized Controlled Trial. H. Ralph Schumacher[4], Manuela Berger[3], Julie Li-Yu[5], Fernando Perez-Ruiz[1], Ruben Burgos Vargas[2] and Chunming (Mark) Li[3]. [1]Hospital de Cruces, Baracaldo, Spain, [2]Hospital General de México, México City, Mexico, [3]Pfizer Inc., New York, NY, [4]University of Pennsylvania VA Medical Center, Philadelphia, PA, [5]University of Santo Tomas Hospital, Manila, Philippines

Background: Although nonsteroidal anti-inflammatory drugs (NSAIDs) such as indomethacin are widely used for the treatment of acute gouty arthritis, adverse events (AEs) have limited their use to date. This study was performed to evaluate the efficacy and tolerability of various doses of the cyclooxygenase (COX)-2 selective NSAID celecoxib in the treatment of moderate to extreme pain and inflammation associated with acute gouty arthritis.

Methods: Multinational, randomized, double-blind, double-dummy, active-controlled trial in patients (aged ≥ 18 y) with acute gouty arthritis (onset of pain ≤48 h prior to enrollment). Patients were required to have moderate to extreme pain in the index joint over the previous 24 h (5-point Patient's Assessment of Pain Intensity) and to be candidates for daily therapy with NSAIDs and/or analgesics. Patients with polyarticular (> 4 joints affected)/chronic gout, or other form of arthritis (except mild to moderate osteoarthritis not affecting the index joint) were excluded. The study consisted of an 8-day treatment period followed by 1-week follow-up. Patients were randomized 1:1:1:1 to receive: 1) celecoxib 50mg bid, 2) celecoxib 400mg followed by 200mg on Day 1 and then 200mg bid for 7 days, 3) celecoxib 800mg followed by 400mg on Day 1 and then 400mg bid for 7 days and 4) indomethacin 50mg tid. The primary objective was to evaluate the analgesic efficacy of a high-dose celecoxib regimen (800/400mg) compared with a low-dose regimen (50mg bid) in the treatment of moderate to extreme pain at Day 2. Secondary objectives included the evaluation of the analgesic and anti-inflammatory effects of different celecoxib doses compared with indomethacin 50mg tid; safety and tolerability were also assessed.

Results: Of 443 patients screened, 402 patients were randomized and 400 received treatment. Baseline demographics were comparable between treatments. For the primary end point, patients receiving high-dose celecoxib (800/400 mg) experienced a significantly greater reduction in patients' assessment of pain intensity on Day 2 compared with low-dose celecoxib (50 mg bid; least squares [LS] mean difference −0.46, $P=0.0014$). For high-dose celecoxib 800/400mg, the change in pain scores from baseline to Day 2 was comparable to indomethacin 50mg tid (LS mean difference 0.11, $P=0.4331$). Compared to indomethacin 50mg tid, celecoxib 400/200mg and 50mg bid produced small reductions in pain (LS mean difference 0.33 [$P<0.05$] and 0.57 [$P<0.0001$], respectively). Secondary efficacy and safety findings are presented below.

Table

	Celecoxib 50 mg bid (n = 101)	Celecoxib 400/200 mg bid (n = 99)	Celecoxib 800/400 mg bid (n = 98)	Indomethacin 50 mg tid (n = 102)
Physician's Assessment of Tenderness of the Index Joint (measure of inflammation on Day 5-change from Baseline)				
vs Celecoxib 50mg bid				
LS mean Difference (SE)	—	−0.08 (0.11)	−0.20 (0.11)	—
95% CI		−0.29, 0.14	−0.42, 0.02	
P value		0.4743	0.0737	
vs Indomethacin 50 mg tid				
Ls Mean Difference (SE)	0.26 (0.11)	0.18 (0.11)	−0.06 (0.11)	—
95% CI	0.04, 0.47	−0.04, 0.39	−0.16, 0.27	
P value	0.0200	0.1050	0.0737	
Safety, number (%) of Patients				
Number of AEs	59	43	51	80
AEs	33 (32.7)	27 (27.3)	28 (28.6)	44 (43.1)
Headache	5 (5.0)	4 (4.0)	3 (3.1)	4 (3.9)
Diarrhea	3 (3.0)	2 (2.0)	2 (2.0)	5 (4.9)
Dizziness	2 (2.0)	1 (1.0)	2 (2.0)	6 (5.9)
Upper Abdominal Pain	1 (1.0)	0	1 (1.0)	5 (4.9)
Severe AEs	5 (5.0)	3 (3.0)	2 (2.0)	1 (1.0)
Discontinuations due to AEs	5 (5.0)	3 (3.0)	1 (1.0)	9 (8.8)
Deaths	0	0	0	0

SE=standard error; CI=confidence interval

Conclusions: High-dose celecoxib (800/400 mg) is significantly more effective than low-dose celecoxib (50 mg bid) in the treatment of moderate-to-extreme pain and inflammation associated with acute gouty arthritis. Furthermore, this regimen is comparable in efficacy to indomethacin 50 mg tid and appears to offer an improved tolerability profile.

Evaluation of Rilonacept for Prevention of Gout Flares during Initiation of Urate-Lowering Therapy: Results of a Phase 3, Randomized, Double-Blind, Placebo-Controlled Trial. Robert Terkeltaub[6], H. Ralph Schumacher[5], Kenneth G. Saag[4], James Clower[7], William Jennings[1], Robert R. Evans[2], Jian Wang[3], Shirletta King-Davis[3] and Steven P. Weinstein[2]. [1]Radiant Research, San Antonio, TX, [2]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [3]Regeneron Pharmaceuticals, Inc., [4]University of Alabama-Birmingham, Birmingham, AL, [5]VA Medical Center and UPenn, Philadelphia, PA, [6]VA Medical Ctr, San Diego, CA, [7]Westside Center for Clinical Research, Jacksonville, FL

Background: The present study evaluated the efficacy and safety of rilonacept (IL-1 Trap) for the prevention of gout flares (GFs) during initiation of urate-lowering therapy (ULT) with allopurinol. While attaining target serum levels is critical to the long-term management of gout, ULT can elicit or prolong acute attacks during the initial months of therapy. This paradoxical finding may be attributable to remodeling of crystal deposits during dissolution.

Methods: This North American multicenter trial included adults with gout (ARA criteria), urate levels ≥7.5 mg/dL, and self-reported history of ≥2 GFs in the previous year. Eligible patients were initiated on allopurinol 300 mg daily (or lower dose in those with renal dysfunction, with subsequent titration to achieve urate <6 mg/dL) and randomized to receive treatment with weekly subcutaneous (SC) injections of placebo (Pbo; n=80), rilonacept 80 mg (R80; n=80), or rilonacept 160 mg (R160; n=81) (loading dose on Day 1). GFs were reported by the patient via interactive voice response diary and treated, as appropriate, with NSAIDs or oral glucocorticoids while continuing study treatments. Efficacy endpoints included the number of GFs, % of patients with 1 or more flares, and number of flare days. Safety and tolerability were also assessed.

Results: Baseline characteristics were similar among treatment groups; 92.9% were male, the mean ± SD age was 52.3±12.6 years, and the number of flares reported in the prior year was 4.6 ± 3.3. Fewer patients on Pbo completed the 16-wk treatment period (72.5%) compared with those receiving active treatment (80.0% R80; 86.4% R160). Observed serum urate levels decreased similarly in all 3 groups. Through wk 16, the mean number of GFs per patient (primary endpoint) was significantly lower in both R groups relative to Pbo: 1.06 (84 flares) for Pbo; 0.29 (23 flares) for R80, and 0.21 (17 flares) for R160 (95% CI, 0.22 to 0.46; p<0.0001 vs Pbo). One or more flares were reported by 46.8% Pbo, 18.8% R80, and 16.3% of R160 patients (p<0.0001). The number of flare days per patient was significantly lower with rilonacept: 5.52, 2.36, and 0.98 for Pbo, R80, and R160, respectively (p<0.0001 vs Pbo). From day 1 to wk 16, the proportion of patients who experienced multiple flares was 31.6% Pbo (95% CI, 21.6 to 43.1) vs 5.0% R80 (95% CI, 1.4 to 12.3) vs 3.7% R160 (95% CI, 0.8 to 10.6; p<0.0001 for both comparisons), resulting in an 84% and 88% reduction in the respective R groups. The overall incidence of adverse events (AE) was similar between Pbo (60.8%) and rilonacept (63.4%). Injection site reactions were the most frequent AE with rilonacept (14.3% vs 1.3%). Other common AEs, reported by ≥5% of patients, were respiratory infections, musculoskeletal system disorders, and headache, and rates were generally similar among the treatment groups. Three patients in each group experienced serious AEs; no rilonacept-related SAEs, deaths, or serious infectious AEs were reported.

Conclusions: This phase 3 trial confirmed that IL-1 blockade with rilonacept markedly reduced the occurrence of gout flares during initiation of urate lowering therapy. Rilonacept demonstrated an acceptable safety and tolerability profile.

Evaluation of Rilonacept in Patients with Gouty Arthritis Experiencing an Acute Gout Attack. Robert Terkeltaub[6], H. Ralph Schumacher[5], Craig Curtis[1], Neil Patterson[2], Robert R. Evans[3], Jian Wang[4], Shirletta King-Davis[4] and Steven P. Weinstein[3]. [1]Compass Research, Orlando, FL, [2]Private Practice, Oviedo, FL, [3]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [4]Regeneron Pharmaceuticals, Inc., [5]VA Medical Center, Philadelphia, PA, [6]VA Medical Ctr, San Diego, CA

Background: The role of IL-1β as a central mediator of acute gouty inflammation has been confirmed by animal models and gout prevention studies in patients initiating urate lowering therapy. Although IL-1 appears to trigger gout flares (GFs), available data on IL-1 inhibition in the treatment of GFs is limited to case reports and a single dose-ranging study.

Objective: To report initial findings from SURGE (Study of Rilonacept in Gout Exacerbations), a large phase 3, randomized, double-blind, double-dummy, active-controlled study of the IL-1β and IL-1α blocker rilonacept for the treatment of acute GFs, conducted at approximately 80 sites in North America.

Methods: Eligible patients with gout aged ≥18 to ≤70 y presenting within 48 hrs of onset of a GF with at least moderately severe pain, evidence of swelling and tenderness in the gouty index joint (most painful joint), and who had not initiated treatment for GF symptoms were randomized to 1 of 3 regimens: SC placebo (Pbo) at baseline (BL), plus oral indomethacin (IN) for at least 3 days (d) [50 mg TID × 3 d, then 25 mg TID × 9 d] (IN group); SC rilonacept 320 mg at BL, plus IN for at least 3 d (R+IN group); or SC rilonacept 320 mg at BL, plus oral Pbo for at least 3 d (R group). Patient assessment of pain intensity in the gouty index joint was recorded using a 5-point Likert scale (0= none; 4=extreme) at BL (pre-dose) and 4, 8, 12, 24,

48, and 72 h after administration of SC study drug, and then daily up to 12 d via electronic diary. The primary efficacy endpoint was change from BL pain score to the averaged values at 24, 48 and 72 h. Sequential testing of 2 primary endpoints was planned: R+IN vs IN group, followed by R vs IN group, with the second comparison contingent upon $p<0.05$ for the first. Secondary efficacy analyses included change from BL in pain scores at 24, 48 and 72 hours under the same conditions.

Results: 225 patients with an acute GF were randomized to treatment (IN n=76; R+IN n=74; R n=75). Baseline characteristics were similar among groups. IN resulted in a statistically significant ($p<0.0001$) within-group reported reduction from BL in pain intensity similar to that reported in previous studies of IN. Although a numerically greater reduction in pain intensity was observed with R+IN compared with IN alone (mean ± SD change R+IN −1.55±0.92 vs IN −1.40±0.96), the difference was not statistically significant (95% CI, −0.44 to 0.15; $p=0.33$). Therefore, comparison of the IN with the R group (mean change ± SD R −0.69± 0.97 from baseline) was not performed, per the analysis plan.

Treatment with rilonacept was generally well-tolerated, with 3 patients reporting serious adverse events in the R+IN group, none considered drug-related. Adverse events reported at an incidence of at least 5% in any group were headache and dizziness.

Conclusions: Under conditions in which the reduction of acute gout flare pain in the indomethacin alone group was similar to published reports, inhibition of IL-1 with rilonacept did not provide additional pain relief within 72 hours of flare onset. In comparison with prior studies, the results suggest that blockade of IL-1 for treatment of an early, established acute gout flare is less effective clinically than for acute gout flare prophylaxis.

Febuxostat Versus Allopurinol in the Treatment of Gout in Subjects ≥65 Years of Age: A Subgroup Analysis of the CONFIRMS Trial. Eswar Krishnan[1], Patricia A. MacDonald[2], Barbara Hunt[2] and Robert Jackson[2]. [1]Stanford University, Stanford, CA, [2]Takeda Global Research & Development Center, Inc., Lake Forest, IL

Purpose: Efficacy and safety of urate-lowering therapy (ULT) in an older gout population has been infrequently reported. Febuxostat is a novel, non-purine, selective inhibitor of xanthine oxidase for the treatment of hyperuricemia in patients with chronic gout. This is a subset analysis of 374 elderly subjects (≥65 years of age) from a total of 2269 subjects treated with febuxostat (FEB) or allopurinol (ALLO) for 6 months from the CONFIRMS study.[1]

Methods: Subjects with gout and serum urate levels (sUA) ≥8.0 mg/dL were randomized to FEB 40 mg, FEB 80 mg, or ALLO (200/300 mg based on renal function) once daily. Gout flare prophylaxis (colchicine or naproxen) was provided for the entire study duration. The outcomes of interest were percent of elderly subjects with sUA <6.0 mg/dL by renal functional status and safety in this at-risk population.

Results: The 374 subjects were predominately male (86%), Caucasian (85%), and obese (51% with body mass index [BMI] ≥30 kg/m^2), with a mean age of 71 years. Baseline characteristics and comorbidities were similar across groups; 82% had hypertension, 25% diabetes, 24% coronary artery disease, 21% cardiac arrhythmia, and 11% previous myocardial infarction. The three treatment groups were similar in age, gender, race, and duration of gout. Mean duration of gout was 15 years with a baseline sUA 9.4 mg/dL, with history of tophi (19%) and kidney stones (20%); 98% of subjects had some degree of renal impairment. Urate-lowering therapy use, at some time prior to study entry, was reported by 71% of subjects (ALLO 63% and 15% FEB). The proportions of subjects whose final sUA was <6.0 mg/dL were 62% (71/115), 82% (105/128), and 47% (62/131) in the FEB 40 mg, FEB 80 mg, and ALLO groups, respectively. Results by renal function status are presented in the table. The most frequently reported AEs irrespective of treatment were diarrhea (10%) and upper respiratory infection (8%). The majority were transient and resolved while on treatment. Serious AEs were reported by 8% in the FEB 40 mg, 6% in the FEB 80 mg, and 11% in the ALLO group. The most common serious AEs were cardiac disorders, 1%, 2%, and 3%, and lower respiratory tract infections, 1%, 0%, and 2%, in the FEB 40 mg, FEB 80 mg, and ALLO treatment groups, respectively. There were no hypersensitivity reactions. Overall response rates were similar to those seen in the combined CONFIRMS population.

Percent of Subjects Achieving sUA <6 mg/dL	FEB 40 mg n/N (%)	FEB 80 mg n/N (%)	ALLO 200/300 mg n/N (%)
Normal (CLcr ≥90 mL/min)	2/3 (67)	1/2 (50)	1/1 (100)
Mild (CLcr ≥60 to 89 mL/min)	33/45 (73)	39/44 (89)*	31/50 (62)
Moderate (CLcr >30 to 59 mL/min)	36/67 (54)	65/82 (79)*,**	30/80 (38)

* $p<0.05$, FEB 80 mg vs ALLO; **$p<0.05$, FEB 80 vs FEB 40 mg.

Conclusions: Treatment with FEB reduced sUA to <6.0 mg/dL in this elderly population with significant cardiovascular comorbidities and was well tolerated. Response in the elderly moderately renally impaired population was statistically significantly better with either dose of FEB vs ALLO.

Healthcare Utilization and Productivity at Home and Work Place in Tophaceous vs. Non-Tophaceous Gout. Puja Khanna[3], Jay Persselin[1], Ron Hays[2], Daniel Furst[2], Harold Paulus[2], Paul Maranian[2] and Dinesh Khanna[2]. [1]Greater Los Angeles VA, [2]UCLA, [3]UCLA and Greater Los Angeles VA

Objective: Gout is a painful inflammatory arthritis that causes debilitating acute attacks and is associated with increased resource utilization. Retrospective claims data has shown economic impact of gout on both direct and indirect medical costs including office visits, emergency room visits, medications, and time lost from work. However, there is lack of prospective data in a well-defined gout cohort. In addition, no study has reported the impact of gout on productivity. We assessed the impact of gout on health care utilization and productivity at home and work place.

Methods: Patients with tophaceous and non-tophaceous gout were recruited at VA and University medical centers. Productivity was assessed using Work Productivity Survey (*Osterhaus, J, Arthritis Research & Therapy 2009*). Patients indicated whether or not they were employed outside of the home, how many days in last month they missed work (employment or household work) due to gout, how many days/month productivity was decreased 50% due to gout, and how much gout interfered with work/household chores (0–10 scale), days/month they missed family and social activities, and days/month they required outside help. Health care utilization was assessed using UCSD Health Care Utilization Questionnaire (HCU). HCU asked about resource utilization during past 3 months on office/ hospital visits, surgeries, medical supplies, prescription and OTC medications due to their ongoing medical conditions (not just gout).

Results: Of 71 patients, 45 (63%) patients had non-tophaceous gout. There were no statistical differences in demographics between tophaceous and non-tophaceous gout. On average, patients were 68.2 years old, 96% were male, 70% were Caucasian. Patient with tophaceous gout had similar disease duration, serum uric acid and Charlson comorbidity index; patients with tophi had worse HAQ-DI score (1.1 vs. 0.7, $p=0.06$). Only 20% of patients were employed. Patients missed an average of 3.7 days of work at home or work place per month, had work or home productivity reduced by more than 50% in 3 days per month, had 3 days with reduced family and social activities, and had 1.4 days where they required outside help to do work at home. Tophaceous gout was associated with greater loss of productivity at home and work place compared to non-tophaceous gout (Table). Resource utilization was not significantly different between the 2 groups.

Patient Characteristics	Total Population (N=71)	Non-Tophaceous (N=45)	Tophaceous (N=26)
Age (years), mean (SD)	68.2 (10.0)	67.5 (10.1)	68.7 (9.9)
Charisons Comorbidity index, mean (SD)	3.0 (2.6)	3.0 (2.7)	13.1 (2.4)
Severity of Gout scale, 0–10 mean (SD)	3.0 (2.9)	2.1 (2.3)	4.7 (3.2)
Productivity			
Employed, N (%)	14 (19.7)	8 (17.8)	8 (23.1)
Days missed due to gout, mean (SD)	3.7 (8.1)	3.2 (7.5)	4.5 (9.1)
Days with reduced productivity due to gout, mean (SD)	3 (7.1)	2.4 (6.1)	4.2 (8.6)
Gout interfered (0–10), mean (SD)	3.3 (3.6)	2.8 (3.4)	4.4 (3.7)*
Days with reduced family and social activities, mean (SD)	3 (6.8)	1.6 (3)	5.6 (10.4)
Days requiring outside help due to gout, mean (SD)	1.4 (5.3)	0.4 (1.7)	3.1 (8.4)
UCSD Health Care Utilization (in last 3 months), mean (SD)			
Health care professional visit	5.1 (5.8)	5.2 (6.8)	4.8 (3.4)
Phone calls to healthcare professional	2 (3.1)	1.9 (3.5)	2.1 (2.3)
Triage or urgent care	0.7 (1)	0.7 (1)	0.7 (0.9)
Health care visit to home	0.6 (2.6)	0.8 (3.1)	0.4 (1.4)
Hospital admissions	3 (11.4)	14 (14.2)	1.3 (2.9)
Prescription medications	8.7 (4.7)	8.5 (4.8)	9.1 (4.6)
Non-prescription medications	2.4 (2.8)	2.8 (3.3)	1.6 (1.5)

* $p<0.05$ for comparison between tophaceous and non-tophaceous gout

Conclusions: Tophaceous gout negatively impacts work place and home productivity. The lack of significant differences in utilization in patients with and without non-tophaceous gout is likely due to similar comorbidity profiles.

Patient Knowledge and Beliefs Concerning Gout and Its Treatment. Leslie R. Harrold[4], Kathleen M. Mazor[2], Daniel Peterson[3], Cassandra Firneno[3] and Robert A. Yood[1]. [1]Fallon Clinic, Worcester, MA, [2]Meyers Primary Care Insitute/UMass Medical School, [3]Meyers Primary Care Institute, [4]UMass Medical Schl, Worcester, MA

Objectives: We sought to examine patients' knowledge and beliefs concerning gout and its treatment to order to identify ways to improve gout care.

Methods: We identified all members (≥18 years of age) of a group-model health maintenance organization (HMO) with documentation of at least one health care encounter associated with a gout diagnosis during the period 2008–2009 (n=1346). From this population a random sample of 500 subjects were sent a questionnaire assessing knowledge with regard to gout, beliefs about prescription medications used to treat gout, satisfaction with physician-patient communication, and trust in the physician.

Results: Two hundred and forty patients returned surveys and research authorization forms (response rate of 51% after excluding patients who reported never having gout). The majority of patients were male (80%), white (94%), and aged 65 and older (66%). Only 14 (6%) patients were cared for by a rheumatologist. The vast majority of patients were aware that gout was related to uric acid and flares were the result of crystals inducing inflammation. Many participants were unaware of foods that may lead to a gout flare. Specifically, more patients reported vegetables (58%), chicken (55%) and legumes (39%) as triggers as compared to seafood (23%), beef (22%) and pork (7%). Only 43% reported beer could increase the chances of a gout flare. Awareness of dietary triggers was not greater among those with more encounters for gout or chronic gout (identified by use of urate-lowering drugs [ULDs]). For the management of acute flares, nonsteroidal anti-inflammatory drugs were considered easy to take (86%) and effective in decreasing pain (78%) with only 22% having side effects to the agents. Among colchicine users, colchicine was considered easy to take (91%) and effective (76%) but 37% reported side effects to the medication. There were 101 patients prescribed a ULD of whom 21% reported forgetting to take their medication in the past month. Only a minority of ULD users (12%) were aware of the risk of flare when initiating treatment with this medication class. The majority of patients reported high levels of trust in their physician and good patient-provider communication.

Conclusion: In this gout patient population cared for mostly by primary care providers, we identified several knowledge deficits that may worsen disease management including lack of knowledge regarding dietary triggers and lack of awareness of the risk of gout flare with initiation of ULDs. In addition, providers should explore with their patients reasons for missed doses of ULDs in order to improve adherence.

Progressive Reduction in Tophus Burden with Pegloticase Therapy in Patients with Chronic Gout Refractory to Conventional Therapy. Herbert Baraf[1], Sergio R. Gutierrez-Urena[4], Janitzia Vazquez-Mellado[5], Claudia Rehrig[6], Faith Ottery[6], John S. Sundy[2] and Robert A. Yood[3]. [1]Arthritis & Rheumatism Association, Wheaton, MD, [2]Duke University Medical Center, Durham, NC, [3]Fallon Clinic, Worcester, MA, [4]Hospital Civil de Guadelajara, Guadalajara, Mexico, [5]Hospital General de México, México City, [6]Savient Pharmaceuticals, Inc

Purpose: To evaluate the effect of up to 30 months of i.v. pegloticase therapy on tophi in patients (pts) with treatment refractory chronic gout.

Methods: Pts completing one of two 6-month, randomized, double-blind, placebo-controlled Phase 3 trials (RCT) of pegloticase were eligible for continued therapy in an open label extension study (OLE). Treatment in RCT was pegloticase (PGL) 8 mg (q2wk or q4wk) or placebo (PBO) and in OLE was PGL (q2wk or q4wk). OLE pts could switch dose arms after 6 months. Primary response endpoint in RCT was plasma uric acid (PUA) <6.0 mg/dL 80% of the time in months 3 and 6. Secondary outcomes included treatment effects for tophus, flares, other rheumatologic variables and pt reported outcomes. Tophus response was assessed using **CAPER (C**omputer-**A**ssisted **P**hotographic **E**valuation in **R**heumatology) methodology (Abstract 1111, ACR 2009) with blinded central readers of standardized serial digital photos taken of hands, feet (accounting for maximum of 5 target tophi for serial assessment) and up to 2 other tophus sites at RCT baseline and throughout RCT and OLE. While PGL effect on tophi was analyzed in a number of ways using CAPER, this analysis addresses individual target tophus response. Complete response (CR) for each target tophus was defined as 100% decrease in the area (or disappearance) of the tophus from baseline.

Results: At RCT baseline, 154 of 212 (73%) dosed pts had ≥1 tophus; 107 had ≥1 tophus entering OLE. 151/157 (96%) of RCT completers enrolled in the OLE (82 q2wks, 67 q4wks, 2 observation). 50 of 60 RCT PUA-responders maintained serum UA <6 mg/dL during OLE. Tophus response was related to UA-responder status, with tophus progression during OLE in 13 RCT nonresponders and 0 RCT responders. Individual target tophus complete response data for pts on pegloticase in both RCT+OLE are summarized below. In addition, 12 of 28 pts with ≥1 tophus on PBO in RCT had their first target tophus CR in the OLE (data not shown).

Complete Responses (CR) for Target Tophi in Patients on Pegloticase in Both RCT and OLE

Total number of patients with baseline target tophi, N	79
Total # target tophi	308
Total number of patients having ≥ 1 tophus CR, n/N (%)	53/79 (67%)
• Pts having 1st CR for target tophi during RCT, n/N (%)	29/79 (37%)
• Pts having 1st target tophus CR during OLE, n/N (%)	24/79 (30%)
Total # of target tophi CRs during RCT + OLE	180 (58%)
• Number of tophi undergoing CR in RCT	85/308 (28%)
• Additional tophi undergoing CR in OLE in pts who had their	42/308 (14%)
• Number of tophi undergoing CR in OLE in pts who had their first CR during OLE	53/308 (17%)

Conclusion: Pegloticase has a remarkable effect on tophus resolution in pts with chronic gout refractory to conventional therapy. Approximately 28% of baseline target tophi assessed by digital photography completely resolved during the first 6 months of pegloticase therapy. Resolution continued during pegloticase therapy for up to 30 months with a total of 58% of baseline target tophi eliminated.

Safety and Efficacy of Febuxostat (FEB) Treatment in Subjects with Gout and Severe Allopurinol (ALLO) Adverse Reactions. Saima Chohan and Michael A. Becker. University of Chicago, Chicago, IL

Background: ALLO, a purine base analogue inhibitor of xanthine oxidase (XO) activity, remains the standard for pharmacologic urate-lowering (UL) management of gout. ALLO is efficacious and safe in most patients, but intolerance is estimated to occur in up to 10% of treated patients. Severe or life-threatening ALLO adverse reactions (AEs) precluding re-challenge with the drug occur much less frequently (~0.1 to 0.4% of treated patients), and include severe cutaneous ALLO reactions (SCAR), vasculitis, and/or a multisystem ALLO hypersensitivity syndrome (AHS). During clinical development of FEB, a recently approved non-purine analogue inhibitor of XO, subjects with severe ALLO intolerance were excluded from randomized double-blind FEB/ALLO comparative trials.

Methods: In this retrospective study, safety and UL efficacy of FEB was assessed in13 successively encountered gout patients (8 men, 5 women; age range, 52 to 85 years) with prior documented severe ALLO reactions: SCAR only, 10 patients; multisystem involvement, 3 patients, including skin (2 patients), acute or acute on chronic renal insufficiency (3), hepatitis (1) and/or hematologic abnormalities (2). All patients had impaired baseline renal function: eCLcr 60–89 ml/min, 4; 30–59 ml/min, 5; 15–29 ml/min, 4. FEB treatment was initiated at 40 mg/day in 12 patients and 20 mg/day in 1. FEB dose was titrated, if permitted by safety and renal function monitoring, to achieve and maintain serum urate levels (sUA) $<$6.0 mg/dL.

Results: All 13 patients were hyperuricemic (range: sUA 7.5 to 14 mg/dL) prior to FEB therapy. FEB was well tolerated in 12 patients, each of whom remains on treatment (mean FEB exposure 10 months; range 1.5 to 15 months). sUA decreased from 25 to 59% in these 12 patients: 6 remain on the initial FEB dose (20 mg/day, 1 patient; 40 mg/day, 5 patients), and 10 patients have maintained sUA $<$6.0 mg/dL on FEB doses from 20 to 80 mg/day. In 2 patients, sUA remains $>$6.0 mg/dL despite 32% and 38% sUA reductions from baseline, respectively, on FEB 40 mg/day and 80 mg/day. One patient (an 85 year old woman), previously hospitalized with documented exfoliative erythroderma during ALLO treatment, developed biopsy-confirmed cutaneous leukocytoclastic vasculitis after 4 days exposure to FEB 40 mg/day. No evidence for other organ system involvement was detected, and the rash resolved promptly after FEB withdrawal. This patient had also received seasonal influenza vaccination on day 1 of FEB treatment. None of the other 12 patients treated with FEB showed rash, worsening hepatic function, blood cytopenia or eosinophilia. One patient with baseline moderate CKD, progressed to severe CKD; renal biopsy showed focal segmental glomerulosclerosis.

Conclusion: In 12 of our 13 gout patients with previously documented severe ALLO AEs, FEB treatment was safe; in 10, goal range sUA was achieved and maintained over a mean treatment period of 10 months. However, the development of a hypersensitivity type cutaneous vasculitis (likely but not definitively FEB-related) early in treatment mandates caution, careful dose escalation, and close monitoring when FEB UL therapy of ALLO-intolerant patients is considered.

Serum Urate Levels Have an Impact on Renal Function in Patients with Gout Withdrawing Urate-Lowering Therapy (ULT). Fernando Perez-Ruiz[1], Ana M. Herrero-Beites[2] and Miguel A. Gonzalez-Gay[3]. [1]Hospital de Cruces, Jopelana, Spain, [2]Hospital de Górliz, [3]Hospital Univesitario Marqués de Valdecilla

Objective: to evaluate whether serum urate levels have an impact on renal function in patients with gout.

Methods: patients who gave consent to withdraw ULT after 5-yr treatment (for non-tophaceous) or 5-yr after disappearance of tophi were included in an ongoing observational study of recurrence of flares (Perez-Ruiz F, Arthritis Rheum 2006, Arthritis Rheum 2009-abstract). Renal function was estimated with clearance of creatinine at baseline and treatment, and with MDRD formula after withdrawing ULT. Outcome measure for renal dysfunction was considered as MDRD renal function estimation $<$ 60 ml/min at last observation of follow-up. Patients with recurrence of gout were started on ULT, and stopped for follow-up in this cohort. Kaplan-Meier survival analysis (log rank test) was used to identify variables associated with outcome, including age, time from onset of gout, tophi, serum urate at baseline, withdrawal (average) and follow-up (average), time on ULT, clearance of creatinine at baseline and withdrawal, urate-lowering drugs, hypertension, diabetes, hyperlipidemia, vascular episodes, proteinuria ($>$ 500 mg/day). Multivariant Cox proportional hazard regression analysis was used to study those variables associated with the outcome as survival variable.

Results: from a 202 patient cohort, 179 had all variables to estimate renal function with MDRD equation at last observation, and were included in analysis. Mean age at ULT withdrawal was 61$\pm$11 (35–89), time on treatment was 65$\pm$6 months (60–116), time on follow-up 34$\pm$23 months (1–124). Serum urate was 8.91$\pm$1.31, 4.90$\pm$0.83, and 8.53$\pm$1.45 at baseline, withdrawal and follow-up. Tophi were present at baseline in 25%, 49% received allopurinol, and 51% benzbromarone. Hypertension (37%), diabetes (14.9%), diuretics (13.7%), hyperlipidemia (49.7%), and vascular events (17.1%) were common in this hospital-based cohort. Renal dysfunction was present in 24 (13.4%), 33 (18,4%), and 39 (21.8%) patients at baseline, withdrawal and follow-up respectively, 8 patients showing proteinuria. Multivariant Cox regression analysis showed three variables to be independently and significantly associated with renal dysfunction: lower clearance of creatinine at withdrawal, presence of proteinuria, and increasing serum urate levels during follow-up, but only for the two upper quartiles of the distribution (median 8.45 mg/dl).

Variables	Hazard ratio	95% CI limits	p
Proteinuria ($>$500 mg/day)	4.423	2.021–9.675	0.000
CrClearance (ml/min)	0.922	0.902–0.941	0.000
Serum urate ($>$8.45 mg/dl)	3.853	1.866–7.956	0.000

Conclusions: renal function and proteinuria, but also the highest quartiles of serum urate levels, are independently associated with poor renal outcome after ULT withdrawal.

The Combination of Tranilast with Allopurinol Results in Enhanced Urate Lowering. John S. Sundy[4], Michael M. Kitt[5], Sue G. Griffith[1], Randall R. Stoltz[2] and Ronald Goldblum[3]. [1]ClinPharma Resources, San Diego, CA, [2]Covance, Evansville, IN, [3]CPC Inc, Carlsbad, CA, [4]Duke University Medical Center, Durham, NC, [5]Nuon Therapeutics, Inc., San Mateo, CA

Background: Reduction of serum urate (sUA) can be achieved with uricosuric drugs, which enhance excretion of uric acid, or with inhibitors of xanthine-oxidase, which interrupt the enzymatic cascade converting xanthine to urate. Combination therapy utilizing both mechanisms may be useful in producing lower sUA levels and higher responder rates than a single mechanism in patients with hyperuricemia and gout.

Study Design: A double-blind, 5-treatment period, crossover Phase 2 study evaluated co-administration of tranilast and allopurinol in patients with hyperuricemia. Subjects were randomized 1:1:1 in an initial 3-treatment crossover phase to 300 mg tranilast (T_{300}), 300 mg allopurinol (A_{300}), or a combination of A_{300} + T_{300} (C_{300}). At end of the third period, patients were randomized 1:1 in a 2-treatment crossover phase of allopurinol 400 mg (A_{400})

or a combination of A_{400} + T_{300} (C_{400}). Each period within a phase was 14 days in duration with 7 days treatment orally once daily (Days 1–7), followed by a 7-day washout interval. sUA levels were obtained each day of dosing and 24 hours after last dose. Plasma concentrations of tranilast, allopurinol, and oxypurinol (allopurinol's active metabolite) were evaluated over the 24-hour interval after last dose of each 7-day period. The primary objective was to compare % change from baseline sUA of the combination with tranilast or allopurinol alone.

Results: Twenty male patients were enrolled with mean age 43 years, BMI 29.7 kg/m^2, and baseline sUA 8.1 mg/dL. Combination treatment resulted in greater percentage decrease in sUA than tranilast or allopurinol alone (see table). With $C_{400,}$ 61% of patients achieved sUA levels <4.0 mg/dL, which was significantly greater than the 11% achieved with C_{300} or A_{400} alone (p=0.0027).

	T_{300} N=19	A_{300} N=19	C_{300} (T_{300} + A_{300}) N=18	A_{300} N=19	C_{300} (T_{300} + A_{300}) N=18
Mean % sUA Change from Baseline[a]	−14%	−35%	−43%[b]	−38%	−49%[c]
Responders <6 mg/mL sUA	28%	94%	100%	94%	100%
Responders <4 mg/mL sUA	0%	6%	11%	11%	61%

[a] 24 h after Day 7 dose
[b] *P*-value for LSMean difference between T_{300} or A_{300} and C_{300}; ≤0.0002.
[c] *P*-value for LSMean difference between A_{300} and C_{300}; ≤0.0001.

Coadministration of allopurinol with tranilast did not affect plasma tranilast C_{max} or AUC. Although tranilast had no effect on plasma allopurinol pharmacokinetics, tranilast decreased plasma oxypurinol C_{max} and AUC by ~25–30%, which was an expected interaction, as uricosurics such as tranilast inhibit the reabsorption of both uric acid and oxypurinol in the renal tubules. All treatment regimens were well-tolerated.

Conclusion: In patients with hyperuricemia, combining tranilast 300 mg with allopurinol 400 mg is more effective in reducing sUA to normal levels than allopurinol alone.

The Effect of Allopurinol on Renal Function in Patients with Hyperuricemia: A Case-Control Study. Aneesa Krishnamurthy[1], Deana M. Lazaro[5], David R. Blumenthal[4], Donald A. Gerber[2] and Peter L. Flom[3]. [1]SUNY Downstate Medical Center, Kew Garden Hills, NY, [2]SUNY Downstate Medical Center, Brooklyn, NY, [3]SUNY Downstate Medical Center, [4]VA New York Harbor Healthcare System, Short Hills, NJ, [5]VA New York Harbor Healthcare System and SUNY Downstate Medical Center, Brooklyn, NY

Purpose: Animal models and human studies suggest that hyperuricemia has a deleterious effect on renal function, although the effect of lowering serum uric acid on renal function in humans is unclear. The objective of this study is to determine the effect of allopurinol, a uric acid lowering agent, on kidney function in a male veteran population.

Methods: This was a retrospective case-control study using pharmacy, medical and laboratory records from October 2000 to November 2006 of veterans enrolled at the VA New York Harbor Healthcare System. Cases were patients with hyperuricemia defined as a serum uric acid greater than 7 mg/dl who were newly started on allopurinol for any reason and who had evidence of treatment compliance. Controls were patients with hyperuricemia who were not treated with allopurinol or any other uric acid lowering agent. Control patients were matched to cases for race, gender, age, length of follow-up and creatinine clearance (CrCl). Exclusion criteria were treatment with hemodialysis, prior uric acid lowering therapy and acute kidney failure during the observation period. The average length of follow-up was 3.4 years.

Results: The study included 50 cases and 50 controls (100% male, mean age 65.3 years for cases and 64.8 years for controls, 56% African American, average CrCl for cases 70.4 ml/min for cases and 70.7 ml/min for controls). The mean final serum uric acid for the allopurinol group, treated with an average dose of 221 mg/day, was 6.35 mg/ml versus 8.93 mg/ml for the untreated control group (p<0.001). The mean final CrCl for the allopurinol group was 83.23 ml/min, with an average improvement of 12.87 ml/min. There was a significant improvement in CrCl at the end of the observation period in the cases compared with the controls (p=0.037). Adverse events were seen in 3 treated cases: one episode of elevated liver function tests, one patient who experienced diarrhea and another patient with nausea.

Conclusion: Treatment of hyperuricemic patients with allopurinol over an average of 3.4 years resulted in a significant improvement of kidney function in this male cohort from the VA Healthcare system. Clinicians should consider this potential benefit of allopurinol in the treatment of patients with hyperuricemia.

The Impact of Deficits in Gout Care on Hospitalizations. Prachaya Nitichaikulvatana[1], Katherine Upchurch[2] and Leslie Harrold[2]. [1]University of Massachusetts Medical School, Worcester, [2]University of Massachusetts Medical School

Objective: To identify hospital admissions and complicated hospital stays due to gout and examine the contribution deficits in gout care had on hospitalizations.

Methods: We performed a retrospective chart review of all hospitalized patients between January 1, 2008 and December 31, 2009 in whom a rheumatology consultation was requested and a diagnosis of gout was made by the treating rheumatologist. We included only the first inpatient consultation on each patient. Deficits in gout care were identified based on published gout treatment recommendations and quality of care indications. Descriptive statistics were performed.

Results: A total of 700 rheumatology inpatient consultations were performed during the study period of whom 120 patients were diagnosed with gout and met inclusion criteria. At the time of hospitalization, 33 (28%) had no prior diagnosis of gout, although tophi were present in 7 (21%). In the 87 patients with a prior diagnosis of gout, 32 (27%) were crystal proven while in 55 (46%) the diagnosis was made clinically. The majority of patients were Caucasian (82%) and male (78%). The mean age was 69 years. Comorbidities such as hypertension (71%) and renal disease (54%) were common, as well as outpatient use of diuretics (56%) and low dose aspirin (40%). Deficits in pre-hospital gout care were found in 29%. Specifically, urate lowering drugs were not used in the setting of tophi, radiographic erosive changes presumed to be secondary to gout or recurrent gouty attacks. Therefore, acute gout episodes in these settings were considered preventable. Patients with non-crystal proven gout were found to have the most pre-hospitalization deficits of care (21 out of 35). Thirty two patients had a prior evaluation by a rheumatologist (27%). Previous outpatient rheumatology management of gout improved the quality indicators of gout care (P value < 0.02 in patients with a history of gout).

Nine patients (8%) among the study group were rehospitalized due to gout or complications related to gout during the two year study period. Five out of nine (56%) were not treated with urate lowering agents when indicated during their initial hospitalizations.

Table 1. Identification of potential gout triggers stratified by gout diagnosis prior to admission.

	Prehospitalization Diagnosis of Gout			
	Crystal proven gout N = 32	Non-crystal proven gout N=55	No previous history of gout N = 33	Total N=120
Prevention predisposing factors				
Lack of ULD use when indicated	7	21	7	35 (29%)
Nonadherence to ULD treatment	0	2	0	2 (2%)
Nonpreventable predisposing factors				
Worsening renal function	5	11	6	22 (18%)
Aggressive diuretic use	1	8	1	10 (8%)
Fluid shifts from surgery	2	2	2	6 (5%)

Conclusion: This study demonstrates that both outpatient and inpatient deficits in gout quality of care occur commonly and were associated with both complicated hospitalizations and inpatient admission. Addressing gout quality of care in order to reduce the frequency and intensity of acute flares has the potential to reduce the frequency of hospitalizations, and hospital length of stay.

The Safety and Efficacy of Anakinra in the Treatment of Acute Gout in Hospitalized Patients. Michael Cho[1], Pradipta Ghosh[3], Gurpreet Hans[4], Julia J. Rhiannon[2], Gregory C. Gardner[1] and Peter A. Simkin[1]. [1]University of Washington, Seattle, WA, [2]University of Washington, Seattle, WA, [3]University of Washington, Lake Forest Park, WA, [4]University of Washington, Kirkland, WA

Background: The management of acute gout in the hospital setting can be a difficult clinical problem due to co-morbidities that may limit the use of traditional anti-inflammatory medications. The anti-IL1 receptor antagonist, anakinra, has been successful in the treatment of acute/chronic gout in two published series and 4 case reports totaling 24 patients. The purpose of this study was to review our use of anakinra in acute gout in the hospital setting for efficacy of single and multiple courses of anakinra and to investigate any potential safety concerns.

Methods: We reviewed our consult records over the past three years to identify patients with acute gout treated with anakinra while hospital inpatients. Data extracted from the charts included age, gender, BMI, co-morbidities, uric acid level, results of arthrocentesis, number of anakinra courses, joint(s) and soft-tissue sites involved, anakinra dosing, time to initial improvement, time to complete resolution of signs and symptoms of inflammation, and any possible side effects in particular infection or leukopenia.

Results: We identified 15 patients with acute gout who had received 22 courses of anakinra. The group consisted of 13 males and 2 females, mean age of 53 years (range 32–72 yrs). The major co-morbidities, often in combination, were CKD in 10 patients, DM in 5, CHF in 5, post-solid organ transplant in 2, acute leukemia in 2, and systemic infection in 1. Seven patients had tophaceous disease. The mean BMI was 34.9 (range 22.8–57.8).

Reasons for choosing anakinra were failure of prophylactic low dose colchicine and therapeutic steroids (oral, IV or IA) to reduce pain and inflammation in 14 courses of anakinra and co-morbid disease limitations in 8. Dosing of anakinra was generally 100 mg subcutaneously daily for 3 days. In 18 of the 22 courses, joint involvement was pauci-polyarticular. Ten patients received 1 course of anakinra and 5 patients had 2–4 courses during different hospital stays. In 19/22 anakinra courses, patients reported pain improvement (often dramatic) in 1 day or less. In 3/22 courses pain improvement was noted by day 2. In 9/22 courses patients had complete resolution in 5 or less days, 11/22 in 6–10 days, and in 1/22 it took $>$10 days for the gouty attack to completely resolve. There was no decrement in response to multiple courses separated by time. There were no cases of anakinra-associated leukopenia but one patient developed a post-operative wound infection 5 days after starting an anakinra course.

Conclusion: Anakinra is an effective therapy for acute gout in hospitalized patients with multiple co-morbidities. It was successful in 14 courses where the patients had no apparent response to steroids. It also appears to be effective in multiple courses in the same patient. Dosing strategies, length of therapy, and positioning of anakinra therapy in this setting are areas that will continue to be investigated. The post-operative wound infection is of concern but of uncertain significance. Use of anakinra in the post-operative period should be considered with caution.

Tranilast Inhibits Urate Transport Mediated by URAT1 and GLUT9. Asim Mandal[3], Daniel Emerling[1], Tito Serafini[1] and David B. Mount[2]. [1]Nuon Therapeutics, Inc., San Mateo, CA 94403, [2]Renal Division, VA Boston Healthcare System and Brigham & Women's Hospital, Harvard Medical School, Boston, MA, [3]Renal Division, VA Boston Healthcare System and Brigham & Women's Hospital, Harvard Medical School, Boston, MA 02115

Background: Gout is a disease first described nearly five millennia ago that still has a large unmet need and a growing incidence. Gout occurs when crystals of monosodium urate (MSU), deposited in joints and soft tissues, lead to acute as well as chronic, local and systemic inflammation. Treatment of gout has focused on chronic treatment of the underlying hyperuricemia that leads to MSU crystal deposition. The kidney mediates two thirds of urate elimination, excreting urate as the net sum of absorption and secretion in the proximal tubule. In humans, proximal tubular urate reabsorption of urate from the glomerular filtrate requires the apical urate-anion exchanger URAT1; basolateral exit is accomplished by GLUT9. Loss of function in either protein is a genetic cause of renal hypouricemia; more common variants in GLUT9 exert a significant effect on serum uric acid. Tranilast, the active ingredient of a drug marketed in Japan and South Korea, has recently been shown both to lower serum uric acid in humans via a uricosuric mechanism and to suppress MSU crystal-mediated inflammatory responses in a animal model of gouty inflammation. Given the critical roles of GLUT9 and URAT1 in urate homeostasis, we determined the effect of tranilast on these two transporters.

Objectives: To determine if tranilast can inhibit urate transport mediated by the two key reabsorptive urate transporters, URAT1 (SLC22A12) and GLUT9 (SLC2A9).

Methods: Urate transport assays were established in *Xenopus* oocytes, injecting cRNA transcribed *in vitro* from expression constructs in the pGEMHE vector. Constructs were generated from full-length cDNAs encoding the long form of human GLUT9 (Genbank sequence BC110414) and human URAT1 (BC053348). [14C]Uric acid was used to monitor transport. Tranilast was prepared in a DMSO stock solution and diluted immediately prior to use. Benzbromarone was utilized as a positive inhibition control for both GLUT9 and URAT1.

Results: Urate transport was robust in *Xenopus* oocytes injected with GLUT9 and URAT1 cRNAs, with urate uptakes as much as 45-fold and 26-fold higher, respectively, than in buffer-injected controls. Urate transport via GLUT9 in this system was inhibited by tranilast with an IC50 of approximately 16 microM. Likewise, tranilast inhibited urate transport mediated by URAT1, with an IC50 of approximately 24 microM.

Conclusions: Tranilast can inhibit urate transport through both GLUT9 and URAT1 proteins, with an IC50 consistent in each case with the level of exposure in humans resulting from doses that produce a uricosuric effect. This suggests that the uricosuric activity of tranilast is due to inhibition of these reabsorptive urate transporters in the kidney.

Urate-Lowering (UL) Efficacy and Safety of Febuxostat (FEB) and Allopurinol (ALLO) in Women with Gout, an Older Subset of Gout Subjects with Increased Comorbidity. Saima Chohan[3], Michael A. Becker[3], Patricia A. MacDonald[1], Solomon Chefo[2] and Robert Jackson[2]. [1]Takeda Global R&D Inc, Lake Forest, IL, [2]Takeda Global Research & Development Center, Inc, Deerfield, IL, [3]University of Chicago, Chicago, IL

Background: Although the incidence and prevalence of gout is increasing in the older population of both genders, literature on women with gout confirms later mean onset of the disease in women than men (averaging a decade or more after menopause) and suggests that the frequent comorbidities (renal impairment, cardiovascular disease, metabolic syndrome components, diuretic use) accompanying hyperuricemia/gout in men may be even more common in women. Given this background, we evaluated the UL efficacy and safety of therapy with FEB or ALLO in the subset of women enrolled in a series of randomized controlled clinical trials (RCTs) comparing these xanthine oxidase inhibitors.

Methods: 4101 subjects (3875 men/226 women) participated in the 12-month FACT or the 6-month APEX or CONFIRMS trials. This post-hoc subset analysis focuses on female subjects with gout and serum urate levels (sUA) $\geq$8.0 mg/dL who were randomized (study specific) to daily PBO (n=11 subjects), FEB (n=139), or ALLO (n=76). Baseline renal functional status was assessed by estimated creatinine clearance (eCLcr) calculated using the Cockcroft-Gault formula. UL efficacy results are reported according to study drug and dose administered and stratified by baseline renal function.

Results: The 5.5% women subjects in these RCTs had a mean age of 62 y (vs 52 y men), and 74% had BMI ≥30 kg/m^2 (62% men). Comorbid history (women vs men), was significant for hypertension (81% vs 48%), diabetes (26% vs 10%), hyperlipidemia (46% vs 37%) and renal impairment (64% eCLcr <60 mL/min vs 13%). Gout history: 19% of women and 21% of men had tophi; 86% and 85%, respectively, had experienced a gout flare in the prior year, and mean disease duration was 8 y women and 12 y men. Mean sUA at baseline was 9.7 mg/dL for both men and women. Proportions of women subjects with final visit sUA <6.0 mg/dL are presented by renal functional status in the Table.

Table. Proportions of Women Subjects With Final Visit sUA <6.0 mg/dL

Baseline Renal Function (eCLcr)	PBO n/N (%)	FEB 40 mg n/N (%)	FEB 80 mg n/N (%)	FEB 120 mg (n/N (%)	FEB 240 mg n/N (%)	ALLO 100/200/ 300 mg* n/N (%)
Normal (≥90 mL/ min)	0/1 (0)	1/2 (50)	7/7 (100)	1/1 (100)	NA	1/2 (50)
Mid (≥60–<90 mL/min)	0/5 (0)	8/10 (80)	21/25 (84)	4/5 (80)	3/3 (100)	9/18 (50)
Moderate or severe (17–59 mL/min)	0/5 (0)	10/23 (44)	35/42 (83)	12/15 (80)	4/4 (100)	24/54 (44)

* 2 subjects with CLcr <80 mL/min received ALLO 100 mg and 32 received ALLO 200 mg NA=not applicable

The most frequently reported AEs among women were: URI (16%), diarrhea (11%), and musculoskeletal/connective tissue (11%). The majority of AEs were transient and resolved while on treatment. The most common serious AEs were cardiac disorders: FEB (all doses 2%) and ALLO (4%).

Conclusions: In this female population with gout and significant comorbidities, including renal impairment, UL with FEB 80 mg and FEB 120 mg were both superior to that of ALLO ($p<0.05$). This is the largest number of female hyperuricemic gout subjects treated in RCTs with either FEB or ALLO. Treatment with febuxostat was effective in reducing sUA to <6.0 mg/dL, independent of renal function, and was well tolerated.

Use of Pegloticase in Chronic Gout Refractory to Conventional Therapy Is Associated with Significant Clinical Benefit: Tender Joint and Swollen Joint Counts and Patient Global Assessment (Health Assessment Questionnaire).

David R. Mandel[3], Herbert Baraf[1], Claudia Rehrig[5], Zebulun D. Horowitz[6], Faith D. Ottery[4] and Robert A. Yood[2]. [1]Arthritis & Rheumatism Association, Wheaton, MD, [2]Fallon Clinic, Worcester, MA, [3]Private Practive, Mayfield Village, OH, [4]Savient Pharmaceuticals, Inc, [5]Savient Pharmaceuticals, Inc., [6]Savient Pharmaceuticals, Inc., Baskingridge, NJ

Purpose: To assess the therapy response of pegloticase for a spectrum of non-flare, non-tophus, gout-related rheumatologic variables in patients (pts) with treatment refractory chronic gout (TRCG) in 2 replicate Phase 3, randomized, double-blind, placebo-controlled trials (RCTs).

Methods: TRCG was defined as: ≥3 flares in the previous 18 months, or ≥1 tophus, or gouty arthropathy; serum urate >8.0 mg/dL; and prior failure of maximum medically appropriate dose of allopurinol or contraindication to allopurinol. 212 pts were treated with IV pegloticase or placebo (PBO) in the Phase 3 RCTs. Pts were randomized to PGL 8 mg q2wk (n=85), 8 mg q4wk (n=84), or PBO (n=43) and were infused every 2 weeks for 6 months in a blinded fashion. Primary response endpoint was plasma uric acid (PUA) <6.0 mg/dL 80% of the time in months 3 and 6. Data were pooled for secondary endpoints: reduction of tophus size, gout flare incidence, swollen joints (SJ), tender joints (TJ), pt-reported outcomes by SF-36 and Health Assessment Questionnaire (HAQ). Change from baseline for each secondary rheumatologic variable was compared by regimen and PUA responder status.

Results: Baseline characteristics: 82% male; mean age 55 yrs; high degree of comorbidity: hypertension (71%), chronic kidney disease (43%), cardiovascular disease (31%), and diabetes (22%). As previously reported at ACR 2008, both pegloticase groups were significantly superior to PBO for the primary efficacy endpoint in both studies. Tender joint or swollen joint counts (Table 1) and HAQ-Patient Global Assessment (Table 2), assessed for change from baseline to last visit (last observation carried forward) or week 25, were significant for pooled PGL vs PBO (≤0.001). Changes within each pegloticase group were consistently better in PUA responders® vs non-responders (NR).

A Specific Chemokine Expression Pattern Is Associated with Synovial Inflammation and Symptoms in Patients with Traumatic Knee Injury Undergoing Arthroscopic Meniscectomy. Carla R. Scanzello[7], Brian McKeon[6], Bryan H. Swaim[6], Edward DiCarlo[5], Eva Umoh[4], Veero Kanda[8], Anjali Nair[8], David M. Lee[2], John C. Richmond[6], Jeffrey N. Katz[1], Mary K. Crow[3] and Steven R. Goldring[3]. [1]Brigham & Womens Hosp, Boston, MA, [2]Brigham and Womens Hospital, Boston, MA, [3]Hospital for Special Surgery, New York, NY, [4]Hospital for Special Surgery, New York NY, [5]Hosptial for Special Surgery, New York NY, [6]New England Baptist Hospital, Boston MA, [7]Rush University Medical Center, Chicago, IL, [8]Rush University Medical Center, Chicago IL

Objective: In established OA, the presence of synovitis is associated with pain and progression, but a relationship between synovitis, symptoms and meniscal pathology in isolated meniscal disease has not been previously investigated. The present studies were undertaken to characterize synovial pathology in patients with traumatic knee injuries associated with meniscal tears, and to determine the relationship between synovial inflammation, meniscal and cartilage pathology, and symptoms. Furthermore, the synovial gene expression patterns were analyzed to gain insight into the gene products and molecular pathways that may contribute to development of meniscal pathology and synovial inflammation in these patients.

Methods: Patients without clinical or radiographic evidence of OA undergoing athroscopic menisectomy for traumatic knee injuries were recruited. Pain and function were assessed preoperatively utilizing the Lysholm score (a patient-administered questionnaire measuring knee-specific symptoms and dysfunction); meniscal and cartilage abnormalities were documented at the time of surgery. Inflammation was scored histologically on synovial biopsies and associations between inflammation and Lysholm scores determined. Microarray analysis of synovial tissue was performed and expression patterns in patients with or without inflammation compared. The microarray results were confirmed by real-time pcr.

Results: Synovial inflammation was present in 42% of the patients and was associated with worse pre-operative Lysholm scores, independent of age, gender, or pre-existing cartilage pathology. Microarray analysis and real-time PCR revealed a chemokine signature in synovial biopsies with increased inflammation scores. Increasing synovial transcript levels of the chemokine/receptor pair CCL19/CCR7, identified by microarray and quantitated by real-time PCR, were significantly associated with worse Lysholm scores (Spearman $r = -0.86$ and -0.79 respectively, $p = 0.002$).

Conclusion: In patients with traumatic meniscal injury without clinical or radiographic evidence of OA undergoing arthroscopic menisectomy, synovial inflammation was a frequent finding and was associated with increased pain and dysfunction. Synovium with inflammatory infiltrates exhibited a chemokine signature, and expression levels of CCL19 and its receptor CCR7 were strongly associated with symptoms measured by the Lysholm score. Chemokines play a role in the development of synovial inflammation in patients with meniscal pathology and represent potential therapeutic targets to reduce inflammatory symptoms and potentially modulate the long-term risk for the development of OA.

A Systematic Review and Meta-Analysis of the Impact of Total Shoulder Arthroplasty on Health-Related Quality of Life. Michael J. Carter[1], Ted R. Mikuls[1], Smita Nayak[2], Edward V. Fehringer[1] and Kaleb D. Michaud[1]. [1]Univ of Nebraska Med Ctr, Omaha, NE, [2]University of Pittsburgh, Pittsburgh, PA

Background: Total shoulder arthroplasty (TSA) is becoming more common as an arthritis treatment. However, the effect of TSA on health related quality of life (HRQoL) has not been established. The goal of this systematic review and meta-analysis was to characterize the change in HRQoL as a result of TSA. A quantitative value would establish the potential benefit from the procedure, and also help to evaluate future modifications to the TSA procedure.

Methods: We identified published studies that showed preoperative and postoperative HRQoL outcomes for patients receiving TSA. Articles were included if: 1) patients received primary TSA with an unconstrained prosthesis, with synthetic humeral and glenoid components, and 2) preoperative and postoperative HRQoL measures with at least 6 months of follow-up were reported. Reports were examined to identify all HRQoL measures reported, and meta-analysis was used to calculate standardized mean differences (SMD, reflective of the effect size) and 95% confidence intervals (CI) for each scale.

Results: There were 20 studies (1576 total shoulders) examining TSA outcomes meeting criteria for inclusion in the meta-analysis. Nearly all shoulders had treatment indications of primary osteoarthritis (n=1499) and rheumatoid arthritis (n=60). The most commonly examined HRQoL outcome measures included the Short Form-36 (SF-36), the visual analog scale for pain (VAS), and three shoulder specific measures: Constant score, American Shoulder and Elbow Surgeons score (ASES), and Simple Shoulder Test (SST). Effects of TSA on study outcomes are summarized in the Table, with the average follow-up at 45.2 months:

HRQoL Outcome (number of studies reporting)	Standardized Mean Difference (95% CI)	Mean Difference in Outcome Measure (SD)
SF-36 physical component score (n = 4)	0.69 (0.52 to 0.86)	7.02 (1.78)
SF-36 mental component score (n = 4)	−0.04 (−0.20 to 0.13)	−0.10 (3.56)
Constant score (n = 11)	2.67 (2.55 to 2.79)	38.1 (19.9)
ASES (n = 5)	2.61 (2.43 to 2.80)	53.6 (25.3)
SST (n = 3)	2.20 (1.96 to 2.44)	6.51 (2.60)
Pain VAS (n = 5)	−2.63 (−2.86 to −2.40)	−5.79 (2.58)

Conclusions: Total shoulder arthroplasty is efficacious, offering significant improvement in both function and pain. Shoulder-specific measures demonstrate far greater changes postoperatively than does the global SF-36 instrument. However, the change in SF-36 physical component score is statistically significant, and an SMD of 0.69 is a moderate to large effect size. Because most patients receive TSA on an elective basis, establishing the effect of TSA on HRQoL measures via systematic review and meta-analysis has important implications for both patients and payers.

Cane Use in Hip Osteoarthritis. Karen L. Perell-Gerson[1], Constance Heiney[4], Nancy D. Harada[4], Jennifer M. Yentes[2], Sulabha Masih[4] and Meika A. Fang[3]. [1]Georgia Gwinnett College, Lawrenceville, GA, [2]University of Nebraska at Omaha, [3]VA Greater Los Angeles Healthcare System, Los Angeles, CA, [4]VA Greater Los Angeles Healthcare System, Los Angeles, CA

Purpose: Symptomatic hip osteoarthritis (OA) affects ~5% of the population over the age of 60 years, is often highly disabling and progressive, and accounts for most total hip replacements in Western countries. Although canes are often prescribed as part of the therapy for hip OA, little information is available regarding the impact of canes on pain, function, and gait characteristics. The aim of this pilot study was to evaluate the effects of walking aids on hip OA by testing the hypothesis that the use of a single-point cane would alter gait characteristics, decrease pain and improve function in hip OA patients.

Methods: Fourteen male participants with symptomatic hip OA (mean Kellgren-Lawrence grade 2.6) were given a single point cane to use contra-lateral to the painful limb for four weeks. All participants underwent gait assessment with and without a cane at baseline and after four weeks of cane use via a three-dimensional motion capture system (Motion Analysis Corp., Santa Rosa, CA) and an in-shoe dynamic pressure distribution system (Novel Electronics, St. Paul, MN). OA-related pain, stiffness, and function were assessed with the Western Ontario and McMaster Universities Osteoarthritis Index. Participants also completed a questionnaire regarding frequency of cane use, falls, and their opinions regarding cane use.

Results: Fourteen male participants (mean age 67.5 ±5.8 years) completed the study. At the baseline visit, mean cadence was 99 steps/min when subjects ambulated without a walking aid and the cadence decreased to 85 steps/min when they walked with a cane contralateral to the painful limb

($p<0.001$). They also walked slower when using a cane compared to walking unaided with the gait speed decreasing from 80 to 68 cm/sec ($p<0.005$). The decrease in cadence and gait speed when walking with a cane compared to walking unaided persisted in these participants after using the cane for four weeks. Step length and stride length did not differ when participants walked without a cane and with a cane contralateral to the painful limb. Force (%BW) and pressure (%BW) on the whole foot were decreased on the painful limb compared to the unaffected limb when walking with and without a cane. There were no significant changes in OA pain, function, and stiffness after using the cane for four weeks. Eight of the participants reported using the cane six or more times a week. Most of them (13/14) noted that using the cane prevented them from losing their balance and half of the participants reported a history of falls or near falls prior to enrolling in the study.

Conclusion: This pilot study suggests that decreased gait speed and cadence when walking with a cane may be one strategy people with symptomatic hip OA adopt to improve gait stability. However, cane use may not be as effective in relieving hip pain for some people and this may be due in part to insufficient offloading of the affected limb and to intermittent use of the cane during ambulation.

Comorbid Subjective Health Complaints in Patients with Sciatica, a Prospective Study Including Comparison with the General Population. Lars Grøvle[2], Anne J. Haugen[2], Camilla Ihlebaek[5], Anne Keller[1], Bård Natvig[4], Jens I. Brox[6] and Margreth Grotle[3]. [1]Department of Physical Medicine and Rehabilitation, Oslo University Hospital, Ullevaal, [2]Department of Rheumatology, østfold Hospital Trust, Fredrikstad, Norway, [3]FORMI (Communication Unit for Musculoskeletal Disorders), Oslo University Hospital, Ullevaal, [4]National Resource Centre for Rehabilitation in Rheumatology, Diakonhjemmet Hospital & Department of General Practice and Community Medicine, ASAM, University of Oslo, [5]Research Group of Nature, Health and Quality of Life, Norwegian University of Life Sciences, Aas, [6]Section for Back Surgery and Physical Medicine and Rehabilitation, Orthopaedic Department, Oslo University Hospital, Rikshospitalet

Background: Chronic nonspecific low back pain is accompanied by high rates of comorbid mental and physical conditions. The aims of this study were to investigate if patients with specific back pain, that is, sciatica caused by lumbar herniation, reported higher rates of subjective health complaints (SHC) than the normal population, and if there is an association between change in sciatica symptoms and change in subjective health complaints over a 12-month period.

Methods: A multicenter cohort study of 466 sciatica patients was conducted with follow-up by mailed questionnaires at 3, 6 and 12 months. All patients had radiating pain or paresis below the knee, and a lumbar disc herniation verified by an MRI or CT scan of the corresponding level and side. SHCs were measured by 27 items of the SHC inventory which is a list of common somatic and psychological complaints. The SHC number in each patient was calculated by summing all complaints present. Items directly related to sciatica were not included. Sciatica severity was measured by the Maine Seattle Back Questionnaire. Patient recovery was assessed by a 7 point sciatica global change scale. Odds ratios for each SHC, with adjustments for age, sex and education, were calculated with comparison to a general population sample (n = 928) by logistic regression. Change in the SHC number between baseline and 1 year as function of patient recovery was calculated by Wilcoxon's matched pairs signed-rank sum test or paired *t*-tests.

Results: At baseline, the sciatica patients reported a mean (SD) SHC number of 7.5 (4.4), compared to 5.2 (4.4) in the reference population ($p < 0.01$). The ORs for reporting SHCs for the sciatica patients were significantly higher in 15 of the 27 items. The most prevalent complaints were sleep problems (OR= 8.3 [95% CI= 6.3–10.8]), constipation (OR=5.8 [95% CI 4.1–8.2]), sadness/depression (OR=5.3 [95% CI 4.1–6.8] and heat flushes (OR= 4.6 [95% CI 3.3–6.4]). During the one-year follow-up period, the mean number of SHCs remained stable while the sciatica severity improved. Spearman's correlation coefficient between the change in the SHC number and the change in the MSBQ was − 0.25. Of those patients who at 1 year follow-up rated their sciatica as *completely gone* (n=61), the mean SHC number was significantly reduced from 6.3 (*SD* = 4.2) at baseline to 4.6 (*SD* = 4.0) at 1 year (mean difference= –1.8 [95% (CI) = –0.8 to –2.8], $p < 0.01$). Of those who rated their sciatica as *unchanged* or *worse* (n=74), the mean number of SHCs increased significantly from 8.0 (*SD* = 4.8) to 9.4 (*SD* = 5.5) (mean difference = 1.4 [95% CI = 0.4–2.3], $p < 0.01$).

Conclusion: Among those patients who fully recovered from their sciatica, the number of SHC was reduced to the level of the general population. Among those with persisting or worsening sciatica, the number of complaints increased to a level almost double that of the general population.

Early Progressive Rehabilitation Following Total Knee Arthroplasty Improves Outcomes. Michael J. Bade[2], Tami Struessel[2] and Jennifer E. Stevens-Lapsley[1]. [1]University of Colorado Denver, Aurora, CO, [2]University of Colorado Denver

Background: Although total knee arthroplasty (TKA) reliably reduces pain, research indicates that current rehabilitation methods do not adequately rehabilitate patients to the level of their healthy peers. The purpose of this study was to assess the initial efficacy of a progressive rehabilitation program (PROG) compared to a standard rehabilitation program (historical controls).

Patients: Eight patients (PROG group) undergoing a unilateral, primary TKA for end-stage osteoarthritis participated(65.3 ± 11.5 years; 5 women, 3 men). Patients were compared to a historical cohort of 37 patients (64.9 ± 8.6 years; 19 women, 18 men). Patients from both groups were excluded if they had uncontrolled hypertension, uncontrolled diabetes, body mass index >35 kg/m2, contralateral knee pain, other significant lower extremity orthopaedic problems, or neurological impairments.

Methods: Active range of motion (AROM) was measured by goniometry. Maximum isometric quadriceps strength was assessed using an electromechanical dynamometer and normalized to body weight. Activation was assessed using a doublet twitch interpolation technique. Functional performance was assessed using the 6-minute walk test (6MW), timed up and go test (TUG), and timed stair climbing test (SCT). All measures were assessed preoperatively, 1 month, 3 months, and 6 months after surgery.

Rehabilitation: The historical cohort completed a previously published standard rehabilitation program. The PROG group completed a rehabilitation program that differed in several key ways: a longer duration of treatment (12 weeks vs. 10 weeks); a higher frequency of treatment (28 vs. 18 sessions); the use of single-leg, machine-based resistive exercise; and an emphasis on higher level functional exercises (e.g. lunges, step-downs).

Results: There were no differences in baseline demographics between groups (age, BMI or sex). Compared to historical controls at one month after surgery, the PROG group walked 78.3 m farther on the 6MW, were 3.5s faster on the TUG, were 10.1s faster on the SCT, demonstrated 57.4% greater quadriceps strength, and 17.4% better quadriceps activation. At 3 months, the PROG group walked 47.2 m further on the 6MW, were 1.4s faster on the TUG, were 1.9s faster on the SCT, demonstrated 33.9% greater quadriceps strength, and 7.8% better quadriceps activation than controls. At 6 months after surgery, the PROG group walked 67.0 m further on the 6MW, were 1.1s faster on the TUG,1.2s faster on the SCT, demonstrated 35.5% greater quadriceps strength, and 9.3% better quadriceps activation than controls. Although there were baseline differences on AROM, at 6 months the PROG group demonstrated better knee extension (-1.9° vs. 1.2°) and better flexion (120° vs. 113°).

Conclusions: A progressive program of rehabilitation which includes higher frequency, longer duration, and higher level of exercise leads to improved outcomes compared to a standard rehabilitation program. This higher intensity rehabilitation did not impair ROM and did not result in any increased incidence of injury.

Facet Joint Injections for Low Back Pain Improve Quality of Life. Cecilia Mercieca[2], Stefania Chetcuti Zammit[2], Josef Lauri[1] and Andrew Albert Borg[2]. [1]Department of Mathematics, University of Malta, Malta, [2]Department of Rheumatology, Mater Dei Hospital, Msida, Malta

Aim: To ascertain whether facet joint injections improve Quality of Life in chronic low back pain. Secondary endpoints studied included procedure efficacy and safety.

Patients and Methods: 40 patients suffering from low back pain due to facet joint disease [1] were recruited. All patients had degenerative changes in

their facet joints on radiographs. Severity of back pain was assessed at baseline and after one month. Patients were asked about any improvement in back pain, activities of daily living (ADLs) and walking ability they expected as a result of the procedure. These responses were measured using 10mm VAS and correlated with the actual outcomes one month after injection. The Roland-Morris disability (RDQ) [2] and the Oswestry [3] questionnaires were also administered at baseline and one month after the intervention.

Results: 40 patients underwent facet joint injection (11 males, 29 females). There was significant improvement in pain and disability according to the RDQ. The mean score at baseline was 13.1 (CI 12.33–17.76) while after one month it was 10.4 (CI 9.63–15), p=0.008. No significant improvement was found using the Oswestry questionnaire (p=0.9). There was a strong correlation between high expectations of improvement at baseline and actual improvement at one month in ADLs (r=0.7; p=0.001), improvement in back pain (r=0.37; p=0.026), but not for walking ability (r=0.25; p=0.132). Gender, BMI, age and severity of back pain did not influence outcomes.

The lack of correlation between severity of back pain at baseline and the actual improvement in back pain at one month suggests that the degree of improvement depended more on the individual's expectation of benefit rather than the actual back pain severity.

More than 70% felt the procedure helped and 60% of them were willing to undergo the procedure again. Prior to the procedure over 60% expected complications although none occurred, confirming that the procedure is safe.

Conclusions: Evaluating treatment outcome for low back pain has always generated considerable interest. This study shows that facet joint injections reduce disability as measured by the RDQ with a clinically significant change of nearly three points in the scale. This study further suggests that the two disability measures studied should not be used uncritically as their complexity varies and the domains that they cover are different.

Additionally, the patient's expectation of improvement from the facet joint injection was a better predictor of improved outcome than the initial severity of back pain reinforcing the concept of a multifactorial aetiology for the pain. Patients with very low expectations of benefit from this procedure tended to have poorer outcomes and little improvement in quality of life. This is relevant when selecting patients for facet joint injection. Facet joint injections are a safe and useful adjunct in the treatment of low back pain.

Fat Mass Is a Predictor of Disabling Foot Pain: A Cross-Sectional Study. Stephanie Tanamas[4], Anita Wluka[4], Patricia Berry[4], Hylton Menz[2], Boyd Strauss[4], Miranda Davies-Tuck[4], Joseph Proietto[5], John Dixon[1], Graeme Jones[3] and Flavia Cicuttini[4]. [1]Baker IDI Heart and Diabetes Institute, [2]La Trobe University, [3]Menzies Research Institute, [4]Monash University, [5]University of Melbourne

Background: To examine the relationship between body composition and disabling foot pain as assessed by the Manchester Foot Pain and Disability Index (MFPDI).

Methods: 137 subjects aged 25–62 years were recruited as part of a study examining the relationship between obesity and musculoskeletal health. Disabling foot pain was determined from the MFPDI and defined as current foot pain and pain in the last month, and recording ≥ 1 disability item on the MFPDI (an MFPDI score of ≥ 1). Body composition was measured using dual x-ray absorptiometry.

Results: The BMI in this population was normally distributed around a mean of 32.2 kg/m^2.The prevalence of foot pain was 54.7%. In multivariate modelling, there was a positive association between BMI and disabling foot pain (OR 1.11, 95% CI 1.05, 1.17). Similarly, the risk of disabling foot pain was positively associated with total body fat mass (OR 1.05, 95% CI 1.02, 1.08) adjusted for age, gender, strenuous physical activity, and skeletal muscle mass. Total body fat mass was also positively associated with functional limitation, foot pain intensity and self consciousness regarding feet/footwear, independent of skeletal muscle mass.

Conclusions: Fat mass, but not muscle mass, is associated with foot pain. This suggests that obesity may affect foot pain not only through increased loading but also act via a systemic mechanism through increased adiposity. Further work is needed to clarify the mechanisms for this effect and the importance of reducing body fat rather than simple weight loss in the reduction of foot pain.

Is There an Association between Living Situation and Pain Severity at the Time Patients Choose Total Hip Replacement? Yvonne C. Lee[1], Huong T. Do[3] and Lisa A. Mandl[2]. [1]Brigham and Women's Hospital, Boston, MA, [2]Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgery

Background: Living situation is an important measure of social support and could influence when patients choose to undergo total hip replacement (THR). We examined whether living situation is associated with pain severity, the main reason patients decide to undergo THR, and whether living situation is a potential effect modifier of the relationship between sociodemographic variables and pain.

Methods: This single center study evaluated a cohort of 3079 patients over 40 years of age who decided to undergo primary unilateral THR between May 2007 and September 2009. Participants with a systemic inflammatory disease were excluded. Living situation was categorized as: 1) those who lived alone and 2) those who lived with others. Education was dichotomized as < college or some college or more. Self-reported pain after scheduling THR surgery was assessed using the WOMAC pain score. Univariate associations between clinical variables and pain were assessed using two sample t-tests. Variables associated with pain with P-value < 0.01 were considered for inclusion in the multivariable model, in which pain at time of THR was the dependent variable. The final multivariable model was obtained using a backward selection process. Stratified analyses were performed to assess the role of living situation as an effect modifier.

Results: Mean age was 62.5 ± 11.0 years. Fifty percent were female. Ninety-four percent were Caucasian. In univariate analyses, living situation was significantly associated with pain at the time of THR (P-value= 0.01). In multivariable analyses adjusted for age and sex, living situation was not significantly associated with pain severity at the time of THR. Race, education level, Elixhauser comorbidity index, fatigue and vitality were significantly associated with pain severity. In analyses stratified by living situation, age, sex, fatigue and vitality remained significantly associated with pain severity in both models. Non-Caucasian race was more strongly and significantly associated with greater pain at the time of THR (B = 5.3, P-value = 0.03) among patients living alone (N = 659) than among patients living with others (N = 2383) (B = 2.1, P-value = 0.18). Less education was more strongly and significantly associated with more severe pain (B = 4.6, P-value < 0.0001) among patients living with others than among patients living alone (B = 2.9, P-value = 0.16).

Conclusions: Although living situation is not independently associated with pain severity at the time of THR, it appears to act as an effect modifier. This raises the possibility that living situation could influence how much pain patients are willing to tolerate before choosing THR. While statistical significance is dependent on sample size, these differential relationships should be explored further.

OMERACT Responder Analysis of Patients Treated with Duloxetine for Chronic Low Back Pain. Vladimir Skljarevski[1], Matthew J. Bair[2], Melissa J. Ossanna[1], Eli Frakes[1], Shuyu Zhang[1] and Karla Alaka[1]. [1]Eli Lilly and Company, [2]Roudebush VA Medical Center

Background: There are no standardized outcome measures to assess treatment effect in chronic low back pain (CLBP) clinical trials. The OMERACT (Outcome Measures in Rheumatology) group proposed a preliminary approach to assessing treatment responders in CLBP trials (Simon et al, 2007). This current analysis utilizes the OMERACT approach to measure response in trials of duloxetine for the treatment of CLBP.

Methods: We analyzed three randomized, double-blind, placebo-controlled clinical trials of duloxetine in the treatment of adult patients with

CLBP. Duloxetine treatment dose was 60 mg daily, 120 mg daily or flexible doses of 60–120 mg daily over 12 or 13 weeks. OMERACT treatment response was a composite outcome defined as a ≥30% reduction in Brief Pain Inventory average pain, a Patient Global Impression score PGI-I ≤2 ("much improved") at endpoint and Roland Morris Disability Questionnaire (RMDQ) total score reduction from baseline ≥2.

Results: In Study 1, 35.4% of patients taking duloxetine 60–120 mg (N=99) met the defined response criteria versus 18.1% of patients assigned to placebo (N=105; p=0.007). In Study 2, response criteria was met by 36.1% of patients taking 60 mg duloxetine (N=83) and 34.1% of patients taking 120 mg duloxetine (N=82), versus 27.2% of patients taking placebo (N=92; p=0.254 and p=0.328, respectively). In Study 3, 37.9% of patients taking duloxetine 60 mg (N=177) responded versus 26.8% of those taking placebo (N=179; p=0.031).

Conclusions: Our analysis demonstrates that duloxetine was more efficacious than placebo in 2 out of 3 separate trials of patients with chronic low back pain, as assessed by the OMERACT composite outcome, including pain severity, patient perception of improvement and functional limitations. These findings suggest that duloxetine may be helpful in the clinical armamentarium for the treatment of chronic low back pain.

The Clinical Benefit of Joint Distraction in Treatment of Advanced Ankle OA May Be Partly Explained by Subchondral Bone Changes. F. Intema[1], T. P. Thomas[2], D. D. Anderson[2], J. Elkins[2], S. C. Mastbergen[1], F. P. J. G. Lafeber[1], T. D. Brown[2], A. Amendola[2] and C. L. Saltzman[3]. [1]Rheumatology & Clinical Immunology, University Medical Center Utrecht, The Netherlands, [2]The University of Iowa, Iowa City, IA, [3]The University of Utah, Salt Lake City, UT

Background: In osteoarthritis (OA), it has long been understood that cartilage degeneration is accompanied by sclerosis of subchondral bone. The subsequent stiffening of the bone decreases its capacity to absorb mechanical impact energy, which might play a role in the development and/or progression of cartilage degeneration. Joint distraction as a treatment for advanced ankle OA has been shown to provide pain relief and improve clinical function, with some evidence accruing that cartilage repair is involved. However, the underlying mechanism(s) remain unclear. This study evaluated whether long-term changes in subchondral bone density are associated with extended joint distraction.

Methods: Twenty-six patients with advanced post-traumatic ankle OA were treated with joint distraction for three months using an Ilizarov frame. Follow-up was two years, and clinical outcome was assessed using the ankle OA scale (AOS).

Dual-contrast CT scans were obtained at baseline (before treatment), and at one- and two-year follow-ups after treatment, to analyse joint space width and bone density. The tibia and talus bones were manually segmented at each time point, and the bone segmentations from the two follow-up CT scans were registered to the baseline scans for each patient. The resulting spatial transformations were then used to bring all CT datasets for a given patient into a common spatial reference frame, using purpose-written MATLAB code. Changes in bone density (Hounsfield Units (HU), relative to baseline) were calculated at a number of discrete locations beneath the tibial and talar weight-bearing regions. The measurement grid covered a subchondral patch of nominally 650 mm2, with ~4000 point measurements per surface (~0.17mm2/point). Bone density calculations were performed at 1 mm intervals beneath the bone surface, along the surface normals and extending subchondrally up to 8 mm (total of roughly 30,000 sampled point locations for each bone).

Results: Joint distraction resulted in a statistically significant long-term decrease in pain (mean value decreased from 60 to 35, on a scale of 100; p<0.01) and function (mean decreased from 67 to 36; p<0.01) at two years post-treatment. These clinical changes were accompanied by changes in bone density. The initial subchondral bone density was 569±14 HU for the tibia, and 490±19 HU for the talus. The average decrease in density was 133±17 HU (p<0.01) for the tibia and 95±17 HU (p<0.01) for the talus, one year after treatment. These density changes persisted two years after treatment (124±16 HU; p<0.01, and 88±18 HU; p<0.01, for tibia and talus, respectively), and they were not significantly different from the bone density one year after treatment (p=0.11).

Conclusion: Treatment of advanced post-traumatic ankle OA with three months of joint distraction produced decreases in subchondral bone density that persisted for at least two years of follow-up. This could lead to a more physiologically normal distribution of mechanical stresses by the less dense bone, encouraging cartilage repair activity. As such, these prolonged bone changes may in part explain the clinical benefits of joint distraction.

The Safety and Patient Acceptability of Suprascpular Nerve Block. E. Michael Shanahan[2], Kieran Ross Shanahan[2], Catherine Hill[1], Malcolm Smith[2] and Michael John Ahern[2]. [1]Adelaide University, Adelaide, South Australia, Australia, [2]Flinders University, Adelaide, South Australia, Australia

Background: Suprascapular nerve block is an effective therapy for shoulder pain from arthritis. To date however, the safety of the procedure has not been fully validated. This is because the numbers of patients in the trials to establish the efficacy of the treatment are far smaller than those required to establish its safety. Since 2003 the rheumatologists at the Repatriation General Hospital Flinders Medical Centre and the Queen Elizabeth Hospital have been regularly performing this procedure for the relief of shoulder pain.

The safety and patient satisfaction of their experience with this procedure has now been assessed.

Aim: To audit the safety and patient satisfaction of patients receiving at least one suprascapular nerve block performed by rheumatologists in South Australia between 2003 and 2009.

Methods: All nerve blocks performed between 2003–2009 were included in the study. The interventions were sourced through an electronic search of the medical records. In all, 1005 individual procedures were reviewed. Case note reviews of all the procedures were performed and each patient contacted. Case notes were audited for patient demographics, and recorded complications. Patients were surveyed for complications and also satisfaction using the Patient Satisfaction Questionnaire in Musculoskeletal Care. Supplementary questions were added to enquire specifically about satisfaction for the nerve block procedure.

Results: 1005 nerve block were performed on 293 patients (mean age 78, 75% with one or more co morbidities). 6 minor complications (presyncope, transient arm weakness and facial flushing) were reported or recorded. There were no major complications, giving a maximum significant complication rate of 0.3%. The overall response rate to the satisfaction survey was 55%. 87% of respondents were satisfied with the results of the nerve block.

Conclusion: Suprascapular nerve block is a safe procedure which is well tolerated by patients, even those with multiple co morbidities. Patients rate the procedure highly in terms of the ease of procedure and the pain relief that it confers.

Using the Patient Generated Index (PGI) To Measure Personalized Quality of Life (QoL) in Patients Undergoing Total Knee Arthroplasty (TKA). Maria A. Lopez-Olivo[2], Michael A. Kallen[2], Chong H. Pak[2], Sherwin J. Siff[1], Glenn C. Landon[1], David Edelstein[1], Kausha C. Robinson[2] and Maria E. Suarez-Almazor[3]. [1]St. Luke's Episcopal Health System, Houston, TX, [2]The University of Texas M.D. Anderson Cancer Center, Houston, TX, [3]University of Texas, MD Anderson Cancer Center, Houston, TX

Background: Personalized respondent-generated measures such as the Patient-Generated Index (PGI) can be used as an adjunct to other measures to assess individual quality of life, to improve patients' outcomes through interventions aimed at targeting patients' values for health, and to identify changes in individual responses. The objective of this study was to assess how patients redefine their components of quality of life after a total knee arthroplasty (TKA) during the first six months of recovery.

Methods: We interviewed 122 patients with knee osteoarthritis (OA) at baseline, 12 and 24 weeks post TKA. PGI, a semi-quantitative instrument that

allows patients to select the areas of their lives that are most affected by their disease, and to rate them using ranking and ordinal scores. The PGI is made up of three stages; each stage is linked to the other stages in sequence: i) the first stage focuses on those areas of life affected by the patients' health; ii) the second stage rates how badly patients are limited by their condition; and iii) the third stage reduce ambiguity in the weighting of life areas by rating the relative importance of potential improvements in the area.

Results: 66% of the patients were female; mean age was 65 (8.9) yrs. 63% were married, 70% were White and 25% African American. At baseline, patients were able to select the areas of their lives that were most affected by their knee OA. Patients presented with different combinations problem areas. To reduce the amount of possible combinations, we use the same areas reported at baseline for the 12 and 24 weeks assessments. Five major areas were identified as the most salient: (i) family—this included relationships with family; (ii) physical function—e.g. walking, kneeling, activities of daily living; (iii) health—sleep, fatigue, personal care; (iv) professional life—work and school; and (v) spirituality—church, religious activities. There was a statistically significant difference between observed PGI total scores pre and post TKA: 2.5±1.2 at baseline, 4.2±1.4 at 12 weeks ($p<0.001$), and 4.3±1.4 at 24-weeks ($p=<0.001$). Mean score for each area are shown in table 1. Substantial variation was observed in the areas that patients described as affected. Additionally, we observed that the perception of the area that is most affected by the knee OA changed over the time in each patient.

Table 1. Weighted mean PGI scores specific to each domain – 6 months.

	Baseline		12 weeks		24 weeks		24 weeks (fresh)	
	n(%)	*score*	*n(%)*	*score*	*n(%)*	*score*	*n(%)*	*score*
Family	29%	2.8	31%	4.5	34%	4.5	14%	4.1
Physical function	36%	2.5	36%	4.2	31%	4.1	52%	4.7
Gen health	12%	2.5	8%	4.2	11%	4.9	14%	4.9
Professional life	11%	2.2	7%	0.4	8%	4.3	15%	4.2
Spirituality	7%	2.5	7%	4.7	5%	3.8	3%	3.5
Other areas	5%	2.4	11%	4.2	11%	4.3	2%	4.2

Conclusion: Physical function and interference with family life were the most frequent areas identified by patients as detrimental to their QoL. The PGI was responsive to changes in patient's chosen domains for QoL.

Adiponectin but Not Leptin and Resistin, Is Associated with the Progression of Hand Osteoarthritis. Erlangga Yusuf[1], Andreea Ioan-Facsinay[2], Jessica Bijsterbosch[2], Joanneke Kwekkeboom[2], P. Eline Slagboom[2], Tom W. J. Huizinga[2] and Margreet Kloppenburg[2]. [1]LUMC, Leiden, The Netherlands, [2]LUMC, The Netherlands

Purpose: The link between obesity and osteoarthritis (OA) may be explained by the increased joint stress accompanying obesity. However, it does not explain why being obese is also associated with OA in non-weight-bearing joints, such as the hands. It is suggested that systemic products of fat with systemic metabolic activity (adipokines) may influence the onset and/or progression of osteoarthritis. We investigated here the association between three most common adipokines: leptin, adiponectin and resistin and the progression of hand OA.

Methods: We selected patients with radiographic hand OA from a cohort consisted of Caucasian sibs with symptomatic OA at multiple sites. We defined hand OA as Kellgren and Lawrence score ≥2 in at least two from 20 hand joints (four proximal interphalangeal joints (PIP's), four distal interphalangeal joints (DIP's), one interphalangeal (IP-1) and one carpometacarpal (CMC-1) on each hand). Using the Osteoarthritis Research Society International atlas, the baseline and 6-years follow-up radiograph were assessed for the joint space narrowing (JSN, grade 0 to 3: 0 normal, 3: severe narrowing) of 20 joints (four DIP's, four PIP's, one IP-1 and one CMC-1) per patient. JSN reflects articular cartilage damage. The radiographs were assessed by two readers in consensus and the intra-class correlation coefficient for intra-reader reproducibility based on 25 randomly selected pairs of radiographs was high (0.87). Progression was defined as a change in JSN above the smallest detectable change (SDC) of 2, reflecting change above measurement error. Baseline serum adiponectin concentration was measured by Bio-Plex Pro Assay (Bio-Rad, USA). With logistic regression analysis odds ratios of hand OA progression were computed and transformed to risk ratio (RRs). Adjustments for confounders as age, sex, body mass index (BMI) and family effect were made. We categorized all adipokines in tertiles.

Results: Complete follow-up data were available from 164 patients out of 248 included patients, (66%, mean age [SD]: 60 [7] years, 81% female, mean BMI [SD]: 27 [5] kg/m^2). Fifety-five patients showed hand OA progression. BMI was positively correlated with leptin (Pearson's correlation coefficient, r=0.3) and resistin (r=0.2) and negatively correlated with adiponectin (r=-0.2). Leptin, adiponectin and resistin did not significantly correlate to each other. BMI was not associated with radiographic hand OA progression (β-regression coefficient −0.04 (95% confidence interval −0.08 to 0.05). The association between adipokines and progression of hand OA is shown in the Table.

Adiponectin	Risk Ratio (95% Confidence Interval)	Risk Ratio (95% Confidence Interval) after adjustment for age, sex, BMI and family effect
Leptin (ng/mL)		
<4.4	1 (reference)	1 (reference)
4.41 to 8.2	0.7 (0.3 to 1.6)	0.7 (0.3 to 1.5)
>8.2	1.1 (0.5 to 2.3)	1.2 (0.4 to 2.5)
Adiponectin (μg/mL)		
<16.6	1 (reference)	1 (reference)
16.6 to 28.4	0.3 (0.1 to 0.7)‡	0.2 (0.1 to 0.5)‡
>28.4	0.3 (0.1 to 0.6)‡	0.2 (0.1 to 0.5)‡
Resistin (ng/mL)		
<0.8	1 (reference)	1 (reference)
0.8 to 1.4	1.0 (0.4 to 2.1)	0.9 (0.4 to 1.8)
>1.4	0.8 (0.4 to 1.7)	0.7 (0.3 to 1.5)

‡ Statistical significant at $p<0.05$

Conclusions: We show for the first time a substantial inverse association between serum adiponectin levels and radiographic worsening of hand OA. Further studies on the use of adiponectin as biological markers for OA progression and studies on the biological role of adiponectin in OA are needed.

Association of Knee, Ankle, and Midfoot Osteoarthritis and Physical Performance. Gary McDaniel[1], Jordan B. Renner[2], Richard Sloane[1] and Virginia B. Kraus[1]. [1]Duke University Medical Center, Durham, NC, [2]University of North Carolina School of Medicine

Purpose: The direct measurement of the ability to perform physical tasks yields information about factors contributing to poor function and insights into strategies for preventing disability. The Short Physical Performance Battery (SPPB) measures walking speed, balance, and the ability to rise from a chair. Previous studies evaluating the contribution of knee to physical function have relied solely on the Kellgren-Lawrence (KL) grading system, whereas studies of the ankle's contribution to physical function have failed to assess the association of radiographic ankle or midfoot OA. Our goal was to evaluate the relationship of SPPB with specific radiographic features of osteoarthritis (OA), joint space narrowing (JSN) and osteophyte (OST), of the knee, ankle, and midfoot.

Methods: SPPB was performed by 138 [101 females, 37 males, mean age 66 (SD 11.6) years and BMI 31.3 (SD 6.9)] participants of a longitudinal observational study of knee OA progression (POP study). Radiographic features of OA severity, joint space narrowing (JSN, a surrogate for cartilage loss) and osteophyte formation (OST) were assessed for the knee, ankle, and midfoot. The association of SPPB with radiographic OA was evaluated using non-parametric Spearman correlation analysis, adjusted for age, gender, BMI, and number of comorbidities.

Results: Knee, ankle tibiotalar joint (TTJ), ankle subtalar joint (STJ), and midfoot talonavicular joint (TNJ) radiographic features of OA were negatively associated with specific SPPB tests: walking speed was associated with knee JSN (Spearman rho=-0.20, p=0.02), balance with ankle (subtalar joint)

JSN (-0.22, 0.01), and chairs stands with midfoot (talonavicular joint) JSN (-0.18, 0.04).

Table 1. Associations of knee and ankle/foot osteoarthritis with physical performance measures (unadjusted and adjusted for age, gender, BMI, number of comorbidities).

Joint Site		OA Feature	Gait Velocity (m/sec) (higher better)	SPPB Standing Balance (higher better)	SPPB Chair Stand (higher better)	SPPB Total (higher better)
			Spearman Correlation Coefficients: r unadjusted (or r adjusted for age, BMI, number of comorbidities, and gender)			
Knee		JSN	−0.19* (−0.20*)	−0.04 (−0.03)	−0.07 (−0.05)	−0.09 (−0.08)
		OST	−0.16 (−0.16)	−0.01 (−0.01)	0.01 (0.02)	0.001 (0.01)
		KL	−0.12 (−0.12)	−0.02 (−0.01)	−0.07 (−0.06)	−0.07 (−0.06)
Ankle	TTJ	JSN	−0.06 (0.01)	−0.15 (−0.06)	−0.19* (−0.12)	−0.19* (−0.09)
Ankle	STJ	JSN	−0.12 (−0.09)	−0.29*** (−0.22**)	−0.19* (−0.11)	−0.24** (−0.17*)
Ankle	TTJ	OST	0.03 (0.06)	−0.03 (<0.01)	−0.02 (0.03)	<−0.01 (0.05)
Ankle	STJ	OST	−0.03 (−0.16)	−0.10 (−0.01)	−0.04 (0.02)	−0.06 (0.01)
Ankle	TTJ	KL	−0.01 (−0.04)	−0.19* (−0.12)	−0.21** (−0.13)	−0.20* (−0.12)
Midfoot	TNJ	JSN	−0.06 (−0.05)	−0.15 (−0.16)	−0.16* (−0.18*)	−0.18* (−0.21*)
Midfoot	TNJ	OST	−0.16 (−0.16)	−0.04 (−0.02)	0.07 (0.13)	0.03 (0.08)

OA = osteoarthritis; p values; * <0.05, **≤0.01, *** ≤ 0.001

These relationships remained significant upon further control for knee and ankle pain.

Conclusions: To our knowledge this is the first study describing a relationship between individual SPPB tests and specific radiographic features of knee, ankle and midfoot OA (JSN and OST). We discovered that ankle OA negatively impacts balance; knee OA slows you down; and midfoot OA negatively impacts chair stands. Structural joint damage due to OA (JSN in contrast to OST) negatively impacted these specific domains of physical performance. These results indicate that radiographic evidence of OA in specific joints may inform strategies targeting specific functional outcomes for early intervention to prevent disability in an older population.

Associations between Composite Measures of Multi-Joint Osteoarthritis, Gait Speed, and Health Assessment Questionnaire Scores: The Johnston County Osteoarthritis Project.

Amanda E. Nelson[6], Robert F. DeVellis[5], Jordan B. Renner[5], Jama Purser[3], Todd A. Schwartz[5], Philip G. Conaghan[1], Virginia Byers Kraus[2] and Joanne M. Jordan[4]. [1]Chapel Allerton Hospital, Leeds, United Kingdom, [2]Duke Univ Med Ctr, Durham, Durham, NC, [3]Duke Univ Med Ctr, Durham, NC, [4]Thurston Arthritis Research Center, Univ of North Carolina, Chapel Hill, Chapel Hill, NC, [5]Thurston Arthritis Research Center, Univ of North Carolina, Chapel Hill, NC, [6]UNC School of Medicine, Chapel Hill, NC

Objective: As there is no widely accepted definition of multi-joint osteoarthritis (OA), it is difficult to quantify the effect of multiple joint involvement on OA outcomes. We used factor analysis to create composite variables reflecting multi-joint radiographic OA, and determined associations between these variables and systemic outcomes (gait speed and health assessment questionnaire [HAQ] scores).

Methods: Data were from a cross-sectional sample of the Johnston County OA Project, including individuals with multi-joint radiographs, HAQ, and gait speed (n=1350, 66% women, 33% African Americans, mean age 67 ± 10 years, mean body mass index [BMI] 31 ± 6 kg/m^2). HAQ scores were categorized as 0, 0 to < 1, or ≥ 1. Mean seconds to complete an 8-foot walk were converted to gait speed in m/s. Radiographs of the bilateral hands, tibiofemoral joints (TFJ), and hips were read for Kellgren-Lawrence grade (KL 0–4) at each joint. Lateral lumbosacral spine (LS) films were read for osteophytes (OST 0–3) and disc space narrowing (DN 0–3) at 5 levels, and patellofemoral joint (PFJ) radiographs were read for OST (0–3), using the Burnett atlas. During factor analysis using these scores, the hip and LS variables did not load onto factors and were assessed separately (Hip OA if KL ≥ 2 at either hip, LS OA if OST and DN ≥ 1 at a single level). Linear and partial proportional odds regression models for gait speed and HAQ, respectively, were used to determine associations between OA variables and outcomes, adjusting for age, BMI, gender, and race.

Results: Factor analysis produced 3 factors. The 1st consisted of the 1st interphalangeal (IP) joints, distal IP joints 2–5, and proximal IP joints 2–5 (IP factor, α=0.96); the 2nd included the metacarpophalangeal joints 2–5 (MCP factor, α=0.81); the 3rd included TFJs and PFJs (Knee factor, α=0.87). The mean gait speed in the sample was 0.7 ± 0.2 m/s. Proportions by HAQ categories were 30% (0), 24% (> 0 to < 1) and 46% (≥ 1). Gait speed was negatively associated with hip OA and the 3 factors, but the associations were greatly attenuated after adjustment (Table). For HAQ, a 1-SD increase in either the IP or knee factor resulted in 18% and 16% increased odds, respectively, of being in a higher HAQ category after adjustment (IP factor cumulative odds ratio [cOR]=1.18 [95% CI 1.03–1.36]; knee factor cOR 1.16 [95% CI 1.03–1.30]).

Association between composite factors representing multi-joint OA and functional outcomes.

OA variable[c]	HAQ[a] Unadjusted[d] cOR	95% CI	Adjusted[e] cOR	95% CI	Gait speed[b] Unadjusted[d] Beta	95% CI	Adjusted[e] Beta	95% CI
IP factor	1.45	1.29, 1.64	1.18	1.03, 1.36	−0.025	−0.038, −0.012	−0.003	−0.016, 0.010
MCP factor	0.94	0.84, 1.06	1.15[f]	0.96, 1.35	−0.014	−0.026, −0.001	−0.006	−0.018, 0.006
Knee factor	1.24	1.11, 1.39	1.16	1.03, 1.30	−0.030	−0.043, −0.018	−0.010	−0.022, 0.002
Hip OA	1.23	0.98, 1.53	1.12	0.89, 1.40	−0.044	−0.070, −0.019	−0.015	−0.038, 0.009
LS OA	1.11	0.90, 1.37	1.02	0.82, 1.27	−0.016	−0.041, 0.006	−0.001	−0.024, 0.022

HAQ: Health Assessment Questionnaire; cOR: cumulative odds ratio; CI: confidence interval; DIP: distal interphalangeal joint; PIP: proximal IP joint; MCP: metacarpophalangeal joint; TFJ: bibotemoral joint; PFJ: patellofemoral joint; Hip OA-KL grade 82 in either hip; LS OA-Lumbosacral spine OA, defined as an osteophyte 81 and disc narrowing at the same level.
a. Partial proportional odds regression model
b. Linear regression model
c. Factor scores are the standardized average of the radiographic scores of the included joints (average/std deviation)
d. Unadjusted results are for aI OA variables only.
e. Adjusted for age, BMI, gender, and race, with all OA variables in the model.
f. Factor 2 does not meet proportional odds assumption for categories of HAQ: the given OR is for the lowest category of HAQ (0) vs. the higher 2, for the lower 2 vs. the highest, OR 0.93 (95% CI: 0.81, 1.05)

Conclusions: Composite factors representing multi-joint OA involvement were associated with reduced gait speed and higher HAQ scores, although the estimates were attenuated by covariates, particularly age and BMI. Such composite factors can represent multiple joints in a single variable, reducing dimensionality and allowing more precise estimation of the effects of multi-joint OA involvement in models.

182

Associations between Radiographic Hand Osteoarthritis and Femorotibial Cartilage Thickness and Thinning in Subjects with Prevalent or at High Risk of Knee Osteoarthritis—Data from OAI.

Ida Kristin Haugen[2], Sebastian Cotofana[5], Martin Englund[3], Tore K. Kvien[1], Donatus Dreher[4], Michael C. Nevitt[6], Nancy E. Lane[7] and Felix Eckstein[5]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Diakonhjemmet Hospital, [3]Lund University, Boston University, Lund, Sweden, [4]Merck Serono SA, [5]Paracelsus Medical University, Chondrometrics GmbH, [6]UCSF, San Francisco, CA, [7]Univ of California at Davis, Hillsborough, CA

Introduction: Hand osteoarthritis (HOA) may represent generalized OA and a predisposition for knee OA. Previous studies have suggested that HOA is a risk factor for incident and progressive knee OA, but the relationship between HOA and MRI-based knee cartilage thickness has not been previously studied.

Aim: To evaluate whether radiographic HOA features are associated with knee cartilage thickness (cross-sectionally) and/or 1-year cartilage thinning.

Methods: We studied 765 knees from 765 OAI participants (455 women, mean (SD) age 62.5 (9.4) years) with prevalent or at high risk of knee OA. The dominant (n=467) or both hands (n=298) were imaged at baseline. One investigator scored the x-rays for presence of osteophytes (OP) and joint space narrowing (JSN) (grade 0–3) in the DIP, PIP, MCP and CMC-1 joints. If both hands were imaged, the hand with the highest total score was used for analyses. Total scores for OP (range 0–45) and JSN (range 0–45) were calculated. Femorotibial cartilage thickness (ThCtAB) was measured quantitatively from coronal FLASHwe images (0.E.1, 1.E.1) by Chondrometrics GmbH. In the cross-sectional analyses (linear regression), ThCtAB in the medial femorotibial compartment (MFTC) was the primary outcome. In the

longitudinal analyses (logistic regression), the ordered values (OV) of subregional cartilage thickness changes were used to define the outcome. OV1 represented the knee subregion with greatest cartilage thinning. The cut-off between progressors (cartilage thinning) and non-progressors (no/less cartilage thinning) was set to the median OV1 value. In the primary models, we evaluated the associations between radiographic HOA feature scores and ThCtAB with adjustment for age, sex and BMI. In the secondary models, separate analyses were done with knees grouped into two strata of knee OA at baseline (Kellgren-Lawrence grade (KLG) 0–2 and KLG 3–4)

Results: Most patients had mild HOA with median (quartiles) scores of 3 (1–6) for OP and 8 (5–12) for JSN. Hand JSN and OP scores were significantly associated with reduced ThCtAB in MFTC at baseline after adjustment for covariates (table). The associations were greater in KLG 3–4 than KLG 0–2. The risk of 1-year cartilage thinning was inversely related to higher hand JSN score in the total sample, while not significant for the hand OP score or in the stratified analyses (table).

Table. Associations between hand features and ThCtAB in MFTC (cross-sectionally) and 1-year cartilage thinning in OV1 (longitudinally) (beta (p value)).

	All patients (n = 765)	KLG 0–2 (n = 364)	KLG 3–4 (n = 401)
Cross-sectionally (MFTC)			
Hand OP score	−0.01 (0.05)	−0.002 (0.81)	−0.02 (0.06)
Hand JSN score	−0.02 (<0.001)	−0.01 (0.007)	−0.03 (<0.001)
Longitudinally (OV1)			
Hand OP score	0.01 (0.74)	−0.02 (0.45)	0.02 (0.35)
Hand JSN score	−0.03 (0.05)	−0.03 (0.23)	−0.03 (0.14)

Conclusion: Radiographic HOA features were significantly associated with reduced knee cartilage thickness cross-sectionally, assessed by quantitative MRI. This may support an endogenous and generalized susceptibility for OA. In contrast, we found no consistent association between HOA and 1-year knee cartilage thinning, and re-evaluation of the sample after a longer period of follow-up is warranted.

Change in Weight over 10 Years Is Associated with Bone Marrow Lesions in a Population-Based Cohort Study of Adult Women. Sharon Brennan[1], Flavia Cicuttini[1], Julie Pasco[1], Margaret Henry[2], Yuanyuan Wang[1], Mark Kotowicz[2], Geoffrey Nicholson[2] and Anita Wluka[1]. [1]Monash University, [2]University of Melbourne

Background: Although obesity is a modifiable risk factor for knee osteoarthritis (OA), the effect of change in weight on knee structure in young and healthy adults has not been examined. The aim of this study was to examine the relationship between body mass index (BMI), and change in BMI over the preceding 10-year period, and knee structure [cartilage defects, cartilage volume and bone marrow lesions (BMLs)] in a population-based sample of young to middle-aged females.

Methods: One hundred and forty two healthy, asymptomatic females (range 30–49 years) in the Barwon region of Victoria, Australia, underwent magnetic resonance imaging (MRI) during 2006-08. BMI measured 10 years prior (1994-97), current BMI and change in BMI (accounting for baseline BMI) over this period, was assessed for an association with cartilage defects and volume, and BMLs.

Summary of the Results: After adjusting for age and tibial plateau area, there was a trend for a 1 unit increase in current BMI to be associated with cartilage defects (OR 1.06 [95%CI 1.00, 1.13] p=0.05), and for a 1 unit increase in BMI over 10 years to be associated with reduced cartilage volume (–17.8ml [95%CI –39.4, 3.9] p=0.1). BMLs were associated with baseline BMI (OR 1.14 [95%CI 1.03, 1.26] p=0.009), current BMI (OR 1.13 [95%CI 1.04, 1.23] p=0.005), and per 1 unit increase in BMI (OR 1.14 [95%CI 1.03, 1.26] p=0.01). Results remained similar after excluding those with osteophytes.

Conclusions: This study provides longitudinal evidence for the importance of avoiding weight gain in women in during early to middle adult-hood as this is associated with adverse structural changes at the knee. Avoiding weight gain even in early adulthood may play an important role in the prevention of knee OA.

Comorbidity and Health Status in Early Osteoarthritis of Hip and Knee; CHECK Cohort. J. Wesseling[2], S. M. A. Bierma-Zeinstra[1], J. Dekker[4], K. J. Gorter[3], J. W. J. Bijlsma[3] and on Behalf of the CHECK Group. [1]Erasmus University Medical Center Rotterdam, [2]Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht, The Netherlands, [3]University Medical Center Utrecht, [4]VU University Medical Center Amsterdam

Background: Osteoarthritis (OA) is the most common diagnosis made in elderly patients with knee or hip pain. Like OA the prevalence of many other disabling conditions increases with age and many chronic conditions can be found together with OA. The objective of the present study is to describe the relationship between comorbidity (count as well as the presence of specific comorbidities) and complaints (like pain and limitation in activity) and the physical and mental status of participants with complaints of early osteoarthritis.

Methods: In the Netherlands a prospective 10-year follow-up study was initiated by the Dutch Arthritis Association in participants with early OA related complaints of hip and/or knee: the CHECK study, to study the onset and progression of OA. Individuals were eligible if they had pain and/or stiffness of knee and/or hip, were aged 45–65 years, and had never or not longer than 6 months ago visited the general practitioner for these symptoms for the first time. The WOMAC was utilized to measure pain and limitations in activity. Physical functioning and mental functioning were measured bij SF36. Comorbidity is assessed with a self-reported health module of the Agency of Statistics in the Netherlands with consists of 24 chronic diseases. Linear regression analysis was used to determine the influence of the 'comorbidity count' on the outcome variables pain, and physical and mental functioning.

Results: In CHECK 1002 participants were included, mean age of 56 years, mean BMI of 26 kg/m^2 and 79% female. Over 67% of the total study population had comorbidity: disorders of neck, shoulder, elbow, wrist or hand (23%), hypertension (20%) and back disorders (18%) were most prevalent. The results indicate that the pain score and physical function score on the WOMAC deteriorates with about 3 and 4 points respectively with every (extra) comorbidity. The physical and mental status of the SF36 deteriorates with respectively about 2 and 1 point with every (extra) comorbidity. Results of the final model (controlling for age, gender, Kellgren & Lawrence grade) show that severe back disorders have the most negative effect on WOMAC pain, physical functioning and one of the most negative effects on physical status of SF36. The presence of this disorder increases WOMAC pain score on average with 7 points, WOMAC function score with 8 points, and SF36 PCS score with 4 points. The mental status was negatively influenced by the presence of duodenal/gastric, thyroid disease, and migraine or regular headache.

Conclusions: In the early stage of osteoarthritis the effect of the presence of especially diseases in the locomotor system have negative effect on complaints and health status. The clinical implications are that to improve the physical health of participants with early OA of knee and/or hip not only the complaints related to OA have to be treated but also the additional diseases, especially back, neck, shoulder, elbow, wrist or hand disorders or obesity. Apart from the physical status also the mental status is affected in the early stage of OA by the presence of comorbidity and this is a further reason to take comorbidity into account in the management of early OA.

Do Bony Enlargements Correlate with Radiological Findings in Hand Osteoarthritis (HOA)? Roshan Dhawale[3], Niveditha Mohan[2], Michael J. Hannon[4] and C. Kent Kwoh[1]. [1]Univ of Pittsburgh, Pittsburgh, PA, [2]Univ of Pittsburgh Arth Inst, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA, [4]University of Pittsburgh

Purpose: Symptomatic Hand Osteoarthritis (HOA) affects 20% of patients above the age of 55 years, a large proportion of whom have bony enlargements. The relationship between bony enlargements and radiological findings of HOA is unclear and has not been well-studied. We assessed the correlation between bony enlargements and radiological findings and whether all patients with bony enlargements had radiological evidence of HOA.

Methods: The study utilized data from the Osteoarthritis Initiative, a community-based cohort aged 49–75 years with symptomatic knee OA or with risk factors for developing knee OA. Dominant hand films of 200

women were read by two independent trained investigators using the ICRS/OARSI Radiographic Atlas. The 1st carpometacarpal (CMC), 2nd-5th distal interphalangeal (DIP) and proximal interphalangeal (PIP) joints were assessed for joint space narrowing (JSN) and osteophytes (OST) on a scale of 0–3 and the presence of central erosions (CE) and lateral deviation (LD)(>15 degrees) was read. Trained study personnel assessed the presence of nodal enlargements. Grades 2 and 3 JSN and/or OST were considered as definite radiological evidence of HOA. Statistical analysis was performed by logistic regression adjusted for clustering by person with age over 65, race, BMI, smoking and family history of OA as covariates.

Results: The sample was predominantly Caucasian (83.5%); mean age was 61.6 ± 9.2 years. Three subjects had LD at the 1st CMC and 1 had LD at the 5th DIP. Thirty-six central erosions were found in 20 subjects, of which 86% were at the 1st CMC and DIP joints. Fifteen and 6 subjects had JSN and 3 and 2 subjects had OST in all four DIPs and PIPs respectively. One hundred and twenty-two subjects (61%) had bony enlargements on exam. Of 792 DIP joints, 101 had both bony enlargements and radiological evidence (JSN or OST). Having a bony enlargement was highly predictive of finding radiological evidence for OST (OR 23.03, 95% CI 9.62–55.18) and JSN (OR 9.73, 95% CI 5.43–17.44). When adjusted for covariates, the association was maintained for OST (OR 13.26, 95% CI 4.98–35.31) and JSN (OR 7.0, 95% CI 3.68–13.27). Only 27 subjects had radiological findings without bony enlargements on examination, but 182 subjects, a significantly higher number, had a bony enlargement without any radiological evidence of OA.

Table 1. Distribution of HOA

	JSN (Grade 1)		JSN (Grades 2,3)		OST (Grade 1)		OST (Grades 2,3)	
Joint	*n*	**(%)**	*n*	**(%)**	*n*	**(%)**	*n*	**(%)**
CMC	99	49.5	41	20.5	73	36.5	41	20.5
DIP 2	65	32.5	26	13	34	17	24	12
DIP 3	66	33	26	13	20	10	15	7.5
DIP 4	65	32.5	31	15.5	7	3.5	8	4
DIP 5	79	39.5	33	16.5	39	19.5	20	10
PIP 2	70	35	9	4.5	24	12	10	5
PIP 3	86	43	15	7.5	20	10	7	3.5
PIP 4	97	48	19	9.5	11	5.5	8	4
PIP 5	89	44.5	15	7.5	21	10.5	7	3.5

Conclusion: The presence of bony enlargement strongly correlates with radiological evidence of HOA, but having a bony enlargement does not always predict having radiological findings. A possible explanation for why a large number of patients had bony enlargements without radiological evidence of hand OA may be because we excluded Grade 1 JSN and OST from our analysis. However, it appears that radiological evidence is more specific for HOA. Our study suggests that radiological evaluation is an inexpensive diagnostic tool to confirm HOA.

Frailty and 3-Year Mobility Outcome in Persons with or at Higher Risk for Knee Osteoarthritis. September Cahue[4], Karen W. Hayes[2], Jing Song[4], Dorothy D. Dunlop[3], Joan S. Chmiel[4], Marc C. Hochberg[5], Carmelita J. Colbert[1] and Leena Sharma[3]. [1]Northwestern University, LaGrange, IL, [2]Northwestern University, Downers Grove, IL, [3]Northwestern University, Chicago, IL, [4]Northwestern University, [5]University of Maryland, Baltimore, MD

Purpose: Frailty has been examined in the context of aging, but little is known about its role in health outcomes in persons with knee osteoarthritis (OA). Risk of knee OA increases with age, and knee OA is a leading cause of chronic disability in older individuals; however, how best to identify persons who are likely to decline and/or benefit from intervention is unknown. The Osteoarthritis Initiative (OAI) cohort represents the continuum of knee OA from the stage of high risk prior to radiographic change through advanced disease and is uniquely suited to our goals: 1) determine the prevalence of frailty in this population; and 2) evaluate whether frailty at baseline predicts subsequent 3-year mobility outcome.

Methods: OAI data from public release data set 0.2.2 were used. We adapted the frailty index of Ensrud et al (Arch Int Med 2008), including inability to rise five times from a seated position without using arms and self-reported exhaustion (CES-D) (but not the weight criterion due to varied implications of weight loss in this population and because BMI was the basis of enrollment for a subset of the OAI cohort). Mobility outcomes were: baseline-to-3-year increase in difficulty in WOMAC mobility items (walking, ascending stairs, descending stairs); poor SF12 physical component outcome (persons were grouped by quintile of baseline function, and "poor" defined as moving into a worse quintile group or remaining in the worst 2 groups at 3 years). We used logistic regression to analyze the relationship between frailty at baseline (≥ 1 item) (vs. not frail, reference) and baseline-to-3-year outcome, adjusting for age, gender, race, education, comorbidities, and K/L grade (worse of the two knees) in the overall sample and in BMI strata.

Results: In 4138 persons, mean age was 61 years, mean BMI was 28, and 58% were women. At baseline, 14% of women and 11% of men were frail. Frailty was also associated with being African-American, having a lower education level, and poorer self-assessed health. By three years, 35% had worse WOMAC mobility, and 52% had poor SF12 physical component outcome. In the overall sample (Table), frailty at baseline was associated with worse 3-year WOMAC mobility and poor SF12 physical component outcome in adjusted analyses. These results persisted in the normal weight and overweight strata but were not significant in the obese stratum (Table).

Table. Frailty and 3-Year Mobility Outcome, Odds Ratios (OR) (95% CI)

	WOMAC Mobility Item Worsening OR (95% CI)		Poor SF12 Physical Component Outcome OR (95% CI)	
	Unadjusted	**Adjusted***	**Unadjusted**	**Adjusted***
Overall N = 4138**	*1.73 (1.44, 2.08)*	*1.56 (1.29, 1.89)*	*1.79 (1.48, 2.17)*	*1.63 (1.34, 1.99)*
BMI Categories	Unadjusted	Adjusted*	Unadjusted	Adjusted*
Normal (BMI <25) N = 1027**	*2.06 (1.36, 3.11)*	*1.79 (1.16, 2.75)*	*1.55 (1.02, 2.37)*	1.48 (0.96, 2.28)
Overweight (25≤BMI<30) N = 1027**	*1.91 (1.42, 2.57)*	*1.71 (1.25, 2.32)*	*2.30 (1.67, 3.17)*	*2.21 (1.59, 3.08)*
Obese (BMI ≥30) N = 1483**	*1.33 (1.00, 1.76)*	1.27 (0.94, 1.70)	*1.39 (1.03, 1.88)*	1.23 (0.89, 1.68)

*Adjusted for age, gender, race, education, comorbidities, K/L grade
**SF-12 outcome sample sizes; Overall n = 3968; BMI Categories; Normal n = 967; Overweight n = 1569; Obese n = 1432

Conclusion: A simple frailty index, easily usable in a clinical setting, was independently associated with worse 3-year mobility in persons at high risk for or with knee OA. These results also suggest that a frailty index may not function similarly across BMI strata in this population. Further work to refine the ability to capture the frailty phenotype—decreased reserve and resistance to stressors—should occur, as a simple but potentially powerful means of ultimately aiding the prevention of adverse outcomes in persons with knee OA.

Greater Burden of Disease in Erosive Hand Osteoarthritis. Mariko L. Ishimori[1], Roy D. Altman[4], Myles J. Cohen[2], Jerome I. Rotter[2] and Michael H. Weisman[3]. [1]Cedars Sinai Medical Center, Los Angeles, CA, [2]Cedars-Sinai, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]UCLA, Agua Dulce, CA

Purpose: The goal of our study was to evaluate relationships between patients with erosive vs. non-erosive hand osteoarthritis (OA) by radiography and features such as extent of joint involvement, body mass index (BMI), and pain, stiffness, and physical disability as assessed by the Australian/Canadian (AUSCAN) Hand Osteoarthritis Index.

Methods: Consecutive patients with clinical and radiographic hand OA were evaluated by examination, BMI, radiography, and AUSCAN as part of The Genetics of Hand Osteoarthritis Study (GHOST). Radiographs were scored by radiographic atlas and analyzed for relationship to degree of joint involvement, BMI and AUSCAN subscales. Subjects were grouped as 1) erosive involvement of distal interphalangeal (DIP), proximal interphalangeal (PIP) and interphalangeal (IP) joints with hand OA, 2) non erosive (nodal) involvement of DIP, PIP and IP joints with hand OA, and 3) non-erosive involvement of 1st carpo-metacarpal (CMC) joints only. Subjects with any one joint with erosive change were classified as having erosive hand OA. Two scores were generated: 1) Total Count—number of selected joints with osteophytes and 2) Total Score—Sum of osteophytes scores from selected joints (DIP, PIP, IP, CMC).

Results: A total of 279 subjects were enrolled with a mean age of 68.7 years. The majority of study subjects were women (90.7%) and Caucasian (91.0%). The breakdown of radiographic findings was as follows: 105 (37.6%) with erosive changes, 124 (44.4%) with non-erosive (nodal) involvement and 50 (17.9%) with non-erosive CMC involvement. The group of subjects with erosive hand OA had greater Total Score ($p<0.0001$) and Total Count ($p=0.001$) than subjects with non-erosive (nodal) hand OA or CMC involvement. The AUSCAN subscore of stiffness was significantly greater in erosive hand OA ($p<0.0003$) and nodal hand OA ($p=0.027$) than in subjects with CMC only involvement (Wilcoxon rank sum). Within the erosive hand OA group, increasing number of joints involved with HOA correlated with worsening Stiffness ($p=0.0099$) and Physical Function ($p=0.0175$) subscales of the AUSCAN index (Spearman's correlation).

Conclusion: In a cross-sectional analysis of clinical and radiographic hand OA, subjects with erosive hand OA generally had a greater burden of joints involved that the non-erosive (nodal) group. This may be related to erosive OA potentially being a more severe manifestation and a different group than traditional non-erosive (nodal) OA, suggesting genetic differences. Within the erosive hand OA group, greater Stiffness and worse Physical Function by AUSCAN index correlated with increasing numbers of joints involved with hand OA. This occurred even when there were very few or only one joint with erosive change. The concepts of nodal versus erosive IP arthritis may represent distinct clinical and etiologic groups, and not two sides of a spectrum, reflecting the heterogenity of hand OA which may have implications for genetic studies. Future studies need to include careful descriptions of disease phenotypes, particularly in relation to genetic investigations.

Image Processing and Machine Learning Methods Applied to MRI Trabecular Morphometry in Knee Osteoarthritis. Jason Nochlin[4], Eric Miller[4], Grace H. Lo[2], Anna Tassinari[1] and Timothy E. McAlindon[3]. [1]Tufts Medical Center, Boston, MA, [2]Tufts Medical Center, Houston, TX, [3]Tufts Medical Center Box 406, Boston, MA, [4]Tufts University, Medford, MA

Purpose: We can image periarticular bone in vivo, a tissue involved in the pathology of knee osteoarthritis (OA). In digital images such as MRIs, *texture* refers to patterns in pixel intensity. Using texture filters, the original image is transformed into a new image where the value of each pixel corresponds to how well the region around that pixel "matches" the pattern encapsulated in a filter. Such techniques are used to characterize regions of an image. In a natural scene, though the image may not resolve single blades of grass, the pixel patterns formed by these structures infer information about the individual components. In this instance where individual trabeculae are not resolved in images of the periarticular bone, our hypothesis is that variations in texture correlate with relative periarticular bone mineral density (paBMD), a known correlate of structural OA severity.

Methods: Using a sample of 39 right knees from an ancillary study to the Osteoarthritis Initiative, we analyzed 3T MRIs (Trio, Siemens) coronal 3D FISP trabecular sequences. From each of 20 central slices, a region of interest (ROI) in the periarticular tibia was extracted by identifying the top edge of the bone and selecting a region of 24mm wide by 8mm high. 24 texture filters (8 Gabor and 16 Laws' Masks) were applied to each ROI. All pixels in each transformed slice's ROI formed a data array for that filter. With each Laws' Mask, pixel values were squared to form a new data array, totaling data arrays (20 slices $\times$ 2) for each knee MRI. On each array we computed mean, standard deviation, skewness, entropy, and kurtosis. Knee DXAs were obtained using a GE Lunar scanner to calculate measures of the medial:lateral tibial paBMD. The 200 statistics from the 40 data arrays were used as regressors for predicting medial:lateral tibial paBMD. The regression problem was solved using kernel-Support Vector Regression. A wrapper approach was used to limit the number of regressors in solution to 15. All computations were done using MATLAB r2007b.

Results: Thirty-nine patients were studied, 53% males; age 68 ($\pm$9.3); BMI 27.8 ($\pm$4.6). The predictive model estimated the medial:lateral paBMD ratio for each patient in a cross-validation scheme, a regression coefficient of.870 was found between the predicted and actual values, (p-value of $p<.0001$).

Of the 15 selected regressors, several patterns were found. The most prominent textures were Laws' Masks derived from a 1mm (5 pixel) *wave* or *ripple* pattern. The wave pattern roughly corresponds to texture with frequent, large changes in contrast (brightness highs and lows nearby each other). The ripple pattern corresponds to texture where the maxima are extremely prominent. Gabor Filters, which match sine wave patterns in the texture, with a wavelength of.8mm (4 pixels) with various orientations were also significant differentiators.

Conclusion: Using image processing and machine learning techniques, we developed a novel method for analyzing bone structure MRI images that correlate well to paBMD. Further development of such tools will help in better understanding of the periarticular bone pathology in those with knee OA. Future studies are needed to validate these measures against histopathology.

Knee Confidence and Physical Function Outcome in Persons with Knee Osteoarthritis. Carmelita J. Colbert[1], Jing Song[4], Dorothy D. Dunlop[3], Joan S. Chmiel[4], Karen W. Hayes[2], September Cahue[4], Kirsten Moisio[4], Alison H. Chang[3] and Leena Sharma[3]. [1]Northwestern University, LaGrange, IL, [2]Northwestern University, Downers Grove, IL, [3]Northwestern University, Chicago, IL, [4]Northwestern University

Purpose: Given the central role of the knee in all weightbearing activity, confidence in the knees may be a proximal factor influencing activity choices and self-efficacy, factors thought critical to function and disability. We evaluated whether knee confidence at baseline was associated with physical function outcome over the subsequent two years in persons with knee OA, and whether any relationship persisted after adjusting for other factors.

Methods: Osteoarthritis Initiative (OAI) participants have or are at risk for developing knee OA. Knee confidence was assessed using the KOOS item (How much are you troubled with lack of confidence in your knees?) and function assessments included the WOMAC function scale and chair stand test performance. We grouped participants with knee OA ($K/L \geq 2$) by quintile of baseline function; poor outcome was defined as moving into a worse quintile group or remaining in the 3 worst groups at 24 months. To evaluate the relationship between baseline confidence and poor outcome, logistic regression was used, sequentially adjusting for nested groups of covariates: 1) age, gender, race; 2) previous covariates + depression, comorbidity, falls; 3) all previous + BMI; 4) all previous + physical activity, alcohol use; 5) all previous + hip, ankle, foot pain; 6) all previous + knee injury, knee surgery; and 7) all previous + knee pain severity, knee OA severity, extensor strength.

Results: Among 2243 OAI participants (mean age 62 years, BMI 29, 57% women) with knee OA, the percentage with poor outcome increased with worse baseline knee confidence category (Table 1).

Table 1. Proportion of Persons with Poor Baseline-to-2-Year Function Outcome by Baseline Confidence Level

	Percent with Poor Baseline-to-2-Year Function Outcome of Persons within Baseline Knee Confidence Category	
Knee Confidence Category	Poor WOMAC Physical Function Outcome	Poor Chair Stand Outcome
Not troubled by lack of confidence (n = 923 persons)	32.9%	47.6%
Mildly troubled by lack of confidence (n = 692)	48.8%	50.5%
Moderately troubled by lack of confidence (n = 422)	56.9%	51.9%
Severely or extremely troubled by lack of confidence (n = 206)	69.4%	59.3%

As shown in Table 2, compared to persons not lacking confidence, the odds of a poor WOMAC outcome and a poor chair stand outcome increased with worse knee confidence category resulting in significant trend tests. For the WOMAC outcome, this held for all intermediate nested covariate groups (not shown) and in the final fully adjusted analysis (Table 2). In contrast, the relationship between confidence and poor chair stand outcome was weaker and significance did not persist in the fully adjusted analysis (Table 2). For

both outcomes, the reduction in the odds ratio was most pronounced after further adjustment for the final covariate group.

Table 2. Odds Ratios and 95% Confidence Intervals (CIs) Associated with Knee Confidence for Poor Baseline-to-2-Year Function Outcome

	Poor WOMAC Physical Function Outcome		Poor Chair Stand Outcome	
Knee Confidence Category	OR (95% CI)	Adjusted* OR (95% CI)	OR (95% CI)	Adjusted* OR (95% CI)
Not troubled by lack of confidence (reference)	reference	reference	reference	reference
Mildly troubled by lack of confidence	1.94 (1.59, 2.38)	1.67 (1.35, 2.08)	1.12 (0.92, 1.38)	1.08 (0.87, 1.35)
Moderately troubled by lack of confidence	2.69 (2.12, 3.40)	1.90 (1.45, 2.48)	1.19 (0.94, 1.51)	1.02 (0.78, 1.35)
Severely or extremely troubled by lack of confidence	4.62 (3.33, 6.40)	2.59 (1.76, 3.80)	1.61 (1.16, 2.22)	1.23 (0.83, 1.82)
P for trend	< .0001	< .0001	.005	.44

*model including all covariate groups

Conclusion: In persons with knee OA, lower knee confidence at baseline was associated with poor 2-year WOMAC function outcome but not with poor chair stand outcome in adjusted analyses. The role of confidence in the trajectory of physical function decline in knee OA should be further examined; better understanding of its role may empower strategies to reduce the likelihood of poor outcome.

Lateral Compartment Unloading in People with Medial Knee Osteoarthritis. Deepak Kumar, Katherine S. Rudolph and Kurt Manal. University of Delaware, Newark, DE

Background: It is well known that people with medial knee osteoarthritis (MKOA) exhibit high knee adduction moments (KAM) during walking. Investigators have speculated that a failure to generate sufficient muscle force to counter high external loads could result in the lateral femoral condyle lifting off the tibia. Lateral condular lift-off has not been confirmed by modeling techniques that account for subject specific EMG patterns, kinematics and kinetics. The aims of this study are (1) to estimate articular loads in people with MKOA using an EMG-driven model and, (2) to examine the relationship between passive laxity, varus malalignment, functional knee instability (FKI) and loading patterns.

Methods: 16 MKOA and 12 control (C) subjects walked while kinematic, kinetic and EMG data were collected. Muscle forces and moments were calculated from an EMG-driven model previously described. Loading of the medial and lateral compartments were calculated by balancing the internal/external moments at the knee. One walking trial was used to optimize the model parameters and the average of 3 separate trials was used to predict articular loading during stance. Functional Knee Instability (FKI) was assessed from the Knee Outcome Survey. Stress radiographs were used to assess frontal laxity and long cassette radiographs were used to assess alignment. ANOVAs and Pearson's correlation coefficients comprised the statistical analyses.

Results: MKOA subjects walked more slowly and had greater laxity, static and dynamic varus alignment, less flexion and greater KAM than controls. Loading, when normalized to BW was no different between the groups but MKOA subjects had greater absolute medial load than C and maintained a greater %total load on the medial compartment. Lateral compartment unloading during mid-late stance was observed in 50% of OA subjects which was related to greater KAM, dynamic varus alignment and FKI but not to laxity or static malalignment. MKOA subjects with lateral joint unloading had lower hamstring force and lower force in the lateral muscles.

Discussion: Loading for C subjects matched that measured from instrumented knee prostheses, supporting the veracity of the model. Speculations about greater medial loading in people with MKOA are confirmed with our data, as well as, the phenomenon of lateral condylar lift-off. It was interesting that the unloading did not occur during weight acceptance phase when the loads are greatest but rather occurred during mid-late stance when the knee experiences its greatest varus angulation. The relations between unloading to FKI rather than laxity or malalignment suggest that it is due to a failure of neuromuscular strategies and not only mechanical factors. This was confirmed by the muscle force data where we found that MKOA subjects who showed unloading, had poor quadriceps-hamstring and medial-lateral muscle force balance resulting from lower hamstring and lateral muscle forces. These data support the need for neuromuscular retraining interventions for people with MKOA that address loading and FKI rather than quadriceps strengthening alone.

Lower Extremity Muscle Function, Quality of Life and Physical Function Outcomes and Their Relation to Subsequent Knee Replacement in a 24 Month Period—Data from the Osteoarthritis Initiative (OAI). Bjoern Buehring[1], Boris Bershadsky[2] and M. Elaine Husni[1]. [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic

Background: Patients with osteoarthritis (OA) of the knee have functional disability and reduced muscle performance. The impact of lower extremity muscle function and its recovery after total knee arthroplasty (TKA) is largely unknown. In a previous analysis of the OAI database we found that muscle performance is associated with health related quality of life (HRQoL) and physical function in individuals with both evidence of knee OA or at risk for developing OA. We hypothesize that these parameters change over time and that preoperative values can predict the likelihood of TKA.

Methods: Baseline and 24 months data from OAI were examined using three cohorts labeled as: 1) a "progressive" group (PRO) with evidence of knee OA at baseline, 2) an "incidence" group (INC) with risk factors for developing OA, and 3) normal controls. Parameters of interest were isometric upper leg strength, rapid chair-stands, and 20 and 400-meter walks as well as the WOMAC, KOOS, and Study Short Form (SF12) questionnaires. We compared changes between baseline and 24 months data and differences among groups using t-tests. The relation of baseline parameters to TKA within the next 24 months was examined using binary logistic and linear multivariate regression models. This analysis was done separately for persons that received a right TKA, a left TKA and for all TKAs combined.

Results: 4796 volunteers (PRO: 1390, INC: 3284, control 122) from the OAI cohort were included. 41.5% were men and 58.5% women. Muscle power assessed by the 400m walk time worsened by approx 2% whereas chair-stand pace improved by 2% in PRO and INC, 20m walk pace declined in PRO only ($p<0.05$ or lower). Muscle strength worsened in both groups ($p<0.0001$) by 6–10%. WOMAC and KOOS scores improved in PRO and INC (all $p<0.0001$) and varied between 1–9%. SF-12 scores worsened ($p<0.05$ or lower) but changes were small (2%). No changes were found in the control group for any of the measures. At 24 months there were 35 new right and 27 new left TKA. Baseline parameters that best correlated with future TKA were SF12, WOMAC disability score, 400m walk time and right quadriceps strength. Knee specific analysis revealed better prediction ability than if new TKA was assessed for both knees combined. Models remained significant after adjusting for age, BMI and gender. When comparing baseline muscle tests and HRQoL of individuals undergoing a TKA at 24 months to those without, persons with TKA had worse scores in all parameters ($p<0.05$ or lower).

Conclusions: Our analysis demonstrated that both HRQoL and muscle performance tests were able to distinguish between individuals with knee OA and those at risk for OA. WOMAC scores, SF12, 400m walk time and quadriceps strength were able to independently predict the likelihood of subsequent TKA. Side specific knee analysis was better than combined knee (L and R) analysis. Individuals that underwent a TKA within 24 months had worse scores in all HRQoL and muscle performance parameters at baseline suggesting these measures should be included in routine clinical assessment of knee OA patients. Improving muscle function and HRQoL should be a focus of preoperative risk stratification to optimize potential outcomes for TKA patients.

Morphological Changes in Articular Cartilage and Subchondral Bone in Tibiofemoral and Patellofemoral Joints Following Arthroscopic Partial Medial Meniscectomy. Yuanyuan Wang[2], Alasdair Dempsey[3], David Lloyd[3], Peter Mills[1], Tim Wrigley[4], Kim Bennell[4], Ben Metcalf[4], Fahad Hanna[2] and Flavia Cicuttini[2]. [1]Griffith University, [2]Monash University, [3]The University of Western Australia, [4]University of Melbourne

Background: Although meniscectomy is an important risk factor for tibiofemoral osteoarthritis (OA), there is a paucity of studies examining the

relationship between meniscectomy and patellofemoral OA. This study aimed to examine the morphological changes in articular cartilage and subchondral bone in tibiofemoral and patellofemoral joints in a meniscectomy population.

Methods: 158 patients aged 30–55 years, without evidence of knee OA when undergoing isolated arthroscopic partial medial meniscectomy (APMM), and 38 controls with similar characteristics with APMM patients but without the surgery were recruited. Magnetic resonance imaging (MRI) of the operated knee was obtained at 3 months, 2 years, or 4 years post-surgery. MRI of the randomly assigned knee of the controls was also obtained. Cartilage volume and cartilage defects, bone area or volume were assessed using validated methods in tibiofemoral and patellofemoral compartments.

Summary of Results: Compared with controls, patients undergoing APMM had an increased prevalence of cartilage defects in the medial tibiofemoral (OR = 3.17, 95% CI 1.24 – 8.11, P = 0.02) and patellofemoral (OR = 13.76, 95% CI 1.52 – 124.80, P = 0.02) compartments, and increased medial tibial plateau bone area (B = 143.8, 95% CI 57.4 – 230.2, P = 0.001). Time from APMM was positively associated with the prevalence of cartilage defects in the medial tibiofemoral (OR = 1.02, 95% CI 1.00 – 1.03, P = 0.09) and patellofemoral (OR = 1.04, 95% CI 1.01 – 1.07, P = 0.02) compartments, and medial tibial plateau area (B = 2.5, 95% CI 0.8 – 4.3, P = 0.005), but negatively associated with lateral tibial cartilage volume (B = −4.9, 95% CI −8.4 to −1.5, P = 0.005). The association of APMM and time from APMM with patellar cartilage defects was independent of medial tibial cartilage volume.

Conclusions: Meniscectomy has adverse impacts on both tibiofemoral and patellofemoral joints within 5 years post-surgery. Strategies aimed at preventing the development of OA and reducing morbidity in meniscectomy populations should focus on both tibiofemoral and patellofemoral joints.

MRI-Defined Risk Factors for Cartilage Loss over a 6 Months Period. Frank W. Roemer[1], C. Kent Kwoh[2], Michael J. Hannon[2], Stephanie M. Green[2], John M. Jakicic[2], Robert Boudreau[2], Michel D. Crema[1] and Ali Guermazi[1]. [1]Boston University, [2]University of Pittsburgh

Purpose: Cartilage morphology may only be directly assessed by MRI. Cartilage loss over short observational periods is rare but not uncommon. Aim of the study was to assess several non-MRI and MRI-features as baseline (BL) risk factors that may predict patello-femoral (PF) and tibio-femoral (TF) cartilage loss over a 6 months follow-up (FU) period.

Materials and Methods: The JOG study is a double-blind randomized trial investigating the effect of oral glucosamine supplementation over a 6 months period. 177 subjects aged 35–65 with chronic, frequent knee pain were included. 3 T MRI of both knees was performed at BL and 6 months FU using the same pulse sequence protocol as in the Osteoarthritis Initiative. Knees were semiquantitatively assessed according to the WORMS system. Cartilage status was scored on a scale from 0–6. A change of +0.5 in any subregion, indicating within-grade progression, was defined as the minimum requirement for cartilage loss. Bone marrow lesions (BMLs) in the same subregion, meniscal damage or meniscal extrusion in the TF compartment, synovitis and effusion were scored in addition and assessed as baseline risk factors.

All MR joint morphologic features were dichotomized into present (≥ 1) vs. absent (0). Logistic regression models were applied to assess the risk of cartilage loss for knees exhibiting risk factors when compared to knees without the risk factor at baseline. We performed a subregion-based analysis using general estimating equations (GEE) to account for the clustering of subregions within a knee and knees within an individual. Multivariate models were adjusted for age, gender, treatment (oral glucosamine) and BMI. In addition MRI-based risk factors were adjusted for each other in a multi-adjusted model.

Results: 51.2 % of participants were men, mean age was 52.3 (± 6.2), mean BMI was 29.1 (± 4.1). Baseline Kellgren/Lawrence grades (for worst knee) were: K/L 0: 37 (20.9%) knees, K/L 1: 14 (7.9%) knees, K/L 2: 26 (14.7%) knees, K/L 3: 81 (45.8%) knees K/L 4: 19 (10.7%). Of the 353 knees, 304 knees (87.9%) and 1,153 subregions (23.8%) exhibited prevalent cartilage damage at baseline. 79 (1.6%) subregions showed incident or worsening cartilage damage at 6 months FU. Predictors for PF cartilage loss at 6 months were baseline presence of effusion and prevalent cartilage damage in the same subregion. Risk factors for TF cartilage loss were baseline ipsi-compartmental meniscal extrusion, prevalent BMLs and cartilage damage in same subregion.

Table 1. Risk factors for patello-femoral and tibio-femoral cartilage loss over 6 months of follow-up

Risk factor	Reference	Adjusted Odds Ratio[3] (95% confidence intervals)
Patello-femoral		
Effusion (WORMS ≥ 1)[1]	Effusion absence (WORMS score = 0)	3.54 (1.30–9.64)*
Synovitis (modified WORMS ≥ 1)[1]	Synovitis absence (modified WORMS score = 0 in both synovitis subregions)	0.79 (0.28–2.07)
Prevalent cartilage damage (WORMS ≥2)[2]	No cartilage damage in subregion (WORMS score = 0 or 1)	4.32 (1.35–13.85)*
BML (WORMS ≥ 1)[2]	No BML in subregion (WORMS score = 0)	1.61 (0.67–3.84)
Tibio-femoral		
Effusion[1] (WORMS ≥ 1)[1]	Effusion absence (WORMS score = 0)	1.79 (0.76–4.23)
Synovitis[1] (modified WORMS ≥ 1)[1]	Synovitis absence (modified WORMS score = 0)	0.68 (0.32–1.45)
Meniscal damage[4]	No meniscal damage	1.98 (0.76–5.15)
Meniscal extrusion[4]	No meniscal extrusion	3.62 (1.29–10.12)*
Prevalent cartilage damage (WORMS ≥ 2)[2]	Absence of cartilage damage in subregion (WORMS = 0 or 1)	15.90 (5.08–49.79)*
BML(WORMS ≥ 1)[2]	No BML in subregion (WORMS = 0)	4.58 (1.08–19.44)*

[1]cartilage loss at 6 months in any of 4 PF/10 TF subregions
[2]cartilage loss or worsening of BML in same subregion at 6 months follow-up
[3]multi-adjusted GEE model accounting for correlations within and between knees, and adjusted for age, gender, BMI, treatment, and the other MR features
[4]cartilage loss in same compartment as meniscal damage or extrusion (5 subregions medial or lateral)
*statistically significant at p ≤ 0.05

Conclusion: Cartilage loss over 6 months is rare, but may be detected semiquantitatively by MRI. The strongest predictors of PF cartilage loss were presence of baseline effusion and prevalent cartilage damage in the same subregion. The greatest predictor of TF cartilage loss was also prevalent cartilage damage, but prevalent BMLs and meniscal extrusion were also significant predictors of compartment-specific TF cartilage loss.

Neuromuscular Responses to Perturbations during Walking in Knee Osteoarthritis: Influence of Instability, Strength, Proprioception and Stiffness. Deepak Kumar, Darcy Reisman, Charles B. Swanik and Katherine S. Rudolph. University of Delaware, Newark, DE

Background: Neuromuscular interventions that reduce disability and slow disease progression are needed for people with knee osteoarthritis (OA). Effective interventions would depend on the ability of the neuromuscular system to adapt to changing external demands, in spite of the deficits in afferent and efferent pathways seen in people with knee OA. The ability of the neuromuscular system to adapt has been studied through the response to repeated perturbations; however, no studies report mechanisms that may accompany successful neuromuscular adaptation in people with knee OA. The aims of this study are to (1) analyze the responses to repeated perturbations during walking in people with knee OA compared to controls, and (2) to analyze the effect of quadriceps strength, functional knee instability (FKI), proprioceptive loss and altered knee stiffness on the responses to repeated perturbations.

Methods: 43 subjects with medial knee OA and 21 healthy controls (C) participated. Kinematic and EMG data were collected as subjects walked overground (Level) for 10 trials and over a platform that translated laterally (Perturbed) at initial contact (IC), for 30 trials. FKI was assessed from the response to the instability question in Knee Outcome Survey. Isometric quadriceps strength was measured at 90° flexion. Proprioception was assessed using Threshold to Detect Passive Motion and Joint Repositioning Sense techniques at 15° flexion. Knee stiffness (toque/degree motion) was assessed by

a rapid knee flexion from 30°-50° while seated. Walking data were analyzed over- Preactivation (Pre:100 msec before IC), Loading Response (LR: IC to peak knee flexion) and Midstance (MSt: end of LR to peak knee extension) phases. Mixed ANOVAs and Pearson's correlations were used for statistical analyses.

Results: OA had lower quadriceps strength than C. There were no differences in proprioception or stiffness. OA had less motion and higher activation than C across all conditions. All groups showed an increase in activation and decrease in motion in the 1st perturbation trial compared to normal walking. No adaptation was seen during preactivation and LR phases but during MSt, there was increased knee motion and deceasedmuscle activation over the 1st 5 trials. Quadriceps strength, knee stiffness, proprioception and FKI were not related to the rate of adaptation.

Discussion: This is the 1st report of neuromuscular adaptation in people with knee OA, and also for knee stiffness in this population. We found that people with knee OA respond similarly to controls when exposed to repeated lateral perturbations during walking, with an increase in knee motion and decrease in muscle activations. The knee OA related impairments in quadriceps strength, proprioception, stiffness and dynamic stability are not related to the ability to adapt. The results provide evidence that rehabilitation strategies aimed at modifying movement and muscle activation strategies to improve knee stability and reduce joint contact forces may be effective for people with knee OA. Further study is needed to determine the goals and best methods for improving neuromuscular control in this population.

Peri-Articular Bone Density Is Strongly Correlated with Static Alignment and Varus Thrust.

Grace H. Lo[1], William F. Harvey[2], Melanie Ripley[3], Erica McAdams[3], Melynn Nuite[2] and Timothy E. McAlindon[4]. [1]Baylor College of Medicine, Houston, TX, [2]Tufts Medical Center, Boston, MA, [3]Tufts Medical Center, [4]Tufts Medical Center Box 406, Boston, MA

Purpose: Knee bone mineral density (BMD) has been associated with radiographic and MRI features of OA. Therefore, we hypothesized that tibial peri-articular BMD (paBMD) would be associated with static and dynamic alignment, both predictors of OA structural progression.

Methods: This is a cross-sectional study of a convenience sample from a randomized controlled trial (RCT) of vitamin D for symptomatic radiographic knee OA. Participants had standing PA semi-flexed knee x-rays read for anatomic alignment, a measure of static alignment. All consenting participants who did not use ambulatory devices and had video recordings of their gait using a standard digital video camera (60 Hz) walking at a self-selected speed were measured for varus thrust (VT), a measure of dynamic alignment. These videos were viewed at separate reading sessions by two rheumatologists trained to evaluate VT. Disagreements were adjudicated by consensus of both readers. Knee DXA scans were obtained using a GE-Lunar scanner and customized regions of interest were placed to calculate the medial:lateral tibial paBMD (ICC = 0.98).

Anatomic alignment measures were modified to reflect mechanical alignment; < 178°, 178° – 182°, and > 182° categorized participants as varus, neutral, or valgus respectively. Low, normal and high tibial paBMD groups were defined using biological cut offs of 1 and 1.25. We ran ANOVAs of medial:lateral paBMD stratified by mechanical alignment and VT groups. We also performed chi-squared tests of mechanical alignment and VT prevalences stratified by tibial paBMD groups.

Results: Participants (N=82) were 60% female, had a mean age 63.0 (±8.5), BMI 30.2 (±5.4), and tibial medial:lateral paBMD 1.19 (±0.21). 49% and 23% had varus and valgus alignment while 31% had VT.

Varus and valgus were associated with higher and lower medial:lateral paBMDs respectively. Mechanical alignment accounted for 59% of the variability in medial:lateral paBMD. (Table 1) VT was associated with higher medial:lateral paBMD. (Table 1).

Table 1. Medial: Lateral paBMD stratified by biomechanical categories.

		Mean Medial: Lateral paBMD	R^2	Overall p-values	Individual p-values
Static Allignment	Varus (n = 40)	1.35	0.59	< 0.0001	<0.0001
	Neutral (n = 23)	1.11			Referent
	Valgus (n = 19)	0.95			0.0014
Varus Thrust	Present (n = 25)	1.33	0.20	< 0.0001	n/a
	Absent (n = 57)	1.13			

The high medial:lateral paBMD had a high varus (93%) and a low valgus (0%) prevalence. (Table 2). The low paBMD group had the opposite findings.

Table 2. Prevalence of biomechanical categories stratified by the medial:lateral paBMD groups.

	VARUS Prevalence		VALGUS Prevalence		Varus Thrust Prevalence	
Medial:Lateral paBMD Groups						
Low	0/16 (0%)	p<0.0001	12/16 (75%)	p<0.0001	1/16 (6%)	p<0.0001
Normal	12/36 (33%)		7/36 (19%)		6/36 (17%)	
High	28/30 (93%)		0/30 (0%)		18/30 (60%)	

Conclusion: Static and dynamic alignment are strongly associated with medial:lateral tibial paBMD, accounting for nearly 60% and 20% of its variability. This may indicate that peri-articular bone responds to biomechanical derangements in those with knee OA. Modification of static or dynamic alignment may therefore lead to a change in peri-articular bone. Alternatively, treatment of bone health may be important in mediating the effects of alignment in knee OA.

Prediction of Total Knee Replacement in a Two-Year Multi-Centre Clinical Trial in Knee Osteoarthritis: Results from a 4–6 Year Observation.

Jean-Pierre Raynauld[3], Johanne Martel-Pelletier[1], Marc Dorais[5], François Abram[4], Boulos Haraoui[2], Denis Choquette[2] and Jean-Pierre Pelletier[6]. [1]CR-CHUM, Notre-Dame Hospital, Montreal, QC, Canada, [2]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, Canada, [3]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, [4]Research and Development, ArthroVision Inc., Montreal, [5]StatSciences Inc., Notre-Dame de l'Ile-Perrot, [6]University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, Canada

Background: The aim of this study was to predict, using data from quantitative magnetic resonance imaging (qMRI), the incidence of total knee replacement (TKR) during the long-term follow-up of knee OA patients who formerly received treatment with licofelone or naproxen.

Methods: Knee OA patients participating in a previous 2-year randomized, double-blind controlled trial evaluating the impact of licofelone (200 mg BID) vs. naproxen (500 mg BID) who had serial MRI acquisitions of the symptomatic knee[1] were recently contacted to evaluate retrospectively the incidence of TKR of the study knee. A sub-group of patients (n=123) who had taken all the study medication and had all the MRI evaluations (according-to-protocol [ATP]) were selected for this post-hoc retrospective analysis. The TKR incidence was assessed blindly to the treatment allocation with a standardized phone interview.

Results: The patients' mean age was 63.5 years, 63.5% were female and the average body mass index (BMI) was 31.9 kg/m^2. A total of 18 TKRs (14.6%) were performed upon this sub-population in the time frame of 4–6 years after completion of the original study. Interestingly, there were significantly more TKRs performed within the naproxen group than the licofelone group (61% vs. 39%, Fischer's exact test p=0.23). Further, we investigated the predictors of long-term TKRs by comparing, within the ATP cohort, the patients who had TKR to those who did not, using data at baseline or the change at 2 years. Data revealed that baseline values of bone marrow lesions (BMLs) of the medial tibial plateau (p=0.0001; Fisher's exact test), medial joint space width (X-ray) (p=0.0008), presence of severe medial meniscal tear (p=0.004), medial meniscal extrusion (p=0.01), and C reactive protein (CRP) level (p=0.05) were strong predictors of TKR. Changes at 2 years also yielded strong predictors including change in the cartilage volume of the medial compartment (p=0.005) and of the global joint (p=0.03), as well as change in WOMAC pain (p=0.009) and function (p=0.02) scores. Logistic regressions that included age, sex, and BMI in the model, yielded that baseline severe medial tear (p=0.006) and the presence of a medial BML (p=0.002) were the strongest independent predictors of long-term TKR.

Conclusion: These data demonstrate that, in a knee OA clinical trial, it is possible to predict a "hard" outcome such as TKR using clinical and qMRI

data. The results are highly encouraging and support the use of qMRI as a surrogate for joint tissue damage upon which a DMOAD may act.

Prevalence of MRI-Detected Joint Pathology of the Knee in a Population-Based Sample: Framingham Osteoarthritis Study. Jingbo Niu[3], Yuqing Zhang[1], Ali Guermazi[4], Frank W. Roemer[4] and David T. Felson[2]. [1]Boston Univ School of Medicine, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]Boston University School of Medicine

Magnetic resonance imaging (MRI) allows direct visualization of cartilage and other soft tissues and is becoming a common method to image knees osteoarthritis (OA) in studies. MRI-detected intraarticular pathology may be common in persons without disease. Previous work has shown that meniscal tears are common even in persons without radiographic OA. For other features, this is unknown because little population based data are available on the prevalence of pathologic lesions.

Residents (age ≥ 50) in Framingham, MA were contacted by random-digit telephone dialing advertising a study of health in general and of bone health. Of 1039 subjects recruited, 992 had MRIs (1.5 T) on the knee(s) without contraindication to acquisition and MRI of one knee, right side preferred, was read. MRI features were scored using the WORMS system by two MSK radiologists. Each MRI feature was scored at multiple subregions in a knee. Kappa statistics for inter-rater reliability were 0.51–0.82 depending on feature. The presence of a lesion was defined by the worst score among subregions exceeding a pre-defined cut-point. We estimated sex- and age-specific prevalence of each lesion in the whole knee, then in the tibiofemoral (TF) and patellofemoral (PF) joint separately. We calculated the age-standardized prevalence of each lesion in men and women respectively, using the age distribution in the whole sample as the standard. Finally, we repeated the analysis among subjects without radiographic TF OA (K/L grade 0–1) and without radiographic PF OA, respectively.

Included in the analyses were 992 subjects (57% women, 93% White, mean age: 62.5 years, sd=8.8, range 50–92; mean BMI: 28.6 kg/m^2, sd=5.6). 791 (80%) had no radiographic TF OA, and 895 (90%) had no PF OA. The prevalence of each lesion detected on MRI increased with age among men. However, in women, the prevalence reached a plateau at age 65 then either leveled off or slightly decreased. As shown in the table, age standardized prevalence of MRI features was high and similar between men and women. The prevalence of MRI features in the TF joint was similar to or higher than that in the PF joint except for cartilage lesion in women. Over 70% of knees showed at least erosions of cartilage, about 60% showed at least small bone marrow lesions, roughly 1/4 knees showed at least moderate osteophytes, and over 40% showed synovitis or effusions. In knees without radiographic TF or PF OA, over 40% had cartilage lesion and over 30% had bone marrow lesion.

Pathologic lesions typical of osteoarthritis are common on MRIs among people aged 50 and older drawn from the community, even among subjects without radiographic OA. The prevalence of MRI lesions increased with age and was similar between men and women.

Table age-standardized prevalence of MRI features by gender (as % of knees)

MRI lesion (score range)	definition	Whole knee	TF joint	Med TF	Lat TF	PF joint	Med PF	Lat PF

Relation of Hand Enthesophytes on Plain Radiographs with Findings of Knee Enthesopathy: Is Osteoarthritis a Generalized Enthesopathy? Nadia Gibson[1], Mary M. Clancy[4], Jingbo Niu[3], Peter Grayson[2], Piran Aliabadi[6], Ali Guermazi[2] and David T. Felson[5]. [1]Boston Medical Center, Boston, MA, [2]Boston Medical Center, [3]Boston University, Boston, MA, [4]Boston University Sch Med, Boston, MA, [5]Boston University School of Medicine, Boston, MA, [6]Brigham's and Women Hospital

Purpose: Enthesopathy, an abnormality at the attachment of a tendon or ligament to bone, has been reported as a feature of osteoarthritis (OA) in the DIP joints. Some patients have central bone marrow lesions (BMLs) on MRI at the insertion sites of the ACL and PCL suggesting enthesopathy in the knee that might be similar to that seen in the hand. We have reported that these central BMLs on MRI are associated with OA (Arthritis Rheum 2008; 58: 130– 136). In this study, we evaluated whether hand enthesopathy was related to this presumed knee enthesopathy and whether in those with knee OA, hand enthesopathy was associated with these central BMLs.

Methods: We studied knee and hand x-rays of subjects from the Framingham Osteoarthritis Study, a population based study. Subjects seen in 2002–2005 had bilateral PA hand x-rays, weight bearing knee x-rays and knee MRI's using a 1.5 T magnet. We used T-2 weighted fat suppressed images to identify central BMLs. Knee x-rays were read for K/L grade. Hand x-rays were read for enthesophytes defined as bony spurs at the juxta-articular nonsynovial areas of MCP, PIP and DIP joints (excluding osteophytes) and midshafts of proximal, middle and distal phalanges. We scored lesions as 0: none, 1:small, 2:moderate, 3:large. The intra-observer kappa was 0.67. To determine whether there was a relation of presence of enthesophytes in either hand with central BML's in the knees (one knee/person), we selected 100 cases of knees withcentral BML's and 100 matched controls without this finding of the same age (2 year categories) and sex. We assessed the association by using conditional logistic regression adjusting for worst K/L grade in the knee. To determine if hand enthesopathy was related to central BMLs in the context of knee OA, further analyses restricted cases and controls to those with knee OA.

Results: Mean age of subjects was 68 years, mean BMI 29.5. Those with enthesophytes of at least one score ≥ 2 at DIP, PIP and/or MCP were less likely to have central BMLs of the knee (OR = 0.49, 95% CI 0.17–1.40), than those without such enthesophytes, although this was not statistically significant (see Table). Similarly, having at least one score ≥2 on the shafts (distal, middle and/or proximal) was not significantly associated with having central knee BMLs (OR=0.59, 95% CI 0.23 –1.51). Considering all hand sites, the number of subjects with at least one score ≥2 was 38 in the cases and 42 in the controls (OR = 0.57, 95% CI 0.26–1.27). Analyses using enthesophyte score ≥ 1 yielded similar results. When we examined only cases and controls with OA, we found similarly null results.

Conclusions: We found no relation between hand enthesophytes and central BML's in the knee. We also found no clear association of hand enthesophytes with central BMLs in patients with established OA. This provides evidence against a generalized enthesopathic disorder in association with knee OA.

Responsiveness and Reliability of MRI in Osteoarthritis: Analytic Literature Review. David J. Hunter[5], Weiya Zhang[1], Philip G. Conaghan[4], Kelly Hirko, Leo Menashe, William M. Reichmann[2] and Elena Losina[3]. [1]United Kingdom, [2]Brigham and Womens Hosp, Boston, MA, [3]Brigham and Womens Hospital, Boston, MA, [4]Chapel Allerton Hospital, Leeds, United Kingdom, [5]University of Sydney, Sydney, NSW, Australia

Objective: To summarize literature on the responsiveness and reliability of MRI-based measures of osteoarthritis (OA) structural change.

Methods: An online literature search was conducted of the OVID, EMBASE, CINAHL, PsychInfo and Cochrane databases of articles published up to the time of the search, April 2009, with the search entries "MRI", and "osteoarthritis". The abstracts of the 1338 citations received with this search were then preliminarily screened for relevance by two reviewers. Of these, 243 were selected for data extraction for this analysis as well as a distinct analysis on validity. We extracted data on responsiveness and reliability from both longitudinal and cross-sectional studies for all synovial joint tissues as it relates to MRI measurement in OA. Reliability was defined by inter- and intra-class correlation (ICC) and kappa statistics. Higher ICCs and kappa values indicate more reliable estimates. Responsiveness was defined as standardized response mean (SRM)—ratio of mean of change over time divided by standard deviation of change. For the quantitative analysis negative SRMs indicate a loss of cartilage. For the semi-quantitative analysis, loss in cartilage is defined by positive SRMs. Random-effects models were used to summarize data from multiple studies.

Results: The reliability analysis included data from 89 manuscripts. The inter-reader and intra-reader ICC were all excellent (range 0.81–0.94).The inter-reader and intra-reader kappa values for quantitative, semi-quantitative and compositional measures were all moderate to excellent (range 0.52–0.88).

Table 1. Results of random-effects pooling of reliability

Inter-reader intra-class correlations (ICC)	Number of Estimates (Studies)	Mean Sample Size	Pooled ICC	95% Confidence Interval
Quantitative				
Cartilage	10 (4)	196	0.90	0.86, 0.95
Meniscus	2 (1)	291	0.81	0.72, 0.89
Inter-reader kappa	**Number of Estimates (Studies)**	**Mean Sample Size**	**Pooled Kappa**	**95% Confidence Interval**
Semi-Quantitative				
Cartilage	15 (4)	136	0.57	0.44, 0.71
Bone Marrow Lesion	2 (2)	237	0.88	0.79, 0.97
Meniscus	3 (3)	418	0.73	0.63, 0.84
Ligament	3 (3)	209	0.80	0.69, 0.90

The responsiveness analysis included data from 42 manuscripts. The pooled SRM for quantitative measures of cartilage for medial tibiofemoral joint was −0.58 (95%CI −0.75 to −0.41). The pooled SRM for the semi-quantitative measurement of cartilage for the medial tibiofemoral joint was 0.55 (95%CI 0.47 to 0.64).

Table 2. Results of random-effects pooling of standardized response mean

Stratification	Number of Estimates (Studies)	Mean Sample Size	Pooled SRM	95% Confidence Interval
Quantitative Cartilage				
Medial Femoral	54 (12)	118	−0.39	−0.48,−0.30
Medial Tibial	55 (17)	134	−0.33	−0.39,−0.26
Medial Tibio-Femoral	31 (12)	92	−0.58	−0.75,−0.41
Lateral Femoral	32 (8)	151	−0.19	−0.27,−0.11
Lateral Tibial	44 (14)	152	−0.44	−0.51,−0.36
Lateral Tibio-Femoral	14 (5)	110	−0.56	−0.92,−0.20
Patella	13 (9)	131	−0.60	−0.83,−0.37
Semi-Quantitative Cartilage				
Medial Tibial-Femoral	3 (3)	224	0.55	0.47, 0.64
Lateral Tibial-Femoral	3 (3)	224	0.37	0.18, 0.57
Patella	2 (2)	238	0.29	0.03, 0.56
Semi-Quantitative Other				
Synovium	3 (2)	68	0.52	0.28, 0.76
Osteophytes	4 (1)	150	0.36	0.28, 0.44
Bone Marrow Lesion	6 (2)	130	0.19	0.07, 0.30
Meniscus	2 (1)	264	0.27	0.14, 0.40

Conclusion: MRI has evolved substantially over the last decade and its strengths include its ability to visualize individual tissue pathologies, which can be measured reliably using both quantitative and semi-quantitative techniques. Using MRI it is possible to accurately and feasibly measure change in cartilage morphology over 12 months for knee OA. Studies also suggest that cartilage and synovium are responsive measures on semi-quantitative assessment.

The Effects of Hip Muscle Training on Knee Joint Loading in Medial Knee Osteoarthritis. Julia Daher[1], Joel A. Block[2], Markus Wimmer[1], Dale R. Sumner[1] and Laura E. Thorp[3]. [1]Rush University Medical Center, [2]Rush University Medical Center, Chicago, IL, [3]Rush University Medical Center, Chicago, IL

Objective: The purpose of this investigation was to analyze the effects of a focused hip muscle training program on knee joint loading in subjects with medial compartment knee OA. Specifically, we hypothesized that focused hip musculature training in individuals with mild to moderate knee OA would produce favorable changes in dynamic loading of the medial knee during walking, as evidenced by decreased external knee adduction moments.

Methods: To date, 12 subjects with mild to moderate medial compartment knee OA ranging in age from 35–69 years of age completed the study protocol. Subjects underwent gait analysis at their self-selected normal walking speed and both the peak external knee adduction moment and the knee adduction angular impulse were calculated before and after participation in a 4-week supervised, physical therapy intervention targeted at the hip abductor musculature. Response to treatment was defined as a reduction in either parameter. Additionally, subjects wore an accelerometer-based activity monitor for 7 days after the baseline visit.

Results: 8 of the 12 subjects responded to therapy. For these subjects, the mean percent decreases in the peak external knee adduction moment were −9.6 ± 8.7% and −12.4 ± 7.7% for index and contralateral knees respectively. In the index and contralateral knees, the mean percent decreases in knee adduction angular impulse were −7.1 ± 3.8% and −22.0 ± 8.3% respectively. The magnitude of change in the responders was greater in the contralateral knee than in the index knee. The responders tended to be more active than the non-responders, though this difference was not significant. Nonetheless, when non-responders were included in the analysis, there were no significant changes in either peak adduction moment or adduction angular impulse.

Conclusion: The discrepancy between responders and non-responders is unexplained, though may relate to activity and/or adherence. While more subjects are needed to determine the efficacy of hip muscle training on joint loads in medial compartment knee OA, these preliminary results suggest hip muscle training may have use in prevention of contralateral disease development. It is possible that this type of intervention may be best suited for more active individuals.

The Relationship between Symptoms of Medial Tibiofemoral Osteoarthritis and Toe-Out Angle during Walking: The MOST Study. K. Douglas Gross[4], Jingbo Niu[3], Yuqing Zhang[1], Michael C. Nevitt[6], Cora E. Lewis[5], James Torner[7] and David T. Felson[2]. [1]Boston Univ School of Medicine, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]MGH Institute of Health Professions, Boston, MA, [5]University of Alabama, Birmingham, Birmingham, AL, [6]University of California, San Francisco, San Francisco, CA, [7]University of Iowa, Iowa City

Background: Many people with symptomatic medial knee osteoarthritis (OA) walk with an increased toe-out angle, an adaptation that can reduce compressive load on the medial tibiofemoral (TF) compartment and offer protection against worsening disease. Despite these advantages, it is not known why some people with medial TF OA spontaneously modify their gait in such a way as to increase toe-out, while others do not. It is possible that the presence and severity of knee pain provides a necessary incentive.

Methods: The Multicenter Osteoarthritis Study (MOST) is a NIH-funded longitudinal study of individuals who have or are at high risk for knee OA. From among participants who completed the 60-month exam, we selected all knees with radiographic medial TF OA (K&L grade >/=2 on fixed flexion x-ray with OARSI medial joint space narrowing score >/=1 and greater medial than lateral JSN). We inquired about knee pain in three ways: 1) presence of 'current knee pain' during the walking exam, 2) presence of 'frequent knee pain' during the past 30 days, and 3) 'knee pain severity' (none, mild, >/= moderate) when walking during the past 30 days. Toe-out angle was measured in degrees between the line of progression and the midline of a footprint at self-selected normal and fast walking speeds using a 14' GAITRite instrumented walkway. Linear regression with generalized estimating equations compared mean toe-out angle between knees with and without pain while adjusting for covariates (baseline age, BMI, sex, race, and mean walking velocity).

Results: 269 participants (mean age 62.9 +/− 8.0 yrs, mean BMI 32.1 +/− 6.7 kg/m2, 34.6% female, 84.0% white) contributed 374 knees (25.4% with current pain, 53.0% with frequent pain, and 51.1% with pain of at least mild severity when walking). Crude mean toe-out angle was 7.0 +/− 5.5 (range −8.2, 24.7) degrees at normal walking speed and 6.2 +/− 5.3 (range −7.9, – 24.4) degrees at fast walking speed. Adjusted mean toe-out angle at normal and fast speeds (respectively) was smaller among knees with current (p=0.09, p=0.05), frequent (p=0.33, p=0.14), and more severe knee pain (p=0.36, p=0.12), although the differences were not statistically significant (see table).

Conclusions: These findings do not lend support to the hypothesis that the presence or severity of knee pain among persons with medial TF OA is associated with greater toe-out angle during walking. On the contrary, because toe-out angle may be diminished among those with current, frequent, or more severe pain, an opportunity exists for gait training to increase toe-out among those with medial TF OA symptoms.

Toe-Out angle and Medial TF OA Pain during Normal and Fast Paced Walking

The Relationship between Varus and Valgus Thrust and Meniscal Damage in Persons with Knee Osteoarthritis. Alison H. Chang[4], Ali Guermazi[1], Frank Roemer[1], Kirsten Moisio[5], Jing Song[5], Dorothy D. Dunlop[4], Michael C. Nevitt[6], Carmelita J. Colbert[2], John A. Lynch[7], Karen W. Hayes[3] and Leena Sharma[4]. [1]Boston University, [2]Northwestern University, LaGrange, IL, [3]Northwestern University, Downers Grove, IL, [4]Northwestern University, Chicago, IL, [5]Northwestern University, [6]UCSF, San Francisco, CA, [7]UCSF

Purpose: Varus thrust observed during gait has been shown to be associated with a 4-fold increase in the risk of medial knee osteoarthritis (OA) progression. It is plausible that a varus thrust may trigger or exacerbate medial meniscal damage as a cumulative effect of the acute increase in medial load with each step of walking. A parallel relationship may exist between valgus thrust and the lateral meniscus. We tested the hypotheses: 1) varus thrust is associated with medial meniscal damage (tear, maceration, extrusion); and 2) valgus thrust is associated with lateral meniscal damage.

Methods: The sample included Osteoarthritis Initiative (OAI) participants with symptomatic radiographic knee OA (data from public release data sets version 0.2.2 and 1.2.1 and from an NIH-funded ancillary study). Trained examiners assessed all participants at the 12-month visit for varus and valgus thrust presence by gait observation. The following sequences from the OAI protocol were used for meniscal assessment: sagittal IW 2D TSE FS, sagittal 3D DESS WE, axial MPR of SAG 3D DESS WE, coronal MPR of SAG 3D DESS WE. Meniscal status was scored according to the BLOKS system in the anterior, body and posterior horn of the medial and lateral meniscus. In addition, extrusion was scored from 0–3, with presence defined as > 0. We used logistic regression to specifically evaluate the relationship of varus thrust to medial meniscal damage (tear, maceration, and extrusion) and valgus thrust to lateral meniscal damage, adjusting for age, gender, and BMI.

Results: 496 persons (1 knee/person) (mean age 62 years, BMI 30, 58% women) were examined. Varus thrust was present in 169 knees (34%) and valgus thrust in 31 knees (6%). As shown in Table 1, varus thrust was significantly associated with medial meniscal tear and with medial meniscal maceration.

Table 1. Varus Thrust and Medial Meniscal Damage

Thrust Status (n = 496 knees)	Number of Knees (row %) with Medial Meniscal Tear (238 knees, 48.0%)	Medial Meniscal Tear Adjusted OR (95% CI)	Number of Knees (row %) with Medial Meniscal Maceration (172 knees, 34.7%)	Medial Meniscal Maceration Adjusted OR (95% CI)
No varus thrust (reference) (n = 327 knees)	142 (43.4%)	Reference	99 (30.3%)	Reference
Varus thrust (n = 169 knees)	96 (56.8%)	1.50 (1.01, 2.22)	73 (43.2%)	1.53 (1.02, 2.29)

As shown in Table 2, valgus thrust was significantly associated with lateral meniscal maceration; the association with lateral meniscal tear approached significance.

Table 2. Valgus Thrust and Lateral Meniscal Damage

Thrust Status (n = 496 knees)	Number of Knees (row %) with Lateral Meniscal Tear (121 knees, 24.4%)	Lateral Meniscal Tear Adjusted OR (95% CI)	Number of Knees (row %) with Lateral Meniscal Maceration (77 knees, 15.5%)	Lateral Meniscal Maceration Adjusted OR (95% CI)
No valgus thrust (reference) (n = 465 knees)	109 (23.4%)	Reference	68 (14.6%)	Reference
Valgus thrust (n = 31 knees)	12 (38.7%)	2.12 (0.98, 4.56)	9 (29.0%)	2.38 (1.04, 5.45)

Neither varus thrust nor valgus thrust was significantly associated with meniscal extrusion (not shown).

Conclusion: Varus thrust during ambulation was associated with medial meniscal tear and maceration, but not with extrusion, with similar findings for valgus thrust and lateral meniscal damage. Longitudinal studies may help elucidate the cause-effect relationship between these factors and how they might act in concert to accelerate OA progression.

Thigh Muscle Quality Correlates with Function, Leg Strength, and Walking Speed, but Not with Alignment in Individuals with Obesity and Knee Osteoarthritis. Rachel W. Holt[3], Richard F. Loeser[5], Cralen Davis[4], Claudine Legault[4], Barb Nicklas[4], Jeffrey Carr[4], David J. Hunter[1] and Stephen P. Messier[2]. [1]New England Baptist Hospital, Boston, MA, [2]Wake Forest Univ, Winston-Salem, NC, [3]Wake Forest Univ., Winston Salem, NC, [4]Wake Forest Univ., [5]Wake Forest University, Winston-Salem, NC

Purpose: The effect of obesity on risk for disease progression in osteoarthritis is mediated by the extent of malalignment but it is not known if adiposity and alignment are related. Adipose tissue in the thigh varies in distribution with some individuals having greater subcutaneous fat and others more between (intermuscular) and within (intramuscular) adipose tissue. In addition, muscle associated triglyceride can be determined by the CT attenuation of muscle and is a measure of muscle quality. The **objective of this study** was to determine the relationship between CT measures of thigh fat and lower extremity alignment and then with measures of pain and function in overweight and obese adults with mild to moderate knee OA.

Methods: Data were collected at baseline from participants entering the Intensive Diet and Exercise for Arthritis (IDEA) study. Inclusion criteria were BMI of 27–40.5 kg/m^2, age>55 years, self reported disability due to knee pain, and radiographic evidence of mild to moderate (K-L score II-III) tibiofemoral OA in at least one knee. Mechanical alignment was measured using full-length lower extremity x-rays and Image J software. Subcutaneous and inter/intramuscular (IM) thigh adipose tissue and thigh muscle quality were measured by CT. Self reported pain and function were evaluated using WOMAC. Strength was measured on a Kin-Con isokinetic dynamometer. Data were analyzed using SAS to calculate Pearson correlation coefficients and ANOVA (for analysis of alignment type).

Results: Data were available on 129 IDEA participants with the following characteristics: 70% female, mean±sd age of 65.9±6.2 years, BMI of 33.2±3.7 units, subcutaneous thigh fat of 876.2±285.9 cm^3, IM thigh fat of 30.4±16.1 cm^3, thigh muscle quality of 52.0±6.2 Hounsfield units, WOMAC function of 23.4 ±10.4, WOMAC pain of 6.0±2.9, concentric extensor strength of 61.2±23.9 Nm and 236.3±83.4 N, and walking speed of 1.2±0.2 m/s. 25% of the subjects had neutral alignment, 25% valgus, and 50% varus. The analysis of muscle quality showed significant negative correlations with age, BMI, IM thigh fat, and WOMAC function and positive correlations with strength and walking speed (Table 1). The analysis of the magnitude of the alignment angle (Table 1) revealed weak but significant correlations with WOMAC pain and function but not the CT measures. Furthermore, the mean thigh muscle quality did not differ significantly between the three alignment types (ANOVA not shown).

		Quadriceps quality		Alignment (angle)	
Variable	N	r	p	r	p
Age	129	−0.31	0.0003	0.02	0.86
BMI	129	−0.19	0.04	0.13	0.15
Subcutaneous thigh fat (cm^2)	129	−0.18	0.04	−0.001	0.99
IM thigh fat (cm^2)	128	−0.31	0.0002	0.02	0.86
Quadriceps quality	129			−0.03	0.71
WOMAC pain	129	−0.04	0.63	0.25	0.01
WOMAC function	129	−0.19	0.03	0.18	0.04
Leg strength (Nm)	102	0.26	0.01	−0.02	0.86
Leg strength (N)	102	0.30	0.003	−0.04	0.67
6 minute walk speed	129	0.20	0.02	−0.13	0.15

Conclusion: These results suggests that reduced thigh muscle quality due to IM fat correlates with age and BMI and has a detrimental effect on strength, speed, and overall function in this population; however, alignment does not appear to have the same impact. Based on posthoc power calculations, a larger sample size would be needed to detect the observed differences of about 1 HU in thigh muscle quality between alignment types.

Understanding the Individual Burden of Osteoarthritis: Development of a Conceptual Model. Lucy Busija[3], Richard H. Osborne[2] and Rachelle Buchbinder[1]. [1]Cabrini Institute and Monash University, Malvern, Australia, [2]Deakin University, Melbourne, Australia, [3]University of Melbourne

Aims: While the importance of osteoarthritis as a public health burden is well recognised, less is known about the impact of this condition at the individual level. Currently, no unifying framework is available for comprehensively documenting health-related consequences from the individual's perspective as existing frameworks are either not designed to represent the views of people with osteoarthritis or do not capture the full range of osteoarthritis-related consequences. The aim of this study was to develop a conceptual framework for documenting health-related consequences of osteoarthritis in affected individuals.

Methods: Structured concept mapping (SCM) workshops (n=6) were undertaken, three with patients (n=26) and three with health professionals and health policy makers (n=27) in Australia and in Sweden. The participants were asked to generate statements describing the impact of osteoarthritis on individuals with this condition and those around them. The post-workshop analyses used a mix of quantitative (three-dimensional multidimensional scaling analysis) and qualitative (thematic analysis) approaches to indentify major dimensions of the individual burden of osteoarthritis. A relational algorithm was then used to identify the interrelationships among these dimensions and to construct an integrated theoretical model of the Personal Burden of Osteoarthritis (PBO).

Results: A synthesis of the workshops identified 8 potentially independent aspects of PBO, including Physical distress, Fatigue, Physical limitations, Psychosocial distress, Physical de-conditioning, Financial hardship, Sleep disturbances, and Lost productivity. Physical distress was the key influence on individual health and welfare. One of the major effects of physical distress was impaired physical function. In combination, physical limitations and physical distress lead to psychosocial problems, reduced work productivity, financial difficulties, and loss of physical fitness.

Conclusions: The PBO framework was designed to comprehensively capture the consequences of osteoarthritis on individuals with this condition. The framework provides new insight for individual care and program development for people with osteoarthritis.

Vibratory Sense Deficits in Radiographic Knee Osteoarthritis: The Multicenter Osteoarthritis Study (MOST). Najia Shakoor[4], Tuhina Neogi[1], David T. Felson[3], Jingbo Niu[2], Laura Frey Law[7], Cora E. Lewis[6] and Michael C. Nevitt[5]. [1]Boston Univ Schl of Med, Boston, MA, [2]Boston University, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]Rush-University Medical Center, Chicago, IL, [5]UCSF, San Francisco, CA, [6]University of Alabama, [7]University of Iowa, Iowa City, IA

Background: Somatosensory abnormalities, including proprioceptive and vibratory sense deficits, have been observed in osteoarthritis (OA) of the knee. Deficits in vibratory sense were associated with the presence of knee and hip OA in two small cross-sectional studies. We examined the association of vibratory sense with radiographic knee OA (RKO) in participants in a large cohort study of knee OA, the Multicenter Osteoarthritis Study (MOST).

Methods: MOST is a NIH-funded longitudinal study of persons with symptomatic knee OA or at increased risk of OA. At the 60-month visit, participants underwent bilateral evaluation of vibratory perception threshold (VPT), using a biothesiometer (Bio-Medical Instrument Co.) operating at a frequency of 120Hz. The applicator tip of the instrument was placed on three anatomical bony prominences: the dorsum of the first MTP joint, the tibial tuberosity and, the radial styloid. The voltage of the biothesiometer was initially set at "0" and then increased by 1 volt/second until the participant acknowledged sensation and this was defined as the VPT. At each study visit, participants had bilateral weight bearing PA and lateral x-rays which were read for Kellgren Lawrence (KL) grade, and defined as RKO if KL grade was ≥2. Those with knee replacement or diabetes were excluded. In light of large differences in VPT between genders and with age, men and women were evaluated separately and divided into age subgroups, <65 years and ≥65 years. A knee-based analysis was performed with three knee groups: 1) RKO (KL ≥ 2); 2) contralateral "normal" knee of unilateral RKO and 3) control knee (no RKO in either knee). Linear regression with GEE was used to compare VPT between groups adjusted for age and BMI and accounting for between knee correlations.

Results: This analysis included 222 men (mean age (SD) of 67±9 years) and 451 women (mean age (SD) of 68±8 years). VPT values for men were significantly (p<0.001 at all sites) higher compared to women adjusted for age and BMI. In men age ≥65, VPT was higher at the MTP and tibial tuberosity in knees with RKO compared to control knees, but this was not significant after age adjustment (Table). VPT in the nonOA knee of those with unilateral RKO was higher than controls, nearly reaching significance at the radial styloid. There were no significant associations of VPT with RKO status in men less than 65 or women in either age group.

		Mean VPT (95% CI) adjusted for BMI	P value (compared to control)	Mean VPT (95% CI) adjusted for BMI and age	P value (compared to control)
Men Age ≥65 years					
MTP	RKO (n = 84)	33.0 (29.5, 36.5)	0.009*	31.9 (28.3, 35.4)	0.056
	Contralateral (n = 28)	30.7 (25.3, 36.1)	0.190	31.1 (26.0, 36.1)	0.198
	Controls (n = 125)	26.5 (23.3, 29.7)		27.2 (24.1, 30.2)	
Tibial tuberosity	RKO (n = 85)	32.6 (29.9, 35.4)	0.011*	31.3 (28.5, 34.1)	0.142
	Contralateral (n = 29)	31.4 (26.3, 36.4)	0.196	31.5 (26.7, 36.1)	0.270
	Controls (n = 126)	27.6 (24.8, 30.3)		27.2 (24.1, 30.2)	
Radial styloid	RKO (n = 85)	12.1 (11.0, 13.3)	0.368	11.5 (10.3, 12.6)	0.807
	Contralateral (n = 29)	13.9 (11.5, 16.3)	0.069	14.0 (11.9, 16.1)	0.072
	Controls (n = 128)	11.3 (9.9, 12.7)		11.7 (10.3, 13.1)	

Conclusions: In this cohort study, an association between RKO and higher VPTs was present only in men ≥65 years of age, which is also the

group with the highest VPTs overall. No associations were observed in women in the current study. The control knees in our study had higher VPT values compared to previous studies, perhaps because this control group consisted of participants at high risk for OA. These results suggest that the association of VPT and knee OA may differ by age and gender.

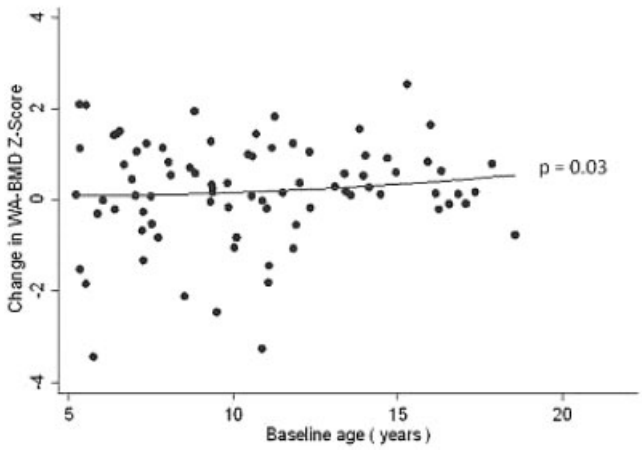
A Critical Appraisal of Lumbar Spine DXA Bone Mineral Density in a Longitudinal Study of Children with JIA. Maureen G. Leffler[1], Justine Shults[6], Sogol Mostoufi-Moab[2], Babette S. Zemel[7], Sarah E. Dubner[5], Mary B. Leonard[4] and Jon M. Burnham[3]. [1]AI duPont Hospital for Children, Thomas Jefferson University, [2]Children's Hospital of Philadelphia, [3]Children's Hospital of Philadelphia, University of Pennsylvania School of Medicine, Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA, [4]Children's Hospital of Philadelphia, University of Pennsylvania School of Medicine, Center for Clinical Epidemiology and Biostatistics, [5]Seattle Children's Hospital, University of Washington School of Medicine, [6]University of Pennsylvania School of Medicine, Center for Clinical Epidemiology and Biostatistics, [7]University of Pennsylvania School of Medicine, Children's Hospital of Philadelphia

Background: Juvenile idiopathic arthritis (JIA) is associated with vertebral fractures. Precise screening methods are needed to identify those at-risk. Lumbar spine posterior-anterior (PA) dual x-ray absorptiometry (DXA) areal bone mineral density (aBMD, g/cm^2), obtained in 2D, is confounded by short stature and superimposes trabecular (vertebral body) and cortical (posterior elements) structures. Volumetric imputation using bone mineral apparent density (BMAD) or height Z-score adjustment (HAZ-aBMD) addresses confounding by stature. 3D width-adjusted volumetric BMD (WA-BMD, g/cm^3) pairs PA and lateral scans to isolate the vertebral body, excluding posterior elements. To evaluate the performance of these DXA measures in JIA, we assessed 1) aBMD, BMAD, HAZ-aBMD, and WA-BMD Z-score deficits and their change from baseline to 12 months, and 2) determinants of WA-BMD Z-scores and their change.

Methods: JIA subjects [n=88, 5 –19 yr, 79% F, 21 oligoarticular (OJIA), 35 polyarticular (PJIA), 16 systemic (SJIA), 16 spondyloarthropathy (SpA)] completed two visits. JIA subjects were compared with controls (n = 909, 5–21 yr). DXA PA spine (L1–4) scans (Hologic Delphi) were used to calculate aBMD and BMAD [bone mineral content/(bone area)$^{1.5}$] and paired PA – lateral scans of L3 were used to determine WA-BMD. DXA Z-scores, derived from controls, were age-, sex- and race-specific. HAZ-aBMD Z-score was calculated according to Zemel et al. (J Clin Endocrinol Metab, 2010). T-tests and multivariable linear and logistic regression were used to compare Z-scores and identify predictors of low Z-scores (< -1).

Results: Baseline: Compared with controls, height Z-scores were low in JIA (0.26 vs. -0.06, $p = 0.001$). In JIA, deficits were observed using WA-BMD ($Z = -0.59$, $p < 0.001$), but not aBMD ($Z = -0.23$, $p = 0.05$), HAZ-aBMD ($Z = -0.14$, $p = 0.62$), or BMAD ($Z = -0.13$, $p = 0.27$). WA-BMD deficits were significant in PJIA, SJIA and SpA. Lower WA-BMD Z-scores were associated with low BMI Z-scores (JIA and controls, $p < 0.001$), low height Z-scores (JIA only, p for interaction < 0.04), steroid use, active arthritis, and high CHAQ scores ($p < 0.05$).

Follow Up: No significant changes were noted for JIA using any DXA measure. WA-BMD Z-scores improved in SpA only ($D = 0.46$, $p = 0.02$). aBMD, HAZ-aBMD and BMAD Z-scores improved in SJIA ($D = 0.18 – 0.21$, $p < 0.05$). Adjusting for baseline WA-BMD Z-scores ($b = -0.58$, $p < 0.001$), no clinical predictors of Z-score changes were detected, but older age was associated with significant improvement (Figure).



Conclusions: In JIA, WA-BMD detects spine deficits obscured using aBMD, HAZ-aBMD, and BMAD. Greater baseline deficits were associated with low BMI and height Z-scores, active disease, disability, and steroid use. WA-BMD improvements were greatest in adolescents and those with lower baseline Z-scores. Future studies should use 3D modalities to define which tool best identifies vertebral fragility in JIA.

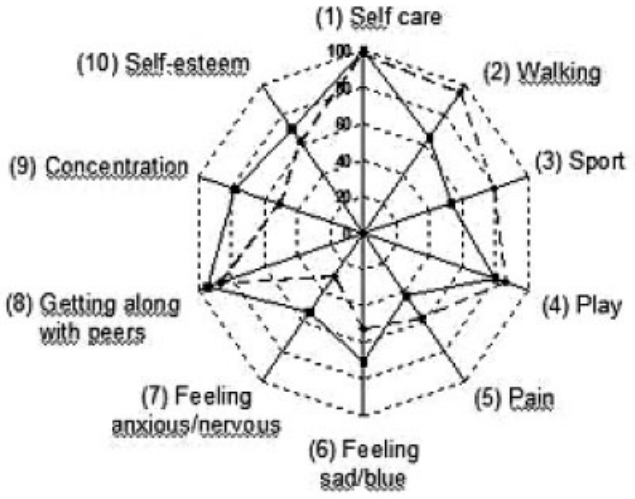
Adolescents with Juvenile Idiopathic Arthritis Currently Followed in a Tertiary Care Hospital Have a Better Psychosocial Well-Being Than Healthy Adolescents. Marta Bertamino[4], Giovanni Filocamo[5], Sara Dalprà[4], Elena Palmisani[4], Nicoletta Solari[4], Silvia Magni-Manzoni[1], Benedetta Schiappapietra[4], Nicolino Ruperto[4], Alberto Martini[3] and Angelo Ravelli[2]. [1]IRCCS Fondazione Policlinico San Matteo, Pavia, Italy, [2]IRCCS G. Gaslini and Università di Genova, Genova, Italy, [3]IRCCS G. Gaslini and Università di Genova, Genova, Italy, [4]IRCCS G. Gaslini, Genova, Italy, [5]Policlinico Sant'Orsola, Bologna, Italy

Background: Assessment of health-related quality of life (HRQL) is increasingly recognized as a fundamental component of the clinical evaluation of children with pediatric rheumatic diseases (PRD). It has been suggested that measurement of HRQL be incorporated into routine pediatric rheumatology care. Several studies have investigated the HRQL of children with PRD. However, comparison with healthy children has seldom been attempted.

Objective: To compare the health-related quality of life (HRQL) of children with juvenile idiopathic arthritis (JIA) and healthy children.

Methods: 472 parents of children with JIA, 232 children with JIA, 801 parents of healthy children, and 796 healthy children completed independently the Pediatric Rheumatology Quality of Life scale (PRQL) (Filocamo et al. Rheumatology 2010). Children with JIA and healthy children who completed the questionnaire were aged > 7–8 years.

Results: As expected, both parents of children with JIA and JIA children provided worse rating on the physical health (PhH) subscale of the PRQL than did parents of healthy children ($p<0.0001$) or healthy children ($p=0.0002$), respectively. However, scores on the psychosocial health (PsH) subscale were comparable between parents of JIA patients and parents of healthy children ($p=0.34$), and were much worse for healthy children than for children with JIA ($p < 0.0001$). Stratification of children by age (< 10 years, 10–13 years, > 13 years) showed that proxy- and self-reported scores on the PsH subscale were much worse for healthy children older than 13 years than for the other age groups. These differences were not related to sex or JIA severity. The figure shows the comparison of the frequency of abnormal values in the 10 items of the PRQL as self-reported by adolescents with JIA (continuous line) and healthy adolescents (dotted line). Items 1 to 5 refer to the PhH, whereas items 6 to 10 refer to the PsH.



Conclusion: To our knowledge, our study is the first to show that psychosocial functioning of adolescents with JIA is better than that of healthy adolescents. This phenomenon may depend, at least partially, on most of the JIA patients attending our clinics for follow-up visits having well-controlled disease with little or no disease activity or disability. This observation deserves further exploration in different populations.

An International Consensus Survey of the Diagnostic Criteria for Macrophage Activation Syndrome in Systemic Juvenile Idiopathic Arthritis. Sergio Davì[4], Alessandro Consolaro[4], Dinara Guseinova[4], Angela Pistorio[4], Alberto Martini[3], Randy Q. Cron[1] and Angelo Ravelli[2]. [1]Children's Hospital of Alabama and University of Alabama at Birmingham, Birmingham, AL, [2]IRCCS G. Gaslini and Università di Genova, Genova, Italy, [3]IRCCS G. Gaslini and Università di Genova, Genova, Italy, [4]IRCCS G. Gaslini, Genova, Italy

Background: Macrophage activation syndrome (MAS) is a potentially life-threatening complication of systemic juvenile idiopathic arthritis (sJIA). Because MAS is a serious condition that can follow a rapidly fatal course, prompt recognition of its clinical and laboratory features and immediate therapeutic intervention are critical. However, diagnosis of MAS can be difficult and hard to distinguish from sepsis-like syndromes. In addition, subclinical forms of MAS in sJIA underscore the importance of establishing criteria sensitive enough to identify MAS from routine disease flare.

Objective: To select the clinical, laboratory and histopathologic features which are more suitable as diagnostic criteria for sJIA-associated MAS through an international Delphi questionnaire survey.

Methods: All members of the Paediatric Rheumatology International Trials Organisation (PRINTO), the Childhood Arthritis & Rheumatology Research Alliance (CARRA), and the Pediatric Rheumatology Collaborative Study Group (PRCSG) were submitted a questionnaire that listed the 28 most typical features of MAS and were first asked to select the 10 features that they deemed most important in the diagnosis of the syndrome, and then to rank order the 10 selected features by assigning 10 to the most important, and end with 1 as the least important.

Results: Of the 505 pediatric rheumatologists who were contacted, 232 (45.9%) participated in the survey. The table shows, for the features selected by more than 30% of respondents, the percentage of investigators who selected the feature and its median rank.

Results are reported for all respondents and for respondents categorized by geographic area. Falling platelet count, hyperferritinemia, evidence of hemophagocytosis in the bone marrow, increased liver enzymes, and falling leukocyte count were the 5 most frequently selected features. Only evidence of hemophagocytosis in the bone marrow, hyperferritinemia, and persistent fever reached a median rank >7. Overall, investigators from Europe and other parts of the world tended to give more weight to clinical manifestations than North American investigators, whereas North American investigators appeared to rely more on laboratory abnormalities than investigators from Europe and other parts of the world.

Feature	No. (%) of respondents who selected the feature	Median rank	Mean (SD) rank	% of respondents giving rank 8–10 to the feature	% of respondents giving rank 5–10 to the feature
Falling platelet count	201 (86.6)	6.5	6.1 (2.3)	24.6	61.6
Hyperferritinemia	194 (83.6)	7	6.5 (3.0)	39.2	53.9
Bone marrow hemophagocytosis	188 (81.0)	9	6.9 (3.6)	44.8	55.2
Increased liver enzymes	174 (75)	5	5.0 (2.4)	13	40.9
Falling leukocyte count	172 (74.1)	5	5.6 (2.5)	20.3	46
Persistent continous fever ≥ 38°C	158 (68.1)	7	6.0 (3.4)	30.2	40.1
Falling erythrocite sedimentation rate	142 (61.2)	6	5.5 (2.7)	15.9	38.8
Hypofibrinogenemia	142 (61.2)	5	5.4 (2.4)	12.9	36.6
Hypertriglic eridemia	135 (58.2)	5	5.1 (2.7)	16.8	31
Central nervous system dysfunction	104 (44.8)	5	5.0 (2.9)	11.6	23.7
Falling hemoglobin level	100 (43.1)	5	4.8 (2.3)	4.3	23.3
Prolongation of clotting times	81 (34.9)	4.5	4.5 (2.3)	4.7	17.2
Increased D-dimer	76 (32.8)	5	5 (2.6)	7.3	19.4
Hemorragic manifestations	72 (31.0)	5	5.3 (3.0)	10	17.7
Liver enlargement	71 (30.6)	4	4.8 (2.8)	7.3	14.2

Conclusions: We identified the features of MAS that were agreed upon by the majority of international pediatric rheumatologists. The ability of each feature to discriminate MAS from potentially "confusable" conditions and the optimal diagnostic threshold for laboratory tests will be assessed through a large-scale data collection, which is ongoing. Altogether, these processes will lead to the development of a new and robust set of criteria for MAS complicating sJIA.

Anakinra as First-Line Disease Modifying Therapy in Systemic Juvenile Idiopathic Arthritis—Report of 46 Patients from an International Multicenter Series. Peter A. Nigrovic[4], Melissa Mannion[14], Andrew S. Zeft[15], Egla C. Rabinovich[8], Marion A. J. van Rossum[9], Elisabetta Cortis[2], Manuela Pardeo[2], Paivi M. Miettunen[1], Ginger L. Janow[5], James D. Birmingham[10], Aaron T. Eggebeen[10], Erin M. Janssen[3], Andrew I. Shulman[4], Mary Beth F. Son[4], Sandy D. Hong[13], Karla B. Jones[11], Norman T. Ilowite[7], Randy Q. Cron[6] and Gloria C. Higgins[12]. [1]Alberta Childrens Hospital, Calgary, AB, Canada, [2]Bambino Gesù Hospital, Rome, Italy, [3]Children's Hospital Boston, Cambridge, MA, [4]Children's Hospital Boston, Boston, MA, [5]Children's Hospital Montefiore, New York, NY, [6]Children's Hospital of Alabama, Birmingham, AL, [7]Children's Hospital Montefiore, Bronx, NY, [8]Duke University Medical Center, Durham, NC, [9]Emma Children's Hospital, Amsterdam, The Netherlands, [10]Michigan State Univ, Grand Rapids, MI, [11]Nationwide Children's Hospital, Columbus, OH, [12]Nationwide Childrens Hosp, Columbus, OH, [13]U of Iowa Children's Hosp, Iowa City, IA, [14]Univ of Alabama at Birmingham, Birmingham, AL, [15]University of Utah, Salt Lake City, UT

Objective: Chronic active systemic juvenile idiopathic arthritis (sJIA) is one of the most devastating rheumatologic diseases of childhood. We hypothesized that early treatment with anakinra could favorably affect the course of this disease.

Methods: Medical records of children receiving anakinra as first-line therapy for sJIA were reviewed to characterize clinical course.

Results: 46 children from 11 centers in 4 countries received anakinra as part of initial disease-modifying anti-rheumatic drug (DMARD) therapy for sJIA, at a median dose of 1.5 mg/kg/day. Anakinra alone was employed as monotherapy in 10 patients (22%), while corticosteroids and additional DMARDs were employed in 67% and 33% respectively. Median follow-up was 14.5 months. Approximately 60% of patients, including 8 of 10 treated

with anakinra monotherapy, attained clinical remission without further escalation of therapy. Fever and rash resolved within 1 month in over 95%, while C-reactive protein and ferritin normalized within this interval in over 80%. Active arthritis persisted at 1 month in 40%, at 3 months in 27%, and at >6 month follow-up in approximately 10%. Disease characteristics and treatment parameters were similar in partial and complete responders, but partial responders were markedly younger at onset (5.8 vs. 9.8 years, p=0.004). Associated adverse events included bacterial infection in 2 patients and hepatitis in 1 patient.

Conclusions: Anakinra is effective first-line therapy of sJIA, enabling rapid resolution of systemic symptoms while forestalling the development of refractory arthritis in 90% of patients. These results justify further study of IL-1 inhibition as first-line, rather than rescue, therapy in sJIA.

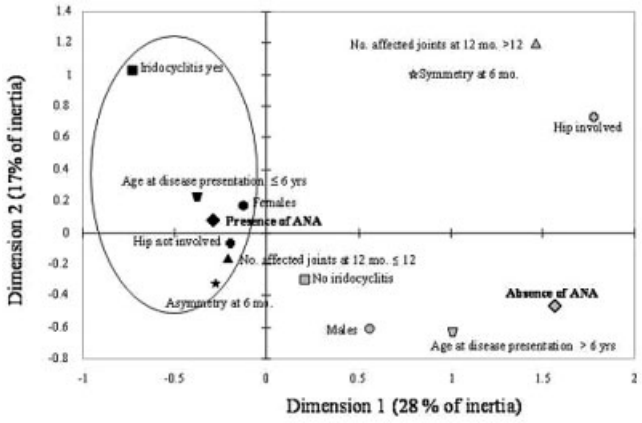
Antinuclear Antibody Positive Patients Should Be Grouped as a Separate Category in the Classification of Juvenile Idiopathic Arthritis. Angelo Ravelli[2], Giulia C. Varnier[4], Sheila K. Oliveira[5], Esteban Castell[4], Olga Arguedas[4], Alessandra Magnani[4], Angela Pistorio[4], Nicolino Ruperto[4], Silvia Magni-Manzoni[1], Bianca Lattanzi[4], Roberta Galasso[4] and Alberto Martini[3]. [1]IRCCS Fondazione Policlinico San Matteo, Pavia, Italy, [2]IRCCS G. Gaslini and Università di Genova, Genova, Italy, [3]IRCCS G. Gaslini and Università di Genova, Genova, Italy, [4]IRCCS G. Gaslini, Genova, Italy, [5]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Objective: We hypothesized that in the International League of Associations for Rheumatology (ILAR) classification of juvenile idiopathic arthritis (JIA), patients with similar characteristics are classified into different categories. We sought to investigate whether ANA-positive patients belonging to the ILAR categories of oligoarthritis, rheumatoid factor (RF)-negative polyarthritis, psoriatic arthritis, and undifferentiated arthritis share homogeneous features and to compare these features with those of ANA-negative patients in the same categories.

Methods: We identified all JIA patients who were followed up during a 22-year period. ANA positivity was defined as ≥ 2 positive results at a titer of ≥ 1:160. Demographic and clinical features were recorded retrospectively and compared among ANA-positive and ANA-negative patients.

Results: A total of 1219 patients fulfilled the ILAR criteria for JIA. Patients with systemic arthritis, RF-positive polyarthritis and enthesitis-related arthritis were excluded from the study. The remaining 971 patients belonging to the ILAR categories of oligoarthritis (n=649), RF-negative polyarthritis (n=223), psoriatic arthritis (n=37), and undifferentiated arthritis (n=62) were combined and classified according to their ANA status as follows: 711 (73.2%) were ANA positive, 149 (15.3%) were ANA negative, and 111 (11.4%) had a doubtful ANA status. Patients with a doubtful ANA status were excluded from the analysis. The number of ANA determinations per patient in the 860 patients who had the ANA status specified ranged from 2 to 20 (mean 5.4); the total number of determinations was 4610. All ANA-positive patients were similar in terms of age at disease presentation, female-to-male ratio, and frequency of asymmetric arthritis and iridocyclitis. Compared with ANA-positive patients, ANA-negative patients were older at disease presentation and had a lesser female prevalence, a lower frequency of iridocyclitis and asymmetric arthritis, a greater number of affected joints over time, and a different pattern of arthritis. The close relationship between the presence of ANA and younger age at disease presentation, female predilection, asymmetric arthritis, and development of iridocyclitis was confirmed by multivariate, multiple correspondence, and cluster analysis. The figure shows the 2-dimensional scatterplot of multiple correspondence analysis.



This analysis led to the identification of 2 patient groups with distinct characteristics: the circle identifies the interrelated variables that define the ANA-positive patient profile.

Conclusion: Our findings substantiate the hypothesis that ANA-positive patients classified into different JIA categories by current ILAR criteria constitute a homogeneous patient population, irrespective of the course of joint disease or the presence of psoriatic features.

Are They Ready for Adult Care? An Assessment of Variables Affecting Patient Autonomy When Transitioning from Pediatric to Adult Rheumatology. Sharon E. Banks[3], Catherine A. Bingham[1] and Brandt P. Groh[2]. [1]Hershey Medical Center, Zionsville, PA, [2]Hershey Medical Center, Hershey, PA, [3]Hershey Medical Center

Background: Transition from a pediatric to adult provider is often difficult for pediatric rheumatology patients and their families. Currently there are no criteria used to determine whom or when to transition. Physicians expect the adolescent to become motivated to be medically independent in caring for his/her own disease without parental influence. However, many adolescents are not ready to assume this role causing a lapse in medical care. We sought to identify factors which, when present, might lead to increased autonomy. Identification of these factors could be used in the clinic to determine which patients would make a more successful transition.

Methods: 69 pediatric and young adult rheumatology patients between the ages of 14 and 21 were surveyed independently without parental input. Information was collected by questionnaire that consisted of two types of questions**. Independence questions** included whom the patient would contact in case of worsening disease, medication refills, medical emergencies, missed appointments, and to make an appointment. **Life skills questions** included whether the patient ever had a summer job, a drivers license, current grades, scholastic level achieved, and family income. Data was analyzed to see if there was any correlation between an individual's response to independence questions and his/her response to life skills questions. Significance was determined using Chi-square statistics and Fishers exact test where applicable. Statistically significant or near significant correlations are shown in the table below.

Results:

Life skill question	Independence question	P-value
Higher scores in school	Take meds without a reminder from parents	P = 0.01
Take meds which require laboratory monitoring	Parents give the meds	P = 0.07
Male gender	Likely to call doctor, not parent, if feel sick	P = 0.02
Take meds daily	Parent (not adolescent) phones doctor for emergency	P = 0.07
Increased household income	Parent makes doctor appointment	P = 0.09
Increased household income	Parent calls doctor for disease flare	P = 0.03
Increased household income	Parent cancels doctor appointment	P = 0.02
College level	Cancel own doctor appointment	P = 0.02
Have summer job	Give self meds	P = 0.04
Have summer job	Call doctor (not parent) if disease flares	P = 0.01
Have a drivers license	Call doctor (not parent) if run out of meds	P = 0.001
Have drivers license	Make own doctor appointment	P = 0.01
Have drivers license	Give self meds	P = 0.09

Conclusions: Higher scores in school, college enrollment, having a summer job, and a drivers license all contributed to independence in medical care. Higher family income, taking medications which require lab monitoring, and taking medications daily were associated with less independence. Physicians could assess this information to determine which patients may need more preparation for transition to adult rheumatology versus those ready to transition.

Assessment of Activity in Children with Enthesitis Related Arthritis Using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Marìa M. Katsicas[2] and Ricardo A. G. Russo[1]. [1]Hospital de Pediatrìa Prof Dr JP Garrahan, Buenos Aires, Argentina, [2]Hospital de Pediatrìa Prof Dr JP Garrahan

Background: Enthesitis related Arthritis (ERA), as defined by ILAR criteria, is characterized by involvement of entheses and pheripheral joints; axial skeleton is affected in some patients The clinical spectrum of ERA overlaps with that of spondyloarthropathy. Bath Ankylosing Spondyliyis Disease Activity Index (BASDAI) is a score designed to determine the degree of activity in patients with Ankylosing Spondylitis. Its value as an outcome measure in children with ERA has not been tested.

Purpose: To assess disease activity using BASDAI in children with ERA. To correlate BASDAI score with disease activity markers.

Methods: Cross Sectional observational-descriptive study.Consecutive patients with ERA were included. Variables recorded were: presence of axial involvement [AI] (spinal pain and reduced spinal mobility or chest expansion), enthesitis, HLA-B27, number of active joints, number of joints with reduced mobility, duration of stiffness, ESR, physician'sglobal evaluation of activity (phy) [0–3], patient's assessment of well-being (p) [0–3] and pain [0–3] meassured on a 10 cm visual analogue scale (VAS), BASDAI, Bath Ankylosing Spondylitis Functional Index (BASFI) and CHAQ scores. BASDAI score was administered by a pediatric rheumatologist (MK) and answered by children (> 8 y) or parents (3–8 y). Association between disease activity markers (ESR, number of active joints, phyVAS, pVAS, painVAS) and BASDAI score was analysed (Spearman's correlation). Patients with AI were compared with those with peripheral involvement.

Results: 57 patients were enrolled (50 M,7 F). Age at onset: 9 ± 2.9 (3–15) years. Age at evaluation: 10 ± 2.9 (6–17) years. AI: 47 %. Enthesitis: 57%. Presence of HLA-B27: 42 %; # active joints: 2 (0–14) [median, range]; # joints with reduced mobility: 2 (0–12); duration of stiffness: 15 (0–180) minutes; Schöber test: 4,5 (2–7) cm; ESR= 2 (15–110) mm/h; phy VAS: 0.35 (0–1.9); pVAS: 0.48 (0–2.62); pain VAS: 0.41 (0–2.43). BASDAI >0 was recorded in 43 (86%) patients. Median BASDAI score: 1.90 (0–7.50). BASDAI correlated with: pVAS (r: 0.67; p=0,003), duration of stiffness (r: 0.65; p=0,004), phyVAS (r: 0.63; p=0,005) and ESR (r: 0.56; p=0,01). Patients with AI showed higher BASDAI score than patients with peripheral involvement. (median BASDAI score: 2.6 vs 1.7). BASDAI score corresponding to patients with AI strongly correlated with: duration of stiffness (r: 86%; p=0,006); ESR (r: 86%; p=0,01); phy VAS (r: 82%; p=0,01). Individual BASDAI score items correlations were: fatigue with pVAS (r: 59%; p=0,01) and phy VAS (r: 50%; p=0,03); spinal pain with painVAS (r: 63%; p=0,007); joint pain with pVAS (r: 64%; p=0,006) and phyVAS (r: 53%; p=0,03); areas of localized tenderness with pVAS (r: 64%; p:0,006); morning stiffness with duration of morning stiffness (r: 60%; p=0,01); ESR (r: 58%; p=0,01) and phy VAS (r: 51%; p=0,03).

Conclusion: BASDAI showed correlation with certain activity disease markers, especially in patients with AI. BASDAI score ranged in the low-medium spectrum of the scale. BASDAI should be included as a useful outcome measure in the asssessment of activity in children with ERA.

Benefit of Intra-Articular Corticosteroid Injections by Oral and Maxillofacial Surgery Treating Temporomandibular Joint Arthritis in Children with Juvenile Idiopathic Arthritis. Tyler Sharpe[2], Jennifer Good[2], Timothy Beukelman[3], Peter Waite[2] and Randy Q. Cron[1]. [1]Children's Hospital of Alabama, Birmingham, AL, [2]Univ of Alabama-Birmingham, [3]University of Alabama-Birmingham, Birmingham, AL

Background: Temporomandibular joint (TMJ) arthritis in juvenile idiopathic arthritis (JIA) is often asymptomatic and leads to joint destruction and micrognathia. MRI is the most sensitive tool at detecting TMJ arthritis in JIA patients, with prevalence rates ranging from 63–81%. Intra-articular corticosteroid injections (IACSi) of the TMJ under CT or ultrasound guidance are reported to reduce effusion and increase maximal-incisal opening (MIO) in JIA. Herein, MRI was used to determine the prevalence of TMJ arthritis among all subtypes of a large cohort of JIA patients. The efficacy and safety of delivering TMJ IACSi under anesthesia by an oral and maxillofacial (OMF) surgeon without the need for prolonged sedation and image guidance was evaluated.

Methods: A retrospective chart review of 192 patients diagnosed with JIA (ILAR revised criteria) seen at a single children's hospital between January 2008 and June 2010 was executed. MRI with contrast using a TMJ surface coil was performed and read by experienced pediatric radiologists. Sixty-three patients diagnosed by MRI underwent IACSi (0.5 ml of Aristospan per TMJ) by OMF surgery. Data collected included age, JIA subtype, age at diagnosis, immunosuppressive therapy, prior, MIO pre- and post-IACSi, changes on MRI, post-IACSi complications, and TMJ arthritis symptoms.

Results: MRI evidence of acute and/or chronic TMJ arthritis was noted in 46%. Of those with TMJ arthritis, 85% and 79% had received methotrexate and anti-cytokine (TNF or IL-1) therapy, respectively. All 7 JIA subtypes had relatively similar rates of TMJ arthritis (range, 40–57%). Forty-six (48%) of 95 patients with data available had MIO below mean values in age-matched normal subjects, and this was up to 61% (33 of 54 patients) in the subpopulation of patients diagnosed with TMJ arthritis and available data. Forty-two (47%) of 89 patients diagnosed with TMJ arthritis reported TMJ symptoms, particularly among 11–19-year-olds (74%). Sixty-three received TMJ IACSi; 66% showed MIO improvement, 27% decreased, and 7% no change. Post-IACSi MRI completed an average of 6 months post-injection (range 1.5 to 13 months) revealed improvement in 51% of patients (greatest improved opening in the systemic subtype), worsening in 34% of patients, and no change in 15% of patients. 21% reported improvement or symptom relief after IACSi. Only 3 patients (5%) reported post-TMJ IACSi complications, including localized swelling in 2, and 1 injection site hypopigmentation 10 months post-IACSi.

Conclusion: The prevalence of TMJ arthritis (46%) in this large JIA cohort was less than predicted but still substantial. Interestingly, all 7 JIA subtypes were roughly equally involved suggesting screening by MRI for TMJ arthritis in all JIA patients. No subtype had a notably worse response to TMJ IACSi, but the biggest MIO increase was in the oligoarticular subset. When using post-IACSi MRI data, similar outcomes are noted in this large JIA cohort compared to prior studies. Moreover, there is a higher frequency of MIO improvement than prior reports. Thus, TMJ IACSi by OMF surgery is similarly effective and safe as studies using radiographic guidance.

Cancer Risk in Juvenile Idiopathic Arthritis. Sasha R. Bernatsky[1], Ann E. Clarke[5], Kiem G. Oen[9], Ciaran M. Duffy[4], Alan M. Rosenberg[8], Jeremy Labrecque[2], Elizabeth M. Turnbull[3], Jennifer L. F. Lee[7] and Rosalind Ramsey-Goldman[6]. [1]McGill UHC/RVH, Montreal, QC, Canada, [2]McGill University, Canada, [3]McGill University Health Ctr, Montreal, QC, Canada, [4]Montreal Childrens Hospital, Montreal, QC, Canada, [5]Montreal General Hospital, Montreal, QC, Canada, [6]Northwestern University, Chicago, IL, [7]RI McGill Univ Health Ctr, Montreal, QC, Canada, [8]Royal Univ Hosp, Saskatoon, SK, Canada, [9]University of Manitoba, Winnipeg, MB, Canada

Purpose: There is considerable interest in the increased risk of malignancy in adult rheumatoid arthritis, particularly for lymphoma and lung cancer. However, to date there are few assessments specifically in juvenile idiopathic arthritis (JIA). Our objectives thus were to assess the observed malignancy incidence in JIA, and compare this to the expected incidence, based on general population cancer data.

Methods: We examined cancer occurrence within JIA registries at three Canadian pediatric rheumatology centers. The subjects in the clinic registries were linked to regional tumor registries to determine the occurrence of invasive cancers over the observational interval (spanning 1974–2006). The total number of cancers expected was determined by multiplying the person-years in the cohort by age, sex, and calendar year-specific cancer rates. The standardized incidence ratio (SIR, ratio of cancers observed to expected) was generated, with 95% confidence intervals(CI).

Results: The study sample was comprised of 1,834 patients. The female proportion was 67.6%; average age at cohort entry was 8.6 years(standard deviation, SD=5.1). The majority of cohort members were Caucasian. Subjects contributed 22,341 patient-years (average 12.2, SD=7.8). Within this observation interval, one invasive cancer occurred, compared to 7.9 expected (SIR 0.12, 95% CI 0.0, 0.70). This was a haematological cancer (Hodgkin lymphoma), representing a SIR for haematological malignancies of 0.76 (95% CI 0.02, 4.21).

Conclusion: Only one invasive cancer was demonstrated in this large sample of individuals with JIA, observed for an average of 12.2 years each. These data suggest that, at least in the initial years following JIA diagnosis, the risk of invasive cancers over-all is not markedly increased. However, the results do not rule out the possibility of a baseline increased risk of haematological malignancies. Potential limitations include the small number of specific minorities (e.g. blacks, Asians, Hispanics, etc.) and the difficulty in identifying risk related to specific JIA subtypes. A larger multi-center, multi-ethnic cohort study is underway, to provide more precise results for specific cancer types, and additional years of long-term follow-up.

Childhood Idiopathic Chondrolysis: A Form of Monoarthritis? Rafka Chaiban[1] and Robert P. Sundel[2]. [1]Children's Hospital Boston, Boston, MA, [2]Childrens Hosp Medical Center, Boston, MA

Background: Childhood idiopathic chondrolysis of the hip is condition characterized by substantial destruction of the articular cartilage without an identifiable cause. The incidence of this entity is low, and few pediatric cases have been reported in the literature.

Objectives: We sought to identify cases of idiopathic chondrolysis and determine whether modern diagnostic techniques offered a clearer etiopathologic explanation for the condition

Methods: A retrospective review of all children diagnosed and treated for chondrolysis of the hip since 1988 at a single tertiary care children's hospital was conducted. Subjects were identified from a search of clinic and hospital admissions for cartilage abnormalities. Patients with no definite etiology (idiopathic) were picked for further review. Demographic data, clinical presentation and treatment were studied. Diagnostic imaging and procedures were also noted.

Results: A total of 224 patients with chondrolysis of the hip were found. Out of these, seven had no known etiology (idiopathic chondrolysis of the hip). All seven patients had negative serum inflammatory markers and rheumatologic evaluation (including HLA-B27, ANA, RF). Synovial biopsy showed non-specific inflammatory changes with negative cultures for infectious organisms. Three patients were evaluated by rheumatology at the time of hospitalization for synovial biopsy, and were found to have a psoriasiform rash, dactylitis, nail pitting, or other signs of psoriatic arthritis. Two more patients had a positive family history of RA. Patients were treated for presumed inflammatory arthritis with intra-articular steroids, methotrexate, pulsed-dose methylprednisolone, and TNF inhibitors. All patients improved rapidly, and four who have been followed for a range of 4–6 years have remained well, without recurrence or progression of their chondrolysis. No patient has required joint replacement.

Conclusions: In a series of seven children at a single children's hospital diagnosed with idiopathic chondrolysis, clinical features and response to treatment were consistent with psoriatic arthritis or JIA. Aggressive therapy resulted in excellent clinical outcomes. The possibility that idiopathic chondrolysis might represent an unusually aggressive form of seronegative mono-arthritis should be considered in such patients.

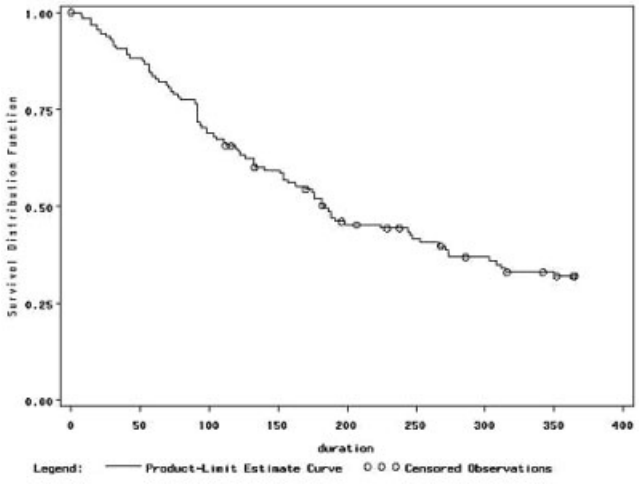
Clinical Outcomes after Withdrawal of Anti-Tumor Necrosis Factor-Alpha Therapy in Juvenile Idiopathic Arthritis: A Twelve-Year Experience. Kevin W. Baszis[2], Dana Toib[2], Richard Brasington[1], Allison King[3], Jingnan Mao[3], Andrew J. White[2], Jane Garbutt[3] and Anthony R. French[2]. [1]Washington Univ Schl of Med, St Louis, MO, [2]Washington University School of Medicine, Department of Pediatrics, St Louis, MO, [3]Washington University School of Medicine, Department of Pediatrics

Objective: To determine length of time to flare and likelihood of clinical remission after discontinuation of tumor necrosis factor-alpha (TNF-α) blockers in patients with juvenile idiopathic arthritis (JIA).

Methods: This is a retrospective cohort review of 241 patients with JIA treated with TNF-α inhibitors at our center between January 1, 1998, and November 1, 2009. Primary outcomes were time to flare after withdrawal of TNF-α inhibitor and proportion of treatment episodes resulting in clinical remission after cessation of anti-TNF-α therapy. Time points of interest were based on preliminary criteria for inactive disease and remission in JIA[1]. Inactive disease (ID) is defined by no active arthritis/uveitis, no systemic symptoms or elevated ESR/CRP attributable to JIA, and physician global assessment indicating no disease activity. Clinical remission on medication (CRM) is defined by ID for 6 months, on medication. Clinical remission (CR) is defined by ID for 12 months while off all anti-arthritis/uveitis medications. For our purposes, patients were not excluded if remaining on anti-rheumatic drugs after stopping anti-TNF-α therapy, but any further use of corticosteroids or biologic agents was cause for exclusion. Descriptive statistics, survival analyses, and hazard ratios were calculated.

Results: One hundred seventy-one patients met inclusion criteria, yielding 255 discrete episodes of anti-TNF-α treatment. Two hundred thirteen (83.5%) episodes resulted in ID; 127 (49.8%) episodes achieved CRM. After cessation of anti-TNF-α therapy in patients with ID, 50% of episodes remained in ID at 6 months, and 32% of episodes achieved CR off of anti-TNF-α therapy.



The median duration of anti-TNF-α therapy after ID was obtained was 6.1 months; there was no correlation between this duration and time to flare (r=0.01, p=0.91). Using hazard ratios and covariance analysis, subtype of JIA, sex, and age at diagnosis did not significantly affect risk of relapse. Median patient observation was 59.7 months.

Conclusion: In 171 patients with JIA achieving inactive disease on TNF-α inhibitors, 50% remained in remission at 6 months and 33% at one year. Results did not significantly vary by JIA subtype, sex, age at diagnosis, or duration of therapy. Although these results support the observation that JIA is a chronic relapsing/remitting disease, they suggest that one-third of patients can be successfully withdrawn from TNF-α antagonists for at least one year and be spared the cost and potential morbidity of treatment. Further studies are needed to identify predictive factors for those patients who successfully obtain clinical remission after anti-TNF-α cessation.

Contribution of TNFalpha–308 and T676G TNF-RII Polymorphism on Response to Etanercept and Posibility To Discontinue Treatment. Jelena Vojinovic[1], Gordana Susic[3], Jelena Basic[2], Dragana Lazarevic[1] and Nemanja Damjanov[3]. [1]Dept Ped Rheumatology, University Clinic Center Nis, Nis, Serbia, [2]Institute of Biochemestry Faculty of Medicine Nis, Nis, Serbia, [3]Institute of Rheumatology Belgrade, Belgrade, Serbia

Background: Genetic contribution of TNFα–308 promoter and T676G TNF-RII polymorphism on response to TNF-blocking agents in JIA is not yet well established. Primary endpoint of this study was to evaluate influence of these promoter polymorphisms, as biomarkers, in JIA patients treated with etanercept, on clinical outcome and possibility to discontinue treatment.

Methods: Genomic DNA was extracted and TNFα–308 promoter and T676G TNF-RII polymorphism was evaluated using the PCR-RFLP method in 60 JIA patients treated with etanercept, included in Serbian JIA registry who donated blood samples. Time cut of point for outcome data analysis was 4 years after first drug dose.

Results: At enrolment JIA patients mean age was 14.7±4.22, disease duration 6.59±2.76, average dose of MTX 11.91±6.68 mg/m2/week. Average duration of etanercept therapy was 34.61±12.11 months. Disease subtype distribution was 6.78% systemic, 54.24% polyRF- and extended oligo, 18.64% polyRF+, 16.95% ERA and 3.38 PsA. The distribution of TNFα308 and T676G genotypes was not significantly different among JIA subtypes. TNFα308 genotypes distribution was 6.78% AA, 30.51% GG and 62.71% GA while T676G genotypes were 59.3% TT, 8.3% GG and 26.4% TG. T676G genotype polimorphism did not significantly influenced outcome. ACR Pedi 30,50,70 and 100 improvement was significantly faster and sustained in TNFα308 GG-genotype patients compared to GA genotype.

ACR	30		50		70		100	
%	GG	GA	GG	GA	GG	GA	GG	GA
1 year	5.6	18.9[a]	22.2	35.14[a]	22.2	32.43[a]	50.9	13.51[a]
2 years		14.71[a]	5.6*	17.65**	44.4*	44.12*	50.0	23.52**

Results in table: *significant compared to 1 year; a-significant compared to GG Treatment could stopped (remission) in 35.14%, had to be reintroduces due to disease worsening in 16.22%, disease was in remission under medication in 21.62% or still active in 24.32% GA patients while respectively in 38.9%, 16.7%, 27.8% and 11.1% in GG patients. Patients with systemic or RF+ disease course were mostly treatment resistant in both genotypes.

Conclusion: JIA patients with GG TNFα308 genotype can achieve better outcome and etanercept treatment can be stopped earlier compared to GA genotype patients who need two years of treatment to achieve same results. TNFα308 genotype could be useful clinical predictive biomarker for treatment response in all disease subtypes except systemic and RF positive JIA.

Effectiveness of Dexamethasone Iontophoresis in Temporomandibular Joint (TMJ)-Arthritis in Juvenile Idiopathic Arthritis (JIA). Rina Mina[3], Paula G. Melson[3], Stephanie Powell[2], Claas H. Hinze[1], Joshua Pendl[2], Thomas B. Graham[5] and Hermine I. Brunner[4]. [1]Children's National Medical Center, Rockville, MD, [2]Cincinnati Children's Hosp Medical Ctr, [3]Cincinnati Children's Hospital Medical Ctr, Cincinnati, OH, [4]Cincinnati Children's Med Ctr, Cincinnati, OH, [5]Vanderbilt Children's Hospital, Nashville, TN

Background: TMJ-arthritis is common in JIA and the best treatment approach is unknown. The effectiveness of dexamethasone iontophoresis, a non-invasive method of transdermal steroid administration, has not been evaluated for TMJ-arthritis in JIA.

Objective: Evaluate the effectiveness of dexamethasone iontophoresis for the treatment of TMJ-arthritis in JIA.

Methods: Medical records of all JIA patients who underwent TMJ iontophoresis at Cincinnati Children's Hospital from 1997–2010 were reviewed. Effectiveness was assessed by comparing primary outcomes (i.e. inter-incisor distance and lateral translation) and secondary outcomes (pain, clicking and crepitus) before and after treatment using two-sided paired t-test.

Results: There were 28 JIA patients (all subtypes; median age ± IQR = 12 ± 8 years) who received TMJ iontophoresis. At baseline (median ± IQR) the number of active joints was 3 ± 4 and ESR was 5 ± 7. Medications included methotrexate (29%), biologics (25%) and NSAIDS (53%), with no clinically relevant medication-change during the treatment period. Iontophoresis was done using a standard dose of dexamethasone (6 mg) per TMJ per session (average number of sessions = 8, 45% bilateral). Statistically significant improvement was observed in the inter-incisor distance and right lateral translation (*see Table*). Improvement in TMJ pain (70%), clicking (80%) and crepitus (40%) were noted in those who initially presented with these findings. Side effects reported were transient and included site erythema (46%) and metallic taste (27%). Imaging with MRI was available only in select number of patients and thus not useful as study endpoint.

TMJ measurements at initial and final iontophoresis visit

	Initial Visit				Final Visit				
TMJ measurements	N	Median	IQR	Range	N	Median	IQR	Range	p-value
Inter-Incisor distance (mm)	24	34.5	14.5	20–55	24	38.5	10	26–55	0.0005
Right lateral deviation (mm)	11	7	6	4–15	14	10	1	5–20	0.04
Left lateral deviation (mm)	11	8	2	2–13	14	10	2	2–17	0.34

Conclusion: Dexamethasone iontophoresis appears to be effective in the management of TMJ-arthritis in JIA. Because of its ease of use and relative lack of side effects, it may be a good initial therapy for TMJ-arthritis and thus warrants prospective evaluation with focus on durability of response, imaging outcomes and optimization of treatment protocol.

Effectiveness of Etanercept in Juvenile Psoriatic Arthritis and in Children with Enthesitis Related Arthritis. Marieke H. Otten[3], Femke H. M. Prince[4], Marinka Twilt[7], Nico M. Wulffraat[12], Rebecca ten Cate[7], Esther P. A. H. Hoppenreijs[9], Yvonne Koopman-Keemink[6], Simone L. Gorter[10], Wineke Armbrust[11], Koert M. Dolman[8], Joost F. Swart[13], Arnold P. Oranje[4], Flora B. de Waard-van der Spek[2], Marion A. J. van Rossum[1] and Lisette W. A. van Suijlekom-Smit[5]. [1]Academic Medical Centre Emma Children's Hospital and Jan van Breemen Institute Amsterdam, [2]Erasmus MC Rotterdam, [3]Erasmus MC Sophia Children's Hospital Rotterdam, Rotterdam, The Netherlands, [4]Erasmus MC Sophia Children's Hospital Rotterdam, [5]Erasmus MC Sophia Children's Hospital Rotterdam, The Netherlands, [6]Haga Ziekenhuis Juliana Children's Hospital The Hague, [7]Leiden University Medical Centre, [8]St Lucas Andreas Hospital and Jan van Breemen Institute Amsterdam, [9]St Maartenskliniek Nijmegen, [10]University Hospital Maastricht, [11]University Medical Centre Groningen Beatrix Children's Hospital, [12]Utrecht Medical Centre Wilhelmina Children's Hospital, [13]VU Medical Centre and Jan van Breemen Institute Amsterdam

Background: Etanercept (ETN) has proven to be effective in children with systemic and polyarticular Juvenile Idiopathic Arthritis (JIA). Experience with ETN in the treatment of Juvenile Psoriatic Arthritis (JPsA) and Enthesitis Related Arthritis (ERA) subtypes is limited. We therefore explored the effectiveness of ETN in these subtypes.

Methods: This study is embedded in the ABC-register, a since 1999 prospective ongoing multicentre, observational study of all Dutch JIA patients using biological agents. Patient and disease characteristics are collected at baseline. At start of treatment, after 3, 6, 15 months and thereafter yearly variables of the JIA disease activity score; physician's global (VAS), Childhood Health Assessment Questionnaire (CHAQ), including global assessment of wellbeing (VAS), number of active and limited joints and ESR, are retrieved. Response was assessed by the ACR pediatric criteria, and Wallace criteria for inactive disease. We collected additional data regarding the diagnostic ILAR criteria for JPsA and ERA.

Results: Our register includes 17 JPsA and 14 ERA patients treated with ETN.

JPsA patient characteristics: 71% female, median age at onset 11.0 (range 3.3–13.3) years, 47% with psoriatic skin lesions, 41% nail psoriasis, and 24% dactylitis. Median follow-up since start etanercept of 26 (range 3–62) months.

ERA patient characteristics: 79% male, median age at onset 10.4 (range 2.3–17.0) years, presence of enthesitis in 86%, SI-joint tenderness and/or inflammatory lumbosacral pain in 57%, and HLA-B27 positivity in 79%. Median follow-up since start etanercept of 46 (range 6–110) months.

After 3 months of treatment 82% of JPsA and 86% of ERA patients achieved ACRpedi30 response, increasing after 15 months to 100% and 91% resp. Of the JPsA patients reaching 39 months of follow-up (n=6) 67% achieved inactive disease and of the ERA patients (n=4) 50% (Figure 1).

In only 4 of the 8 patients with pre-existing psoriasis the skin lesions improved. Two JPsA patients and 2 additional JIA patients with other subtypes from our register developed *de novo* psoriasis during ETN treatment.

In both subtypes there was no ETN discontinuation because of inefficacy. Six JPsA patients and 1 ERA patient discontinued treatment after good clinical response. However, all except 1 JPsA patient flared again. They all restarted treatment with good clinical response.

Conclusion: We showed that ETN is very effective to treat the arthritis in the JPsA and ERA subtypes, with more than 90% achieving ACRpedi30 response after 15 months of treatment. However the psoriatic skin lesions did not respond very well and *de novo* psoriatic skin lesions occurred in JPsA patients and in patients with other JIA subtypes during ETN treatment. In most patients the arthritis flared after discontinuation of treatment, emphasizing the need to investigate optimal duration of therapy.

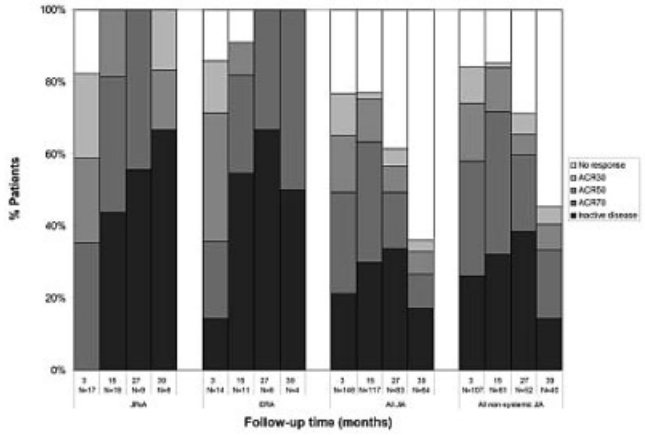

Figure 1. Improvement and inactive disease based on an intention-to-treat modus. Shown are percentages of JPsA and ERA patients that met the criteria for the ACR Pedi 30, 50 and 70 and inactive disease compared to all JIA subtypes and all non-systemic JIA subtypes (i.e. subtypes other than systemic JIA), as published from our register in 2009.

Efficacy and Safety of Oral and Parenteral Methotrexate Therapy in Children with Juvenile Idiopathic Arthritis. Gerd Horneff[2], Gerd Ganser, Ivan Foeldvari[1], Andreas Urban and Ariane Klein. [1]Hamburg, Germany, [2]Asklepios Clinic Sankt Augustin, Germany

Background: Methotrexate is widely used as first-line disease-modifying antirheumatic drug in juvenile idiopathic arthritis (JIA). Both, oral and parenteral administrations have been shown to be effective.

Methods: In the German Methotrexate Registry data concerning efficacy and safety of methotrexate treatment are collected since 2005. In a retrospective analysis we compared oral and parenteral methotrexate treatment regarding efficacy, adverse events and rate of and reasons for discontinuation of treatment.

Results: Between 2005 and 2009 1066 JIA patients were documented in whom treatment with methotrexate has been initiated. 612 patients received methotrexate for at least 6 months, 3 patients had to be excluded because of concomitant treatment with biologics and 198 who changed the mode of application. 259 patients (63%) received oral (0.42+/−0.24mg/kg) and 152 patients (37%) parenteral (0.43+/−0.15mg/kg) methotrexate. At start of treatment patients of the two groups did not differ in numbers for active joints, joints with limited range of motion, CHAQ score, duration of disease, MTX dosage and concomitant steroid therapy. At 6 months, comparable numbers of patients treated orally or parenterally showed a PedACR 30, 50 and 70 response (oral 75.6%/68.8%/52.8% and s.c. 76.1% /72.1%/54.4%).

In the evaluated group 151 adverse events (AE) were reported, 76 in the group of 259 patients with oral (0.3/patient) and 75 in 152 patients with parenteral MTX (0.44/patient), gastrointestinal AEs (40 and 25) being the most frequent, followed by infections (10 and 12) and elevated liver enzymes (7 and 8).

10 patients in the oral group and 9 patients in the parenteral group discontinued methotrexate treatment during the first 6 months of treatment. Until last observation, significantly more patients with parenteral application discontinued methotrexate because of adverse events (11 of 152 versus 6 of 259, p = 0.016). However, significantly more patients in the oral group received folic acid (46.7% vs. 31.6%, p-value = 0.001).

	Patients on oral MTX			Patients on parenteral		
Parameter	month 0 Mean (SD)	month 6 Mean (SD)	Mean improvement	month 0 Mean (SD)	month 6 Mean (SD)	Mean improvement
Number of active joints	5.4 (+/−6.4)	1.5 (+/−2.4)	72%	6.1 (+/− 7.9)	1.3 (+/−2.2)	79%
Number of joints with LOM	4.8 (+/−5.6)	1.9 (+/−0.6)	60%	5.5 (+/−7.8)	1.6 (+/−2.5)	71%
Parent's global VAS 0–100	38 (+/−24)	13 (+/−18)	66%	44 (+/−27)	16 (+/−18)	64%
Physician's global VAS 0–100	39 (+/−23)	12 (+/−18)	69%	49 (+/−24)	16 (+/−20)	67%
CHAQ 0–3	0.57 (+/−0.69)	0.21 (+/−0.34)	63%	0.61 (+/−0.63)	0.25 (+/−0.41)	59%
ESR mm/h	21 (+/−18)	10 (+/−10)	52%	28 (+/−25)	13 (+/−14)	54%

Conclusion: In this patient group parenteral administration of methotrexate was not superior to oral administration regarding efficacy and tolerability. JIA patients treated with methotrexate did not show significantly different PedACR responses whether they received oral or parenteral MTX. These results could not argue for a possibly painful and more expensive application mode of methotrexate especially in younger children until controlled, randomised prospective studies have been performed.

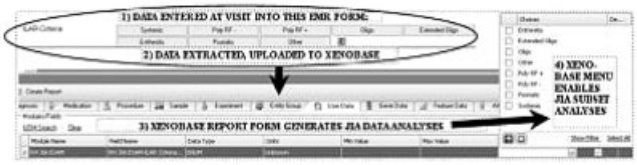
Electronic Medical Record (EMR) Entries Can Provide a Source for Quality Improvement Projects for Juvenile Idiopathic Arthritis (JIA): Results of a Pilot Study. Michael L. Miller[2], Jason Ruprecht[1], George Lales, Sean McKenna and Frank Dupont. [1]Chicago, IL, [2]Childrens Memorial Hospital, Chicago, IL

Although EMRs have facilitated care for children with juvenile idiopathic arthritis, relevant quality improvement projects have required use of paper or manual re-entry of clinical data. To establish continuous, periodic QI activities tracking care of JIA patients, we have started EMR discrete data

entry for joint examination and related clinical parameters. This IRB approved pilot study reports successful data extraction from our EMR to Xenobase™, an application permitting cohort analysis of a clinic JIA population, stratified by disease subtype and disease severity.

Methods: During clinic visits, starting March, 2010, data were entered into flow sheet rows in EpicCare™ (Epic Systems, Verona, WI), extracted every 2 weeks, using Clarity Reports, as de-identified data. Data were de-identified and uploaded to Xenobase™. Parameters included detailed joint examination, ILAR diagnosis, MD disease activity assessment (10 = very active), Patient/Parent global assessment (10 = very good), Pain Score (10 = most severe).



Results: Data on 175 patients with JIA seen from March-May, 2010 were extracted from EMR records and analyzed in Xenobase™. Number, age, and gender distribution were: oligo (64; 52 females; 10.3±4.6yrs); extended oligo (6; 5 females; 15.5±3.8 yrs); poly rf- (50; 41 females; 11.8±4.2yrs); poly rf+ (15;14 females; 14.3±3.6yrs); systemic (18; 7 females; 11.1±3.9yrs); enthesitis (19; 10 females; 16.1±8yrs); psoriatic (3; 2 females; 13.0±4.5yrs). Patient Global assessment showed weak correlation with joint counts in active polyarticular JIA, RF positive and negative (r=0.409), but in no other group.

Conclusion: Data extraction from the EMR is feasible and useful to track JIA patients for QI projects. In this pilot study, we found data accurately reflected distribution of age, gender, and numbers typically seen in pediatric rheumatology clinics. Further data extraction and analyses (IRB approved) will compare longitudinal response to treatment. This approach may be helpful in contributing data to national disease registries.

Evaluation of the Role of Bone Mass Determinants in the Prediction of Bone Strength in Patients with Juvenile Idiopathic Arthritis (JIA): Bone Status Assessment Using pQCT, DXA and QUS. Fernanda Falcini[1], Loredana Cavalli[2], Laura Masi[2], Serena Capannini[1], Giovanni D'Elia[4], Valentina Denaro[1], Marco Matucci Cerinic[1], Stefano Stagi[3] and Maria Luisa Brandi[2]. [1]Department of BioMedicine, Section of Rheumatology, Transition Clinic, Florence, Italy, [2]Department of Internal Medicine, Endocrinology Unit, University of Florence, Florence, Italy, [3]Pediatric Unit, Villamarina Hospital, Piombino, Livorno, Italy, [4]Radiology Unit, AOC Careggi, Florence, Italy

Background: Despite the current more effective drugs, JIA pts have a low bone mass. The main reasons are disease activity, medications, reduced physical activity, and unbalanced nutrition. Using peripheral Quantitative Computed Tomography (pQCT) emerged that altered bone geometry, reduced muscle cross sectional area and muscle force, are the major responsible of bone loss in JIA.

Aim: To evaluate bone status in a cohort of pts affected with JIA.

Methods: 139 pts with JIA (median age 16.2 years, range 8.9 to 21.1 years: 101 oligoarticular, 29 polyarticular, and 9 systemic onset), after informed consent, entered the study. In all pts, peripheral Quantitative Computed Tomography (pQCT), Dual energy X-ray Absorptiometry (DXA) at lumbar spine 1–4, and phalangeal Quantitative Ultrasound (QUS) were performed. The data obtained were compared with 62 age- and sex- matched healthy subjects.

Results: Patients with JIA showed a reduced spine Bone Mineral Apparent Density (BMAD) SDS in comparison to controls ($p < 0.01$). These results were confirmed when the subjects were divided into JIA subtypes: systemic onset pts showed more impaired parameters than polyarticular and oligoarticular ($p < 0.005$). Spine BMAD SDS significantly correlated with JIA onset type ($p < 0.05$), age at JIA onset ($p < 0.005$), flares ($p < 0.01$), sex ($p < 0.01$), and corticosteroids exposure ($p < 0.01$). Also Amplitude-Dependent Speed of Sound (AD-SoS; $p < 0.005$) obtained by QUS, and volumetric cortical Bone Mineral Density (cBMD; $p < 0.001$), muscle cross-sectional area (mCSA; $p < 0.005$) and Stress-Strain Index (SSI; $p < 0.05$) obtained by pQCT were reduced in comparison to controls. Otherwise, the fat area was increased in JIA patients ($p < 0.001$). These results were confirmed also when the subjects were divided into JIA subtypes; systemic pts showed more impaired parameters than polyarticular and oligoarticular ($p < 0.001$).

Conclusions: JIA pts have decreased skeletal size, muscle mass, cortical bone density, cortical bone geometry, and muscle strength. These pts have also a higher fat mass. Not surprisingly, these bone abnormalities are more pronounced in pts with more severe disease activity. To reduce the risk of impaired bone mass, a close monitoring of BMD, a better control of disease activity, physical activity, and a dietary intake of calcium and vitamin D are advocated.

Gut Inflammation in Pediatric Spondyloarthritis. Matthew Stoll[2], Marilynn G. Punaro[3] and Molly Dempsey-Robertson[1]. [1]Texas Scottish Rite Hospital for Children, [2]UT Southwestern Med Ctr, Dallas, TX, [3]UT Southwestern Medical Ctr, Dallas, TX

Purpose: Sub-clinical gut inflammation has been identified in two-thirds of adult spondyloarthritis (SpA) patients[1]. Similar findings were observed in a study of 12 pediatric SpA patients[2]. These studies used colonoscopy, an expensive and invasive test not well-suited for routine use in research studies. Although non-invasive tests have been studied in patients with inflammatory bowel disease (IBD), they have not been used to evaluate for sub-clinical gut inflammation among SpA patients. Our intention in this study is to evaluate whether non-invasive tests can detect gut inflammation in pediatric SpA patients.

Methods: Stool samples were obtained from children with active juvenile idiopathic arthritis (JIA). Calprotectin levels were assayed in a commercial lab (ARUP). Children with elevated calprotectin (calp) levels were offered an MRI of the intestines. Flavored sports drink containing polyethylene glycol 3350 was used as oral contrast. Glucagon was used to arrest peristalsis. Patients were imaged in the prone position on a 1.5-T scanner. Heavily T2-weighted fat-suppressed coronal and axial images using breath-hold technique were obtained, followed by post-gadolinium fat-suppressed T1-weighted gradient echo images.

Results: Results are available on 7 children with enthesitis-related arthritis (ERA) and 5 controls with oligo-articular (n = 3) or poly-articular (n = 2) JIA. 3 of the ERA patients and none of the controls reported mild gastrointestinal (GI) symptoms. Median fecal calp levels were 171 in the ERA patients, compared to 37 in the controls ($p = 0.073$; Figure 1.) The presence of GI symptoms was not associated with calp levels among ERA patients (median levels 210 in those without GI symptoms, versus 125 in those with complaints, $p = 0.480$). Two of the patients with abnormal calp levels underwent MRI of their intestines; one of them had evidence of terminal ileitis (Figure 2). Colonoscopy in this child was consistent with IBD primarily limited to the terminal ileum.

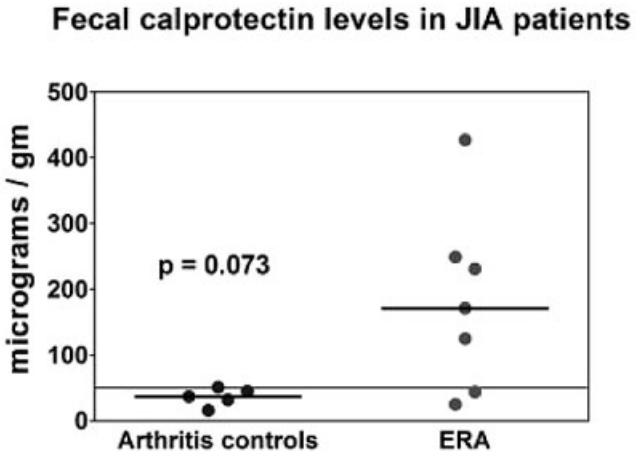

Figure 1. Calprotectin level in patients with ERA compared to patients with oligo-articular or poly-articular JIA.

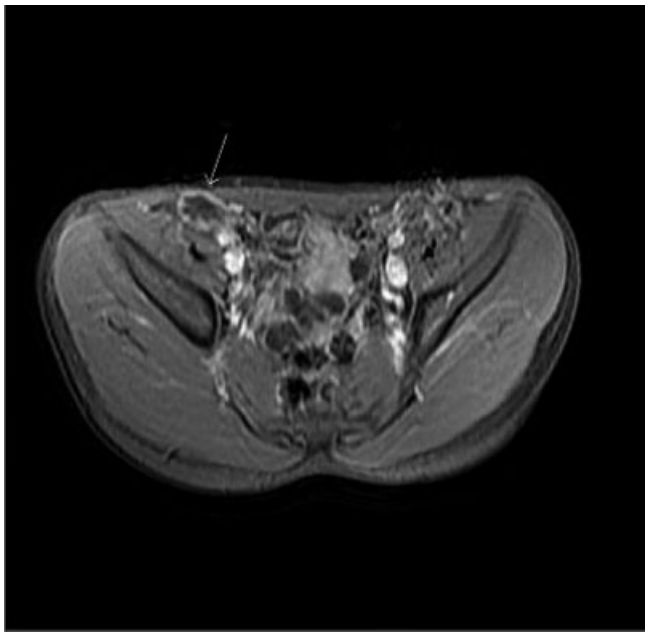

Figure 2. Axial T1 fSPGR with fat saturation post contrast. Arrow indicates site of abnormal enhancement in terminal ileum.

Conclusions: Although preliminary, the data from this study suggest that non-invasive markers can be used to evaluate for sub-clinical gut inflammation in children with SpA. This may have both research and clinical implications.

Immunogenicity and Short Term Safety of Pandemic Influenza Vaccine (Anti-H1n1) in Patients with Juvenile Idiopathic Arthritis. Nadia E. Aikawa[3], Lucia M. A. Campos[5], Clovis A. Silva[5], Vanessa R. Guissa[5], Adriana M. Sallum[5], Adriana A. Jesus[5], Julio B. Moraes[4], Cleonice Bueno[4], Maria C. S. T. Timenetsky[1], Alex R. Precioso[2] and Claudia Goldenstein-Schainberg[4]. [1]Adolpho Lutz Institute, University of Sao Paulo, [2]Butantan Institute, [3]Division of Rheumatology, Pediatric Reumatology Unit, Universidade de Sao Paulo, [4]Division of Rheumatology, Universidade de Sao Paulo, [5]Pediatric Reumatology Unit, Universidade de Sao Paulo

Purpose: To assess immunogenicity and safety of pandemic influenza vaccine (anti-H1N1) in patients with juvenile idiopathic arthritis (JIA).

Methods: 60 JIA patients and 55 age-matched healthy controls were vaccinated with cepa A/California/7/2009 (NYMC X-179A) anti-H1N1 vaccine. All participants received 1 dose of immunization, and those <9yrs of age received a second dose 3 weeks apart. All subjects were evaluated before and 3 weeks after complete vaccination. Serology against H1N1 virus was performed by hemagglutination inhibition (HI) antibody (Ab) assay. Appropriate endpoints included the percentage of subjects achieving HI Ab titer ≥1:40 (seroprotection) and rates of seroconversion, defined as the percentage of subjects with either a pre-vaccination HI titer <1:10 and a post vaccination HI titer >1:40 or a pre-vaccination HI titer >1:10 and a minimum 4-fold rise in post-vaccination HI Ab titer. Demographic data, JIA onset subtype, disease duration, activity status, patient VAS and CHAQ score were analyzed. Post-vaccination adverse events (AEs) were searched. Fisher's exact and Mann Whitney tests were used for statistical analysis considering $p<0.05$ significant.

Results: Mean age of JIA patients and controls was 13.5±5.3yrs and 12.3±2.6yrs, (p=0.08); median JIA disease duration was 6.7±5.3yrs.

JIA subtypes were 48% polyarticular, 27% oligoarticular, 13% systemic and 12% others. Thirty seven patients (62%) were taking at least one DMARD and 17 (28%) were under biologic therapy (22% anti-TNF; 7% abatacept). Patient VAS, CHAQ score, ESR and CRP levels remained unchanged after immunization (p>0.05). Seroprotection rates against H1N1 influenza virus increased from 23 to 83% in JIA and from 22 to 95% in controls (p=0.08). Seroconversion rates were achieved in 78% JIA and 89% controls (p=0.14). Following vaccination, mean HI Ab titers ranged from 39±103 to 495±634 for patients and from 24±44 to 457±497 for controls (p=0.44). Seroprotection, seroconversion and mean HI Ab titers were not associated to use of DMARDs and/or biologic agents by JIA patients, although, mean HI Ab titer was significantly lower in patients <9yrs of age compared to those between 9–18yrs (217±354 vs. 628±723, p=0.016); notably, frequencies of MTX and DMARDs use were higher in the former group (71% vs. 35%, p=0.03 and 86% vs. 46%, p=0.01, respectively). AEs were reported by 40% patients and 42% controls with rates of 2.4 AE/JIA patient and 1.6 AE/control. Most frequent AEs in patients and controls were local pain (23% vs. 29%, p=0.53), headache (18% vs. 18%, p=1.0), malaise (15% vs. 7%, p=0.24), myalgia (13% vs. 7%, p=0.37), arthralgia (13% vs. 2%, p=0.07) and fever (5% vs 3.6%, p=1.0).

Conclusion: Vaccination of JIA patients against pandemic influenza A (H1N1) generated successful protective antibody production with short term safety profile.

Intra-rater Reliability of the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Bath Ankylosing Spondylitis Functional Index (BASFI) in Children with Spondyloarthritis. Michelle Batthish[2], Alisa Rachlis, Bertha Wong, Samantha Stevens, Michelle Anderson, Brian M. Feldman[1], Ronald M. Laxer[1], Joanne Marcuz, Margaret Reaume, Lynn Spiegel, Kristi Whitney-Mahoney and Shirley M. L. Tse[1]. [1]Toronto, ON, Canada, [2]The Hospital for Sick Children, The University of Toronto, Toronto, ON, Canada

Background: Juvenile spondyloarthritis (JSpA), referred to as enthesitis-related arthritis (ERA) sub-type under the International League of Associations for Rheumatology (ILAR) classification of juvenile idiopathic arthritis (JIA), is characterized by inflammation in the joints and entheses. Axial involvement is uncommon at presentation but may develop in the second decade of life. Several instruments assessing disease activity in ankylosing spondylitis have been validated including the BASDAI and BASFI. At this time, there are no disease activity scores for JSpA or ERA. The objective of this study is to measure the intra-rater reliability of the BASDAI and the BASFI in JSpA/ERA.

Methods: Patients diagnosed with ERA (ILAR criteria) and followed at The Hospital for Sick Children Spondyloarthritis Clinic were included in this study. Patients were excluded if they were unable to understand, speak or write English, if they were less than 6 years of age or greater than 18 years of age. Prospective subjects were consecutively enrolled (June 2009 to June 2010) and, the patient and/or one parent completed the BASDAI and BASFI at baseline and 2 weeks later (a period during which little change is expected). Intra-class correlation coefficient (ICC) was calculated and values greater than 0.6 were considered indicative of good reliability.

Results: Forty-eight patients (39 males, 81.2%) were enrolled. The average age at diagnosis was 12.5 years (range, 7.6 to 16.7 years). 41.7% were HLA-B27 positive, 18.8% had a positive family history for ankylosing spondylitis, 52% had involvement of the hip and 40% had radiographic evidence of sacroiliitis. Eight patients dropped out or were excluded due to protocol violation. 40 patients completed both sets of questionnaires. All subjects reported their overall health as "the same" when compared to their baseline visit. The mean BASDAI at baseline was 1.97 ± 1.90 and at 2 weeks was 1.69 ± 1.80 – the reliability was substantial; ICC = 0.74, Bland-Altman limits of agreement (LOA) = 2.4 to −2.8. The mean BASFI at baseline was 0.99 ± 1.49 and at 2 weeks was 0.75 ± 1.00 – likewise the reliability was excellent; ICC = 0.87, Bland-Altman LOA = 1.1 to −1.4. When examining individual questions from the BASDAI and BASFI, the following had the highest ICCs, respectively: "How long does your morning stiffness last from the time you wake up?" and "Doing a full day's activities, whether it be at home or at work", ICC = 0.88 each. Meanwhile, from the BASDAI, "How would you describe the overall level of AS neck, back or hip pain you have had?" resulted in the lowest reliability; ICC = 0.57.

Conclusions: At this time, there is no validated disease activity score for JSpA/ERA. Both the BASDAI and BASFI showed excellent intra-rater reliability in a cohort of ERA patients. Next steps will include the measurement of the construct validity and responsiveness of these tools in JSpA/ERA in order to determine if pediatric rheumatologists can use these as validated

disease activity/functional impairment measures in the clinic and in clinical research.

Juvenile Idiopathic Arthritis (JIA) Classification: An Audit of a Tertiary Paediatric Rheumatology Service's Adherence to ILAR (Edmonton 2001) Classification Criteria. Angela J. Cox[2], Sern Chin Lim[1], Roger C. Allen[3], Jonathan D. Akikusa[1] and Jane Munro[1]. [1]Royal Children's Hospital, Melbourne, Victoria, Australia, [2]Royal Children's Hospital, Melbourne, Australia, [3]Royal Childrens Hospital, Melbourne, Australia

Background: The International League of Associations for Rheumatology (ILAR) classification criteria for Juvenile Idiopathic Arthritis are widely used in prospective and retrospective studies of chronic arthritis in childhood. They define seven subtypes of chronic arthritis based on strict inclusion and exclusion criteria involving both clinical and laboratory parameters, some of which may not appear relevant in certain clinical situations and therefore may not be tested for in daily practice. The inaccuracy in patient classification that this may produce could have a significant impact on the results of research conducted using such cohorts.

Aim: To determine whether patients newly diagnosed with JIA within a year at the Royal Children's Hospital (RCH), Melbourne met strictly applied ILAR classification criteria for their assigned JIA subtype.

Methods: All newly diagnosed JIA patients seen in the Rheumatology Department at the RCH in 2009 were identified using the RCH rheumatology database. A retrospective review of the clinical and laboratory data collected for these patients was performed. The JIA subtype entered into the database for each patient was checked against ILAR classification inclusion and exclusion criteria. If they did not meet the designated subtype criteria or could not be classified because of incomplete data, the reason was recorded.

Results: 56 patients were included (35F, 21M). The diagnoses recorded in the database were Oligoarthritis 32(57%), Polyarthritis Rheumatoid Factor negative (RF-ve) 10(17.9%), Systemic arthritis 3(5.4%), Extended Oligoarthritis 2(3.6%), Polyarthritis Rheumatoid Factor positive (RF +ve), 2(3.6%), Psoriatic arthritis 2(3.6%), Enthesitis-related Arthritis (ERA) 1(1.8%) and Undifferentiated arthritis 4(7%). Only 13(23%) had complete clinical and laboratory information allowing classification by ILAR criteria. In 11 patients this matched the diagnosis assigned in the database. Two patients were reassigned to another subtype; one from Oligoarthritis to Undifferentiated arthritis due to the presence of psoriasis in a first degree relative, the other from Polyarthritis RF +ve to Polyarthritis RF-ve due to a negative follow-up RF. 43 patients had insufficient information to allow classification using ILAR criteria. The commonest reason was failure to test for RF, in 34(60%) patients. The majority of these patients, 20(58%), were Oligoarthritis. The second most common reason was an incompletely documented family history in 17(30%) patients, followed by 7(14%) patients who had not had a HLAB27 performed or documented.

Conclusion: The strict application of the ILAR classification criteria for JIA requires information that may not be routinely collected in daily clinical practice. At our centre collection of all data required to classify children with chronic arthritis according to strictly applied ILAR criteria was uncommon, seen in less than 25% of patients. We suggest that for centres wishing to participate in research involving patients with JIA that a minimum dataset be devised and applied to all newly diagnosed JIA patients to enable accurate ILAR classification.

Long-Term Outcome of Patients with Juvenile Idiopathic Arthritis Treated with Etanercept – Results of the Biologic Register JuMBO. Kirsten Minden[3], Martina Niewerth[4], Angela E. Zink[2], Eva Seipelt[6], Ivan Foeldvari[5], Hermann Girschick[7] and Gerd Horneff[1]. [1]Asklepios Kinderklinik St. Augustin GmbH, [2]German Arthritis Res Centre, Berlin, Germany, [3]German Rheumatism Research Center Berlin, a Leibnitz Institute, Berlin, Germany, [4]German Rheumatism Research Center Berlin, a Leibnitz Institute, [5]Hamburger Zentrum für Kinder- und Jugendrheumatologie am Klinikum Eilbek, Hamburg, Germany, [6]Immanuel Krankenhaus Berlin-Buch, Germany, [7]Scientific Advisory Board

Purpose: To assess the outcome of patients with juvenile idiopathic arthritis (JIA) who received Etanercept in childhood.

Methods: JIA patients ≥ 18 years who were formerly included in the nation-wide child Etanercept/Methotrexate register were contacted and asked to participate in the prospective cohort study JuMBO (Juvenile arthritis Methotrexate/Biologics long-term Observation). For those included in JuMBO, clinical status, therapy, and patient-derived data, e.g. functional capacity, quality of life and socioeconomic status, were documented every 6 months. Here, data of the last available visit of patients included and treated with Etanercept at any time were analyzed.

Results: Until April 2010, 486 out of 645 (75%) patients could be relocated and contacted, 398 of them agreed to participate in JuMBO. Baseline or follow-up data were available for 285 patients ever treated with Etanercept. These patients had a mean age of 20 years (SD 2.8) and a mean disease duration of 11 years (SD 5.3). At last documentation more than 80% of the patients still received DMARDs, 58% Etanercept. Twenty four percent of the patients had an inactive disease, 45% reported no functional limitations (HAQ-score = 0). The patients rated their quality of life lower than age-matched controls, but only regarding physical functioning, vitality, bodily pain, general health, and physical role.

Three deaths occurred in this cohort, all patients died of complications connected to their rheumatic disease. Considering the years of observation of all patients contacted (2,320 patient-years), the calculated standardized mortality ratio was 6.2 (95% CI 1.04–20.48) for women and 1.4 (95% CI 0.12–11.6) for men.

Co-morbidities or serious adverse events reported over the observation period of 1,097 patient years included the following: three new-onset inflammatory bowel diseases of which two occurred under Etanercept, seven newly diagnosed uveitis cases (four in patients receiving Etanercept), and 16 medically important infections (1.5/100 patient-years). Only six of the serious infections occurred under Etanercept, one was an infection of an endoprosthesis. No malignancy was recorded.

Conclusion: First data of the JuMBO register point to a better functional long-term outcome of patients with severe JIA treated in the biological era as compared to those treated before the year 2000. There seems to be an acceptable safety profile of Etanercept long-term use, however, more data are needed to confirm this.

Magnetic Resonance Imaging Findings of Temporomandibular Joint in Patients with Active and Inactive Juvenile Idiopathic Arthritis. Liete Zwir, Soraia Souza, Maria Teresa Terreri, Antônio Sérgio Guimarães, Artur Fernandes and Maria Odete Hilário. UNIFESP

Introduction: The temporomandibular joint (TMJ), like any other synovial joint, may be involved in Juvenile Idiopathic Arthritis (JIA). According to literature, the frequency of TMJ involvement varies from 17 to 87%, depending on the population under study, on the subtype of the disease and on the method of image used.

TMJ involvement is, generally, associated to early onset of the disease, polyarticular subtype JIA, and long-duration of the disease. Condylar damage may be present early in the disease course and progress, even in absence of clinical symptoms or signs.

Gadolinium-enhanced magnetic resonance imaging (MRI) is a well-established technique considered to be the gold standard to detect TMJ arthritis in JIA even in asymptomatic cases.

Materials and Methods: Ninety-three consecutive patients (61 girls and 28 boys) who presented to our outpatient pediatric rheumatology clinic and fulfilled the ILAR criteria of JIA were included in this study. The mean age was 12.7 years (range 5 – 20 years) and the median follow-up time at the examination was 6.2 years (0.6 to 18).

The patients were divided into 3 groups: patients with active disease (40 children), patients with inactive disease on medication (20 children) and patients with inactive disease off medication (29 children). For practical reasons the patients were classified in oligoarticular and polyarticular course type.

All patients underwent Gadolinium Enhanced MRI. The findings were blindly evaluated by two observers. Presence of TMJ synovial enhancement was considered to be pathological.

Results: Forty-eight patients were oligoarticular (16 active, 13 in remission on medication and 19 in remission off medication) and 45 were

polyarticular (26 active, 8 in remission on medication and 11 in remission off medication). The tables below show MRI findings according to JIA activity status and subtype of the disease.

TMJ Synovial Enhancement	Active (n = 40)	Remission on medication (n = 20)	Remission off medication (n = 29)	Total
Yes	32	14	19	65
No	8	6	10	24
Total	40	20	29	89

TMJ Synovial Enhancement	Oligo	Poly	Total
Yes	33	32	65
No	12	12	24
Total	45	44	89

Conclusion: A large number (65%) of patients considered as being in remission off medication presented inflammatory TMJ alterations in RMI. Although synovial enhancement is considered the gold standard in assessing TMJ involvement, we should be cautious in interpreting this finding.

Methotrexate and Leflunomide Combination Therapy Is a Safe and Effective Alternative to Methotrexate and Etanercept in JIA. Arturo Borzutzky[1], Tamy Lagunas[2], David Zurakowski[2] and Robert P. Sundel[3]. [1]Children's Hospital Boston, Boston, MA, [2]Children's Hospital Boston, [3]Childrens Hosp Medical Center, Boston, MA

Background: Methotrexate combined with TNF-inhibitors is generally regarded as the most effective treatment for recalcitrant juvenile idiopathic arthritis (JIA). Ongoing studies are evaluating the possibility that this should be first-line treatment in some situations. TNF inhibitors, however, are currently available only as parenteral formulations, and they are associated with significant immunosuppression, an increased risk of opportunistic infections, and possibly an increased risk of malignancies. These factors make the combination less than ideal for treating children with JIA. Combination therapy with methotrexate and leflunomide (MTX-LEF) has been shown to be effective in active rheumatoid arthritis as an alternative to the use of biologic agents. However, there is little information on the use of this combination in JIA.

Objectives: To compare the efficacy and safety of MTX-LEF to that of MTX and etanercept (MTX-ETN) in children with polyarticular JIA incompletely responsive to MTX or LEF monotherapy.

Methods: We retrospectively reviewed the clinical data of children with JIA treated at a single tertiary care children's hospital between 1999 and 2009. We compared outcomes and adverse events in patients treated with combination MTX-LEF to those treated with MTX-ETN after failure of methotrexate monotherapy. Inactive disease was defined as absence of active arthritis and normal inflammatory parameters. Remission was defined as 6 months of inactive disease.

Results: 56 patients met inclusion criteria: 25 patients treated with MTX-LEF and 31 patients treated with MTX-ETN were available for evaluation. Groups did not differ significantly for age, sex, race, time from diagnosis to combination therapy, follow-up length, JIA subtype, initial joint count or initial ESR (Table 1). Outcomes and significant adverse events did not differ significantly between the two groups after a mean follow-up of 20.5 ± 13 months. No serious adverse events were identified in any of the treatment groups. Inactive disease was achieved in 52% of the MTX-LEF group and 61.3% of the MTX-ETN group (P = 0.59). Remission was achieved in 28% of the MTX-LEF group and 35.5% of the MTX-ETN group (P = 0.58). Kaplan-Meier survival distributions for time to inactive disease and to remission were comparable between groups (P=0.94 and P=0.86, respectively).

Conclusions: In a retrospective pilot study of 56 children with JIA, MTX-LEF was a safe and effective alternative to MTX-ETN in patients with arthritis refractory to DMARD monotherapy. Lower costs, availability of oral dosing, and an absence of risk of opportunistic infections or malignancies favor the use of combination DMARDs over biologics. Randomized controlled trials are necessary to evaluate this prospectively.

Table 1. Clinical characteristics of patients.

Characteristic	MTX+LEF (n = 25)	MTX+ETN (n = 31)	*P*
Age, mean ± SD	12 ± 5.2	10.55 ± 5.1	0.3
Female sex, %	72	84	0.34
Race (% white)	84%	90.3%	0.56
Diagnosis to combination therapy (months)	56.7 ± 50	47.9 ± 44	0.49
Duration of follow-up (months)	18.5 ± 11.7	22.1 ± 13.9	0.3
ILAR JIA diagnosis			0.81
Polyarthritis (RF+)	16%	16%	
Polyarthritis (RF−)	56%	42%	
Oligoarthritis	4%	10%	
Psoriatic arthritis	16%	19%	
Enthesitis related arthritis	8%	13%	
Initial joint count, mean ± SD	8.5 ± 8.6	6.7 ± 6.9	0.37
Initial ESR, mean ± SD	12.9 ± 9.6	13.9 ± 14.5	0.77

Methotrexate Gives Protection Against the New Onset of Uveitis in Combination with Etanercept. Data from the German Etanercept Registry. Ivan Foeldvari[1], Nina Thome[2] and Gerd Horneff[2]. [1]Hamburger Zentrum Fuer Kinder- und Jugendrheumatologie, Hamburg, Germany, [2]Kinder- und Jugendrheumatologie Asklepios Clinics, Sankt Augustin, Sant Augustin, Germany

Introduction: Uveitis occurs in 10 % of patients with juvenile idiopathic Arthritis (JIA). Methotrexate (MTX) and corticosteroids (ST) appear to be an effective treatment for uveitis, We evaluated the occurrence of uveitis under different treatment combinations in the German Etanercept Registry.

Methods: We evaluated the prevalence of uveitis flares or new onset of uveitis in patients in the different treatment arms of the German Etanercept Registry.

Results: We reviewed the data of 868 patients. We grouped the patients in 8 therapy arms, these were Etanercept(ETA) monotherapy (n=74); ETA + glucocorticoids (ST) (n=34); ETA + Methotrexate (MTX)(n=246); ETA+ MTX+ST(n=290); ETA + other DMADs (n=45); ETA + other DMARDs + ST(n=45); ETA+MTX+ other DMARDs(n=32); ETA+MTX+ other DMARDs +ST(n=102).

Treatment group	Number of patients	AE-Uveitis	Uveitis/ Patient	Patient - Treatment years	Uveitis/100 year of treatment Mean value
Etanercept (Eta)	74	4	0.05	113.75	3.5
Eta + Steroids	34	1	0.03	54.10	1.8
Eta + MTX	246	4	0.02	431.49	0.9
Eta + MTX + Steroids	290	7	0.02	703.65	0.9
Eta + other DMARD	45	2	0.04	79.83	2.5
Eta + other DMARD + Steroids	45	3	0.06	92.66	3.2
Eta + MTX + other DMARD	32	2	0.06	82.80	2.4
Eta + MTX + other DMARD + Steroids	102	6	0.06	267.42	2.2
All patients treated with Steroids	471	17	0.04	1118.00	1.5
All patients treated with MTX	670	19	0.03	1485.00	1.3
All patients treated with other DMARDs	224	13	0.06	523.00	2.5
All Patients	868	29	0.03	1826.00	1.6

We evaluated the rate of uveitis per patient in the different groups. The lowest rate was found in the combination with MTX with ETA with 0.02. We evaluated the mean number of uveitis per 100 patient years and MTX +ETA group showed 0.9 compared to 3.5 for ETA monotherapy. ST in combination with ETA showed a protective effect too. Interestingly the other DMARDs did not had this protective effective of uveitis, the other DMARDs were mostly leflunomide or sulfasalazine.

Discussion: MTX and ST seems to be protective in this group of patients against the new onset of uveitis. Based on this data patients with a history of uveitis should receive a combination therapy of ETA and MTX to prevent flares of uveitis.

Obesity and Disease Activity in Juvenile Idiopathic Arthritis. Christina F. Pelajo[1], Jorge M. Lopez-Benitez[2] and Laurie C. Miller[2]. [1]Floating Hospital for Children at Tufts Medical Center, Boston, MA, [2]Floating Hospital for Children at Tufts Medical Center

Background: Children with physical disabilities may have an increased risk of obesity. In adults, the odds of having arthritis, other than osteoarthritis, are 4.33 higher for the obese population, in comparison to the ideal weight population. Rates of obesity in patients with juvenile idiopathic arthritis (JIA) ranging from 5 to 16.7% have been reported. The aim of this study was to explore the relationship between obesity and disease activity in patients with JIA.

Methods: Body mass index (BMI) and disease activity were determined in 102 consecutive patients with JIA attending a pediatric rheumatology clinic from October 09 to May 10 who were having blood drawn for routine clinical monitoring. Patients who took corticosteroids in the previous 3 months were excluded. Disease activity was determined by physician assessment using a visual analog scale (VAS), along with number of active joints and erythrocyte sedimentation rate (ESR); child well-being was determined by parent completion of a VAS. Children were classified as obese (BMI $\geq$ 95th percentile) or normal BMI (BMI between 5th and 94th percentiles). The results were analyzed using T-tests, ANOVA, Fisher's exact test, and linear regression in the entire patient sample. In addition, the relationship between BMI and active inflammatory joint disease was analyzed on a subset of children with JIA matched by age and gender.

Results: Of the 102 children, the male:female rate was 42:60, and ages ranged from 3–19 years (mean 11.4 years). Twenty-one children were obese (21%) and 81 had normal BMI. 100% of obese and 84% of non-obese children were Caucasian. JIA subtypes were distributed as follows: 40% oligoarticular, 21% RF-negative polyarticular, 21% enthesitis-related arthritis, 11% psoriatic arthritis, 4% systemic, and 3% RF-positive polyarticular. Mean time since disease onset was 48.3 months ($\pm$47.6 SD). BMI ranged from 13.9 to 36.7 (median 19.5); BMI percentiles ranged from 6 to 99 (mean 63.3). Mean BMI percentiles did not differ among JIA subtypes, gender, or age. The mean parent VAS scoring the child's overall well-being was worse for obese than non-obese children [2.9 ($\pm$2.4 SD, range 0–7.5) vs 1.8 ($\pm$1.75, range 0–7.3), ($p=0.015$)]. However, physician assessment of disease activity, joint count, and ESR elevation did not differ between the two groups. In the comparison of 21 age- and gender-matched pairs, there was no difference between obese and normal BMI children, regarding parent or physician VAS, ESR, or number of active joints.

Conclusions: Parent scores for well-being were worse for obese than non-obese children. This might reflect arthralgias due to mechanical overload, qualitative differences in parent perception, or other causes of reduced well-being associated with obesity. There were no differences for other indices of disease activity between subjects with JIA who were obese and those with normal BMI. As obesity confers an additional health risk in children with arthritis, addressing this co-morbidity should be a health priority in patients with JIA.

Disclosure: C. F. Pelajo: None; **J. M. Lopez-Benitez:** None; **L. C. Miller:** None.

Preliminary Definition of Remission and Minimal Disease Activity Cut-Points for the Juvenile Arthritis Disease Activity Score (JADAS). Alessandro Consolaro[3], Giovanni Filocamo[4], Bianca Lattanzi[3], Giulia C. Varnier[3], Angela Pistorio[3], Nicolino Ruperto[3], Alberto Martini[2] and Angelo Ravelli[1]. [1]IRCCS G. Gaslini and Università di Genova, Genova, Italy, [2]IRCCS G. Gaslini and Università di Genova, Genova, Italy, [3]IRCCS G. Gaslini, Genova, Italy, [4]Policlinico Sant'Orsola, Bologna, Italy

Background: Recent advances in treatment of juvenile idiopathic arthritis (JIA), namely the introduction of biologic agents, have markedly increased the potential for achieving a remission or minimal disease activity (MDA) state. These states have been defined so far using a categorical model, which requires simultaneous fulfilment of multiple criteria. This approach has been followed in the development of the current criteria for remission (Wallace criteria) (Wallace CA, et al. Arthritis Rheum. 2005;52:3554-62) and MDA (Magni-Manzoni S, et al. Arthritis Rheum 2008;59:1120-7). However, definition of remission and MDA through the dimensional model, based on pooling individual measures of disease activity into a composite disease activity score, has never been attempted.

Objective: The identification of the remission and MDA cut-points of the recently developed composite disease activity score for JIA, the JADAS (Consolaro A, et al. Arthritis Rheum. 2009;61:658-66).

Methods: For the purposes of this study, the JADAS-10 version was used. The JADAS-10 is computed as the simple sum of 4 variables, each with a 0–10 range: the physician's global assessment, the parent's global assessment, the normalized ESR and the 10-joint reduced count. At each visit, all main physician- and parent-centered outcome measures were recorded. JADAS-10 was calculated for 432 patients in 914 visits. At each visit, both physicians and parents were asked to rate independently the disease status as remission or active disease. Furthermore, we assessed the presence of remission by Wallace criteria and, after grouping patients in oligoarthritis or polyarthritis, of MDA by the preliminary definition. In the first step, we calculated the JADAS-10 values corresponding to the 75th percentile of score distribution among patients' who were classified as having disease remission by physician's and parent's subjective rating and Wallace criteria, or having MDA. In the second step, we calculated, by means of the receiver operating characteristic (ROC) curve analysis, the JADAS-10 values that showed the best trade-off between sensitivity and specificity (i.e. accuracy) in discriminating between patients who had remission or active disease according to the physician, the parent, or the Wallace criteria, or who had MDA according to the preliminary definition.

Results: The results in the 2-step analysis are shown in table.

	Remission			MDA	
	Physician	Parent	Wallace crit.	Oligoarthr.	Polyarthr.
75th pct.	2.1	2.5	1.0	2.0	1.7
Best accuracy	2.9	2.8	1.0	2.6	4.2

The numbers obtained for each definition using the 75th percentile or ROC curve method were then averaged. The values obtained for remission were further averaged achieving the value of 2.0, The values obtained for MDA are 2.3 for oligoarthritis and 2.9 for polyarthrtritis

Conclusion: The value of 2.0 is the remission cut-point for the JADAS-10 proposed for use in future clinical trials on JIA. The proposed cut-points for MDA in oligoarthrtitis and polyarthritis are 2.3 ad 2.9, respectvely.

Prevalence of Enthesitis in Pediatric Patients with Enthesitis-Related Arthritis. Pamela Weiss[2], Andrew J. Klink[4], Edward M. Behrens[1], David D. Sherry[5], Terri H. Finkel[3], Mark Ramos[4], Robert Grundmeier[4], Ron Keren[4] and Chris Feudtner[4]. [1]Childrens Hospital of Phil, Philadelphia, PA, [2]The Children's Hosp of Philadelphia, Philadelphia, PA, [3]The Children's Hospital of Philadelphia, Philadelphia, PA, [4]The Children's Hospital of Philadelphia, [5]The Children's Hospital of Philadelphia, Philadelphia, PA

Background: Juvenile idiopathic arthritis (JIA) is the most common rheumatologic chronic condition in childhood, affecting 1 to 4 per 1,000 children. Enthesitis-related arthritis (ERA) is a JIA category that accounts for 10–20% of JIA. Enthesitis is a distinct pathologic feature of ERA. Descriptions of enthesitis in ERA are sparse and little has been published about which entheses are most commonly affected.

Methods: We conducted a retrospective cohort study of children with ERA who were diagnosed and treated at Children's Hospital of Philadelphia between November 2007 and April 2010. The cohort consisted of children with an ICD-9-CM code of 720, indication "ERA" or "ankylosing spondylitis," given at diagnosis or a subsequent follow-up visit.

Results: During the thirty-month study period there were fifty-nine ERA patients and 256 clinic visits. Subjects ranged from 5.5 to 18.5 years and had a mean age of 14 years at date of initial evaluation. Fifty-three percent were male. Eighty-five percent were white, 5% African American, 3% Asian, and 7% other. The mean number of tender entheses at diagnosis was 5 (95% CI: 0,15). There was at least 1 tender enthesis at 47% of visits. The most commonly affected entheses were the patellar ligament insertion on the inferior pole of the patella (6 o'clock position of patella) and the plantar fascial insertions on the calcaneus and metatarsal heads (Table). Enthesitis was most often asymmetric. The mean number of swollen joints at diagnosis was 1 (95% CI: 0, 7). The most commonly affected joints were the knees ($N=16$ patients, 6 unilateral, 5 bilateral), ankles ($N=11$ patients, 5 unilateral, 3 bilateral), and fingers. Of the finger joints the proximal interphalangeal joints were most commonly affected. The arthritis was most often asymmetric.

Table 1. Sites of enthesitis by visit (N = 256)

Tender enthesis	Any N (%)	Unilateral N (%)	Bilateral N (%)
6 o'clock position of patella	88 (34.4)	34 (13.3)	54 (21.1)
Plantar fascial insertion at calcaneus	47 (18.4)	15 (5.9)	32 (12.5)
Plantar fascial insertion at metatarsal heads	43 (16.8)	10 (3.9)	33 (12.9)
Achilles tendon	38 (14.9)	14 (5.5)	24 (9.4)
2 o'clock position of patella	34 (13.3)	21 (8.2)	13 (5.1)
Greater trochanter	33 (12.9)	13 (5.1)	20 (7.8)
10 o'clock position of patella	31 (12.1)	19 (7.4)	12 (4.7)
Tibial tuberosity	16 (6.2)	7 (2.7)	9 (3.5)
Sacroiliac joint	13 (5.1)	4 (1.6)	9 (3.5)
Base of 5th metatarsal	11 (4.3)	5 (2.0)	6 (2.3)

Conclusions: Enthesitis comprises a significant portion of disease activity in ERA. Future studies should address the pattern of enthesitis over time, enthesitis response to therapy, and the impact of enthesitis on quality of life.

Prospective Study of Infliximab for Treatment of Pediatric Uveitis. Egla C. Rabinovich[4], Janet Wootton[4], Lawrence S. Zemel[3], Lisa F. Imundo[2], Jennifer E. Weiss[5], Leslie S. Abramson[7], Mark F. Hoeltzel[1], Deborah M. Levy[6] and David Wallace[4]. [1]Children's Mercy Hospital, Kansas City, MO, [2]Childrens Hospital of NY, New York, NY, [3]Connecticut Childrens Med Ctr, Hartford, CT, [4]Duke University Medical Center, Durham, NC, [5]Hackensack Univ Med Ctr, Hackensack, NJ, [6]The Hospital for Sick Children, Toronto, ON, Canada, [7]University of Vermont, Morrisville, VT

Background: Uveitis is a persistent disease for which there is little prospective data on treatment. Previous retrospective studies suggest TNF blockade may be efficacious for treatment of uveitis, but do not address time to response or optimal dose.

Methods: Ongoing 9 month multi-center prospective study of infliximab for treatment of persistent pediatric inflammatory uveitis (onset ≤ 16 yrs), randomizing subjects to one of 2 initial doses: 5 mg/kg or 10mg/kg monthly. Scheduled ophthalmologic exams utilized the Standardization of Nomenclature (SUN) criteria. Entry criteria: ≥ 1+ anterior chamber inflammation, failure of at least one DMARD, on stable dose of methotrexate. Primary outcome variable was percent who had improvement per SUN criteria.

Results: 14 subjects (9 female, mean age 11.8 yrs, range 6–19) with persistent inflammatory uveitis (1 sarcoid, 13 idiopathic) from 6 Childhood Arthritis and Rheumatology Research Alliance (CARRA) A sites were randomized to receive 5 mg/kg (N=8) or 10 mg/kg (N=6) initial infliximab dose. At the baseline visit, 5 had unilateral and 7 bilateral inflammation.

Inflammation*	Baseline (n) N = 14	After 1st dose N = 12	After 4th dose N = 12	After 8th dose N = 7
3+ (26–50)	0	0	0	0
2+ (16–25)	4	1	0	0
1+ (6–15)	10	3	0	1
0.5+ (1–5)	0	4	5	3
0 (0)	0	4	7	3

* Inflammation is reported utilizing SUN criteria and on the most active eye. Anterior chamber inflammation is graded as cells per high power field (hpf).

Conclusion: Infliximab works rapidly to decrease inflammation with 57% having 0 to.5+ inflammation after one infusion. Low grade inflammation may persist despite treatment. Improvement persisted 8 months after initiation of infliximab.

Safety and Efficacy of H1N1 Influenza Vaccination in Children with Chronic Inflammatory Rheumatic Diseases. Catherine F. Cortot[1] and Robert P. Sundel[2]. [1]Children's Hospital Boston, Brookline, MA, [2]Childrens Hosp Medical Center, Boston, MA

Background: Children with chronic inflammatory disease are more susceptible to infections and therefore have been considered a priority target group for immunization with the H1N1 influenza vaccine. However, the safety and efficacy of this vaccination in such patients remain unknown.

Objective: We conducted a prospective study to assess the toxicity profile and effectiveness during actual use of the H1N1 vaccination in children with chronic inflammatory rheumatic diseases.

Methods: Patients with a chronic inflammatory disorder from the rheumatology clinic of a large, tertiary care children's hospital, and who had received at least one dose of the influenza A (H1N1) 2009 monovalent, unadjuvanted, inactivated vaccine, were included. Fifty six (54%) of the subjects received the vaccine in the clinic and were assessed prospectively; the remainder received their vaccinations elsewhere are were administered questionnaires during their clinic visit. Information gathered included vaccination side effects and the incidence of flu in study subjects.

Results: One hundred and five patients (median age 12.8 years, range 1.7–26.6) were included. In order of frequency, rheumatologic diagnoses included juvenile idiopathic arthritis (45.7%), psoriatic arthritis (15.2%), enthesitis-related arthritis (8.6%) SLE (8.6%) and other (21.9%). The vast majority of patients (91.4%) were treated with immunosuppressive therapy (IMT) including at least one of methotrexate (71.9%), leflunomide (18.8%), TNF inhibitor (16.7%), corticosteroids (20%) or other (12.3%). During up to 6 months of followup during the peak of the influenza pandemic, one patient (1%) developed presumed H1N1 flu not confirmed by biological tests. Two cases (1.9%) of mild local symptoms at the injection site were observed. Four cases (3.8%) of systemic side effects of the H1N1 vaccine were reported, including 2 cases (1.9%) of flu-like symptoms, one case (1%) of myalgia and fatigue, and one flare of a patient's spondyloarthritis (1%) requiring the use of steroids for 15 days.

Conclusions: Influenza A (H1N1) 2009 monovalent, unadjuvanted, inactivated vaccine was well tolerated and apparently effective in children with chronic inflammatory rheumatic diseases. One patient developed a flare of his arthritis following the immunization, and one developed a flu-like illness despite the vaccination. No one had persistent sequelae or complications requiring hospitalization. These findings support the recommendation that children with rheumatologic conditions should receive the H1N1 monovalent inactivated vaccine.

Disclosure: C. F. Cortot: None; **R. P. Sundel:** None.

236

Status of Vaccination Coverage in Children with Juvenile Idiopathic Arthritis (JIA) Followed at a Pediatric Tertiary-Care Center. Marie-Paule Morin[1], Élise Fortin[3], Caroline Quach[3] and Gaëlle Chédeville[2]. [1]The Montreal Children's Hospital, Montreal, QC, Canada, [2]The Montreal Children's Hospital, Montréal, QC, Canada, [3]The Montreal Children's Hospital

Background: Immunization is recognized as being one of the most efficient ways to prevent mortality, morbidity and complications related to infectious diseases in children. Recent studies reported on the safety and efficacy of single vaccines in patients with juvenile idiopathic arthritis (JIA). However, no data on vaccination coverage rate is available in JIA patients. Factors such as the presence of chronic disease, fear of inducing flare of disease and treatment with immunosuppressive medication may impact on the vaccination schedule of this population.

Objectives: To evaluate the vaccination coverage rate of patients with JIA followed at a pediatric tertiary-care center and to determine the coverage rate for individual vaccine required as per the Quebec Public Health guidelines.

Methods: The Division of Rheumatology at the Montreal Children's Hospital (MCH) follows actively a cohort of 356 patients with JIA. During the period from August 1st 2008 to March 31st 2009, all consecutive JIA patients coming for their scheduled visit were included if they were between 2 and 18 years old and if they had an available written immunization record. Demographic data, ILAR disease subtype, active joint count and medications used since diagnosis were retrospectively collected for each patient. Descriptive statistics were used to evaluate the proportion of children with complete vaccination status according to the Quebec Public Health guidelines at 2.5, 10 years and at the last visit to the clinic.

Results: A total of 200 patients were included, 69% were girls. Mean age of the cohort was 11.4 years, with a median age at diagnosis of 4.8 years (0.5–16.6 years). The diagnosis at onset was oligoarthritis in 51.5% of the children, rheumatoid factor (RF) negative polyarthritis in 20.5%, RF positive polyarthritis in 1.5%, systemic in 6%, psoriatic in 6%, ERA in 7.5%, and undifferentiated in 7%. Over time, NSAIDs were used in 99 % of patients, methotrexate in 51%, steroids in 10.5%, and biologics agents in 7.5%.

Vaccination coverage rates at 2.5, 10 years and at the last clinic visit for each vaccine are shown in the table, as well as the proportion of patients with complete vaccination status.

	At 2,5 years		At 10,5 years		Last visit to clinic	
	N	n (%)	N	n (%)	N	n (%)
Rubella and mumps	198	186 (94)	118	110 (93)	200	194 (97)
Measles	198	114 (58)	118	91 (77)	200	165 (83)
Polio	198	193 (97)	118	116 (98)	200	198 (99)
Diphteria/tetanus	198	197 (99)	118	94 (80)	200	160 (80)
Pertussis	198	197 (99)	118	94 (80)	200	155 (78)
Meningococcus C	47	40 (85)	–	–	49	45 (92)
Hepatitis B	–	–	–	–	98	80 (82)
Hib	198	172 (87)	–	–	–	–
Pneumococcus	31	27 (87)	–	–	–	–
Varicella	12	11 (92)	–	–	14	12 (86)
Complete vaccination status	198	103 (52)	118	80 (68)	200	121 (61)

Conclusion: Despite overall good vaccination coverage rate of single vaccines, only 61% of our cohort has a complete vaccination status at the last clinic visit. Further analysis is required to determine factors that may influence vaccination such as age at diagnosis, activity of the disease and medication use. Further studies need to be done to explore the reasons underlying incomplete vaccination status in the JIA population, both from a parental and a physician perspective. Measures to optimize vaccination coverage, such as catch-up vaccination, should be implanted when possible.

The Clinical Feature of 2009–2010 Influenza Virus Infection during Tocilizumab Treatment for Systemic Onset Juvenile Idiopathic Arthritis. Toru Uchimura[1], Tomoyuki Imagawa[1], Takuma Hara[1], Masako Kikuchi[1], Ryoki Hara[2], Takako Miyamae[1], Masaaki Mori[1], Akiyoshi Nariai[3], Toshihiro Mitsuda[1] and Shumpei Yokota[1]. [1]Department of Pediatrics Yokohama City University, Yokohama, Japan, [2]Department of Pediatrics Yokohama City University, [3]Department of Pediatrics Yokohama Minami Kyosai Hospital, Yokohama, Japan

Background: We had reported that tocilizumab (a humanized anti-IL-6 receptor antibody, TCZ) had been proved to be highly effective in the clinical management of refractory systemic onset juvenile idiopathic arthritis (sJIA).TCZ inhibits interleukin-6 (IL-6) signal which relates to inflammation in sJIA by binding IL-6 receptor. It also affects the inflammatory reaction in infectious disease, such as pneumonia and gastroenteritis. Influenza virus infection has been known to make the disease activity of sJIA worse.

Objective: We evaluated the impact of influenza virus infection during tocilizumab treatment for sJIA.

Method: A total of 76 patients satisfying the WHO/ILAR criteria for sJIA were treated with TCZ, and received intravenous TCZ 8 mg/kg every 2 weeks. The patients who had the positive result of rapid chromatographic immunoassay for the detection of influenza A and B viral antigens from nasopharyngeal swabs were subject of this study from 2009 September to 2010 December. We examined the clinical manifestations and complications of the influenza virus infection, and the deterioration of sJIA.

Results: Seven patients (4 boys and 3 girls) affected with influenza virus infection. The median age was 13.7 years and the median duration of TCZ treatment was 42 months. The disease activities including fever, arthritis, rheumatoid rash, and inflammatory examinations in all patients were well controlled by TCZ. All of seven patients showed the result of influenza virus A by rapid antigen test. Clinical symptoms at the time of the influenza infection were fever (> 38.0 degrees Celsius) in 6 patients (86%), cough in 7 patients (100%), nasal discharge in 5 patients (71%), vomiting in 1 patients (14%), diarrhea in 1 patients (14%) and fatigue in 3 patients (43%). The mean febrile period was 1.8 days (0 to 5 days). No complications including pneumonia, otitis media and influenza encephalopathy were observed. Six of 7 patients were treated with anti-influenzavirus medications; oseltamivir in 5 patinets, zanamivir in 3 patients. One patient switched from zanamivir to oseltamivir because of prolonged fever. One patient relapsed to sJIA after influenza. One patient presented with fever, arthritis and rheumatoid rash. Serum C-reactive protein and amyloid A were increased in 2 patients. None of patients developed macrophage activation syndrome (MAS).

Conclusion: Neither influenza symptoms nor disease progression to MAS were observed in the patients affected with influenza virus infection during TCZ treatment. However, disease activities of sJIA might be aggravated by influenza in these patients. In addition, TCZ might mask inflammatory symptoms of influenza infection.

The Financial Burden of Juvenile Idiopathic Arthritis. Andrea Ens[2], Bianca A. Lang[1], Suzanne E. Ramsey[1], Elizabeth Stringer[2] and Adam M. Huber[1]. [1]IWK Health Ctr, Halifax, NS, Canada, [2]IWK Health Ctr

Objectives: Very little is known about the financial burden of Juvenile Idiopathic Arthritis (JIA), particularly the burden borne by families in Canada. There are considerable medical and non-medical costs related to having JIA that families are expected to pay, in order for their children to receive the standard of care. The primary objective of this study was to determine the annual medical and related non-medical out-of-pocket costs associated with having a child who has JIA borne by families in Nova Scotia (NS).

Methods: All families in NS with a child followed by the Pediatric Rheumatology Clinic at the IWK Health Centre in 2008, with JIA as per the International League of Associations for Rheumatology criteria, were mailed a self-report, parental questionnaire. Families were excluded if there was more than 1 child with JIA, or if there were other chronic illnesses. The questionnaires evaluated medical and non-medical related out-of-pocket costs, as well as gross household income. Dilman's method was used to optimize return rates. One hundred and seventy-three questionnaires were mailed out. Of these, 5 were returned unopened due to incorrect addresses, giving a potential total of 168. Fifty-five (32.7%) were returned completed, and another 11 (6.5%) were returned blank or called to decline participation, for a total return rate of 39.3%.

Results: The majority of questionnaires were completed by the child's mother (81.8%). The mean age of the children was 13.1y (range 5, 20) and 60% were female. The mean household income was $78,850 (median $70,000, range $2,500, $175,000). On average, families lived 116km (median 34.5km, range 4.5km, 530km) from the pediatric rheumatology clinic. The financial burden was rated as large by 1.9%, moderate by 35.2%, minimal by 44.4% and nothing by 18.5%. Resources available to help with the costs were rated as either fair or poor by 54.9% of parents. The mean total annual cost per patient was $1,281.71 (median $641.50, range 0, $12,556) which was on average 2.9% (median 0.9%, range 0, 46%) of their household income. The mean annual medication cost was $357.86 (median 0, range 0, $10,000). The annual mean visit costs for appointments with physicians or related allied health care workers was $276.89 (median $45, range 0, $2,286), and the annual mean non-medication cost was $80.64 (median $0, range 0, $1,850). Non-medication costs included the cost of physiotherapy, assistive aids, and home adaptations. The mean loss of paid work per year was $348.36 (median $0, range 0, $2,600). The Pearson correlation for total costs per year and distance was 0.46 ($P=0.0005$) and for annual visit costs for appointments and distance was 0.68 ($P=0.0000$), demonstrating a moderate direct relationship between distance and costs.

Conclusions: The financial burden associated with having a child with JIA in NS is considerable, particularly for some families. The impact of this burden on outcomes is unknown and warrants further evaluation.

Usage of TNFα Inhibitors for the Treatment of Juvenile Idiopathic Arthritis: Data from a National U.S. Administrative Claims Database. Timothy Beukelman[3], Fenglong Xie[1] and Jeffrey R. Curtis[2]. [1]Univ of Alabama at Birmingham, [2]University of Alabama–Birmingham, Birmingham, AL, [3]University of Alabama-Birmingham, Birmingham, AL

Background: Tumor necrosis factor alpha inhibitors (anti-TNF) have been used for over 10 years in the treatment of juvenile idiopathic arthritis (JIA), but little has been reported regarding their usage in clinical practice. We

analyzed national administrative claims data from a large commercial U.S. health insurer to characterize the usage of anti-TNF in the treatment of JIA.

Methods: Using national administrative claims data for the years 2005 – 2008 inclusive, we identified children less than 16 years old with ≥1 physician diagnosis code consistent with JIA (ICD-9 codes 714, 720, 696.0, or 713.1 with 555 or 556). We identified adults with ≥1 physician diagnosis code for rheumatoid arthritis (RA; ICD-9 code 714.0) for comparison. Pharmacy benefits were determined for each subject. Treatment with anti-TNF, methotrexate (MTX), and leflunomide (LEF) was determined through dispensed pharmacy and infusion claims. New anti-TNF users were defined by no treatment with any anti-TNF in the prior 6 months. Uveitis was defined by ≥1 physician diagnosis code (ICD-9 code 364). We examined anti-TNF usage over time and compared to MTX and LEF. We also performed cross-sectional analyses restricted to claims from 2008. Chi-square test was used for comparisons of proportions.

Results: During the study period, 2442 children with at least 1 JIA diagnosis code and full pharmacy benefits were identified; 55,010 adults with RA were identified. The mean age at first JIA diagnosis code was 10.1 ± 4.3 years. JIA patients were from 48 of the United States; 33% from northeast, 14% from mid-west, 34% from south, and 20% from west census regions. The proportion of JIA patients with full pharmacy benefits who were receiving anti-TNF increased from 7% in 2005 to 19% in 2008, compared to an increase from 15% to 24% for RA.

In cross-sectional analysis restricted to 2008, among all MTX, LEF, or anti-TNF users with JIA, 57% received any anti-TNF compared to 42% for RA. Also in 2008 among JIA patients, there were 1.3 users of any anti-TNF for each 1 user of MTX or LEF without anti-TNF; for RA this ratio was 0.71. From 2005–2008, 45% of all JIA anti-TNF users received concurrent MTX or LEF at any point, compared to 32% for RA. JIA new anti-TNF users with a prior diagnosis of uveitis were much more likely to initiate a monoclonal antibody (infliximab or adalimumab) (74%) compared to those without a prior diagnosis of uveitis (33%; $p < 0.0001$). JIA new anti-TNF users without full pharmacy benefits were much more likely to initiate infliximab (95%) compared those with full pharmacy benefits (13%; $p < 0.0001$).

Conclusions: The prevalence of anti-TNF treatment for JIA more than doubled from 2005 to 2008 and approached the prevalence seen in adult RA. In 2008, there were more JIA current users of anti-TNF than of MTX or LEF without anti-TNF. Less than one-half of JIA anti-TNF users received concurrent MTX or LEF. A prior diagnosis of uveitis and patient's access to prescription drug coverage were strongly associated with the use of specific anti-TNF agents.

Use of Abatacept for Childhood Refractory Vision-Threatening Uveitis. Gabriele Simonini[2], De Libero Cinzia[1], Roberto Caputo[1], Teresa Giani[2], Laura Pascoli[2], Ilaria Pagnini[2] and Rolando Cimaz[2]. [1]Opthalmology Unit, A Meyer Children's Hospital, Florence, Italy, [2]Rheumatology Unit Dpt of Pediatrics, A.Meyer Children's Hospital-University of Florence, Italy

Background: Improvement of refractory JIA-related uveitis has been reported with Abatacept.

Objective: Aim of our study was to evaluate the efficacy and safety of Abatacept in an open-label prospective, monocenter, study of childhood non-infectious chronic uveitis.

Methods: Four patients with refractory, vision-threatening non-infectious uveitis were enrolled to receive Abatacept 10 mg/kg at weeks 0, 2, 4, and thereafter monthly, for at least 6 months. Absence/recurrence rate of uveitis throughout the study period, according to the SUN Working Group criteria, visual acuity pre- and post-Abatacept treatment, and tapering of steroid medication were recorded. *Improved* visual acuity was defined as a doubling of the visual angle (converted in a LogMAR format) in at least one eye. All children had active uveitis: 6 out of 8 eyes were involved, despite treatment with methotrexate (MTX) (15 mg/m^2/weekly) in association with Infliximab (6 mg/kg every 6–8 weeks) followed by Adalimumab (24 mg/m^2, every other week), then by mycophenolate mofetil in 3 cases; and by Adalimumab in 1 case. Due to active uveitis, along with topical steroids, all children were also receiving oral prednisone (1–2 mg/kg/day), at stable doses for at least 6 weeks (range 45–55 days).

Results: Demographics, clinical characteristics and outcomes on treatment are reported in the Table.

	1	2	3	4
Age, years, months	17 y, 6 m	18 y, 4 m	14 y, 1 m	9 y, 4 m

Age at onset of uveitis, (years, months)	10 y, 10 m	3 y, 5 m	4 y, 10 m	2 y, 11 m
Uveitis duration	7 y, 4 m	14 y, 11 m	10 y, 9 m	7 y, 7 m
Diagnosis:				
Age at onset of disease, (years, months)	Idiopathic uveitis 10 y, 10 m	JIA 1 y, 5 m	Blau syndrome 4 y	JIA 2 y, 7 m
Previous DMARD/anti-TNF-α treatment, duration (months)	Infliximab 28	Infliximab 37	Infliximab 32	–
	Adalimumab 8	Adalimumab 7	Adalimumab 21	Adalimumab 17
	MMF 16	MMF 18	MMF 11	–
N* of previous flares, 6 months before	3	6	5	4
Time to remission (weeks)	8	12	14	12
Time to steroid discontinuation (months)	4	6	–	5
Visual acuity 6 months before → 6 months after	R 20/60 → 20/30	R 20/50 → 20/40	R 20/20 → 20/20	R 20/25 → 20/20
	L 20/20 → 20/20	L 20/60 → 20/40	L 20/30 → 20/20	L 20/20 → 20/20
Concomitant therapy (duration, months)	MTX: 15 mg/m^2	MTX: 15 mg/m^2	MMF: 1 gm/m^2	MTX: 15 mg/m^2
	6	6	4	6
Follow-up duration on treatment	12	14	8	6

JIA = Juvenile Idiopathic Arthritis, MTX = methotrexate, MMF = mycophenolate mofetil
R = right eye, L = left eye

Median time of abatacept treatment was 10 months (range 6–14). During treatment, all children achieved a complete remission over a median period of 12 weeks (range 8–14). Steroid administration was discontinued during the first 6 months (range 4–6) in 3/4 children. The patient with Blau syndrome was able to taper the dose down to 0.3 mg/kg/day. In all children, no relapse of uveitis occurred during treatment, whilst during the 6 month-period before starting Abatacept, the median number of relapses was 4 (range 3–6). At 6 months of treatment, all patients, (5/8 eyes), met the criteria for improved visual acuity. Two children reached a completely normal visual acuity, while the other two improved, eventhough the pre-existing complications, due to chronic uveitis, affected a complete recovery. No major side effects, infusion reactions and/or drug-related adverse events were recorded during the treatment period.

Conclusion: Even if limited to a small group, our results suggest that Abatacept may be effective and safe in chronic refractory childhood uveitis, both in JIA-uveitis and in not JIA-uveitis.

Use of TNFα Antagonists in the Treatment of Chronic Non-Bacterial Osteomyelitis (CNO). Sara Stern[2], Katherine Marzan[2], Arturo Borzutzky[1], Evan Steinberg[3] and Andreas Reiff[2]. [1]Boston Children's Hospital, Boston, MA, [2]Childrens Hospital Los Angeles, Los Angeles, CA, [3]Kaiser-Permanente Sunset Hospital, Los Angeles, CA

Purpose: CNO is a chronic autoimmune inflammatory osteopathy syndrome that is culture negative and has no demonstrable organism on histopathology. Anti-inflammatory medications are typically used to prevent pathologic fractures, pain, and disease relapse. The objective of this study was to describe the use of TNFα antagonists in the treatment of CNO in 8 patients with treatment refractory disease.

Methods: We retrospectively analyzed 23 patients with CNO seen from 1985–2009 at Childrens Hospital Los Angeles (18) and Kaiser-Permanente Sunset Hospital Los Angeles, CA, USA (5). CNO disease activity was evaluated by clinical, laboratory and radiographic parameters. Response to treatment was assessed by laboratory values (CRP, ESR) and a global response score, which also included clinical and radiographic parameters. A score of 0 indicated lack of response, 1 indicated partial response, and 2 indicated full response. Descriptive statistics were used for analysis.

Results: 23 patients (14 F: 9M) with a mean age of 9.6 ± 2.9 were followed for a median of 1.83 (0.1–13) years. Patients had a mean of 3.3 ± 2.5 lesions which were most commonly seen in the pelvic bone (9), tibia (8), clavicle (6), calcaneus (5), femur (5), humerus (5), vertebrae (5), and mandible (4). Eight patients (34.7%) had unifocal disease. The most common presenting symptoms included bone pain (90.9%), soft tissue swelling

(45.5%), and fever (29.4%). Extra osseous manifestations were observed in 7 patients including enthesitis (2), myositis/fasciitis (4), anterior uveitis (1), oral ulcers (1), discoid rash (1) and Crohn's disease (1). Pathologic fractures were seen in 11 (47.8%) patients. All but one patient received NSAIDS, which was sufficient to control disease activity in 7 (31.8%) of patients. Eight patients were treated with methotrexate of which 7 failed this treatment and 5 were subsequently switched to TNFα antagonists of whom 3 improved. The overall failure rate in the anti TNFα group was 50%.

		Response			
		Global	Clinical	Radiologic Images	Laboratory
NSAIDs n=22	Lack of Response	4 (17.4%)	3 (13.0%)	7 (48.7%)	6 (30.0%)
	Partial Response	12 (52.2%)	11 (47.8%)	6 (40.0%)	6 (30.0%)
	Full Response	7 (30.4%)	9 (39.1%)	2 (13.3%)	8 (40.0%)
Methotrexate n=8	Lack of Response	2 (25.0%)	2 (25.0%)	2 (33.3%)	5 (62.5%)
	Partial Response	5 (62.5%)	5 (62.5%)	3 (50.0%)	2 (25.0%)
	Full Response	1 (12.5%)	1 (12.5%)	1 (16.7%)	1 (12.5%)
TNFα Antagonists n=8	Lack of Response	0 (0%)	0 (0%)	0 (0%)	2 (28.6%)
	Partial Response	4 (50.0%)	5 (62.5%)	3 (60.0%)	4 (67.1%)
	Full Response	4 (50.0%)	3 (37.5%)	2 (40.0%)	1 (14.3%)

Conclusions: CNO is a chronic autoimmune inflammatory syndrome with a high risk for pathologic fractures and systemic morbidity. Treatment of these patients remains challenging since they tend to respond poorly to traditional NSAID and DMARD therapy. TNFα antagonists offer a viable treatment option and appeared to be the most beneficial in our study.

A Pilot Study of Gene Expression (GE) Profiles in Juvenile Dermatomyositis (JDM) Responders and Non-Responders: Diagnostic and Follow-Up Muscle Biopsy (MBx) Data. Lauren M. Pachman[1], Yi-Wen Chen[2], Peter Hendrickson[1], Sheela Shrestha[1], Gabrielle Morgan[1] and Simone Sredni[1]. [1]Children's Memorial Research Center, Chicago, IL, [2]Children's National Medical Center

Background: Previous data documented that both the TNF-α-308 A allele and a long duration of untreated disease (DUD) before diagnosis contributed to the lack of response of JDM children to therapy. Studies of untreated juvenile dermatomyositis (JDM) muscle biopsies (MBx) had documented a marked increased in IFN-α induced genes (Tezak, JI, 2000). It is not known if there are differences in the GE profiles in the untreated muscle biopsy of responders (R) vs non-responders (NR) at the diagnosis of JDM, or if this dysregulation persists once the children have been classified as having responded by clinical standards to immunosuppressive therapy. Finally, there is no information about the genetic status after a course of therapy that may have improved the muscle symptoms, despite other evidence of active disease.

Objective: To compare the GE profiles in the diagnostic muscle biopsies in untreated children at diagnosis of JDM and after immunosuppressive therapy.

Materials and Methods: Seven children with definite/probable JDM were recruited for this study, along with four healthy age-, race-, and gender-matched controls undergoing orthopedic surgery. All JDM were initially untreated at the time of the diagnostic MBx, mean age 7.43 $\pm$4.21 yrs, 3/7 female; six Caucasian and one Hispanic. Four of the children responded to therapy and were off all medication at the time of follow-up needle MBx, two of the NR still required medication, and one was non-compliant. RNA was extracted and hybridized to Affymetrix U133A arrays (at diagnostic) and U133Aplus2 arrays (post-treatment). Data was normalized and filtered to exclude the controls and probes with maximum expression less than a log scale of 6 across all samples. The GE of R was compared to the NR using two-sample t-tests. Evaluation of gene functions and networks utilized Ingenuity Pathway Analysis software (Ingenuity Systems, Redwood City, CA).

Results: The NR were older at the time of the diagnostic MBx: mean age of 9.6 $\pm$ 5.7 yrs with a longer DUD of 14.0 $\pm$1.24 mos vs mean age of 5.8 $\pm$2.5 yrs and DUD of 3.3 $\pm$1.4 mos for the R. At needle follow-up biopsy, R were mean age of 10.7 $\pm$1.8 yrs vs 17.7 $\pm$7.4 yrs for NR.

A significant number of genes were found to be differentially expressed in R compared with NR. Skeletal-muscular and cardiovascular system development and function were within the main networks represented. Of importance, at diagnostic MBx several apoptosis related genes were significantly up regulated in R compared with NR, including CASP1 (FC 2.3; p=0.03) and CASP7 (FC 1.8; p=0.02). After treatment, the NOS1 gene that is usually expressed in skeletal muscle and is regulated by IL1B and TNF was over-expressed in non-responders compared with responders (FC 3.7; p=0.02).

Conclusion: The results of this preliminary analysis point to specific genetic mechanisms involved with non-responsiveness to treatment in JDM patients. GE studies involving larger cohorts will clarify these mechanisms and allow the identification at diagnosis of patients that may not respond to treatment and may benefit from more aggressive or alternative therapy.

Supported by NIH/NIAMS R01 AR48289 and Cure JM Foundation (LMP).

A Whole Blood Gene Expression Profile of Untreated Children with Polyarticular JIA Enrolled in the TREAT Trial. Mark Barton Frank[3], Kaiyu Jiang[2], Yanmin Chen[2], Melissa Bebak[3], Carol A. Wallace[4], Susan Thompson[1] and James N. Jarvis[2]. [1]Cincinnati Children's Hospital Medical Center, [2]Dept. of Pediatrics, U of OK College of Medicine, [3]Oklahoma Medical Research Foundation, [4]Seattle Children's Medical Center

Background: The Trial of Early Aggressive Therapy (TREAT) in Juvenile Idiopathic Arthritis is a once-in-a-generation, multi-institutional trial comparing methotrexate with etanercept + methotrexate + prednisone as initial treatments of polyarticular JIA. To maximize the scientific utility of this trial, biological samples have been collected for translational research to answer questions of high relevance to the field of pediatric rheumatology; these samples include whole blood preserved in stabilizers to perform gene expression profiling. We report here the first translational study to emerge from the TREAT trial, which will be completed in late October, 2010.

Methods: We received 45 samples from children with untreated polyarticular JIA at the time of their enrollment within the TREAT trial. All children were rheumatoid factor negative. Of these 45 samples, RNA was degraded in 11 and was insufficient for microarray analysis on another 5. Thus, microarray analysis was performed on 29 children entering the TREAT trial and 19 healthy control children. RNA purification, assessment of RNA purity and integrity, labeling, and hybridization were all undertaken using conventional methods. The Illumina microarray platform was used and conventional biocomputational approaches were taken to identifying differentially expressed genes.

Results: 130 genes distinguished TREAT baseline from control samples with a 5% false discovery rate and a minimum 1.5-fold difference between groups. These genes were largely subsumed into 5 large overlapping networks, demonstrating that pathological systems, like physiologic systems, demonstrate a property referred to by systems biologists as modularity. Gene networks also showed the hub-and-node structure (scale free systems) that we have previously described in the pathologic networks associated with childhood-onset rheumatic diseases. As is typical with gene array experiments, signaling molecules (JNK, Akt) and transcription factors (MYC, HNF4A, NFkB) represented prominent hubs in these networks. Small groups of genes regulated by type 1 and type 2 interferons and TGFB were also seen. A network of IL-12-regulated genes, not previously recognized on our earlier array studies, was down-regulated in untreated JIA patients. Hierarchical cluster analysis of the array data suggested that the JIA subjects could be divided into 2 dichotomous groups. As the TREAT study is still blinded, it is not possible at the present time to determine whether there is a specific phenotype associated with those clusters.

Conclusion: Whole blood gene expression profiling of untreated subjects from the TREAT trial demonstrates multiple gene networks that distinguish children with polyarticular JIA from healthy control children. The complexity of these gene networks demonstrates the challenge still facing us in understanding JIA at the cell and molecular level. At the same time, translational

samples collected from the TREAT trial will allow us to understand how these networks change in response to therapy and provide unprecedented insight into the biology of therapeutic response.

Angiopoietin-Like 4 Is Expressed in Human Synovial Fibroblasts and Expression Is Increased in Response to TGFβ. Ndate Fall[2], Malinda Frederick[2], Alexei A. Grom[1] and Sherry Thornton[3]. [1]Childrens Hospital Medical Center, Cincinnati, OH, [2]Childrens Hosp Med Ctr, [3]Childrens Hospital Medical Center, Cincinnati, OH

Objective: We previously identified angiopoietin-like 4 (Angptl4) as a novel angiogenic protein that is highly increased in early inflammatory stages of collagen-induced arthritis. The present study determines the expression of Angptl4 mRNA in human synovium and the factor(s) regulating its expression.

Methods: Quantification of Angptl4 mRNA levels in synovial tissues was performed by RNase protection analysis. JIA (juvenile idiopathic arthritis) synovial fibroblast cultures were generated from joint replacement synovial tissues. Synovial fibroblast cultures were treated for 2 hours with systemic JIA (sJIA) synovial fluid (SF) or TGF-β, with or without the addition of recombinant human TGF-βRI kinase inhibitor (TβRI Inhibitor). RNA was isolated and Angptl4, IL-1β and GAPDH mRNA levels quantified by realtime RTPCR.

Results: Angptl4 is expressed at higher levels in rheumatoid arthritis (RA) and JIA than in osteoarthritis (OA) synovial tissues. JIA synovial fibroblasts express Angptl4 mRNA, which increases dramatically in the presence of systemic JIA (sJIA) SF. Treatment of JIA synovial fibroblasts with TGF-β shows a dramatic increase in Angptl4 expression that is nullified in the presence of TβRI Inhibitor. Angptl4 mRNA expression in response to SF is also dramatically diminished in the presence of TβRI Inhibitor.

Conclusion: Angptl4 is expressed in human arthritic synovium, suggesting a role for Angptl4 in human arthritic disease. The expression of Angptl4 is highly increased in JIA synovial fibroblasts in response to systemic JIA SF, and is abrogated by inhibition of TGF-βRI signaling, suggesting that TGF-β is a major mediator of Angptl4 expression in inflammatory arthritis.

Anti-CCP Antibodies Identify a Subset of RF-Negative Juvenile Idiopathic Arthritis. Anne E. Tebo[2], Troy D. Jaskowski[1], K. Wayne Davis[1], April Vigus[6], Bronte Clifford[4], Andrew S. Zeft[5], Bernadette McNally[5], Harry R. Hill[2], John F. Bohnsack[5] and Sampath Prahalad[3]. [1]ARUP Laboratories, [2]ARUP Laboratories, Univ Utah, [3]Emory Children's Center, Atlanta, GA, [4]Nationwide Children's Hospital, [5]University of Utah, Salt Lake City, UT, [6]University of Utah

Purpose: Juvenile idiopathic arthritis (JIA) is the most common cause of chronic arthritis in children. One subtype of JIA, characterized by rheumatoid factor (RF) positive polyarthritis, phenotypically resembles rheumatoid arthritis (RA) in adults. Recent studies have demonstrated anti-citrullinated protein/peptide antibodies (ACPA), have high specifity for RA. Furthermore most known genetic associations with RA are confined to autoantibody positive RA (ACPA and/or RF). Prior investigations of the prevalence of ACPA in children have mostly been in small cohorts of children with JIA, with very few cases of RF-positive polyarticular JIA included. We sought to investigate the prevalence of ACPA in a large well-characterized cohort of JIA and investigate the relationship between RF and ACPA.

Methods: Cases were 334 children with JIA, 30 of whom had RF+ polyarticular JIA. The mean age of onset in the JIA cohort was 6.7 years. Controls were 50 healthy children with a mean age of 11.5 at the time of blood draw. Sera from all JIA patients and healthy controls were investigated at a single time point for anti-cyclic citrullinated peptide (anti-CCP) IgG by ELISA (INOVA Diagnostics, San Diego, CA), RF IgM, IgA and IgG (Theratest, Lombard, IL), anti-RA33 ELISA (IMTEC, Wiesbaden, Germany), antinuclear antibodies (ANA) screened by ELISA (BioRad, USA) and positives confirmed by IFA on HEp2 cells. Comparisons between cases and controls were made using Chi-square or Fisher exact tests for categorical variable and T-tests for continuous variables.

Results: The prevalence of RF was 8% among controls, and 12% among cases, (not statistically significant). However the mean titer of RF was higher among positive cases. ACPA were detected in one control and 48 cases (2% vs. 14.3 %; OR 8.2, $p < 0.01$). Of particular interest were 23 children (7%) who had a positive ACPA and were negative for RF (IgM, IgG or IgA). These children had a significantly earlier age of onset than those children who had both RF and ACPA (4.6 years vs. 12.1 years, $p < 0.00001$ by T-test), included more males (8/23 vs. 2/30, $p < 0.01$), and included children with polyarticular ($n = 6$) as well as oligoarticular onset ($n = 10$). High resolution HLA-DRB1 genotyping indicated that they had fewer shared epitope alleles compared to those with ACPA and RF, who resembled adults with RA. Twenty-five JIA cases had both RF and ACPA, and generally had higher titers of ACPA than those with only ACPA. Among children classified as having RF+ polyarticular JIA per ILAR criteria, 73% were positive for ACPA. Notably, two children with ACPA and RF had oligoarticular onset and were classified as "undifferentiated JIA" per the ILAR criteria. ANA was positive in 6% of controls and 26% of cases by IFA (OR 5.6, $p < 0.01$). RA-33 antibodies were observed in 6% of controls, and 6% of cases (not significantly different).

Conclusions: Using the largest cohort investigated to date for ACPA, we have demonstrated that anti-CCP antibodies are detectable in 15% of children with JIA. Children with positive ACPA but negative RF are frequent, and may define a distinct subset of children with JIA. If validated in other large JIA cohorts, ACPA testing should be included in the classification of JIA.

CD4+CD161+ Cells with Th1 or Th17/Th1 Profile Accumulate in the Synovial Fluid of Patients with Juvenile Diopathic Arthritis and Correlate with Inflammation Parameters. Rolando Cimaz[1], L. Cosmi[2], L. Maggi[2], V. Santarlasci[2], M. Capone[2], F. Borriello[3], F. Frosali[2], V. Querci[2], G. Simonini[2], G. Barra[3], F. Liotta[2], R. De Palma[3], E. Maggi[2], S. Romagnani[2] and F. Annunziato[2]. [1]University of Florence, Firenze, Italy, [2]University of Florence, [3]University of Naples

Objective: A recently described subset of CD4+ T helper (Th) cells, named as type 17 Th (Th17) cells, has been suggested to be pathogenic in chronic inflammatory disorders, including rheumatoid arthritis and juvenile idiopathic arthritis. We wanted to investigate the phenotype and function of CD4+ T cells in synovial fluid (SF) of affected joints from children with juvenile idiopathic arthritis (JIA), and to establish a possible link with disease activity.

Methods: CD4+ T cells of peripheral blood (PB) and SF of 37 JIA patients, as well as of PB from 15 healthy children were analyzed for expression of CXCR3, CCR6, CD161 and production of IFN$\gamma$and IL-17A. Intracellular cytokine production assays, cytokine secretion assays, and cell cultures were performed. CD161+IL-17+IFNγ- and CD161+IL-17-IFNγ+ cells derived from PB of one healthy donor and the SF of one JIA patient were also cloned. RORC expression was evaluated by real-time quantitative RT-PCR in FACS sorted populations. Spectratyping and clonotypic analyses on different T cell subsets were performed.

Results: Numbers of CD4+CD161+, showing either the Th1 (IFNγ-producing) or the Th17/Th1 (producing both IFN-g and IL-17A) phenotype, were higher in SF than in PB from JIA children. The few Th17 cells from SF of JIA spontaneously shifted in vitro to Th1 cells, whereas Th17 cells from PB of healthy children did it only in presence of SF, this effect being neutralized by blocking IL-12 activity. Spectratyping and clonotypic analyses showed a similar skewing of the TCR-BV repertoire in both SF-derived CD161+Th17 and CD161+Th1 cells from the same JIA patient. The frequencies of CD4+CD161+ cells, particularly of those showing the Th17/Th1 phenotype, in SF of JIA positively correlated with levels of erythrocyte sedimentation rate and C-reactive protein.

Conclusion: These findings suggest that a shifting of CD4+CD161+Th17 cells into Th17/Th1 or Th1 cells in the SF from affected joints of JIA can occur, and indicate that the accumulation of these latter correlates with parameters of inflammation, thus supporting the hypothesis that these cells play a role in disease activity.

Characterization of Granulocyte Transcriptome in Polyarticular Juvenile Idiopathic Arthritis (JIA). Mark Barton Frank[3], Kaiyu Jiang[1], Yanmin Chen[1], Jeanette Osban[3], Pascal Gellert[2] and James N. Jarvis[1]. [1]Dept of Pediatrics, U of OK College of Medicine, [2]Max Planck-Institute for Heart and Lung Research, [3]Oklahoma Medical Research Foundation

Background: Previous studies have demonstrated aberrations in granulocyte activation in patients with polyarticular JIA, and gene expression profiles of patients with active disease and in remission support an important role of these cells in pathogenesis. The goal of this study was to extend our previous work to define molecular aspects of gene differences in JIA.

Methods: Children were grouped as having active JIA (AD, n=18), clinical remission on medication (CRM, n=12) or healthy controls (C, n=15) according to the criteria of Wallace et al. AD ad CRM patients were treated with similar medications. RNA was extracted from purified granulocytes, labeled and hybridized to Affymetrix Exon and microRNA (miRNA) arrays. Statistically significant differences with minimum two-fold changes in exon splicing were characterized by Exon Array Analyzer programs, and miRNA differences were defined using BRB-Array Tools.

Results: Exon splicing differences were detected and confirmed in 4 genes when cohorts of AD were compared to CRM. However, exon splicing occurred in a larger number of genes including amyloid P component, when samples from the same patients in AD were compared to those collected later in CRM. Numerous splice variations were found between AD and C samples including genes encoding Ro60, transcriptional regulators, and an IL-6 cytokine family receptor. These differed from those found when CRM was compared to controls. No differences in miRNA expression were detected between AD and CRM, AD and C, or CRM and C samples.

Conclusions: These results support the hypothesis that the transcriptional differences between patients with JIA and healthy children occur not only at the gene expression level as we and others have previously reported, but also in subtle ways in the usage of exons of genes of pathological interest. The absence of differences in miRNA levels in patients and controls suggests the regulatory events in RNA transcription are not controlled by miRNA or altered by treatment protocols used in these patients. The study further clarifies the important role at the molecular level of granulocytes in the pathogenesis of JIA.

CLARITY: ChiLdhood Arthritis Risk Factor Identification Study. Justine Ellis[1], Jane Munro[2], Anne-Louise Ponsonby[1], Angela Pezic[1], Betty Lim[1], Raul Chavez[1], William Siero[1], Jonathan Akikusa[2] and Roger Allen[2]. [1]Murdoch Childrens Research Institute, Melbourne, Parkville, Victoria, Australia, [2]Royal Children's Hospital, Melbourne, Parkville, Victoria, Australia

Introduction: Juvenile idiopathic arthritis is an autoimmune rheumatologic disease of unknown cause. As a complex disease, it is assumed that an interaction between genetic predisposition and environmental factors determines risk. Research to identify JIA risk factors lags behind that of other childhood autoimmune disorders of similar incidence. Over the last few years, the underlying genetic predisposition has begun to emerge, mainly through candidate gene analyses. However, few studies have examined environmental risk factors for JIA in detail, but past infection is of interest, both as a possible beneficial early life immunomodulator and an adverse trigger of disease (Ellis *et al.* Rheumatology 49:411-25, 2010). In 2008, we established CLARITY, a JIA Biobank that is collecting biospecimens and extensive information about environment from cases presenting to the Royal Children's Hospital (RCH), Melbourne, Victoria, Australia. A control sample of healthy children attending the RCH Day Surgery Unit for specific minor surgical procedures is also been collected. Our goal is to recruit at least 1000 cases and 1000 controls, to allow adequate statistical power to detect not only main effects but also gene-environment interactions. To date we have recruited 260 cases and 400 controls.

Methods: Here we concentrate on a preliminary analysis of a subset of the environmental measures collected in 224 incident and prevalent cases (mean age 9.5 ± 4.5 SD yrs, 69% female) and 272 controls (mean age 7.3 ± 4.1 SD yrs, 39% female) so far entered into a database. We examined the incidence of common childhood illnesses by logistic regression (adjusted for age and sex).

Results: A history of illness such as gastroenteritis (Adjusted odds ratio (AOR) = 0.52; 95% CI: 0.32, 0.83; p = 0.006), colds and flu (AOR = 0.36; 95% CI: 0.22, 0.58; p <0.001), and chest infection (AOR = 0.44; 95% CI: 0.26, 0.74; p = 0.002) were associated with a reduced likelihood of being a JIA case. These associations remained significant when we restricted the dataset to cases diagnosed within 3 years of interview as well as cases and controls born in Victoria with four Caucasian grandparents (case n = 100, control n = 223). The associations between reduced JIA risk and childhood illness remained particularly strong and consistent for colds and flu (AOR = 0.38; 95% CI: 0.21, 0.68, p = 0.001). We then further restricted the dataset to test the association of the incidence of colds and flu prior to school entry (4 years or younger) with diagnosis of JIA at 6 years or greater (case n = 113, control n = 272). The association was observed in this subgroup (AOR = 0.42; 95% CI: 0.15, 0.82; p = 0.016).

Conclusions: To date, these findings are consistent with other work indicating early life microbial exposure that leads to an increased incidence of common childhood illnesses confers protection against autoimmune disease, potentially through more efficient priming of the developing immune system. Further analyses will be undertaken in the larger study to examine whether the indications for control day surgery influenced these findings.

Costimulation Mediated Rescue of Superantigen Stimulated T Cells in Kawasaki Disease. Aaron Wong[2] and Rae S. M. Yeung[1]. [1]Hospital for Sick Children, Toronto, ON, Canada, [2]The Hospital for Sick Children, Toronto, ON, Canada

Background: Kawasaki Disease (KD) causes coronary arteritis and is the leading cause of acquired heart disease in children of the developed world. Evidence suggests that superantigens (SAgs) are involved in the pathogenesis of KD. Lactobacillus Casei cell wall extract (LCWE), a mouse model of KD, closely mimics human KD and SAg activity in LCWE directly correlates with its ability to induce coronary arteritis. Superantigens are potent T cell mitogens, initiating a tremendous inflammatory response with massive cytokine release characterized by production of tumor necrosis factor-alpha (TNFa). Our work suggests that enhanced costimulation can rescue SAg-stimulated T cells from apoptosis and thus could enable survival of autoreactive T cells which persist in our mouse model.

Objective: To determine the mechanisms involved in costimulation mediated rescue of SAg-stimulated T cells.

Methods: Splenocytes from C57BL/6, TNFR1 −/−, B7.2 −/−, and Cbl-b −/− mice were cultured in media containing various stimuli: Staphylococcal Enterotoxin B (SEB)-a prototypic SAg, recombinant TNFa (rTNFa), anti-CD28 antibody, CTLA4-Ig, and anti-TNFa antibody. Expression of B7.1, B7.2, Bcl-2, and Bcl-xl was determined by staining with fluorescent antibodies in flow cytometry experiments. In costimulatory rescue experiments, splenocytes were stimulated for 5 days and the levels of apoptosis within the SAg-reactive T cell population was determined by staining for TCRVb8 and annexin V. To determine the contribution of costimulatory molecules on T-cells versus antigen presenting cells (APC), cell populations were purified by magnetic bead separation, then mixed and co-cultured as described above.

Results: Stimulation with SEB upregulated B7.2 expression in wildtype mice, but this response was diminished in TNFR1 −/− mice. Addition of rTNFa in the absence of SEB independently upregulated B7.2 expression. Enhancing costimulation with stimulatory anti-CD28 antibody rescued superantigen-reactive T cells from apoptosis in wild type and TNFR1−/−, but not Cbl-B −/− mice. Disrupting costimulation by blocking B7 with CTLA4-ig or neutralizing TNF increased apoptosis of SAg-reactive T cells. Mixing experiments with purified wildtype T cells and B7.2 −/− APCs exhibited no change in SAg-induced apoptosis when compared to cultures completely lacking B7.2. Increased expression of the anti-apoptotic markers Bcl-2 and Bcl-xl was found in cells receiving enhanced costimulation.

Conclusion: TNFa plays an important role in regulating costimulation by regulating the expression of costimulatory ligand, B7.2, on APCs. The resultant B7.2/CD28 interaction is functionally relevant, leading to survival of SAg-reactive T cells. Rescued T cells had increased expression of anti-apoptotic markers Bcl-2 and Bcl-xl. As costimulation enables autoreactive cells to evade apoptosis and persist leading to persistent inflammation and tissue damage, this study lends additional mechanistic support to therapies that target TNF and costimulatory molecules for the treatment of KD. These principles are generalizable to many diseases where superantigens are implicated as triggers of a persistent immune response.

Detection of Potentially Disease Associated Copy Number Variants in Children with Rheumatoid Arthritis. Sampath Prahalad[1], Jennifer Gladys Mulle[2], Anne Dodd[3], Jennifer Prozonic[3], Milton Brown[3], Andrew S. Zeft[4], John F. Bohnsack[4], Stephen T. Warren[3], M. Katharine Rudd[3] and Christa L. Martin[3]. [1]Emory Children's Center, Atlanta, GA, [2]Emory University, Atlanta, GA, [3]Emory University, [4]University of Utah, Salt Lake City, UT

Purpose: Rheumatoid arthritis (RA) is a common chronic inflammatory arthropathy with a peak age of onset in the fifth decade. About 5% of children with juvenile idiopathic arthritis phenotypically resemble adult RA. We hypothesize that children with the RA phenotype are a genetically enriched early-onset disease cohort which could enable the identification of additional susceptibility factors for RA. Most studies to date have focused on adults with RA and on single nucleotide polymorphisms (SNPs). Copy number variants (CNVs), defined as duplications or deletions of DNA sequences, occur extensively throughout the human genome and have the potential to explain larger phenotypic effects than SNPs. We sought to identify CNVs which may influence susceptibility through disruption of genes in children with early onset RA.

Methods: Subjects were 13 children with very early onset of RA. The mean age of onset was 8 years (range 2 – 12.8 years). All subjects had at least two positive tests for rheumatoid factor and were positive for antibodies to cyclic citrullinated peptide (anti-CCP). We used a custom-designed oligonucleotide microarray (EmArray Cyto 180K, Agilent Technologies, Santa Clara, CA, USA) to detect CNVs. Following the manufacturer's protocol, DNA isolated from peripheral blood was hybridized to an array containing 180K oligonucleotides, including targeted coverage of known clinically relevant regions and a whole genome backbone with a resolution of ~75 kb. We eliminated common benign CNVs in the population using online databases (http://www.genome.ucsc.edu/ and http://projects.tcag.ca/variation/) and our own internal laboratory database.

Results: Three CNVs were identified. The first CNV was a 168-kb loss of chromosome 10, that includes the gene *HPSE2* (heparanase 2) which cleaves heparan-sulfate proteoglycans into heparan-sulfate side chains and proteoglycans. Heparanase-2 is also implicated in the extravasation of leukocytes. Another CNV was a 106-kb gain of chromosome 18 involving *ROCK1* which encodes a protein kinase that phosphorylates a large number of important signaling proteins, and is involved in regulation of lymphocyte migration. Both these CNVs were not observed in ~11,000 normal individuals in the Database of Genomic Variants ($p < 0.001$ by Fisher's exact test). Both CNVs were confirmed by Affymetrix 6.0 Arrays. A third CNV was a 79.8-kb gain of chromosome 6 which involves *HLA-DRB5*, a paralog of *HLA-DRB1* that is strongly associated with RA. This CNV has been reported previously. Common CNVs not associated with any phenotypes were observed in seven children. We also observed small deletions or gains in some children that were in regions with no relevant genes.

Conclusions: We have identified CNVs potentially associated with childhood presentation of RA. The genes identified are plausible candidates for RA. We are typing additional children with RA for CNVs using a higher density array. These preliminary findings support additional searches for CNVs in children with RA.

Differences in Transcription Profiles in Juvenile Idiopathic Arthritis (JIA) Patients Who Achieved Remission Using Different Therapies. Mark Barton Frank[2], Kaiyu Jiang[1], Yanmin Chen[1] and James N. Jarvis[1]. [1]Dept of Pediatrics, U of OK College of Med, [2]Oklahoma Medical Research Foundation

Background: We have previously shown that remission in JIA represents a distinct biological "state" that can be recognized clinically and at the molecular level. However, remission can be achieved with different medications. While ~30% of children with polyarticular JIA achieve remission on methotrexate (MTX) in combination with an NSAID, most achieve remission only when MTX and NSAIDs are used in conjunction with a TNF inhibitor (TNFi). We undertook this study to determine whether remission in a cohort of children with RF-negative, polyarticular onset JIA induced by MTX differs at the molecular level from remission achieved in the presence of a MTX plus a TNFi.

Methods: RNA was prepared from 29 patients' peripheral blood mononuclear cells (PBMC) and granulocytes to identify differentially expressed (DE) genes using whole genome microarrays between the two patient groups and 15 healthy childhood controls. Statistical analysis and in silico modeling using Ingenuity software were undertaken as described in our previous work.

Results: Only 6 DE genes were found in PBMC from patients who achieved remission using MTX+TNFi v MTX alone. Additional differences became apparent when each treatment group was compared to healthy controls. It is interesting to note that a number of the DE genes in both cell types are known to be regulated by the transcription factors NFkB and HNF4A.

There were 33 DE genes in granulocytes from patients treated with the two regimens, including many whose patterns were previously reported to be modulated in arthritis. As with PBMC, a number of these genes are also regulated by NFkB and HNF4A. Subsequent work from our group (see related abstract) has demonstrated unequivocally that that HNF4A is present in PBMC and granulocytes.

Both cell types from both groups of patients revealed hundreds of DE genes when compared to healthy controls. In granulocytes, these genes were subsumed into 9 large, overlapping networks that included the TGFB, TNFA, and IFNG hubs we have previously described. In PBMC, DE genes were subsumed into 2 networks that included the IFNG, TGFB, and IL1 hubs that have appeared on other JIA transcriptional profiles, including our own.

Conclusions: There appear to be strong similarities in the molecular "signatures" of remission in PBMC of children with JIA, regardless of whether remission was induced by MTX or MTX plus TNFi. The larger number of identified genes in granulocytes suggests important distinctions in innate immunity occur while achieving clinical remission. However, remission is not a return to "normal," but, rather, a homeostatic state in which pro- and anti-inflammatory gene networks are held in balance.

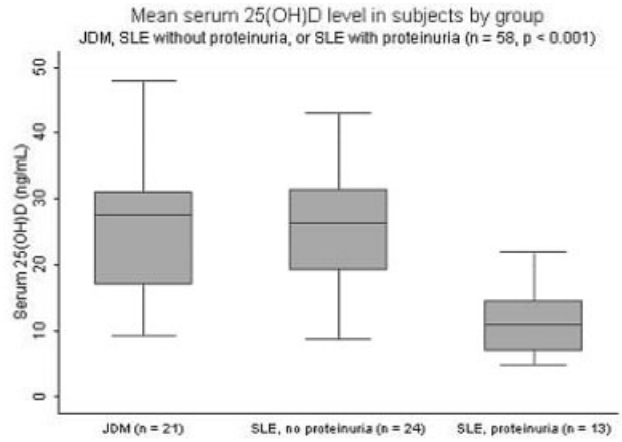
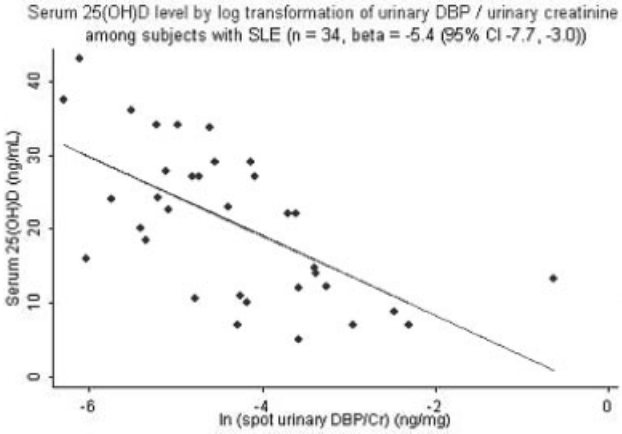
Disease Activity, Proteinuria, and Vitamin D Status in Children with Systemic Lupus Erythematosus and Juvenile Dermatomyositis. Angela B. Robinson[1], Myrtle Thierry-Palmer[2], Keisha L. Gibson[3] and Egla C. Rabinovich[1]. [1]Duke University Medical Center, Durham, NC, [2]Morehouse School of Medicine, [3]University of North Carolina at Chapel Hill

Background: Recent studies have implicated low vitamin D levels with greater disease activity in pediatric systemic lupus erythematosus (pSLE); there is no data on children with dermatomyositis. The objective of this study was to determine whether low levels of 25-hydroxyvitamin D [25(OH)D] are associated with proteinuria and assess the relationship between vitamin D deficiency and disease activity in two photosensitive autoimmune conditions [systemic lupus erythematosus (SLE) and juvenile dermatomyositis (JDM)].

Methods: Subjects diagnosed with JDM or SLE prior to the age of 18 were recruited and given a questionnaire regarding demographics, sunscreen use, and dietary habits to assess conventional risk factors for vitamin D deficiency. Serum 25(OH)D and albumin levels were determined. Disease activity was rated using a 10-cm visual analogue scale (VAS) in all subjects and a SLE disease activity index (SLEDAI) in subjects with SLE. Linear regression was used to examine the association of race, sunscreen use, vitamin D intake, and disease activity with serum 25(OH)D levels. Urine was analyzed for vitamin D binding protein (DBP) and protein to creatinine (UP/C) ratio.

Results: There were 58 subjects; 21 with JDM and 37 with SLE (13 with UP/C values ≥ 0.5). Serum 25(OH)D levels in subjects with SLE were inversely associated with urinary DBP ($r = -0.63$, $p < 0.001$) and urine protein to creatinine ratio ($r = -0.67$, $p < 0.001$), and directly associated with serum albumin ($r = 0.56$, $p < 0.001$). In a multivariate linear regression model adjusting for known risk factors including race and vitamin D supplement intake, serum 25(OH)D levels were inversely associated with disease activity (VAS), SLEDAI, and proteinuria in subjects with SLE. Prednisone dosage was not associated with 25(OH)D levels. UP/C ratios $\geq$ 0.5 were associated with an adjusted mean 10.9 ng/mL (95% CI 5.1 to 16.8 ng/mL) decrease in 25(OH)D level. Excluding subjects with proteinuria from analysis, serum 25(OH)D levels were inversely associated with disease activity in subjects with JDM, but not in subjects with SLE.





Conclusions: Low levels of serum 25(OH)D in systemic lupus erythematosus may result, in part, from urinary loss of DBP-25(OH)D in those patients with SLE-related glomerulonephritis. Serum 25(OH)D levels inversely correlate with disease activity in both JDM and SLE patients, but the relationship between disease activity and serum 25(OH)D levels in SLE patients may be confounded by the presence of proteinuria. Further studies should prospectively assess the effect of vitamin D supplementation on disease activity and outcomes in SLE and JDM.

Effect of Methotrexate and Genotype on RBC Folate Concentrations and Polyglutamate Distribution in JIA. Mara L. Becker[1], Leon van Haandel[5], Roger Gaedigk[3], Bradley Thomas[3], Mark F. Hoeltzel[2], Andrew Lasky[4], John Stobaugh[5] and J. Steven Leeder[3]. [1]Children's Mercy Hospital, Kansas City, MO, [2]Children's Mercy Hospitals and Clinics, Kansas City, MO, [3]Children's Mercy Hospitals and Clinics, [4]Childrens Mercy Hospitals and Clinics, Kansas City, MO, [5]University of Kansas

Purpose: The mechanism of action of methotrexate (MTX) remains incompletely understood. As a potent anti-folate drug, MTX has several enzymatic targets in the folate pathway. We measured intracellular folate redox states and polyglutamates to better understand the effect of drug and genotype upon intracellular folate pools in JIA.

Methods: This single center cross-sectional study evaluated 101 JIA patients on stable doses of MTX, and 94 JIA patients who were not currently on MTX. After obtaining informed consent, blood was obtained during routine lab monitoring. Genotyping for 34 SNPs in 19 genes within the MTX metabolic pathway was performed. Folates were extracted from RBCs and analyzed in a semi-quantitative relative fashion (i.e. without standards) using a similar method as for MTX polyglutamates, involving an ion-pairing chromatographic procedure with mass spectrometric detection.

Results: Measured intracellular folate isoforms included: 5,10 methenyl tetrahydrofolate **(5,10-MTHF)** which included the isoforms 5 formyl THF, 10 formyl THF and 5,10 methenyl THF; 5 methyl tetrahydrofolate (**5-MTHF**); and 5-MTHF polyglutamates **(5-MTHF-PG%$_{3–10}$)**. Subjects on MTX had expectedly lower folate isoform concentrations than those not on MTX including 5-MTHF (678.6 ± 281.2 nmol/L vs. 1022.2 ± 489.3 nmol/L, $p<0.0001$) and 5,10-MTHF (68.4 ± 77.0 nmol/L vs. 91.7 ± 106.3 nmol/L, $p=0.04$). 5-MTHF-PG% distribution revealed higher proportions of long chain polyglutamates in patients receiving MTX.

Table 1. 5-MTHF-PG% Distribution: Means (± SD)

	PG3%	PG4%	PG5%	PG6%	PG7%	PG8%	PG9%	PG10%
No MTX	2.1 (1.6)	6.3 (1.5)	47.7 (5.1)	30.3 (3.6)	8.4 (2.0)	3.5 (0.8)	1.4 (0.4)	0.29 (0.2)
MTX	1.5 (1.4)	7.1 (1.8)	43.9 (3.9)	31.1 (4.0)	9.8 (1.9)	4.2 (2.2)	2.0 (1.6)	0.43 (0.2)
p value	0.0007	0.0006	<0.0001	0.1	<0.0001	<0.0001	<0.0001	<0.0001

Of all clinical variables tested (including the use of folate supplementation) only MTX dose (in mg/kg) was inversely related to 5-MTHF concentrations ($p=0.0009$). Study participants with active arthritis had higher concentrations of summed RBC folates than those without active arthritis ($p=0.01$).

Variations in folate pathway genes were further investigated in the individuals on MTX. Homozygote variant (var/var) subjects in *MTHFD1* (rs2236225) had significantly higher concentrations of 5-MTHF than heterozygotes (wt/var, $p=0.009$) and wild type patients (wt/wt, $p=0.016$). *MTHFR* (rs1801133) var/var subjects had significantly lower concentrations of 5-MTHF than wt/var individuals ($p=0.017$). On the contrary, *MTHFR* (rs1801133) var/var subjects had significantly higher concentrations of 5,10-MTHF than both wt/var and wt/wt patients ($p<0.0001$). Two distinct SNPs in the *ATIC* gene had opposite effects upon 5,10-MTHF concentrations. *ATIC* (rs12995526) var/var subjects had significantly higher concentrations of 5,10-MTHF than wt/wt subjects ($p=0.01$), and *ATIC* (rs4673990) wt/var subjects had significantly lower concentrations than wt/wt subjects ($p=0.015$).

Conclusions: Variation in intracellular folate isoforms may be predictive of drug response in JIA. Genotypic differences beyond *MTHFR* may explain differential intracellular folate concentrations.

Disclosure: M. L. Becker: PhRMA Foundation Faculty Development, 2; **L. van Haandel:** None; **R. Gaedigk:** None; **B. Thomas:** None; **M. F. Hoeltzel:** None; **A. Lasky:** None; **J. Stobaugh:** None; **J. S. Leeder:** None.

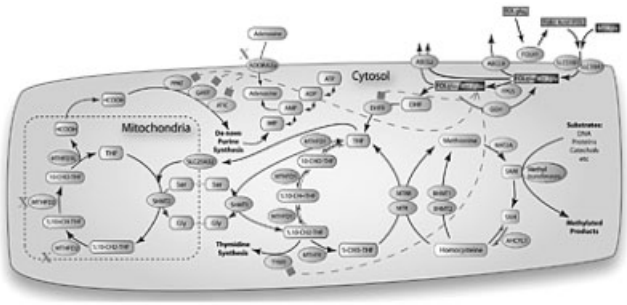
Genetic Variation Associated with Methotrexate Response in Juvenile Idiopathic Arthritis: Role of the Mitochondrial and Purine Synthesis Pathways. Mara L. Becker[1], Roger Gaedigk[3], Bradley Thomas[3], Andrew Lasky[4], Mark F. Hoeltzel[2], Hongying Dai[3] and J. Steven Leeder[3]. [1]Children's Mercy Hospital, Kansas City, MO, [2]Children's Mercy Hospitals and Clinics, Kansas City, MO, [3]Children's Mercy Hospitals and Clinics, [4]Childrens Mercy Hospitals and Clinics, Kansas City, MO

Purpose: Response and toxicity to Methotrexate (MTX) is unpredictably variable in Juvenile Idiopathic Arthritis (JIA). A known folate antagonist, there are several identified folate pathway gene targets for MTX and, therefore, there is a large potential for variation in genotype which may affect drug response. We investigated the combination of folate pathway polymorphisms and MTX response in JIA.

Methods: This is a single center cross-sectional study evaluating JIA patients on stable doses of MTX at a tertiary care children's hospital. After obtaining informed consent, blood was obtained from 104 JIA patients during routine MTX screening labs. Clinical data were collected by chart review. Genotyping for 34 SNPs in 19 genes within the MTX metabolic pathway was performed. Chi square analysis and Multifactor Dimensionality Reduction (MDR) methods were employed to investigate gene to gene interactions associated with the presence of active arthritis.

Results: All genes included in the analysis were in Hardy Weinberg equilibrium. Initial chi square analyses revealed a statistically significant association with the following genes and the presence of active arthritis (active disease): *ATIC* (rs4673990; $P=0.019$), *MTHFD2* (rs12196, and a 5nt ins/16nt del in the promoter; $P=0.005$, and $P=0.015$, respectively), and *ITPA* (rs2295553; $P=0.014$). The MDR method was applied to the outcome of presence/absence of active joints. The most pronounced combination of genes differentiating patients with active arthritis and those without included *ATIC* (rs4673990) and *MTHFD2* (rs56168672).



In fact, subjects who carried the combination of these two SNPs were 9.7 times more likely to have active arthritis [OR 9.66 (95%CI: 3.9, 24; $P<0.0001$)]. Sensitivity was 74%, specificity was 86.7% and overall accuracy was 76%.

Table 1. MDR analysis evaluating gene-gene interactions differentiating subjects with active arthritis from those without

Model	Training Accuracy	Testing Accuracy	CVC	Odds Ratio (95% CI)
One locus		Not significant		
ATIC (rs1673990)	76%	69.4%	9/10	9.66 (3.0, 24)
MTHFD2 (rs56168672)		(P = 0.0145)	(P = 0.0810)	($p < 0.0001$)
Three loci		Not significant		

Conclusions: MTX has a known inhibitory effect on several target enzymes, resulting in disruption of the folate cycle and a subsequent decrease in production of DNA precursors, disruption of methyl-dependent reactions, and accumulation of adenosine, which has anti-inflammatory properties. Due to the importance of the folate pathway it is unlikely that altered drug response is a consequence of variation in a single gene, rather a network or pathway of genes may be of interest. We have identified SNPs in the mitochondrial *(MTHFD2)* and purine synthesis *(ATIC)* pathways which may, in combination, play a role in MTX response in JIA.

Hierarchy of Risk Conferred by the HLA-DR Shared Epitope in Childhood Onset Rheumatoid Arthritis. Sampath Prahalad[3], Susan D. Thompson[2], Karen Conneely[6], Yunxuan Jiang[6], Jennifer Prozonic[6], Milton Brown[6], Sheila Angeles-Han[5], Larry B. Vogler[7], Christine W. Kennedy[4], Carol A. Wallace[14], Carol Wise[12], Marilynn G. Punaro[11], Ann M. Reed[8], Jane L. Park[10], Elizabeth D. Mellins[9], Andrew S. Zeft[13], John F. Bohnsack[13] and David N. Glass[1]. [1]Childrens Hospital Med Ctr, Cincinnati, OH, [2]Cincinnati Childrens Hospital Med Ctr, Cincinnati, OH, [3]Emory Children's Center, Atlanta, GA, [4]Emory Children's Center, Decatur, GA, [5]Emory University, Atlanta, GA, [6]Emory University, [7]Emory University School of Medicine, Atlanta, GA, [8]Mayo Clinic, Rochester, MN, [9]Stanford University Med Ctr, Stanford, CA, [10]Stanford University Med Ctr, San Jose, CA, [11]Texas Scottish Rite Hospital for Children, Dallas, TX, [12]Texas Scottish Rite Hospital for Children, [13]University of Utah, Salt Lake City, UT, [14]University of Washington and Seattle Childerns's Hospital, Seattle, WA

Purpose: Rheumatoid arthritis (RA) is an inflammatory arthritis with a peak age of onset ~50, although childhood cases occur. There is a strong association between certain HLA-DR alleles and RA. RA associated alleles encode DRβ1 chains with conserved amino acid sequence in positions 70–74. The molecular structure encoding the susceptibility residues is termed the shared epitope (SE). While associations between SE and risk of RA is well established, some alleles (e.g. *0401) seem to confer a greater degree of risk than others (*0101). Tezenas Du Montcel et al proposed a classification in which some SE alleles conferred more susceptibility than others. While SE alleles have been evaluated in childhood cases of RA, most cohorts were small ($n < 50$), and used low resolution DNA typing. We sought to investigate possible hierarchy of SE alleles in the largest cohort assembled to date of RA in children.

Methods: Cases were 189 children with JIA who had one or more positive tests for rheumatoid factor (RF) and/or anti-cyclic citrullinated peptide (CCP) antibodies. Controls were 100 healthy Non-Hispanic White (NHW) adults. High resolution sequence based HLA-DRB1 genotypes were determined on cases and controls. In addition DRB1 genotypes were available on 273 healthy NHW controls. Per Tezenas Du Montcel et al, SE alleles were classified as follows: S2: (KRAA at amino acid positions 71–74) *0401, *1303; S3P: (QRAA) *0101, *0102, *0404, *0405, *0408, *1001, *1402. All other alleles were designated as low-risk (L) alleles. Logistic regression was performed using NHW cases and controls to calculate the odds ratio of various combinations of SE alleles (L/L, S3P/L, S2/L, S3P/S3P, S2/S2, S3P/S2).

Results: The mean age of onset of RA was 10.7 years. Of 87 children tested for anti-CCP antibodies, 72% were positive. Of 21 African-American (AA) cases 48% carried 1 or 2 SE alleles. Of 25 Hispanic children 76% carried 1 or 2 SE alleles. Of the 134 NHW cases, 76% carried 1 or 2 SE alleles compared to 54% of controls (OR = 2.73, $p < 0.00001$). A significantly greater proportion of cases carried 2 copies of SE alleles compared to controls (31.3% vs. 5.4%, OR 8.1, $p < 1 \times 10^{-7}$). The effect of the number of risk alleles (SE) was very significant (OR = 2.5 (95% C.I.: 1.5–4.2) for each additional risk allele, p = 0.0003). There was a greater risk for S3P/S2 individuals beyond that expected based on the number of risk alleles alone (OR = 2.9 (95% C.I.: 1.1–7.4), p = 0.025). Genotype-specific risk estimates with L/L as reference group suggested a hierarchy of risk, with highest risk among those who had a S2 and a S3P allele (Table).

Genotype	Number (%) of controls (N = 373)	Number (%) of RA patients (N = 134)	Comparison to L/L genotype OR (95% CI)	P
S_2/S_{3P}	9 (2.4)	28 (20.9)	19.5 (8.4–45.2)	<0.0001
S_2/S_2	3 (0.8)	4 (2.9)	8.4 (1.8–39.2)	0.0069
S_{3P}/S_{3P}	8 (2.1)	10 (7.5)	7.8 (2.9–21.4)	<0.0001
S_2/L	60 (16.1)	22 (16.4)	2.3 (1.2–4.3)	0.0078
S_{3P}/L	92 (24.7)	38 (28.4)	2.6 (1.5–4.4)	0.0004
L/L	201 (53.9)	32 (23.9)	1.0 (referent)	

Conclusions: This is the largest described cohort of children with RA. We confirm the association between SE alleles and susceptibility to RA in children. The excess risk conferred by individuals who carry the combination of S2/S3P risk alleles suggests that children with DRβ1 chains containing KRAA/QRAA might be especially prone to RA.

HLA Associations in Oligo- and Polyarticular RF (-) Juvenile Idiopathic Arthritis-Associated Uveitis. Sheila Angeles-Han[5], Andrew S. Zeft[8], John F. Bohnsack[8], Bronte Clifford[7], Lori Ponder[1], Jennifer Prozonic[3], Milton Brown[3], Christine W. Kennedy[4], Larry B. Vogler[6] and Sampath Prahalad[2]. [1]Children's Healthcare of Atlanta, [2]Emory Children's Center, Atlanta, GA, [3]Emory Children's Center, [4]Emory Children's Center, Decatur, GA, [5]Emory University, Atlanta, GA, [6]Emory University School of Medicine, Atlanta, GA, [7]Nationwide Children's Hospital Research Institute, [8]University of Utah, Salt Lake City, UT

Purpose: Juvenile idiopathic arthritis-associated uveitis (JIA-U) can lead to complications such as cataracts, glaucoma, and synechiae, and increase risk for vision loss and blindness. Retrospective studies show an association between polymorphisms of HLA class II genes and JIA-U, especially in females with the oligoarticular subtype and early disease. While HLA-DR11 and HLA-DR13 alleles increase susceptibility to disease, HLA-DR1 is protective. Most studies have not included children who have poly RF (-) JIA-U. We sought to validate previously reported HLA associations and investigate the association between HLA-DRB1 in oligo- and polyarticular RF (-) JIA-U. Most prior studies also have not examined the effect of carriage of two risk alleles, which we sought to do.

Methods: Thirty children of Northern European ancestry with oligo- or polyarticular JIA-U were followed in pediatric rheumatology and ophthalmology clinics. Chart reviews confirmed the diagnoses of JIA and uveitis. Controls were 100 healthy adults screened for several common autoimmune disorders. Cases and controls were matched for ethnicity. High resolution sequence based typing was performed to determine HLA-DRB1 genotypes. Statistical analysis was performed using chi-square or fisher's exact test for odds ratio (OR).

Results: Of 30 subjects, 43.3% were females, 76.7% were ANA positive, 83.3% had oligo JIA and 16.7% had RF (-) poly JIA. Mean age of JIA

diagnosis was 3.0 years (SD 2.4). Of 10 subjects, mean age of JIA-U diagnosis was 3.4 years (SD 2.5) with a mean of 20 months (SD 28.5) of arthritis before uveitis onset. In our cohort, we found the following DR13 alleles – *0101 (n=9), *1302 (n=2), and *1303 (n=2), and the following DR11 alleles- *1101 (n=7), and *1103 (n=3). There was evidence for an association between JIA-U and DRB1*13 (OR 2.18, p=0.08), and DRB1*11 (OR 6.71, p=0.0003). There was also an association between carriage of either DRB1*11 or DRB1*13 (OR 3.25, P=0.005). There was a very strong association between JIA-U and carrying two copies of risk alleles (DRB1*11 and 13) (OR 30, p=0.0000007). There was a decreased frequency of DRB1*01 among cases with JIA-U compared to controls, although this was not statistically significant, reflecting the modest sample size.

Conclusions: We have validated the reported associations between DRB1*13 and DRB1*11 in JIA-U. We have also demonstrated the strong association between JIA-U and the presence of two risk alleles. These HLA risk genotypes should be further investigated in a large prospective group of children with JIA-U to determine the risk for uveitis severity and associated complications.

Hyaluronidase Mutation (HYAL1) Presenting as JIA, a Description of an Extended Family Provides New Information and Characterizes This Genetic Disorder That Causes Widespread Synovitis. Lisa F. Imundo[2] and Wendy Chung[1]. [1]Columbia University, NY, NY, [2]Columbia University, New York, NY

Background: More than 10 years ago Natowitcz described a single case of Mucopolysaccharidoses IX [1], characterized by a lack of hyaluronidase activity coupled with continued biosynthesis of the substrate. The affected case was 14 years old with painful synovitis and hip erosions that eventually required hip replacements. Only this index case has been characterized

Report: We report a consanguineous Saudi Arabian Family with familial arthropathy in three siblings. Onset ranged from 4yrs-18 yrs. The arthropathy is clinically apparent in large joints primarily hips and knees. Radiographic studies- indicate fulminant inflammatory synovitis with septated cysts and early marginal erosive disease. Synovial biopsy indicated synovial hypertrophy with a prominent histiocytic infiltrate, paillary hyperplasia and focal sclerosis. Notable there is no inflammatory infiltrate. The mononuclear cells contained vacuolated granular cytoplasm. The cytoplasm contained glcosaminoglycans. Genetic testing indicated three of the five siblings were homzygous for MPS IX. The mutation in HYAL 1 (c.44delT) causes premature termination and is predictive of no functional HYAL1 production. The parents and two siblings are heterozygotes. They do not have symptoms of synovitis.

Results: On further radiologic survey of symptomatic and non symptomatic joints by MRI and joint ultrasound indicated that homozygous children have demonstrated abnormalities and synovitis in every synovial joints, including small joints of the hands and feet. In addition the heterozygote asymptomatic siblings may have a mild phenotype. The only homozygous female has an earlier onset of symptoms and more severe radiographic changes similiar to the described index case.

Summary MPS IX is characterized by clinical symptoms isolated to synovial joints and likely represents an important etiology of familial arthritis.We add important information to further characterize this disease and to define features that can differentiate MPS IX from JIA. Treatments for JIA will not be effective for this genetic disorder characterized by a lack of hyaluronidase, however directed treatments may include making use of commercially available hyaluronidase enzyme.

Leukocyte Expression of Transcription Factor HNF4a, a Regulator of Gene Expression in Polyarticular Juvenile Idiopathic Arthritis. Kaiyu Jiang[1], Yanmin Chen[1], Mark Barton Frank[2] and James N. Jarvis[1]. [1]Dept of Pediatrics, U of OK College of Medicine, [2]Oklahoma Medical Research Foundation

Objective: Our previous work has shown that there are distinct gene expression profiles in peripheral blood mononuclear cells (PBMC) and in granulocytes derived from patients with polyarticular juvenile idiopathic arthritis (JIA) compared with healthy control children of the same age and sex. Network analysis of these differentially expressed genes demonstrates that many of those genes are under the control of a single transcription factor, hepatocyte nuclear factor alpha (HNF4A). Furthermore, HNF4a appears to determine both response to therapy and achievement of remission. However, HNF4a has not previously been known to be expressed in leukocytes. To understand the role of HNF4a in JIA, we examined its expression in PBMC subsets and granulocytes.

Method: PBMC, CD4+ T cells, CD8+ T cells, CD14+ monocytes, CD19+ B cells and granulocytes were isolated using conventional methods. RNA was separately extracted and reverse transcription- polymerase chain reaction was used to detect the expression of HNF4a mRNA. Immunofluorescence staining and confocal microscopy were used to observe the expression of HNF4a protein. The DECODE database (SABiosciences Company) was used to search HNF4A binding sites within the differentially expressed genes.

Results: Polymerase chain reaction (PCR) analyses revealed that expression of HNF4a mRNA is leukocyte subset-dependent. PBMC, T cells and granulocytes, but not not CD14+ monocytes or CD19+ B cells, express HNF4a mRNA. Immunofluorescence staining for HNF4a was used to detect HNF4a in leukocyte subsets. HNF4a is expressed in granulocytes in a distinct pattern demonstrating two cell subsets. The first population observed on on confocal microscopy consisted of CD66b bright/HNF4a dim cells, and the second consisted of HNF4a bright/CD66b dim cells. In T cells, the HNF4a signal was significantly brighter in CD8+ cells than in CD4+ cells. All of these findings were observed in healthy children, healthy adults, and children with JIA. Thus, expression of HNF4a is not in itself pathological, and HNF4a may an important and previously unrecognized regulatory protein. Bioinformatics analysis of the promotor regions of ZNF281, IER5 and OAZ2, genes shown in Ingenuity analysis of PBMC array data from children with JIA to be under HNF4a transcriptional control, demonstrated sequence motifs typically associated with HNF4a binding.

Conclusion: HNF4A is an important systems hub that emerges from microarray analysis of JIA leukocytes. This transcription factor, which has not previously been demonstrated in leukocytes, may play a role in both disease pathogenesis and response to therapy. Expression of HNF4a was found in CD4+ and CD8+ T cells and neutrophils and was seen in both healthy children and children with JIA. Given the potential importance of HNF4a is regulating response to therapy in JIA, we believe that these studies may shed light on potential new targets of therapy in this challenging disease.

Low Serum Levels of NT-proCNP in Children with Poly-Articular Onset Juvenile Rheumatoid Arthritis. Fozia Khan[1], Ann Pokelsek[2], Lori Galla[2], Mary Toth[2] and Hulya Bukulmez[3]. [1]Akron Children's Hospital, NEOUCOM, Akron, OH and MetroHealth Medical Center, CWRU, Cleveland, OH, [2]Akron Children's Hospital, NEOUCOM, OH, [3]MetroHealth Medical Center, CWRU, Cleveland, OH

Children with juvenile rheumatoid arthritis (JRA) develop longitudinal growth delay. Increased levels of proinflammatory cytokines (IL-6, TNF-α) in serum and in synovial fluid have been blamed for suppressing the local and/or systemic growth factors that regulate endochondral bone growth. Aside from growth hormone signaling pathway, it is unknown whether other growth factors that regulate the endochondral bone growth are affected in JRA.

C-type natriuretic peptide (CNP) has been recently described as an essential paracrine factor for normal endochondral bone growth. Serum level of N-terminal pro-peptide of CNP (NT-proCNP) has been suggested to be a marker for endochondral bone growth. In this study, we aimed to investigate whether CNP signaling is affected during active juvenile inflammatory arthritis in children by measuring the serum NT-proCNP levels during active disease and investigated whether serum NT-proCNP levels correlated with the serum IL-6 and TNF-alpha levels.

We collected clinical and laboratory data and serum from children diagnosed with juvenile rheumatoid arthritis (JRA) according to ACR criteria (n=18, 9 pauci-articular, 8 poly-articular, and 1 systemic onset JRA). Concurrent clinical and laboratory data were collected from patients during their enrollment in the study as a part of their routine care. Pro-inflammatory cytokine levels and the NT-proCNP levels were measured using ELISA.

Z-scores of NT-proCNP levels for each patient were calculated using NT-proCNP levels of age matched healthy children. Statistical analysis software was used (SAS 9.2) to calculate the correlations between the z-scores, cytokines and laboratory data.

All patients with JRA had low NT-proCNP z-scores compared to age matched controls. Poly- and systemic JRA patient's z-scores were significantly lower. IL-6 levels showed negative correlation with the z-scores in children with poly-JRA ($r=-0.67$, $p=0.06$). When stratified for gender, correlation of z-scores with IL-6 level became significant ($r=-0.99$, $p=0.034$). Sedimentation levels correlated with TNF-α levels in poly-JRA patients ($r=0.91$, $p=0.003$), but TNF-α levels correlation with NT-proCNP z-scores did not reach statistical significance. Seven of eight poly-JRA patients were under treatment with Methotrexate (20mg/m^2) and five were also treated with oral prednisone (>0.5mg/kg/d). The mean z-scores of NT-proCNP in patients who used prednisone ($n=5$) were not different than those who did not use prednisone ($n=3$).

Serum NT-proCNP levels of children with JRA are lower than age matched controls. In poly-articular onset JRA patients, the serum levels of IL-6 show negative correlation with z-scores of NT-proCNP. In addition to ongoing systemic inflammation, patients with poly-JRA were also being treated with medications such as methotrexate and prednisone which might lower the NT-proCNP levels. Further studies with larger JRA patient population are necessary to further delineate the disruption of CNP signaling during JRA. Serum NT-proCNP levels could be a biomarker for endochondral bone growth in children with JRA.

Novel Founder Mutation in *IL1RN* Accounts for Deficiency of the IL-1 Receptor (DIRA) in Brazil. Adriana Almeida Jesus[4], Clovis Artur Almeida Silva[4], Peter W. Kim[2], Tuyet H. Pham[2], Débora Romeo Bertola[4], Magda Carneiro-Sampaio[4], Barbara Yang[2], Deborah Stone[2], Dawn Chapelle[2], Nicole Plass[2], Massimo Gadina[2], John Sims[1], Hatem El-Shanti[3] and Raphaela Goldbach-Mansky[2]. [1]Amgen Inc, Thousand Oaks, CA, [2]NIAMS/NIH, Bethesda, MD, [3]Shafallah Medical Genetics Center, Doha, Qatar, [4]Universidade de São Paulo, Sao Paulo, Brazil

Objective: To describe the clinical, immunological and genetic phenotype of 2 unrelated patients from Brazil presenting with pustular skin disease, osteolytic bone lesions and systemic inflammation and incoplete responses to multiple DMARDs.

Patients and Evaluation: Two Brazilian patients with perinatal onset skin pustulosis and osteolytic bone lesions and systemic inflammation, consistent with the clinical diagnosis of DIRA were evaluated and genetic analysis of the *IL1RN* gene locus was performed. Multi-disciplinary clinical evaluation including a total body MRI, and immunological and laboratory characterization of the structure and function of the mutated gene and encoded protein were performed to characterize the inflammatory phenotype of these patients.

Results: Both patients had classical pustular skin lesions with a neutrophilic infiltrate in the dermis and epidermis. One patient presented with clinically concerning spine lesions, she has non-fusion of the os odontoid with the body of the dens (C2) and an incomplete posterior arch of C1 leading to an over 7 mm atlantoaxial subluxation between head flexion and extension. Post-inflammatory fusion of several lower cervical and thoracic spine lesions led to the formation of a gibbus. Genetic analysis of *IL1RN* (isoform 1) showed a homozygous inframe 15 base pair deletion (c.213–228delAGATGTGGTACCCAT; p.72–77del DVVPI) in both girls leading to 5 amino acid deletion. Expression levels of messenger RNA were reduced on RT PCR and the mutated protein was expressed at low levels compared to healthy controls and heterozygous parents. Modeling of the mutated protein predicted a severe defect in the secondary structre and functional analysis confirmed no binding of the protein to the IL-1 receptor. Both patients had an immediate response to treatment with the rcombinant Il-1 receptor antagonist, anakinra, with complete resolution of skin lesions and normalization of systemic and organ specific inflammation. The patient's parents were carriers for the mutation but clinically asymptomatic.

Conclusions: A novel founder mutation in *IL1RN* accounts for 2 cases of DIRA from 2 unrelated Brazilian families. The clinical signs and symptoms in these patients are similar to those previously reported. In contrast to the previously reported cases of DIRA, in whom the mutated protein is not secreted, patients with the Brazilian mutation express low levels of the mutated protein. The severity of the 5 AA deletion was predicted based on modeling data and the response to the recombinat IL-1 receptor antagonist, anakinra, was immediate with complete resolution of inflammatory disease manifestations.

Determination of the frequency of the mutation in Brazil and establishing neonatal screening in areas with a high prevalence of the disease may be indicated.

Novel Mutations of Camptodactyly Arthropathy Coxa Vara Pericarditis (CACP) Syndrome: A Study on Ten Cases. Sara Ciullini Mannurita[7], Marina Vignoli[7], Lucia Bianchi[7], Chiara Azzari[7], Maurizio de Martino[7], Angelo Ravelli[4], Anuela Kondi[6], Valeria Gerloni[5], Rebecca ten Kate[2], Luciana Breda[3], Eleonora Gambineri[7] and Fernanda Falcini[1]. [1]Department of BioMedicine, Section of Rheumatology, Transition Clinic, University of Florence, [2]Department of Pediatrics, Leiden University Medical Centre, The Netherlands, [3]Department of Pediatrics, University of Chieti, Chieti, Italy, [4]Istituto di Ricovero e Cura a Carattere Scientifico G. Gaslini and Università degli Studi di Genoa, [5]Istituto G. Pini, Milan, Italy, [6]Pediatric Department, University Hospital Centre, Tirana, Albania, [7]University of Florence, Department of Sciences for Woman and Child's Health

Background: The Camptodactyly Arthropathy Coxa vara Pericarditis (CACP) syndrome is an autosomal recessive disease characterised by congenital camptodactyly, no inflammatory arthropathy, joint failure, synovial hyperplasia, coxa vara, and thickening of the pericardium. The causative gene for CACP is *PRG4 that* is located on chromosome band 1q25–31 and consists of 12 exons. It encodes for a mucin-like glycoprotein named "proteoglycan-4" (PRG-4) which acts as the major surface lubricant for joints and tendons.

Objectives: 1.To investigate possible genomic alteration in patients with clinical manifestations of CACP. 2.To perform a comprehensive analysis of the *PRG-4* gene.

Patients and Methods: Six unrelated patients and two pairs of siblings (2 sisters, 1 sister,1 brother) with a phenotype resembling CACP syndrome were referred to us for mutational analysis of *PRG-4* gene. The age of onset was mainly at birth (median age at diagnosis 5.5 years). Genomic DNA was extracted by peripheral blood and polymerase chain reaction was performed to amplify *PRG-4* exon sequences including intro-exon boundaries using specific primers. The coding regions were sequenced, with the exception of 800bp, within exon 6 due to highly repetitive motifs.

Results: Six novel homozygous mutations within *CACP* gene were identified in seven patients. The 2 sisters harboured the same nonsense alteration (Y1216X) that cause a frame-shift that creates a premature stop signal leading to the production of a truncated protein. Four mutations were small deletions of 1bp, 2bp and 5bp, three of which located within exon 6. These deletions cause frame-shift mutations and create a premature stop codon. In the remaining patients, we detected one substitution affecting the donor splice site (IVS8+3A>G); the bioinformatics analysis of this alteration predicts a decrease of the strength of the new splice site sequence that could be responsible for an aberrant splicing of the premature transcript. The analysis of CACP protein would be necessary to test the predicted effect of the mutations.

Conclusions: CACP syndrome is a rare disorder often misdiagnosed with other paediatric connective tissue diseases. This is the first study analysing the largest *PRG-4* coding region, and it allowed identifying a new set of molecular aberrations associated with the occurrence of CACP syndrome.

Plasma Osteopontin as a Marker for Damage in Pediatric Systemic Lupus Erythematosus. Ornella J. Rullo[2], Jennifer M. P. Woo[2], Alice D. C. Hoftman[1], Timothy B. Niewold[5], Angela Presson[4], Deborah K. McCurdy[2] and Betty P. Tsao[3]. [1]CHOC-Children's, Orange, CA, [2]Mattel Children's UCLA, Los Angeles, CA, [3]UCLA School of Medicine, Los Angeles, CA, [4]UCLA School of Public Health, [5]University of Chicago, Chicago, IL

Introduction: Osteopontin (OPN; aka SPP1 and Eta-1) is a secreted phosphoprotein that functions in macrophage and T cell adhesion, migration,

and signaling, and plays an important role in tissue and wound repair. OPN has been implicated in IFN-α production, and participates in monocyte/macrophage recruitment to kidneys in SLE, where it may functionally contribute to dysregulated tissue repair and fibrosis associated with chronic inflammation. We investigated the relationship of OPN protein levels and genetic variants with disease manifestations in pediatric SLE (pSLE), a subset with an increased proportion of lupus nephritis compared with SLE of adult onset.

Methods: DNA and plasma were collected from 72 (52 female; 20 male) pSLE patients (age of SLE onset < 18 years), and 51 healthy controls (32 female; 19 male) consisting of 35 unaffected siblings and 16 unrelated young people. All subjects were ≤ 22 years at time of blood draw. 49 pSLE patients had adequate clinical data to complete SLICC/ACR damage index (SDI) scores; disease activity was scored on all patients using the SELENA-SLEDAI index. Circulating plasma OPN (cOPN) was measured by ELISA. SNP genotyping was performed by Taqman assays. Serum IFN activity was measured by WISH-cell assay in 49 pSLE samples. Immunohistochemistry by standard fluorescence techniques was performed on anonymous WHO class IV lupus nephritis tissue obtained from our tissue core lab. Statistical analysis was performed using Student's t test, Pearson's correlation, Fisher's exact test, and multivariate linear and logistical regression modeling.

Results: pSLE patients with active disease (SLEDAI > 4) had high IFN activity ($p = 0.0009$), as in previous research, but disease activity did not correlate with cOPN in this cross-sectional analysis. Overall, cOPN was significantly higher in pSLE versus healthy unrelated controls ($p < 0.001$) with increasing cOPN correlating with SDI ($R = 0.5$; $p = 0.0003$). High IFN activity was more likely in pSLE patients with cOPN levels in the top quartile compared with those in the lowest ($p = 0.03$); similarly, pSLE patients with an SDI > 0 were more likely to have high IFN activity than those with SDI = 0 ($p = 0.02$). Considering disease status, 5 *OPN* variants previously associated with SLE, and gender as covariates in a multivariate regression analysis, the 3' untranslated region (UTR) single nucleotide polymorphisms (SNPs) of *OPN* (rs1126772 and rs9138) were associated with increased cOPN ($p = 0.004$ and 0.02, respectively). Interestingly, both 3' UTR SNPs as well as a promoter variant, rs2857094, were associated with SDI > 0 (ORs of 1.5–2.2; $p < 0.01$ for each SNP); we also observed rs2857094 allelic association with increased percentage of glomerulonephritis in pSLE (87% vs. 60%; $p < 0.0001$). In 3/3 renal biopsies from patients with diffuse proliferative glomerulonephritis, we noted the co-localization of OPN with macrophage marker CD68.

Conclusion: Genetic variants regulate OPN levels, which may contribute to the progression of tissue injury in pSLE, possibly by tissue-infiltrating monocytes/macrophages. The potential of OPN as a predictor of global and/or renal damage in pSLE requires further study in a longitudinal cohort.

Predominance of Complement Components C1q and C4 Bound to Circulating Immune Complexes (CICs) in Juvenile Idiopathic Arthritis (JIA): Support for Classical Pathway Activation. Brooke E. Gilliam[1], Melinda R. Reed[2], Anil K. Chauhan[1], Amanda Dehlendorf[2] and Terry L. Moore[2]. [1]Saint Louis University, St. Louis, MO, [2]Saint Louis University, St Louis, MO

Purpose: CICs from JIA sera show increased complement activation; however, the scope of involvement from the classical versus alternative pathway remains undefined. To delineate the role of these pathways, we measured activated complement products bound to CICs in sera from JIA patients.

Methods: Sera from 100 JIA patients (87 female, 13 male) were collected, including 68 polyarthritis (41 rheumatoid factor (RF)-negative and 27 RF-positive) and 32 oligoarthritis patients. The mean age was 11.0 years and mean disease duration was 4.1 years. Sera from 17 healthy individuals were also analyzed. C1q, C3, C3d, C4, and membrane attack complex (MAC) bound to CICs were measured by enzyme-linked immunosorbent assays (ELISA). Cut-off values were established as the mean +2 standard deviations of the healthy control results. IgA and IgM RF and IgG anti-cyclic citrullinated peptide (anti-CCP) antibodies were measured by ELISA. C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), and disease activity were obtained from patient records.

Results: Forty-eight patients were positive for C1q CICs, 45 for C4 CICs, 36 for C3 CICs, 29 for MAC CICs, and 25 for C3d CICs. C1q, C3, C4, MAC CICs were significantly elevated in JIA patients compared to healthy controls ($p<0.05$). MAC CICs demonstrated significant correlation with C1q CIC ($r=0.65$), C4 CICs ($r=0.61$), C3d CICs ($r=0.33$), and C3 CICs ($r=0.27$) ($p<0.05$). C1q CICs also correlated significantly with C4 CICs ($r=0.72$), C3d CICs ($r=0.27$), and C3 CICs ($r=0.22$) ($p<0.05$). C3 and C3d CICs demonstrated significant correlation with each other ($r=0.32$, $p=0.002$). IgA RF correlated significantly with C1q CICs ($r=0.20$, $p=0.049$). IgM RF demonstrated a negative correlation with C3 ($r=-0.24$, $p=0.02$), but correlated positively with C4 CICs ($r=0.22$, $p=0.027$). Of the JIA patients positive for MAC CICs (n=29), 21 (72%) were positive for both C1q CICs and C4 CICs and 13 (45%) were positive for C3. In both polyarticular and oligoarticular JIA, the classical complement pathway (C1q: 46–53% and C4: 44–47%) was more prevalent than the alternative complement pathway (C3: 35–38%).

Conclusions: The assay used in this study is able to capture CICs bound to complement, which reflects physiologically active complement. The classical complement pathway can be triggered by IgM and IgG-containing CICs in systemic circulation. Our results show that IgM RF correlated significantly with C4 CICs and MAC correlated significantly with C1q and C4 CICs, suggesting a dominant contribution of classical complement activation. Elevated IgA RF and IgM RF have both been associated with destructive disease in JIA. C1q and C4 CICs both correlated significantly with these RF isotypes, indicating a link between classical pathway activation and aggressive disease.

Rheumatoid Arthritis Susceptibility Loci; *PTPRC*, *PTPN2*, *IKZF3*, *c5orf30*, *BLK* and *CD247* Are Also Associated with Juvenile Idiopathic Arthritis. Anne Hinks[1], Steve Eyre[2], Paul Martin[2], Edward Flynn[2], Jon Packham[3], Anne Barton[2], Jane Worthington[2] and Wendy Thomson[2]. [1]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, University of Manchester, [3]Haywood Hospital, University of North Staffordshire

Background: Rheumatoid arthritis (RA) shares similar clinical and pathological features with juvenile idiopathic arthritis (JIA); indeed the strategy of investigating whether RA susceptibility loci also confer susceptibility to JIA has already proved highly successful in identifying novel JIA loci, such as *PTPN22*, *IL2RA* and *TRAF1/C5*. There has been a plethora of newly validated RA loci reported in the last year. Therefore the aim of this study was to test SNPs robustly associated with RA in a large cohort of JIA cases and controls to investigate the overlap between these diseases and identify novel JIA loci.

Methods: 29 SNPs that showed validated association with RA and had not been investigated previously in JIA were genotyped in JIA cases (n=1337) and healthy controls (n=2781) using Sequenom MassArray technology. Genotype and allele frequencies were compared between cases with JIA and controls using the Cochrane-Armitage trend test implemented in PLINK and allelic odds ratios (ORs) and their 95% confidence intervals (CIs) calculated.

Results: Strong evidence for association with JIA was seen for eight SNPs. These include a SNP, rs10919563, in *PTPRC* (ptrend $=2.5 \times 10^{-6}$ OR 0.68 95% CI 0.58–0.8) rs7234029, in *PTPN2* (ptrend =0.0003 OR 1.26 95% CI 1.11–1.43), rs2872507 in *IKZF3* (ptrend =0.0004 OR 1.21 95% CI 1.09–1.34), rs26232 in *c5orf30* (ptrend =0.002 OR 0.84 95% CI 0.75–0.94), rs2736340, in *BLK* (ptrend =0.003 OR 1.19 95% CI 1.06–1.34) and rs1773560 in *CD247* (ptrend =0.005 OR 0.87 95% CI 0.79–0.96). There was additional evidence for association of two novel SNPs in genes previously associated with JIA, rs13119723, in the *IL2/IL21* region (ptrend $=7.5 \times 10^{-6}$ OR 0.71 95% CI 0.61–0.83) and rs706778 in the *IL2RA* gene (ptrend =0.0002 OR 1.22 95% CI 1.1–1.35).

Conclusions: The association of *PTPN2* with JIA in the current study validates the findings of a previous US study, confirming it as a JIA locus. The other loci identified are novel and will require validation in independent JIA datasets. To date we have investigated 44 RA loci in JIA and of those 27 are associated with both diseases. The overlap is remarkable for two diseases which, although sharing some phenotypic features, are clinically distinct entities.

Role of IL-1b in the Development of Human TH17 Cells: Lesson from Patients Carrying NLPR3 Gene Mutations. Denise Lasigliè, Elisabetta Traggiai, Federica Penco, Silvia Federici, Andrea Accogli, Antonella Buoncompagni, Alberto Martini and Marco Gattorno. G. Gaslini Institute, Genoa, Italy

Purpose: Interleukin 17 (IL-17)-producing CD4+ helper T cells (T_h-17) represents a lineage of effectors CD4 T cells abundant at mucosal interfaces, where they contain infection with pathogenic bacteria and fungi. Beyond this function TH-17 cells have been linked to the pathogenesis of several inflammatory and autoimmune diseases. At present, understanding of Th-17 differentiation is limited to the mouse system and in humans remains still a puzzled issue. Recently it has been proposed IL-1b as a pivotal cytokine in driving Th-17 differentiation. *Cryopyrin-associated periodic syndromes* (CAPS) are a group of inflammatory diseases associated to mutations of *NLRP3* gene encoding the inflammasome component *cryopyrin*. These mutations determine an exaggerated IL-1β secretion by monocytes upon Toll like receptors (TLRs) stimulation. We have investigated whether the altered IL-1β secretion, secondary to *NLPR3* mutations, could affect the IL-23/IL-17 axis in CAPS patients.

Methods: IL-17 serum level has been evaluated by ELISA assay. Expression of CCR6 and CD161, two TH-17 specific markers, has been analyzed on CD4+ memory T cells by flow cytometry Frequency of T_H-17+ cells has been quantified upon stimulation with staphylococcus entherotoxin B (SEB). Production of IL-1β and IL-23 by monocyte derived dendritic cells (MoDCs), in response to TLRs ligands, has been quantified by ELISA. CAPS patients have been analysed before and after anti-IL1β treatment.

Results: Untreated CAPS patients display significant increased level of serum IL-17 as well as of Th-17+ T cells respect to age matched controls. Both IL-7 serum levels as well as Th-17 frequency decrease after IL-1β treatment. Also production of IL-1b and IL-23 by MoDCs is increased in CAPS patients, and after anti IL-1β treatment production of both cytokines is significantly reduced.

Conclusions: These findings further support a central role of IL-1b in the differentiation of T_H 17 in human inflammatory conditions.

Subtype Specific Genetic Associations for Juvenile Idiopathic Arthritis (JIA): *ERAP1* with the Enthesitis Related Arthritis Subtype and *IL23R* with Juvenile Psoriatic Arthritis. Anne Hinks[1], Paul Martin[2], Edward Flynn[2], Steve Eyre[2], Jon Packham[3], Anne Barton[2], Jane Worthington[2] and Wendy Thomson[2]. [1]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, University of Manchester, [3]Haywood Hospital, University Hospital of North Staffordshire

Background: There is now strong evidence supporting the hypothesis of common autoimmune susceptibility loci. There is also evidence to support clustering of loci in diseases that share similar clinical phenotypes e.g. Ankylosing spondylitis (AS), psoriasis (Ps), psoriatic arthritis (PsA) and they appear to have some overlapping susceptibility loci such as *IL23R* and *ERAP1*.

Juvenile idiopathic arthritis (JIA) is an umbrella term for all chronic childhood arthropathies and can be classified into 7 subtypes on the basis of features present in the first 6 months of disease. It includes the enthesitis related arthritis (ERA) subtype which displays symptoms similar to AS and juvenile onset psoriatic arthritis which has similarities to psoriatic arthritis and psoriasis. We therefore hypothesized that the two well-established susceptibility loci *IL23R* and *ERAP1* could also confer susceptibility to these JIA subtypes, to this end the most associated SNP within each of these genes have been selected for genotyping across all JIA and also analysed stratified for each subtype.

Methods: SNPs in *IL23R* (rs1129026) and *ERAP1* (rs30187) were genotyped in JIA cases (n=1054) and healthy controls (n=5200). The numbers genotyped per ILAR subgroup were: Systemic onset (n=164), persistent oligoarthritis (n=297), extended oligoarthritis (n=147), Rheumatoid factor (RF) negative polyarticular JIA (n=215), RF positive polyarticular JIA (n=68), enthesitis related JIA (n=63), psoriatic JIA (n=76) and unclassified (n=24).Genotype and allele frequencies were compared between all JIA cases and controls using the Cochrane-Armitage trend test implemented in PLINK and allelic odds ratios (ORs) and their 95% confidence intervals (CIs) calculated. Stratified analysis by subtype was performed.

Results: Neither the SNP in the *IL23R* gene, rs1129026, nor the SNP in the *ERAP1* gene, rs30187, were significantly associated ($p<0.05$) with the total JIA dataset. Stratification by subtype found that the *IL23R* SNP showed significant association in the psoriatic arthritis subtype (ptrend=0.04 OR 0.4 95% CI 0.16–0.98) and a trend towards association in the enthesitis related subtype (ptrend=0.15 OR 0.52 95% CI 0.21–1.28). The enthesitis related arthritis (ERA) subtype showed strong association with *ERAP1* SNP (ptrend=0.004 OR 1.69 95% CI 1.18–2.44). For both SNPs the association is in the same direction as in the original study.

Conclusions: We present evidence for subtype specific association of the *IL23R* gene with juvenile psoriatic arthritis and *ERAP1* gene with ERA. The findings will require validation in independent JIA datasets. These results suggest distinct pathogenic pathways in these subtypes.

The Role of Platelets and CD40L in the Pathogenesis of Kawasaki Disease. Parnian Arjmand[2] and Rae S. M. Yeung[1]. [1]Hospital for Sick Children, Toronto, ON, Canada, [2]University of Toronto, The Hospital for Sick Children, Toronto, ON, Canada

Background: Kawasaki Disease (KD) is a disease of childhood characterized by systemic inflammation leading to coronary artery damage. Although its etiology remains unknown, superantigens are among the triggers of disease. Lactobacillus Casei Cell Wall Extract (LCWE) induces a disease in mice which mimics KD closely in time-course, histological changes and susceptibility in the young. LCWE contains both a superantigen and a TLR-2 ligand. KD is characterized by marked elevation in platelet numbers. Recent studies have found CD40L expression on platelets and CD4+ T cells to be associated with coronary artery aneurysms in children with KD. CD40L is a member of the TNF family of proteins which is expressed on T-cells. Interestingly, it is also stored in platelet granules and binds to an integrin receptor, gpIIIaIIb, on platelets. Platelets also store and release Matrix Metalleoprotease 9 (MMP-9) upon activation – an enzyme essential for coronary artery break-down and anuerysm formation in KD. Here, we aim to elucidate the role of platelets in the pathogenesis of KD: specifically, the effect of LCWE stimulation on platelet activation, CD40L and MMP-9 expression and release, and its role in coronary artery disease.

Methods: In vivo and in vitro platelet activation (α-granular release, microparticle formation, aggregation, integrin receptor activation) is assayed using flow-cytometry. In vivo, blood is obtained from C57/BL6 mice injected with LCWE or PBS; in vitro, platelets are stimulated with LCWE and assayed. Platelet MMP-9 release is studied by determining protein and enzymatic activity using Western blots and zymography respectively. To differentiate between superantigenic versus TLR-2 agonistic activity of LCWE in stimulating platelets, blood is also drawn from TLR-2 knock-out mice or treated with a TLR-2 blocking mAb prior to analysis.

Results: Stimulation of platelets with collagen and ADP agonists achieves maximal platelet CD40L and P-selectin upregulation in vitro.TLR2 ligand PAM3CSK4, LCWE and SEB are also able to induce CD40L and P-selectin upregulation, gpIIIaIIb activation, leukocyte aggregation and microparticle formation. Upregulation of these platelet activation markers were also observed in vivo after stimulation with the classic superantigen, SEB. Interestingly, LCWE induced platelet activation is unaffected in the absence of TLR-2 signaling, evidenced in assays using TLR2 deficient mice and also with addition of TLR-2 blocking antibody pointing superantigenic and not TLR2 activity as the trigger of platelet activation.

Conclusions: Our results suggest that superantigenic stimulation with LCWE activates mouse platelets α-granular release, CD40L upregulation and integrin receptor gpIIIaIIb. Moreover, we show that TLR-2 signaling does not contribute to platelet activation. Establishing a role for platelets and CD40L in the pathogenesis of KD may have important implications in design of new therapeutic agents in KD.

Urinary Biomarkers To Distinguish Class IV vs Class V Lupus Nephritis. Hermine Brunner[1], Michael Bennett[2], Lindsey Romick-Rosendale[5], Michiko Suzuki[3], Shannen L. Nelson[2], Joshua Pendl[3], Adnan Kiani[4], Lena Das[3], Michelle Petri[4], Kenneth Greis[6], Pavel Shiyanov[7], Michael Kennedy[5] and Prasad Devarajan[3]. [1]Cincinnati Child Hosp Med Ctr, Cincinnati, OH, [2]Cincinnati Children's Med Ctr, Cincinnati, OH, [3]Cincinnati Children's Med Ctr, [4]John Hopkins Med Ctr, [5]Miami University, Oxford, [6]University of Cincinnati, [7]WPAFB, Dayton

Background: Up to 80% of children with systemic lupus erythematosus have lupus nephritis (LN). The ISN/RPS Morphologic Classification of LN reports on histological features that differentiate between various forms of LN, such as Diffuse Proliferative Class IV and Membranous Class V lesions. Kidney biopsies are the choice for diagnosis of LN, but are impractical to accurately assess the course of LN in clinical practice.

Objective: Discover non-invasive urinary biomarkers that can discriminate LN subtypes using proteomics, peptidomics and metabonomics.

Methods: We used 2-dimensional gel electrophoresis (2-DGE), NMR-based metabonomics, surface-enhanced laser desorption/ionization time of flight MS (SELDI), and iTRAQ liquid chromatography tandem mass spectrometry (LC MS/MS2) to investigate novel biomarkers that could distinguish Class IV vs. Class V LN. Urine samples from children with Class IV LN (n=6) and (pure) Class V LN (n=7) collected within 60 days of a kidney biopsy and those of controls with focal segmental glomerulosclerosis (n=4) were tested. Samples were normalized for total protein (2-DGE and LC-MS/MS2) or urine creatinine (NMR and SELDI).

Results: Using 2-DGE and MALDI-TOF-MS/MS, we found serum albumin fragments (25kDa) and alpha1-B glycoprotein (A1BG, 60kDa) significantly over-expressed in class IV vs. class V LN. Using SELDI, we identified Alpha-1 Antitrypsin (A1AT). This protein was significantly ($p < 0.01$; AUC 0.90) over-expressed in Class V vs Class IV LN and FSGS controls. Principal component analysis of NMR metabonomics spectra suggests decreased levels of citrate and increased levels of taurine in Class V when compared to Class IV patients, while iTRAQ -LC-MS/MS2 uncovered the most differences between the groups. Among proteins upregulated in Class V LN were apolipoprotein D, lipocalin-like prostaglandin D synthetase, inter-alpha-trypsin inhibitor heavy chain 4, Caspase 10, uromodulin and CD14. Those most upregulated in Class IV LN were vitamin D binding protein, ceruloplasmin, hemopexin, A1BG and orosomucoid. A1AT has been linked to SLE flares and hemopexin is associated with glomerular disease.

Conclusions: The discovery of non-invasive biomarkers that can distinguish LN subtypes would greatly aid in diagnosing and monitoring treatment in LN.

AC430, a Potent JAK2 Inhibitor, Provides Protection in Multiple Inflammatory and Autoimmune Disease Models. Barbara Belli[1], Daniel Brigham[2], Alan Dao[2], Ron Nepomuceno[2], Eduardo Setti[2], Gary Liu[2], Michael Hadd[2], Shripad Bhagwat[2], Wendell Wierenga[2], Mark W. Holladay[2] and Robert C. Armstrong[2]. [1]Ambit Biosciences, San Diego, CA, [2]Ambit Biosciences

Rheumatoid arthritis is a multi-factorial disease, and a sub-population of patients who are refractory to current therapy continues to exist. Recent clinical trials have demonstrated the safety and efficacy of small molecule inhibitors of the JAK kinase pathway in alleviating RA symptoms.

We have developed a potent JAK2 inhibitor, AC430, which demonstrates *in vitro* and *in vivo* activities comparable or superior to the activities of current clinical stage JAK inhibitors. In *in vitro* binding assays, AC430 binds potently to JAK2 and TYK2 with sub-nanomolar Kd values. In a TF-1 cell-based GM-CSF/JAK2/STAT5 driven transcriptional reporter system, AC430 inhibited reporter activity with an IC_{50} of 63 nM. BaF3 cell lines were generated that harbor an individual JAK family member gene fused to the activating TEL dimerization moiety. In these TELJAK cell lines AC430 inhibited JAK1, JAK2, JAK3 and TYK2 mediated STAT5 phosphorylation with IC_{50} values of 5500, 68, 7500 and 1300 nM, respectively. Each of the four TELJAK cell lines is leukemogenic following IV inoculation into SCID mice. The efficacy of AC430, and the clinical stage compound INCB18424, were tested in each leukemia disease model. Both compounds, when dosed at 60 mg/kg BID, demonstrated significant efficacy in the TELJAK2 driven model, providing an increase in life span (ILS) of 250% and 140% for AC430 and INCB18424, respectively. Marginal to no activity was observed in the other TELJAK driven leukemic models with either compound.

AC430 was tested in a classic delayed type hypersensitivity reaction model. Balb/C mice sensitized and challenged with ovalbumin in the ear pinna develop inflammation quantifiable by caliper measurement and increase in ear weight. AC430 dosed at 100 mg/kg QD led to a 60% reduction in inflammation. In an established mouse CIA model, therapeutic dosing of AC430 at 60 mg/kg BID led to a reduction in disease severity comparable to dexamethasone. AC430 was tested in two models of rat CIA. In the first model, therapeutic dosing initiated on day 1 of arthritis at 60 mg/kg QD or BID led to a significant reduction in disease severity comparable to the effect induced by dexamethasone, but with less toxicity than seen with dexamethasone. In the second model, therapeutic dosing initiated on day 3 of arthritis at 60 mg/kg BID led to a reduction of disease severity comparable to dexamethasone. In both models, clinical score correlated with histological score. In the standard disease model, 60 mg/kg BID resulted in no inflammation, cartilage damage, or pannus formation. AC430 was also tested in a mouse model of Experimental Autoimmune Encephalitis using a prophylactic dosing regimen. All doses greater than 5 mg/kg completed prevented the onset of disease, both clinically and histologically.

These data support the further development of AC430 as a treatment option for autoimmune or inflammatory disease.

Anti-CXCL5 Therapy Ameliorates IL-17 Induced Arthritis. Sarah R. Pickens[4], Michael V. Volin[1], Arthur M. Mandelin[2] and Shiva Shahrara[3]. [1]Midwestern University, [2]Northwester University, Chicago, IL, [3]Northwestern Univ Feinberg, Chicago, IL, [4]Northwestern University

Introduction: Since CXCL1 and 5 are important downstream targets of IL-17, experiments were performed to determine whether CXCL1 and/or CXCL5 play a role in arthritis mediated by local IL-17 expression in mice ankle joints.

Methods: Mice were treated intraperitoneally with IgG, anti-CXCL1, anti-CXCL5 or both anti-CXCL1 and anti-CXCL5 antibodies on days −4, −2, 0, 3, 5, 7 and 9 post-adenovirus (Ad) injection and arthritis was induced by injecting Ad-IL-17 intra-articularly on day 0. The disease activity was determined by measuring ankle circumference and performing histological studies. Since the expression of proinflammatory mediators is characteristic of joint inflammation, the effect of therapy on joint TNF-α, IL-6, IL-1β, CCL2, CCL3, CCL5, CCL20 and CXCL2 was examined by ELISA. Additionally, neutrophil infiltration was measured by staining ankles harvested from different treatment groups with an antibody for neutrophil marker GR1.

Results: The disease activity determined by articular index score and ankle circumference was significantly lower in mice receiving anti-CXCL1 on days 3 and 5 compared to the control group. However, as the arthritis progressed there was no difference noted at later time points (days 7 and 9). In contrast, mice receiving anti-CXCL5 demonstrated significantly reduced clinical signs of arthritis compared to the mice treated with IgG control. The combination of anti-CXCL1 and 5 did not ameliorate IL-17 induced joint inflammation beyond the effect observed using anti-CXCL5 alone. Hence, the clinical efficacy is due to neutralization of joint CXCL5. Consistently, while inflammation, synovial lining thickening, and bone erosion were markedly reduced in the anti-CXCL5 and anti-CXCL1+5 treatment groups, mice receiving anti-CXCL1 antibody had similar clinical scores compared to the control group. The effect of therapy on joint TNF-α, IL-6, IL-1β, CCL2, CCL3, CCL5, CCL20 and CXCL2 was examined. Our results demonstrate that mice receiving anti-CXCL5 or anti-CXCL1 and 5 had significantly lower levels of joint TNF-α and RANTES compared to the control group. Reduction in joint TNF-α levels in the anti-CXCL5 and combination therapy

may be due to the fact that IL-17 induced joint pathology is abrogated in TNF-$\alpha-/-$ mice indicating that in this model TNF-α is required, and therefore suppression in the inflammatory response modulates levels of this cytokine. Additionally, since both TNF-α and IL-17 synergize in inducing the expression of CXCL5 from RA ST fibroblasts, neutralization of CXCL5 may negatively regulate joint TNF-α concentration. GR1 staining demonstrated that the mice receiving anti-CXCL5 or anti-CXCL1 and 5 had significantly reduced neutrophil migration compared to anti-CXCL1 and IgG therapy.

Conclusion: Our results suggest that expression of CXCR2 ligand, CXCL5, and not CXCL1 plays an important role in IL-17 mediated arthritis potentially through modulating TNF-α levels.

Beneficial Effects of Systemic IFNβ Are Mediated by IL-1Ra: Implications for Rheumatoid Arthritis. Mary Corr[4], David L. Boyle[3], Lisa Ronacher[4], Brian R. Lew[4], Lisa G. M. van Baarsen[2], Paul P. Tak[1] and Gary S. Firestein[4]. [1]Academic Med Ctr/Univ of Amsterdam, Amsterdam, The Netherlands, [2]Academic Medical Center, Amsterdam, The Netherlands, [3]UCSD Schl of Medicine, La Jolla, CA, [4]UCSD School of Medicine, La Jolla, CA

Objectives: Systemic IFNβ treatment provides only minimal improvement in rheumatoid arthritis (RA), yet is effective in multiple sclerosis and murine models of arthritis. To explain this paradox, we evaluated the mechanism of IFN-β benefit in passive K/BxN arthritis and the effect of IFNβ treatment on RA synovium.

Methods: Il10 null, Il1rn (which encodes IL-1Ra) null, Il1rn transgenic and wild type mice were administered K/BxN serum and in some cases treated with mouse IFNβ (1000 IU/d) or vehicle. Clinical response and histologic scores were assessed. Gene expression was measured by quantitative PCR. Serum IL-1Ra and IL-6 were measured by ELISA. Pre- and post IFNβ treatment (purified natural fibroblast IFNβ (Frone) s.c. 3 times weekly 6 million IU, 12 million IU, or 18 million IU) synovial biopsy specimens from RA patients were immunostained for IL-1Ra and IL-10.

Results: Il1rn transgenic mice had an attenuated course of arthritis (area under the curve [AUC] for paw swelling=1.0 vs. 4.9 for wild type controls, $P<0.001$). In contrast Il1rn$-/-$ mice (AUC 11.6 vs. 5.7, $P<0.01$) and Il10$-/-$ mice (AUC 7.3 vs. 4.2 $P<0.05$) had more severe serum transfer arthritis than wild type mice. Daily IFNβ treatment in Il1rn$-/-$ mice with serum transfer arthritis had no benefit (AUC 11.6 vs. 13, NS), but significantly decreased clinical arthritis severity in Il10$-/-$ mice (AUC 7.3 vs. 4.4, $P<0.05$). IFNβ treatment also did not reduce the histologic scores in the Il1rn$-/-$ mice or gene expression of articular cytokines and chemokines. Paired synovial biopsy specimens from RA patients treated with IFN-β demonstrated increased IL-1Ra expression ($P=0.05$) and reduced IL-10 expression ($P=0.04$) on Day 85 levels compared with pretreatment specimens.

Conclusions: The anti-inflammatory effects of IFNβ in passive K/BxN arthritis are dependent on IL-1Ra and are mediated by increased IL-1Ra production in this model. However, the benefit of IFNβ is not dependent on IL-10. IFNβ treatment in RA also increases synovial IL-1Ra. Passive K/BxN arthritis is IL-1 dependent, whereas IL-1-directed therapy in RA is only modestly effective. The lack of benefit for systemic IFNβ therapy in RA compared with mouse models is likely in part due the fact that IL-1 inhibition has only modest effect in RA.

Combined Depletion of Interleukin-1 and Interleukin-6 Does Not Exceed Single Depletion of Interleukin-1 in TNF-Mediated Arthritis. Silvia Hayer, Birgit Niederreiter, Josef Smolen and Kurt Redlich. Medical University of Vienna, Department of Internal Medicine III, Division of Rheumatology, Vienna, Austria

Background: Previous studies demonstrated a regulatory role of interleukin 1 (IL-1) in inflammatory cartilage damage and bone destruction in human tumor necrosis factor transgenic (hTNFtg) mice, an animal model for Rheumatoid Arthritis (RA). Moreover, blocking of IL-6 has been shown to reduce local bone erosions in this model. Therefore we wanted to investigate the effect of a combined depletion of IL-1 and IL-6 on the development and severity of inflammatory, erosive arthritis.

Methods: We first crossed IL1α and β deficient (IL1$^{-/-}$) mice with IL6$^{-/-}$ mice to generate IL1$^{-/-}$IL6$^{-/-}$ double knockout mice. We next intercrossed these animals with arthritogenic hTNFtg mice to receive IL1$^{-/-}$IL6$^{-/-}$hTNFtg mice. We weekly assessed clinical signs of arthritis in hTNFtg, IL1$^{-/-}$hTNFtg mice, IL6$^{-/-}$hTNFtg mice and IL1$^{-/-}$IL6$^{-/-}$hTNFtg mice starting from week 4 after birth until week 16. We stained decalcified paw sections from all 4 genotypes with hematoxylin&eosin to determine the amount of inflammatory synovial pannus formation, with tartrate-resistant acid phosphatase (TRAP) to evaluate the number of synovial osteoclasts and the occurrence of subchondral bone erosions, with toluidine-blue to assess articular cartilage damage. Quantitative analysis of histopathological changes were performed using the Osteomeasure Software System.

Results: We found a significant reduction in the clinical signs of arthritis, indicated by an increase of paw swelling and a decrease in grip strength, in IL1$^{-/-}$IL6$^{-/-}$hTNFtg mice when compared to their hTNFtg littermates. In line with these findings we observed a significant decrease in synovial inflammation in IL1$^{-/-}$IL6$^{-/-}$hTNFtg mice when compared to hTNFtg animals. Moreover, the number of synovial TRAP+ osteoclasts was markedly diminished in IL1$^{-/-}$IL6$^{-/-}$hTNFtg mice and reduced osteoclast formation, was accompanied by significantly less subchondral bone erosions. Additionally, we found a conserved articular cartilage structure showing almost no cartilage degradation in IL1$^{-/-}$IL6$^{-/-}$hTNFtg mice compared to their hTNFtg littermates. In IL1$^{-/-}$IL6$^{-/-}$hTNFtg mice clinical, as well as, histological signs of disease, including joint inflammation, bone destruction and cartilage damage were also significantly diminished when compared to IL6$^{-/-}$hTNFtg mice. However, by comparing IL1$^{-/-}$IL6$^{-/-}$hTNFtg mice with IL1$^{-/-}$ hTNFtg mice we found a similar reduction on synovial inflammation, as well as subchondral bone erosions and articular cartilage destruction.

Conclusion: The phenotype of IL1$^{-/-}$IL6$^{-/-}$hTNFtg mice does not differ from IL1$^{-/-}$hTNFtg animals indicating no synergistic effects when IL-1 and IL-6 is simultaneously blocked in TNF-mediated arthritis.

Efficacy of the Selective CSF1R (Fms) Inhibitor PLX5622 in Mouse Models of Rheumatoid Arthritis. Gaston Habets, Jiazhong Zhang, Betsy Burton, Chao Zhang, Prabha Ibrahim, Bernice Wong, Marika Nespi, Wayne Spevak, Ben Powell, Brian West, Paul Lin, Gideon Bollag and Peter Hirth. Plexxikon

Purpose: PLX5622 is a potent inhibitor of the Fms receptor tyrosine kinase activity (K_I = 5.9 nM) with at least 50-fold selectivity over 4 related kinases, and over 100-fold selectivity against a panel of 230 kinases. Fms is the receptor for CSF1 and a key regulator of macrophages, dendritic cells, and osteoclasts. The target cells of this receptor control autoimmune processes involved in many diseases, including rheumatoid arthritis (RA). Therefore, PLX5622 is a valuable compound to test the role of Fms target cells in autoimmune diseases.

Methods and Results: In cell based assays PLX5622 is a potent and selective inhibitor of Fms dependent processes. CSF1 stimulated autophosphorylation of Fms is inhibited in THP1 cells (IC50 20 nM) and CSF1 + RANKL dependent differentiation of human osteoclasts is also inhibited *in vitro* (IC50 52 nM). The attractive pharmaceutical properties of PLX5622 allow once a day oral dosing. Based on these data, the efficacy of PLX5622 was examined in an aggressive, collagen-induced arthritis model of RA. DBA/1 mice were immunized with bovine collagen II in CFA on day 0 and given a collagen boost ip on day 21. By day 19, disease had progressed to a mean paw inflammation score of 2.4 (out of 16), and PLX5622 daily oral dosing was initiated. Within the first week all treatment groups (10, 20 and 50 mg/kg qd po) of PLX5622 experienced significant suppression of disease that continued through the course of treatment. Following three weeks of treatment, the mean disease score of the PLX5622-treated animals was 6.9, 5.5 and 5.0 for the 10, 20 and 50 mg/kg dose groups, respectively, while progressive disease in the vehicle-treated animals reached a mean score of 12.9. The histopathological disease scores for inflammation, pannus formation, cartilage damage and bone resorption in the wrist, paw, and ankle joints

were all significantly lower in the PLX5622 treated animals compared to vehicle-treated animals. The counts of the direct target cell population of macrophages, osteoclasts, and T-cells were lower in the joints of the PLX5622 treatment group. The benefit on joint function of these clinical, histopathological and cellular readouts was also reflected in an increased range of motion in the knee joint of PLX5622 treated animals, compared to the vehicle controls.

Conclusion: Inhibition of Fms kinase activity by the potent and highly selective inhibitor PLX5622 results in substantial efficacy in an aggressive model of RA and warrants further development in clinical studies.

274

HMPL-011, a Small Molecule Compound, Modulates Pro-Inflammatory Cytokine Production, in Part, Via Potentiating IL-10 Production. Weihua Gu[2], Weigang He[2], Yan Qiu[2], Zhenhao Zhou[2], Xiaomin Dai[2], Wuzhong Shen[2], Xiaoning Yang[2], Linfang Wang[2], Yuan Zhou[2], Yu Cai[2], Edwin Lee[2], Wei Deng[2], Weiguo Su[1] and Haoran Zhao[1]. [1]Hutchison MediPharma Ltd, Shanghai, China, [2]Hutchison MediPharma Ltd

Purpose: HMPL-011, a small molecular compound, was shown to be effective in reducing clinical arthritis score and joint swelling in collagen induced arthritis (CIA) in mouse (ACR 2010 Abstract). An inhibition on pro-inflammatory cytokines, such as IL-1β, MCP-1 and IL-6, and an increase in anti-inflammatory cytokine IL-10 was found in the arthritic joints. In this study, the mechanism of action of HMPL-011 was investigated.

Methods: Cytokine mRNA was analyzed by RT-PCR and protein by ELISA or CBA (Cytometric Bead Array). Phosphorylated MKK3/6 and p38 in RAW264.7 was analyzed by WB. For LPS induced inflammation in vivo, female Balb/C mouse was p.o. treated with HMPL-011 followed by LPS stimulation 30 minutes post HMPL-011 administration. Protein and mRNA levels were assessed 2hr and 8hr after LPS dosing. In IL-10 neutralization assay, IL-10 neutralizing antibody (JES5-2A5) was dosed i.v. and concurrently p.o. treated with HMPL-011 for 30min, followed by LPS treatment. Plasma cytokines were analyzed as indicated above.

Results: HMPL-011 was screened at 10 μM against 48 inflammation related targets, include cytokine release, cytokine, chemokine and glucocorticoid receptor binding, caspases, MMPs, phosphatase and kinase activity, T, B cell proliferation, and NF-κB, NF-AT transcription activity. No significant activity of HMPL-011 was identified, except for the inhibition of IL-1β and IFNγ release (IC50=11.0 μM and 9.7 μM, respectively). Furthermore, in a screen against 60 enzymes consisting of receptor tyrosine kinases and other inflammation- related kinases at 10 μM, no significant inhibition was observed. T, B cell activation, macrophage phagocytosis, NK cell cytotoxicity was also not affected by HMPL-011. However, IL-10 expression was found to be elevated by HMPL-011 in LPS stimulated mouse macrophage cells, RAW264.7, and this induction was shown to be inhibited by the p38 inhibitor, SB203580. Moreover, LPS induced MKK3/6 and p38α phosphorylation was shown to be enhanced by HMPL-011 in RAW264.7. In LPS treated mouse, HMPL-011 increased IL-10 at 2hr post LPS treatment, followed by a significant, potent inhibition on IL-6, MCP-1 and IFNγ at 8hr post LPS treatment. In IL-10 neutralized mouse, HMPL-011 anti-inflammatory effect was found to be partially reversed, indicating the anti-inflammatory effect of HMPL-011 is only partially mediated by IL-10.

Conclusion: HMPL-011's anti-inflammatory effect was mediated at least in part through enhancement of IL-10. HMPL-011 may represent a novel class of small molecular drug in arthritis treatment.

IL-1 Driven IL-22 Expression by TH17 Cells Aggravates Experimental Arthritis. Renoud J. Marijnissen[3], Marije I. Koenders[3], Mark H. T. Stappers[4], Leo A. B. Joosten[1], Ruben L. Smeets[2], Cheryl Nickerson-Nutter[5], Annemieke M. H. Boots[2] and Wim B. van den Berg[3]. [1]Department of Internal Medicine, RUNMC, Nijmegen, The Netherlands, [2]Department of Pharmacology, MSD, Oss, The Netherlands, [3]Department of Rheumatology, RUNMC, Nijmegen, The Netherlands, [4]Department of Rheumatology, RUNMC, The Netherlands, [5]Inflammation, Pfizer, Cambridge, MA

Purpose: Our previous studies in IL-1Ra-deficient mice and various other arthritis models have shown an important role for IL-17, not only in the initiation, but also the further progression of experimental arthritis. Although recent papers demonstrate that also mast cells and neutrophils can produce this proinflammatory cytokine, activated CD4+ T cells are considered as the main source of IL-17.

Recently, these IL-17 producing T helper cells (Th17) have been shown to produce other inflammatory cytokines like IL-21 and IL-22 which might contribute to the disease severity as well. In this study, we investigated how the expression of IL-22 is regulated during the induction of TH17 cells from naïve T cells. Furthermore, the therapeutic effects of blocking IL-22 in IL-1Ra-deficient mice, a spontaneous IL-1-driven experimental arthritis model, was investigated.

Methods: For our in vitro experiments, naive murine T cells were cultured under Th17 polarizing conditions using TGFβ, IL-6 and anti-IL-2. During different stages of the differentiation, IL-1 and IL-23 were supplied to influence the IL-17 and IL-22 production. Beadplex technology was used to measure cytokines in the supernatants, and the cells were analyzed for intracellular cytokine production by flowcytometry. From the inflamed ankles of the IL-1Ra-deficient mice, the synovia were isolated and mRNA expression of IL-22 and its receptor were quantified using QPCR. Finally, IL-1Ra-deficient mice were treated after clinical onset of arthritis with neutralizing anti-IL-22 antibodies and isotype controls for four weeks.

Results: Our in vitro Th17 culture experiments demonstrated that differentiated naïve CD4+ T cells could only produce high levels of IL-22 in the presence of IL-1. Accordingly, addition of IL-23 to the culture significantly increased this IL-22 induction. However, following restimulation of the differentiated T cells, IL-1 alone lost its effect on the IL-22 production, while IL-23 alone was sufficient to maintain the IL-22 production.

In addition, the expression of Th17 effector genes was investigated in our arthritis models, and IL-17, IL-22 and IL-22R mRNA levels were found to be significantly and specifically upregulated in the synovium of IL-1ra−/− mice with established arthritis. Moreover, IL-17 and IL-22 protein production by the draining lymph node cells was detected only after anti-CD3/anti-CD28 challenge. Most importantly, anti-IL-22 treatment significantly reduced bone erosion, suggesting an important role of IL-22 in IL-1-driven joint destruction.

Conclusions: Our combined data suggest that not only the IL-1 – IL-17 axis, but also the IL-1 – IL-22 axis plays an important role in experimental arthritis.

IL-27 Is Increased by IL-17 from Synovial Macrophage and Bone Marrow-Derived Dendritic Cells in Collagen-Induced Arthritis. Seunghoon Baek[5], Juin Kim[4], Huashu Jin[4], Seonghu Park[5], Youngeun Park[5], Joungwook Lee[1], MIRA Cho[6], Geuntae Kim[3], Junhee Lee[2] and Sungil Kim[5]. [1]Busan St Mary Hospital, Korea, Republic of, [2]Choonhae Hospital, Korea, Republic of, [3]Kosin University Medical School, Korea, Republic of, [4]Pusan National University Hospital Research Institutes, Korea, Republic of, [5]Pusan National University Medical School, Korea, Republic of, [6]Pusan National University Medical Shool, Korea, Republic of

Background: IL-17 plays important roles in synovial inflammation and bone destruction in CIA. IL-27, produced by activated macrophages and dendritic cells, stimulates Th1 cell-mediated immune response and suppress Th17 cell-mediated immune response. Therefore, IL-27 aggravates inflammation in predominant Th1 immune-mediated disease such as proteoglycan-induced arthritis, and suppress inflammation in predominant Th17 immune-mediated disease such as Experimental Autoimmune Encephalomyelitis, Experimental Autoimmune Uveitis and CIA.

Objectives: To investigate IL-27 expression during CIA, and the effect of IL-17 on IL-27 expression in CIA.

Methods: CIA was induced by type II collagen in DBA1 mice. During CIA, mice were sacrificed at day 0, 28, 35, 39, 47, 56, 63 and 68, and knee joint synovial IL-27 expressions were measured by real-time RT-PCR and western blot. In CIA, phosphate-buffered saline (PBS group) or IL-17 (IL-17 group) was injected into knee joints at day 28 and 32, sacrificed at day 35, and synovial IL-27 expressions were determined by real-time RT-PCR, western blot, and immunohistochemistry. Bone marrow-derived dendritic cells (BMDCs), isolated from femur of CIA mice at day 35, were cultured with IL-17, and IL-27 expressions were determined by ELISA.

Results: Knee joint synovial IL-27 expressions were gradually increased during CIA (fig 1). Synovial IL-27 expressions of IL-17 group were significantly high compared to PBS group (fig 2 and 3), and synovial anti-IL-27p28 antibody positive cells were double-stained with anti-CD68 antibody (fig 3). IL-27 expressions of BMDCs were significantly increased by IL-17 (fig 4).

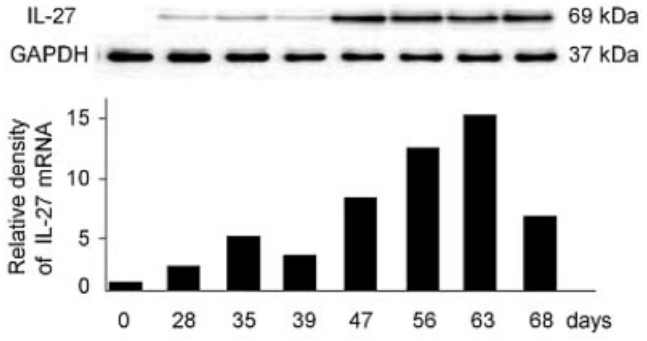

Figure 1. IL-27 expressions were gradually increased during CIA determined by western blot and real-time RT-PCR.

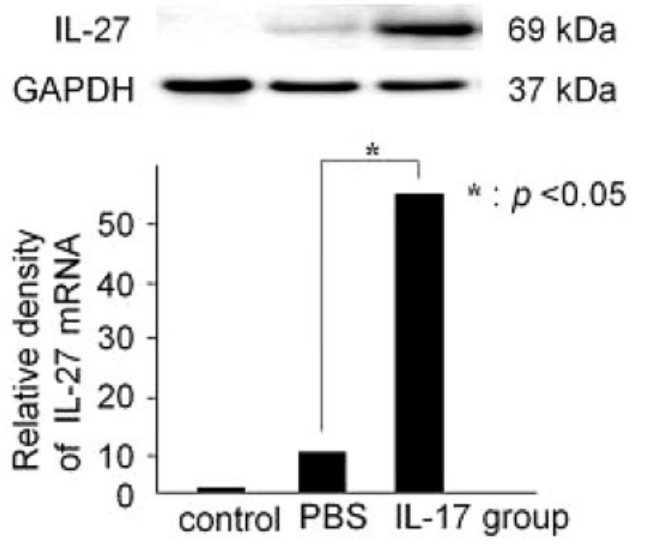

Figure 2. IL-27 expression of IL-17 group was significantly high compared to PBS group determined by western blot and real-time RT-PCR.

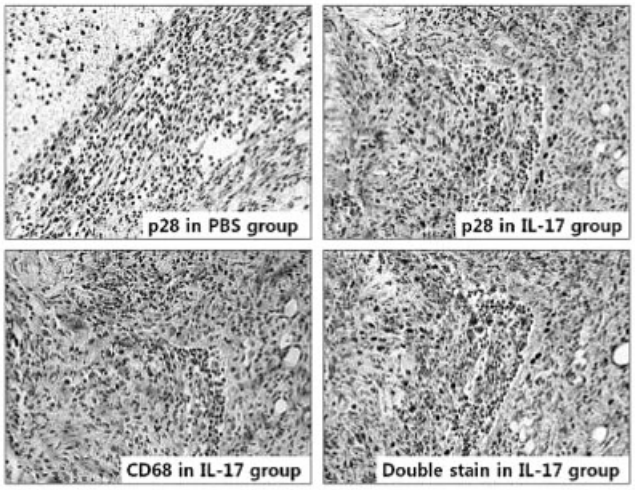

Figure 3. Synovial anti-IL27p28 antibody positive cells were increased in IL-17 group compared to PBS, and double stained with anti-CD68 antibody.

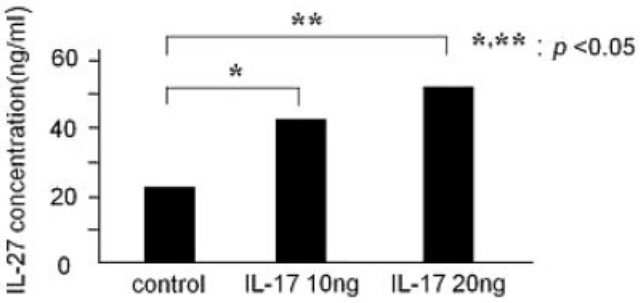

Figure 4. IL-27 expressions were increased by IL-17 in cultured BMDCs of CIA mice determined by ELISA.

Conclusions: Synovial IL-27 expression was gradually increased during CIA. IL-17 increased IL-27 expressions of synovial macrophages and BMDCs in CIA. These results suggest that IL-17 induced increase of IL-27 expressions from synovial macrophages and BMDCs might be involved in immunopathogenesis of CIA, and IL-17/IL-27 networks may play role as an autoregulatory mechanism.

IL-32 Aggravated Synovial Inflammation and Bone Destruction, and Increased Synovial NK Cells in Experimental Arthritis Models.

Geun-Tae Kim[2], Ju-In Kim[4], Hua-Shu Jin[4], Seong-Hu Park[3], Young-Eun Park[3], Seung-Hoon Baek[3], Joung-Wook Lee[1] and Sung-Il Kim[3] [1]Department of Internal Medicine, Busan St. Mary's Medical Center, [2]Department of Internal Medicine, Kosin University, College of Medicine, Busan, Korea, Republic of, [3]Department of Internal Medicine, Pusan National University, School of Medicine, [4]Research Institute, Pusan National University

Purpose: IL-32 is a novel cytokine that is formally known as natural killer cell transcript 4, and appears to play a role in inflammatory processes and diseases including rheumatoid arthritis. NK cells are known as a regulator in infection, tumor and autoimmunity. But the underlying relationship between them and their effects on inflammatory diseases remain largely unclear. Here, we investigated in mouse model of collagen-induced arthritis (CIA), the role of IL-32 in inflammatory process and the effect of IL-32 on NK cells.

Methods: CIA was induced by type II collagen in DBA1 mice, and PBS (PBS group) or IL-32 (IL-32 group) were injected into both knee joints at day 28 and 32, then mice were sacrificed at day 35. Severity of knee joint arthritis was scored by macroscopy, and synovial inflammation and bone erosion were determined by histology. Synovial expressions of proinflammatory cytokines (IL-1β, TNF-α, IL-17, IL-18, IL-21, IL-23, IFN-γ), chemokines (CCL2, CCL3, CC5, and CCL9), chemokine receptors (CCR2, CCR5, CXCR3, and CX3CR1), were measured by real-time RT-PCR and western blot. Expression

of NK cells was determined by real-time RT-PCR, western blot, and immunohistochemistry using NKp46, a surface marker of NK cell.

Results: Scores of knee arthritis, synovial inflammation and bone erosion were significantly high in IL-32 group compared to PBS group. Synovial expression of proinflammatory cytokines (IL-1β, TNF-α, IFN-γ and IL-18), chemokines (CCL2 and CXCL9) and chemokine receptors (CCR2 and CCR5) that are associated with NK cells migration were significantly increased in IL-32 group compared to PBS group ($p<0.05$). Expression of synovial NK cells, comfirmed by real-time RT-PCR, western blot, and immunohistochemisty, were significant increased in IL-32 group compared to PBS group.

Conclusion: IL-32 increased synovial expressions of proinflammatory cytokines, and aggravated synovial inflammation and bone destruction. IL-32 also increased synovial NK cells and expressions of chemokines and chemokine receptor that are associated with NK cells migration. These results suggest that IL-32 induced increase of synovial NK cells might play roles in IL-32 induced aggravation of synovial inflammation and bone destruction in CIA.

IL-7 Correlates with Severity of Proteoglycan-Induced Arthritis, and Arthritis Severity Is Diminished by IL-7 Neutralization. Sarita A. Y. Hartgring[3], Cynthia R. Willis[1], Kim M. G. van der Wurff-Jacobs[3], Femke Broere[2], Johannes W. J. Bijlsma[3], Floris P. J. G. Lafeber[3] and Joel A. G. van Roon[3]. [1]Inflammation Dept. Amgen Inc, Seattle WA, [2]Inst. Infectious Diseases & Immunology, UU, Utrecht, The Netherlands, [3]Rheumatology & Clinical Immunology, University Medical Center Utrecht, The Netherlands

Background: Serum levels of IL-7 are increased in arthritic individuals, including patients with rheumatoid arthritis (RA) compared to healthy controls and serum IL-7 levels correlate with markers of disease activity. IL-7 effects are mediated by heterodimers of the high affinity IL-7 receptor-α chain (IL-7Rα) and the common gamma (γc) chain. IL-7 can activate IL-7Rα^{bright} arthritogenic T cells, overriding suppressive effects of IL-7R$\alpha^{dim/-}$ T cells. CD4 T-cell activation achieved by IL-7Rα-mediated immune activation can be inhibited by soluble huIL-7Rα. IL-7 induces T cell-dependent activation of monocytes, B cells, and osteoclasts. Previously we have shown that administration of IL-7 or TSLP enhanced severity of inflammation and joint destruction in collagen induced arthritis. In this study we analyzed IL-7 expression in experimental proteoglycan-induced arthritis (PGIA). Furthermore, we assessed the effects of IL-7 neutralization on arthritis and inflammatory activity in PGIA.

Methods: Levels of IL-7 were assessed in serum and paw protein lysates of arthritic mice. Splenocytes were cultured in presence of IL-7, PG, or a combination of PG and an anti-IL-7 neutralizing antibody. PGIA was initiated by immunizing aged female BALB/c mice with human proteoglycan (day 0 and 21). Mice were given 200 or 500 μg anti-IL-7 antibody, and PBS or isotype antibody as a control treatment in a prophylactic manner (on day -2, 3, 10, 19, and 24). Clinical arthritis severity was determined by visual examination of the paws. Total cellularity of thymus and spleen, and numbers of T-cell subsets were assessed.

Results: Increased IL-7 concentrations were found in serum of arthritic mice ($p<0.05$) compared to mice that were naive or mice that did not develop arthritis. Moreover, levels or IL-7 in pawlysates correlated with arthritis severity. Blockade of IL-7 significantly reduced PG-induced proliferation of splenocytes (mean inhibition of 70 $\pm$ 8%, $p=0.015$). Most importantly, the low dose of anti-IL-7 mAb (200μg) was more effective than the 500μg dose in reducing arthritis severity and resulted in a mean arthritis inhibition of 37 $\pm$ 5% (mean of day 28–52) as compared to the control-treated mice ($p<0.05$ on day 28, 33, and 35). Treatment with 500μg anti-IL-7 reduced arthritis as compared with control mice with a mean arthritis inhibition of 24 $\pm$ 4 % (mean inhibition day 28–52) although not statistically significant. Total numbers of thymus or spleen, and thymic subsets or splenic subsets were not significantly affected by either dosage of anti-IL-7.

Conclusion: This study for the first time shows that IL-7 is increased in serum and joints of arthritic mice, and that local IL-7 levels correlate with disease severity. *In vitro*, splenocytes from arthritic mice were activated by IL-7 and PG, and PG-induced proliferation of these splenocytes was inhibited by IL-7 neutralization. Blocking IL-7 in PGIA diminished clinical arthritis severity. Together this study demonstrates an important role of IL-7-driven immunity in proteoglycan-induced arthritis in mice and suggests a therapeutic potential of IL-7 neutralization in RA.

Immunomodulatory Properties of Novel CRAC Channel Inhibitors Exhibit Promising Potential in Rheumatoid Arthritis. Kanthikiran V. S. Varanasi, Meyyappan Muthuppalaniappan, Gayatriswaroop Merikapudi, Sridhar Veeraraghavan, Kasi V. Routhu, Srikant Viswanadha and Swaroop Vakkalanka. Incozen Therapeutics Pvt. Ltd.

Background: Calcium release activated calcium channels are the major pathway for calcium influx in developing and mature T- cells and contribute to several aspects of lymphocyte development and function. CRAC channel inhibitors have potent role in treatment of autoimmune disorders, asthma and rheumatoid arthritis. Herein, we describe the immunomodulatory properties of a series of novel and potent CRAC channel inhibitors with scope to be further developed as clinical candidates for rheumatoid arthritis.

Methods: Reductions in pro-inflammatory cytokines such as IL-2, TNFα, and IFNγ in Human Whole Blood and freshly isolated PBMC were estimated by ELISA. *In vivo* efficacy of the compounds in mice and rats was determined in an experimental model of rheumatoid arthritis. Briefly, DBA/1 mice were treated with the test compounds (10mg/kg/po/qd) from day 1 to day 35 and clinical arthritis scores were recorded. In a similar experiment male wistar rats were treated with compounds (10mg/kg/po/qd) for 28 days and paw volumes were measured.

Results: Among the compounds evaluated, RP3120 and 3163 demonstrated marked potency against IL-2 (<100 nM), TNFα (<300 nM), and IFNγ (<100 nM) in both HWB and PBMC. Animals treated with RP3120 displayed much slower onset of CIA and significantly lowered the severity (64% in mice and 46% in rats compared to vehicle control, $P < 0.05$) and much lower incidence (50% in mice and 40% in rats) of arthritis with no effect on body weight. Histopathology analysis revealed reduced cartilage and joint destruction following treatment with compound ($P < 0.005$) in both rat and mice.

Conclusion: Results demonstrate the immense potential of our compounds as immunomodulatory and anti-inflammatory agents as evidenced by cytokine reductions obtained *in vitro*. Delay in arthritic onset and progression upon administration of our compounds indicate their effectiveness as disease modifying anti-rheumatic drugs. Further *in vivo* and *in vitro* studies are in progress to evaluate the efficacy of the compound in other immune- disorders prior to the initiation of clinical trials.

Inhibition of c-Fos/AP-1 Suppresses Passive Anti-Collagen Antibody-Induced Arthritis in Mice. Masaaki Mikami[4], Yukihiko Aikawa[5], Akira Hashiramoto[3], Mari Yamamoto[5], Hidetoshi Murao[5], Hisaaki Chaki[5], Hirokazu Narita[5], Shuichi Hirono[1] and Shunichi Shiozawa[2]. [1]Department of Pharmaceutical Sciences, School of Pharmacy, Kitasato University, Tokyo, Japan, [2]Division of Rheumatology, Kobe University Graduate School of Health Sciences and Medicine/ The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan, [3]Division of Rheumatology, Kobe University Graduate School of Health Sciences and Medicine/ The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan, [4]Research Laboratories, Toyama Chemical Co., Ltd., Toyama, Japan, [5]Research Laboratories, Toyama Chemical Co., Ltd., Toyama, Japan

Purpose: Activator protein-1 (AP-1) directly regulates the genes that participate in rheumatoid arthritis (RA), including inflammatory cytokines and matrix metalloproteinases (MMPs). Anti-collagen antibody (Ab)-induced arthritis (CAIA) in mice is beneficial to study the inflammatory phase of arthritis without involving the priming phase of the immune response. Therefore, to elucidate the involvement of c-Fos/AP-1 in the development of arthritis, the levels of c-Fos/AP-1 in the hind paws were determined, and the effect of a novel c-Fos/AP-1 inhibitor T-5224 on CAIA was investigated.

Methods: CAIA was induced in BALB/c mice by *i.p.* injection of the mixture of anti-type II collagen (CII) Abs on day 0 and LPS on day 3. The levels of c-Fos/AP-1 in extracts from hind paws were determined using TransAM™ kit on day 0, 3, 4, 7, and 15. T-5224 was orally administered once daily. The effect was assessed by arthritis score, pathological examination, and serum biological analysis of IL-1β and MMP-3. Furthermore, effects of methotrexate (MTX) and leflunomide were also evaluated in the same procedure for the comparison.

Results: c-Fos/AP-1 activity increased in the hind paws of mice after day

4 in coincidence with onset of the arthritis. The administration of T-5224 from day 5 efficiently suppressed the development of arthritis at 1 to 30 mg/kg, and the arthritis score on day 14 was inhibited by 81% at 30 mg/kg (ED_{50}: 6.0 mg/kg). Histological changes such as cartilage degradation in the joints of hind paws of mice with T-5224 were also suppressed on day 14. In addition, the increases of IL-1β and MMP-3 levels in sera were reduced by T-5224, and the inhibition rates at 30 mg/kg were 97% and 89%, respectively. On the other hand, either MTX at 3 mg/kg or leflunomide at 30 mg/kg had no effects on passive CAIA.

Conclusions: The activation of c-Fos/AP-1 was observed in the arthritic lesion of mouse CAIA in which the priming phase of the immune response is skipped. Inhibition of c-Fos/AP-1 by T-5224 attenuated the arthritis through suppressing the inflammatory cytokine and matrix degrading MMP. On the other hand, immunosuppressive treatment with MTX and leflunomide did not show the inhibitory effects on CAIA. These data support a key role of c-Fos/AP-1 in the development of arthritis and joint destruction, and suggest that T-5224 with the novel mechanism of action is expected to exert anti-arthritic effects in the therapy of RA.

Innovative Treatment of Experimental Arthritis and Inhibition of Human Osteoclasts Differentiation by Dendrimers. Myriam Hayder[2], Mary Poupot[1], Jean-Pierre Majoral[4], Cédric Olivier Turrin[4], Anne-Marie Caminade[4], Alain Cantagrel[3], Jean-Jacques Fournié[1], Rémy Poupot[1] and Jean-Luc Davignon[3]. [1]INSERM U563, CPTP, IFR150, Toulouse, France, [2]JE2510, IFR150, Paul Sabatier University, Toulouse, France, [3]JE2510, IFR150, Paul Sabatier University, University Hospital Purpan, Toulouse, France, [4]Laboratoire de Chimie de Coordination, CNRS, Toulouse, France

Background: Current treatments of RA depend largely on biotherapies based on monoclonal antibodies directed against pro-inflammatory cytokines. The development of new drugs is needed in order to obtain sustained clinical remission and target multiple factors involved in the pathogenesis and / or inflammation in RA.

Phosphorus-containing dendrimers harbor activating properties towards the human immune system. Among these dendrimers, a particular one, capped with azabisphosphonate groups, activates human monocytes in an anti-inflammatory and immuno-suppressive pathway. These biological properties rely in part on the multivalency of this category of molecules.

Objectives: The goals of this study were:

To use dendrimers to test for their inhibition of osteoclast (OC) differentiation from human monocytes in vitro.

To assess the anti-inflammatory properties of dendrimers in IL-1 ra−/− mice which develop spontaneous arthritis.

To investigate the mechanism of action of dendrimers on the inhibition of inflammation and osteoclastogenesis.

Methods: Dendrimers were synthesized from a core which is derivatized by branches and finally capped with surface groups.

Purified monocytes were differentiated into osteoclasts in the presence of M-CSF and RANKL. OCs were identified using a TRAP assay. Bone resorption was measured in a CTX assay.

IL-1 ra −/− mice which spontaneously develop arthritis were injected intravenously weekly with dendrimers (1mg/kg and 10 mg/kg). Paw swelling was measured and clinical score evaluated. Joint tissues were examined for histopathology. Pro-inflammatory cytokines were quantified in sera by Elisa.

Results: Dendrimers inhibited in a dose dependent manner the in vitro differentiation of human monocytes into OCs and inhibited bone resorption. In vivo, weekly injections of dendrimers in IL-1ra −/− mice, starting at the age of 8 weeks, stopped the development of arthritis and reversed paw swelling, clinical scores and bone erosion. Pro-inflammatory cytokines (IL-1, IL- 6, IL-17, TNF-a) were significantly diminished and returned to normal levels after 8 weeks of treatment while IL-4 and IL-10 were increased.

M-CSF inhibition was identified as a mechanism of inhibition of inflammation and bone erosion.

Conclusion: Our data describe the properties of a novel molecule capable of both anti-inflammatory and anti-OCs activities with great potential in the treatment of RA and other inflammatory diseases.

IRF-1 Reduces TNFα-Induced-IL-18 Bioactivity in Rheumatoid Arthritis Synovial Fibroblasts by Induction of IL-18BPa. Hubert Marotte[1], Adam J. Pinney[2], Tatiana Fedorora[2], Nalin Lalwani[2], Pei-Suen Tsou[2], Bradley J. Rabquer[2] and Alisa E. Koch[3]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Michigan Medical School, [3]Veteran's Administration and University of Michigan

Purpose: The development of alternative therapies remains critical, as one quarter of all rheumatoid arthritis patients fail to respond to current biologic therapies. Interleukin (IL)-18 is an important cytokine in RA, because it induces T helper-1 immune response as well as angiogenesis. IL-18 bioactivity is regulated by its natural inhibitor IL-18 binding protein (IL-18BPa). Interferon regulatory factor-1 (IRF-1) was originally identified as a transcriptional activator of interferon-gamma. We have previously shown that TNF-α induces IL-18 and IL-18BPa in RA synovial fibroblasts. Others have shown that IRF-1 binds to the IL-18BP promoter. Here, we investigate the role of IRF-1 on IL-18BPa expression and IL-18 bioactivity in RA synovial fibroblasts.

Methods: IRF-1 synthesis in RA synovial fibroblasts treated with TNF-α was assessed by qRT-PCR and Western blot. Then, the effect of TNF-α on IRF-1 nuclear translocation in a time dependent manner (2 hr, 4 hr, and 8 hr) was examined using nuclear extracts and Western blots. The critical pathways for TNF-α-induced IRF-1 expression and nuclear translocation were determined by using chemical inhibitors: pyrrolidine dithiocarbamate (PDTC; a nuclear factor kappa-light-chain-enhancer of activated B cells [NFκB] inhibitor; 200μM) or MAPK inhibitors (ERK1/2, PD98059; p38, SB202190; or JNK2, SP600125; 10μM) followed by TNF-α stimulation. IRF-1 antisense or sense oligodeoxynucleotides (ODNs) were used to knockdown IRF-1 in RA synovial fibroblasts. Fibroblasts were then stimulated with TNF-α and examined for IL-18BPa expression by qRT-PCR, Western blot and IL-18 bioactivity assay. IL-18 bioactivity was determined using KG-1 cells.

Results: TNF-α induced RA synovial fibroblast IRF-1 expression at the mRNA and protein levels with a maximal effect at 2 hours ($P < 0.05$; $n \geq 3$ patients). Furthermore, TNF-α induced nuclear translocation of IRF-1 with maximal translocation at 2 hours (~6 fold-induction; $P < 0.05$; $n = 4$). This effect persisted for 8 hours (~6 fold-induction; $P < 0.05$). However, blocking NFκB or JNK2 pathways reduced TNF-α-induced-IRF-1 nuclear translocation by approximately 35% and 50%, respectively ($P < 0.05$; $n \geq 4$). Blocking ERK1/2 or p38 pathways had no effect on TNF-α-induced-IRF-1 nuclear translocation. Finally, using ODN to knockdown IRF-1, we observed a reduction of IL-18BPa expression by qRT-PCR and ELISA. IL-18 bioactivity was higher in the case of knockdown of IRF-1 than in its presence.

Conclusions: These results show that IRF-1 is a key regulator of IL-18BPa expression in RA synovial fibroblasts and can thus regulate IL-18 bioactivity. Hence strategies to augment IRF-1 activity may be beneficial in RA.

Liposomal Targeting of Glucocorticoids to the Synovial Lining during Experimental Arthritis Inhibits M1 Macrophage Activation in Favour of M2 Differentiation. Wouter Hofkens[2], Gert Storm[3], Wim B. Van Den Berg[1] and Peter van Lent[2]. [1]Radboud Univ Nijmegen Med Cntr, Nijmegen, The Netherlands, [2]Radboud University Nijmegen Medical Center, [3]Utrecht University

Background and Objective: Recently we found that systemic delivery of liposomes containing glucocorticoids strongly suppresses joint inflammation during experimental antigen-induced arthritis (AIA). During the course of AIA, macrophages in the synovial lining layer are activated towards a pro-inflammatory ('M1') and in later phases towards an anti-inflammatory ('M2') activation state. M1 macrophages are characterized mainly by an up-regulation of pro-inflammatory cytokines such as TNF-α, IL-1β, IL-6 and IL-12p40 whereas M2 macrophages show an increase in IL-10 expression and expression of membrane markers IL-1 receptor type II (IL-1RII) and CD163. We now explored whether liposomal targeting of synovial lining macrophages with glucocorticoids exerts its effect through M1/M2 macrophage skewing.

Materials and Methods: Mice with established antigen-induced arthritis (AIA) were treated with a single intravenous injection of 10 mg/kg liposomal prednisolone phosphate (Lip-PLP) or PBS. Naïve mice were injected intra-

articularly with IFNg/LPS to induce M1 phenotype and 24 hours thereafter with Lip-PLP or PBS. Mice were sacrificed at day 1 after Lip-PLP treatment and whole knee joints were isolated for histology and synovial biopsies were isolated for RNA analysis. In vitro, murine bone marrow macrophages were differentiated towards M1 phenotype with LPS and IFNγ, treated with Lip-PLP and M1/M2 markers characterized by quantitative RT-PCR, LUMINEX and FACS.

Results: A single intravenous injection with Lip-PLP in mice with established AIA significantly reduced synovial infiltration from control treatment (PBS) within 1 day. At this time point, synovial gene expression was strongly down-regulated by Lip-PLP for the M1 cytokines TNF-α (3.3 fold), IL-1β (10.6 fold), IL-6 (5.6 fold) and IL-12p40 (6.3 fold) compared to PBS treated mice, whereas expression of M2 markers was only slightly down-regulated (IL-10: 2.1 fold and IL-1RII: 1.2 fold) or even up-regulated (CD163: 1.9 fold). Liposomes entered the synovium by blood vessels lying just beneath the lining layer and were directly engulfed by macrophages as detected by gold containing liposomes. To evaluate whether Lip-PLP had a direct effect on M1 macrophages, these cells were induced in vitro by IFNγ and LPS and subsequently incubated with Lip-PLP for 24 hours. Lip-PLP suppressed expression of TNF-α, IL-1β, IL-6 and IL-12p40 and induced expression of IL-10, IL-1RII and CD163 in M1 macrophages *in vitro* suggesting a selective skewing of M1 macrophages towards an M2 phenotype. Local M1 activation and subsequent treatment with Lip-PLP led to a similar gene expression pattern as in the AIA providing cogent evidence for selective skewing of M1 macrophages in favour of the M2 phenotype.

Conclusion: Systemic delivery of liposomal glucocorticoids during experimental arthritis inhibit M1 macrophages in favour of M2 phenotype in the lining layer and may drive their strong suppressive effect.

Nanoparticles of LDE: A Potential Delivery Route for MTX in Sinovial Tissue of Antigen-Induced Arthritis. Suzana B. V. Mello[2], Eloisa D. O. Bonfá[3], Claudete J. Valduga[1], Adriana Bugaralli[1], Elaine R. Tavarez[1] and Raul Maranhão[1]. [1]Heart Institute (InCor), Faculdade de Medicina da Uiversidade de São Paulo, [2]Reumatology Division, Faculdade de Medicina da Unversidade de São Paulo, São Paulo, Brazil, [3]Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo

Objective: Methotrexate (MTX) remains the first choice in the management of rheumatoid arthritis (RA). Resistance to this drug is largely associated to MTX entry into the cell. Uptake of lipidic nanoemulsion has emerged as a new strategy for cancer chemotherapy since it carries drugs directed to affected tissue increasing its concentration with a reduced toxicity. The aim of the present study was therefore to evaluate the anti-inflammatory efficacy of a novel cholesterol-rich nanoemulsion coupled MTX (MTX-LDE) in antigen induced arthritis (AIA) in rabbits.

Methods: Toxicity, pharmacokinetics and biodistribution assays were performed. The dose-effect curve of the complex was also determined (0.05 – 0.4 mg/Kg of MTX-LDE). Arthritis (AIA) was induced in the knee joint of methylated serum albumin sensitized NZW rabbits. Twenty four hours after AIA induction animals were intravenously (IV) or intraarticularly (IA) injected with a single dose of commercial MTX (0.25 mg/Kg), LDE or saline. To give an equivalent dose of MTX-LDE, the amount of drug associated to the nanoemulsion was evaluated by HPLC prior the injection. Animals were sacrificed 48h after AIA induction when synovial fluid (SF) and membrane (SM) were collected. The inflammatory parameters analyzed were: total and differential leukocyte count, protein leakage in the SF and histopathological evaluation of SM.

Results: MTX-LDE did not promote any hematological toxicity. The uptake of this complex was preferentially to liver, spleen and inflamed SM. MTX-LDE intravenously injected promoted a reduction of 65% of leukocyte infiltrate in the joint, and 41% in protein leakage and a significant reduction in the SM cell infiltrate. Likewise, the treatment with MTX-LDE by intraarticular route significantly reduced inflammatory parameters (table). In contrast, a single dose of commercial MTX, a DMARDs that requires several weeks to have a clinical effect, did not alter any evaluated parameter. LDE alone or saline were also ineffective (table).

Treatments	n	Leukocyte/mm^3 of SF	Protein leakage μg/ml of SF
AIA control	15	13514 ± 1254	5.31 ± 0.52
MTX-LDE (IV)	9	4714 ± 415 (p = 0.000)	3.17 ± 0.36 (p = 0.008)
MTX (IV)	6	19450 ± 3896	6.87 ± 2.15
LDE (IV)	6	17375 ± 1504	5.50 ± 1.28
MTX-LDE(IA)	9	8416 ± 997 (p = 0.010)	3.37 ± 0.63 (p = 0.029)
MTX (IA)	4	18750 ± 2125	4.24 ± 0.34

Results are expressed as mean ± SE, p by comparison with control values

Discussion: Our study suggests that MTX-LDE is effective, well tolerated and exhibit a rapid effect, probably as a result of their good uptake by the synovial tissue. This novel therapeutic strategy represents a treatment option for RA.

Novel Small Molecule Aminopyridizines Inhibit Rat Collagen-Induced Arthritis and Suppress Proinflammatory Cytokine Pathways. Soo-In Choi[2], Lori D. Klaman[3], Bruce Connop[3], Aleksandra Pastrak[3] and Ernest Brahn[1]. [1]Division of Rheumatology, UCLA School of Medicine, Los Angeles, CA, [2]Division of Rheumatology, UCLA School of Medicine and VA Greater Los Angeles Healthcare System, Los Angeles, CA, [3]Transition Therapeutics

Introduction: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by aggressive synovial hyperplasia and inflammation. Activated macrophages and synoviocytes produce many key cytokines and mediators that contribute to the inflammation and joint destruction. Blocking proinflammatory cytokines such as TNFα, IL-1, and IL-6 has led to clinical and radiographic benefits in patients with RA. TT301 and TT302 are novel, orally available, small molecule aminopyridizines that can suppress proinflammatory cytokines and reduce inflammation in rodent models of multiple sclerosis and Alzheimer's disease. Here we report the effects of these compounds on inflammatory pathways, *in vitro*, and rat collagen-induced arthritis (CIA), *in vivo*.

Methods: The *in vitro* effects of TT301 and TT302 on cytokine production were examined in stimulated primary human synovial fibroblasts and human RAW264.7 macrophages. Cells were preincubated with compound or vehicle in serum-free media and stimulated with LPS (5μg/mL), IL-1β (5ng/mL) or TNFα (30ng/mL). Supernatants were collected and analyzed by cytokine specific ELISA. *In vivo* studies used Lewis rats immunized with porcine type II collagen on day 0 to induce CIA. A total of 79 rats were randomized to vehicle controls or 4 treatment arms (TT301 at 1mg/kg and 7 mg/kg; TT302 at 1mg/kg and 7 mg/kg). Based on the degree of joint involvement and soft tissue swelling, each limb was scored from 0–4, with a maximum total score of 16. At the end of the study (day 28) serum was harvested for subsequent cytokine profiles, the left hind limbs were fixed for immunohistochemistry, and the right hind limbs were microdissected to obtain pure synovium for gene expression profiles, gene hub, module, and network analysis. All hind limbs were also evaluated by high resolution digital radiographic imaging.

Results: In stimulated human RAW264.7 macrophages and synovial fibroblasts, increasing concentrations of TT301 and TT302 dose-dependently inhibited the induction of key cytokines relevant to the pathology of RA including TNFα, IL-6, RANTES and MCP-1/CCL-2. In Lewis rats, virtually all controls developed CIA on day 11 but TT302 and TT301 recipients had a delayed arthritis onset ($p<0.03$ and $p<0.002$, respectively). The clinical severity was significantly lower than vehicle controls for both agents (at all doses) within 24 hours of disease onset and this was sustained throughout the study. By day 28, TT301 and TT302 (at both doses) markedly inhibited clinical disease ($p< 1 \times 10^{-10}$ vs. controls). Radiographic damage was also suppressed (TT301 at 1mg/kg and 7mg/kg, $p< 2 \times 10^{-6}$ & $p < 2 \times 10^{-7}$, respectively; TT302 at 1mg/kg and 7mg/kg, $p< 2 \times 10^{-5}$ & $p< 2 \times 10^{-8}$, respectively). The analysis of serum cytokines, joint immunohistochemistry, and synovial gene expression profiles is ongoing.

Conclusions: TT301 and TT302 inhibited inflammatory cytokine pathways and suppressed CIA. These studies indicate that these novel small molecules might have therapeutic benefits in RA.

PCI-45292, a Novel Btk Inhibitor with Optimized Pharmaceutical Properties, Demonstrates Potent Activities in Mouse Models of Arthritis. Betty Y. Chang[2], Patricia Thiemann[1], Nadia Moore[3], Michelle Francesco[3], Min Mei Huang[3], Chitra Mani[3], Purvi Jejurkar[3], Danielle Tonev[3], Wei Chen[3], Joseph J. Buggy[3] and David J. Loury[3]. [1]Pharmacyclics, [2]Pharmacyclics, Research, Sunnyvale, CA, [3]Pharmacylics

Purpose: Btk is an essential element of BCR signaling in B cells and FcγR signaling in monocytes/macrophages, and is considered an ideal molecular target for the treatment of autoimmune diseases such as rheumatoid arthritis. PCI-45292, was derived from the chemical scaffold of PCI-32765, a first-in-man Btk inhibitor currently in Phase I/Ib clinical trials in patients with NHL/CLL*. Both PCI-32765 and PCI-45292 are irreversible inhibitors of Btk, forming a covalent bond with the sulfhydryl group of Cys-481 at the ATP-binding site. The two compounds were evaluated in vitro for their effects on human lymphocytes, monocytes, and basophils, and in vivo for therapeutic effects in multiple models of arthritis.

Methods and Results: In Btk biochemical assays, PCI-32765 and PCI-45292 have an IC_{50} of 0.5 nM and 1–2 nM, respectively. PCI-45292 was a more selective inhibitor of Btk than either PCI-32765 or dasatinib, with no significant inhibition of VEGFR2, EGFR, JAK, or Abl. Both compounds were potent inhibitors of human B cell activation following BCR stimulation by anti-IgM with an EC_{50} of 2 nM while failing to inhibit T cell activation at concentrations up to 2 μM. Both inhibited anti-IgE mediated upregulation of CD63 in human whole blood basophils with an EC_{50} of 20–100 nM. In addition, PCI-45292 inhibited cytokine release from human monocytes at 20–100 nM but did not inhibit IgG-mediated phagocytosis up to 10 μM. In vivo, both Btk inhibitors dose-dependently inhibited inflammatory synovitis, synovial fluid cytokines, cartilage damage, and bone erosion in both preventive and established murine CIA models. PCI-32765 and PCI-45292 inhibited overt manifestations of arthritis in mice with EC_{50} values of 2.23 and 0.61 mg/kg/day, respectively. In a murine CAIA model, PCI-32765 and PCI-45292 completely suppressed the development of arthritis at doses of 6.25 and 0.8 mg/kg/day, respectively. In glutathione binding assays, the rate of glutathione conjugation was 20 fold lower for PCI-45292 than for PCI-32765. In human liver microsomes, the half-life of PCI-32765 was 2.5 min compared to 19.2 min for PCI-45292. PK studies in rats showed that the bioavailability of PCI-32765 and PCI-45292 was 22.8% and 24.7%, respectively. Hepatic extraction ratio, a measurement of first-pass metabolism, was 0.690 and 0.289 for PCI-32765 and PCI-45292, respectively. Based on PK/efficacy relationships in mice and interspecies scaling of clearance, the daily efficacious dosage of PCI-45292 was estimated to be ≤10 mg/patient/day.

Conclusions: Both PCI-32765 and PCI-45292 are potent irreversible inhibitors of Btk that suppress B cell activation following BCR stimulation and inhibit monocytes/macrophage release of pro-inflammatory cytokines following FcγR activation. PCI-45292 was shown to have increased selectivity for Btk inhibition over other tyrosine kinases, a reduced potential for off-target protein binding, and improved metabolic stability. Also, PCI-45292 had a more potent effect in ameliorating inflammation and tissue damage in CIA and CAIA models when compared to PCI-32765. PCI-45292 is currently undergoing preclinical development for autoimmune applications.

Recognition of IL-23 Dependent and Independent Stages during Autoimmune Collagen-Induced Arthritis. Ferry Cornelissen[2], Patrick Asmawidjaja[2], Anne-Marie Mus[2], Odilia Corneth[2], Kristine Kikly[1] and Erik Lubberts[2]. [1]Eli Lilly, [2]Erasmus MC, University Medical Center

Background: IL-23 is a heterodimeric cytokine composed of an IL-12/23-p40 subunit together with an IL-23-specific p19 subunit. The critical role of IL-23 in the development of autoimmune collagen-induced arthritis (CIA) has been shown using IL-23p19 knockout mice. However, it is unknown what the role of IL-23 is at later stages of CIA and during T cell memory mediated flare-up arthritis.

Materials and Methods: In one set of experiments, an anti-IL-23p19-specific antibody (anti-IL-23) was injected starting 15 days after the first immunization with type II collagen (CII) but before the booster injection of CIA. In another set of experiments, anti-IL-23 was injected starting after the first signs of CIA. Splenocytes, popliteal lymph-node cells (PLNs) and cells isolated from ankles were assessed for intracellular cytokine production by flow cytometry. Serum IgG and IL-6 levels were measured. To test the role of anti-IL-23 in a memory T cell driven arthritis model we utilized the flare-up induced mBSA arthritis model.

Results: Neutralizing IL-23 starting 15 days after the first CII-immunization significantly delayed and suppressed the onset of CIA. In these anti-IL-23 treated mice, serum IL-6 was lower compared to control mice. In addition, the mean fluorescent intensity (MFI) of splenic CD4+ TNF expressing cells was significantly lower in the anti-IL-23p19 treated group compared to the isotype control group. In the sera of anti-IL-23 treated mice, significantly lower CII-specific IgG1 levels were found compared to the control group as well as a trend to lower IgG2a levels. However, anti-IL-23 treatment did not reduce the proportion of Th1 and Th17 cells analyzed at days 15, 24, and 35. In contrast to the marked suppressive effect of anti-IL-23 given during the onset of CIA, neutralizing IL-23 directly after the first signs of arthritis did not ameliorate the arthritis score. No effect on CII-specific IgG's was noted, indicating that the effector phase of CIA is IL-23-independent. Since CIA is both T cell and immune complex-mediated the IL-23-dependency was further investigated during memory T cell-mediated flare-up arthritis. The mBSA-mediated flare-up arthritis was induced after the primary mBSA-induced arthritis has declined to normal background levels. In mice treated with anti-IL-23, a significant lower disease score was observed compared to mice treated with the control antibody, which was accompanied with lower IL-17 and IL-22 expression in the knee joints of these mice.

Conclusion: These data recognized IL-23 dependent and independent stages during autoimmune CIA. Furthermore, the flare-up reaction of arthritis is IL-23-mediated. These data suggest the importance of early intervention using blocking IL-23 therapy in autoimmune arthritis and beneficial effects of neutralizing IL-23 during arthritis relapses.

RO2492, a Phosphoinositide-3-Kinase d Inhibitor, Shows Inhibitory Effects in a Variety of Human Cell Types and Suppresses Collagen-Induced Arthritis in Mice. Cheng Liao[4], Pei-Yuan Hsu[4], Shu Jin[2], Vaishali Patel[2], Mattew C. Lucas[3], Yong Nam Kim[3], Joe Dalpoto[3], Karim Dabbagh[3], Emma Masteller[3], Brian R. Wong[1], Satwant K. Narula[2] and Julie A. Demartino[3]. [1]Hoffma-La Roche Inc., San Francisco, CA, [2]Hoffma-La Roche Inc., Nutley, NJ, [3]Hoffma-La Roche Inc., [4]Hoffmann-La Roche Inc., Nutley, NJ

Background: Phosphoinositide 3-kinase (PI3K) family controls an array of intracellular signaling pathways and regulates many biological functions in a variety of cell types, including T cells, B cells, macrophages and osteoclasts. In this study, we evaluated the effects of a potent and selective PI3Kd inhibitor, RO2492, in multiple human immune cells as well as in mouse collagen-induced arthritis model.

Methods: Anti-IgM-mediated intracellular calcium fluxes in the Ramos cell were measured by FLIPR. Anti-IgM mediated B cell activation in human whole blood as determined by CD69 upregulation was assessed by FACS analysis. Mixed lymphocytes reactions (MLR) were measured by [^{3}H] thymidine incorporation in response to stimulation by mitomycin C-treated allogeneic lymphocytes. T cell proliferation was induced by anti-CD3/CD28 antibodies. Memory T cell recall responses were measured by intracellular staining of TNF^+ or IFN^+ cells in $CD45RA^-$ memory T cell population. Human monocytes were isolated by plate adherence and TNFa production was quantified after stimulation with human IgG-coated beads. Osteoclasts differentiation from monocytes was induced by RANK ligand for 14 days then counted as TRAP positive multinuclear cells. Murine collagen-induced arthritis was induced by intradermal tail base injection with collagen at day 0 followed by a boost at day 21.

Results: RO2492 is a potent, selective small molecule PI3Kd inhibitor. Inhibition of PI3Kd by RO2492 blocked the anti-IgM mediated B cell receptor signaling in both Ramos cells (IC_{50}=2 nM) and human whole blood

(IC_{50}=24 nM) as demonstrated, respectively, by reduced calcium flux and CD69 up-regulation. In addition, RO2492 blocked Fcg receptor-mediated TNFa production in human monocytes with similar potency (IC_{50}=9 nM). With respect to T cells, PI3Kd blockade inhibited proliferation in MLR assay (IC_{50}=10 nM). Moreover, proliferation of purified CD4 T cells stimulated by plate-bound anti-CD3 antibody was also potently inhibited by RO2492 (IC_{50}=6 nM), although there was an apparent decrease in compound potency in cells co-treated with anti-CD3 plus anti-CD28 antibody (IC_{50}=134 nM, 505 nM with 1 mg/ml, 5 mg/ml anti-CD28 antibody costimulation, respectively). In a memory T cell recall response, anti-CD3/CD28-mediated increases of TNF^+ (IC_{50}=35 nM) or IFN^+ (IC_{50}=40 nM) memory T cells were also blocked by RO2492. RO2492 also inhibited osteoclast differentiation in a dose-dependent manner. Finally, oral administration of RO2492 ameliorated disease severity in mouse collagen-induced arthritis model. Histopathological examination demonstrated diminished inflammation and cartilage destruction in RO2492 treated group compared to vehicle group.

Conclusion: In summary, our data showed that inhibition of PI3Kd blocks several key pathways in B cells, T cells, macrophages and osteoclasts, which are related to inflammation and bone destruction in the pathology of rheumatoid arthritis. Furthermore, RO2492 is efficacious in mouse collagen induced arthritis model. The beneficial effects of RO2492 suggest the therapeutic potential of blocking PI3Kd isoform for treatment of rheumatoid arthritis.

Selective Switch Pocket Kinase Inhibitors Suppress Autoimmune Inflammatory Models of Rheumatoid Arthritis. Soo-In Choi[3], Scott C. Wise[1], Daniel L. Flynn[1], Zejin Zhu[3] and Ernest Brahn[2]. [1]Deciphera Pharmaceuticals, [2]Division of Rheumatology, UCLA School of Medicine, Los Angeles, CA, [3]Division of Rheumatology, UCLA School of Medicine and VA Greater Los Angeles Healthcare System, Los Angeles, CA

Introduction: Kinase activation is controlled by phosphorylation and dephosphorylation of key residues on the activation loop which subsequently binds to an internal region on the kinase domain, known as the switch pocket, resulting in a conformational change to allow substrate binding and phospho-transfer. Certain kinases, including cFMS, cKit, and PDGFR, have recently been identified as targets for treatment of autoimmune disorders including rheumatoid arthritis. We have developed a novel class of compounds which were designed to engage critical switch pocket residues and prevent adoption of an activated conformation, resulting in potent and highly selective inhibitors of these kinases. Switch pocket inhibitors targeting these kinases were tested in collagen antibody-induced arthritis (CAIA) and collagen-induced arthritis (CIA), animal models of chronic autoimmune inflammatory synovitis.

Methods: Initial prevention protocols studied kinase inhibitors DP-3556, DP-4178, and DP-4610 in murine CAIA starting on day 0. In a pilot protocol, Lewis rats were immunized with type II collagen on day 0 with clinically evident CIA on day 11. The rats were allowed to develop established disease (day 22) and then administered DP-4610 for 3 days. Synovium was micro-dissected and on-target kinases, such as pFMS, were assayed. In a subsequent study of established rat CIA (days 11–28), DP-4178 (50mg bid or 100mg qd) was compared to vehicle controls. Recipients were scored for clinical severity and structural damage (based on blinded digital radiographs).

Results: Prevention protocols in murine CAIA demonstrated marked reduction in footpad swelling ($p< 1 \times 10^{-3}$) and clinical scores ($p< 1 \times 10^{-3}$) with DP-3556, DP-4178, and DP-4610. Ankle histology/immunohistochemistry revealed significant suppression of inflammation, pannus, cartilage damage, osteoclast activity, bone resorption, and periosteal reaction. Synovium harvested from established rat CIA treated with 3 days of DP-4610 indicated a 75% inhibition of on-target pFMS. Chronic administration of DP-4178 beginning at day 11 arthritis onset (50mg bid or 100mg qd) significantly suppressed clinical disease ($p< 1 \times 10^{-8}$ and $p< 1 \times 10^{-7}$, respectively) and radiographic damage ($p< 1 \times 10^{-6}$ and $p< 1 \times 10^{-3}$, respectively) compared to controls. On-target kinase suppression with chronic DP-4178, administered for 17 days of clinical disease, was also demonstrated in the synovium by the end of the study on day 28.

Conclusions: Small molecules, generated by structure-based design, had selective kinase inhibitory profiles. They could suppress synovial on-target phospho-kinases in the murine CAIA model and involute established arthritis in the rat CIA model. These studies suggest that specific kinase pathways, including cFMS, may be critical in the induction and propagation of autoimmune inflammatory arthritis and that inactivation by allosteric inhibitors, which bind at the kinase switch control pocket, are a potent and effective intervention.

The Effects of Low Dose Etanercept on Disease Control and Radiographic Progression in Moderate to Severe Rheumatoid Arthritis. Bernd Raffeiner[1], Costantino Botsios[2], Paolo Sfriso[2], Francesca Ometto[2], Livio Bernardi[2], Silvano Todesco[2] and Leonardo Punzi[2]. [1]University Hospital of Padova - Rheumatology Unit, Padova, Italy, [2]University Hospital of Padova - Rheumatology Unit (Italy)

Background: Rheumatoid arthritis (RA) remains a socio-economic emergency: 100 billions of Euros were spent in 2006 for the disease in the USA and Europe. RA leads to disability, work loss and premature death. Biologics changed history of disease and patients' outcome. To justify elevated treatment costs biologics have been proved for cost-effectiveness. Some attempts are reported to reduce treatment costs. Etanercept (ETA) neutralizes TNFα with 20-fold higher potency than do other inhibitors at low concentrations of TNFα as for disease in remission. ETA appears suitable for dose reduction once patients gained remission.

Objectives of the Study: To elucidate efficacy of low dose ETA to maintain remission. To compare radiological progression and safety of low with standard dose. To estimate cost savings of low dose ETA strategy.

Material and Methods: Prospective observational study was performed on consecutive RA patients in DAS28 remission since 12 months by standard dose ETA from January 2004 to December 2009. Patients continued low (25 mg weekly) or standard dose ETA as follows: 56 with severe and 53 with moderate disease activity prior biologic continued with low dose ETA, 54 patients with severe and 54 with moderate activity standard dose. Patients were monitored every three months. Patients who failed dose reduction returned to full dose once remission was lost. Kaplan Meier survival curve was calculated for low dose patients. Modified Sharp score/van der Heijde (TSS) was performed on x-rays at baseline and after one year. Progression was reported as absolute $\Delta TSS > 0$ and as real progression $\Delta TSS \geq 5$ according to the smallest detectable difference of the method. Progression prior to biologic was estimated for each patient using preceding X-rays. Incidence of infections was calculated by Mid-P exact test modified by Miettinen. Cost savings of low dose strategy were calculated based on national pricing including tax. All comparisons were controlled for statistical significance by Mann-Withney or exact Fisher test.

Results: Between low and standard dose patients for both severe and moderate disease no differences for age, sex, disease duration, positivity for auto-antibodies, concomitant and past therapy, HAQ and ΔTSS/year were found. Severe groups resulted more aggressive from x-rays than moderate groups and were treated more likely with concomitant DMARDs. Up to now 89 patients (81,6%) maintained remission with low dose for a mean of 2.59 years. Patients failing dose reduction regained remission with full dose except one. Success was higher in younger patients taking less symptomatic, but was not different between severe and moderate groups. Radiological progression occurred only in a minority of patients in low dose ETA: $\Delta TSS > 0$ in 13.6% and $\Delta TSS \geq 5$ in 0.8% of cases. Capability to arrest radiological progression was identical in low and standard dose and in patients who failed dose reduction. Low dose patients had fewer infections. Low dose ETA strategy produced costs savings of €1,583,273 since its introduction, and continues to save €562,071 per year.

Conclusion: Low dose ETA sustains clinical and radiological remission. Low dose strategy is safe and produces notable cost savings.

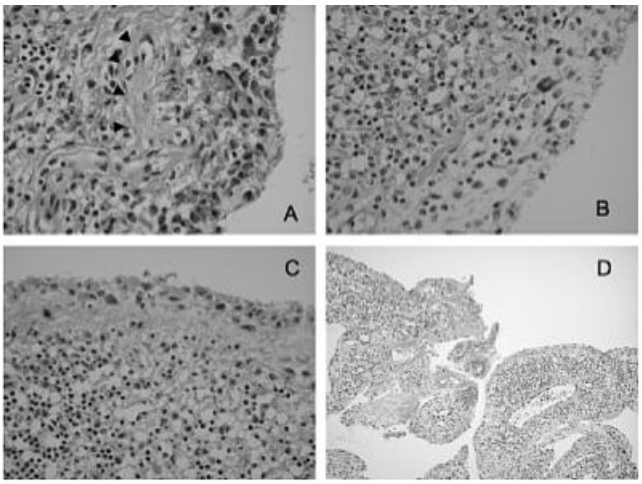
TNF Inhibitors Induce the Fibrosis in Deep Lining Layers of the Synovium with Degeneration of Synoviocytes in Rheumatoid Arthritis. Shunsei Hirohata[1], Tetsuya Tomita[2], Hideki Yoshikawa[3] and Masahisa Kyogoku[4]. [1]Kitasato Univ School of Med, Kanagawa, Japan, [2]Osaka Univ Med School, Suita Osaka, Japan, [3]Osaka Univ Med School, [4]Tohoku Univ School of Med

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by hyperplasia of synovial tissues, leading to the destruction of joint structures. TNF inhibitors, including anti-TNF-α antibodies and soluble TNF receptors, have been demonstrated to have prominent therapeutic efficacy in RA. However, detailed mechanism actions of TNF inhibitors have not been fully understood.

Objective: The current studies were therefore designed to determine the characteristic features of synovial tissues of RA patients treated by TNF inhibitors in order to delineate their mechanism of action.

Methods: Synovial tissues were obtained from 12 RA patients who had been treated with TNF inhibitors in addition to disease modifying antirheumatic drugs (DMARDs) for at least 5 months (5–25months) during the joint surgical operations. As a control, synovial tissues were similarly obtained from 12 RA patients who had been treated with only DMARDs, but not with TNF inhibitors. Synovial tissues were fixed in formaldehyde and embedded in paraffin. The sections were evaluated by hematoxylin and eosin staining and Masson trichrome staining.

Results: There were no significant differences in serum CRP levels and treatment regimen except for TNF inhibitors between RA patients with TNF inhibitors and those with DMARDs alone. The most prominent changes in the synovium from RA patients with TNF inhibitors were hyalinization and fibrosis in deep lining layers of the synovium with degeneration of synoviocytes (mostly type B synoviocytes) and formation of multinucleated small giant cells, accompanying with marked decrease in vasculature. Figure 1 shows A. degeneration of synoviocytes with giant cells and obliterating vessels in the sublining layer (arrow heads), B. disappearance of synoviocytes with residual giant cell, C.decreased synoviocyte stratification and appearance of fibrosis in the lining layer with edematous changes in the sublining, D. extended fibrosis in the deep lining layers of the synovium.



There was no significant difference in the synovial changes between RA patients with infliximab and those with etanercept. Interestingly, appearance of foreign-body giant cells was observed more frequently in RA patients with TNF inhibitors (3 out of 12 patients) than in those without TNF inhibitors (1 out of 12 patients), suggesting the activation of healing process.

Conclusions: These results indicate that not only infliximab, but etanercept might have direct actions on synovial cells, presumably type B synoviocytes in the deep lining layers of the synovium, leading to the fibrosis and hyalinization thereof. Moreover, the data confirm that deep lining layers of the synovium are the most important portion that steer the disease process of RA synovitis.

TNFα-Induced Adipose-Related Protein (TIARP) Regulates Autoimmune Arthritis Via the Suppression of IL-6. Asuka Inoue[1], Isao Matsumoto[2], Yoko Tanaka-Watanabe[2], Kayo Yamamoto[2], Naoto Umeda[2], Yuki Tanaka[2] and Takayuki Sumida[3]. [1]Division of Clinical Immunology, Doctoral Program in Clinical Sciences, Graduate School of Comprehensive Human Sciences, University of Tsukuba/ JSPS Research Fellow, Tsukuba City, Ibaraki, Japan, [2]University of Tsukuba, [3]University of Tsukuba/ Inst Clin Med, Tsukuba City, Japan

Background and Objective: Recently, we found that TNFα-induced adipose-related protein (TIARP) is dominantly expressed in spleens and joints in TNFα-dependent model such as glucose-6-phosphate isomerase (GPI)-induced arthritis. TIARP is a six-transmembrane protein induced by TNFα, interleukin-6 (IL-6) and IL-1β in adipose tissue, although mechanisms in the pathogenesis of arthritis remains unclear. To elucidate the role of TIARP in the development and pathogenesis of autoimmune arthritis, we have generated TIARP-deficient (TIARP$-/-$) mice.

Methods: (1) Collagen induced arthritis (CIA) was induced by immunization with 200μg of chicken typeII collagen (CII) emulsified in complete freund's adjuvant (CFA) to C57BL/6(B6) mice, followed by boost immunization after 21 days of primary immunization. The TIARP mRNA in spleens and joints was evaluated in CIA mice on day 14, 23, 28, by quantitative RT-PCR.

(2) We generated TIARP$-/-$ in B6 background. TIARP$-/-$ and wild type (WT) mice were immunized with CII as described methods above. The severity of arthritis was monitored by clinical score and evaluated histologically on day 60.

(3) The level of anti-CII antibodies (Abs) in serum were assessed by enzyme-linked immunosorbent assay (ELISA).

(4) Draining lymph nodes and splenocytes on day10 were cultured for 96hr with CII in vitro. IFNγ, IL-17 and IL-4 in their culture supernatant were measured by ELISA.

(5) The level of IL-6 and TNFα in serum on day60 after CII immunization were measured by ELISA.

Results: (1) In CIA model, the expression of TIARP mRNA in splenocytes was the highest in the early phase of arthritis (on day23). On the other hand, the expression in joints was accompanied with the joint swelling (on day28).

(2) The arthritis score in TIARP$-/-$ mice was higher than that in WT mice. Histological analyses showed that a lot of neutrophil infiltration, synovial proliferation, and cartilage destruction.

(3) The level of anti-CII Abs in serum were not significantly different between TIARP$-/-$ and WT mice.

(4) The amount of IFNγ, IL-17 and IL-4 was not significantly different between TIARP$-/-$ and WT mice.

(5) The serum IL-6 was significantly increased in TIARP$-/-$ mice, whereas serum TNFα was not detected.

Conclusion: These findings suggest that TIARP might be a negative regulator against autoimmune arthritis via the suppression of IL-6. TIARP might be a future target for the treatment of rheumatoid arthritis.

Tyrosin Kinases Are Essential Mediators in the Development of Antigen Induced Arthritis Regulating Formation of Dendritic Cells and Antigen Presentation. Mats I. Dehlin[1], Sofia Andersson[2], Malin Erlandsson[2] and Maria Bokarewa[2]. [1]Department of Rheumatology and Inflammation Research, Sahlgrenska University Hospital, University of Göteborg, Gothenburg, Sweden, [2]Department of Rheumatology and Inflammation Research, Sahlgrenska University Hospital, University of Göteborg, Sweden

Background: Tyrosine kinases (TKs) are a family of intracellular signaling molecules participating in cell proliferation, development and apoptosis. Inhibition of TKs is effective in the treatment of various malignancies as well as diabetes mellitus. Several families of TKs are implicated in the pathogenesis of rheumatoid arthritis regulating processes in disease onset as well as progression. In previous work we demonstrated that a ligand to TK Flt3 is accumulated in the joints of RA patients and has proarthritic and erosive properties. Here we evaluate the role of TKs and Flt3-signaling in the antigen-induced model of arthritis.

Methods: Mice (n=75) were immunized with mBSA followed by an i.a.

injection of mBSA on day 21. Treatment with TK inhibitor sunitinib (10 an 40 mg/kg/day) was started on day 7 (n=30) and on day 21 (n=30) and continued until day 28. Controls (n=15) received citrate buffer. The mBSA-injected joints were evaluated morphologically and compared to circulating levels of bone (CTX-I) and cartilage (CTX-II) degradation marker and to anti-mBSA antibodies measured by ELISA. The effect of sunitinib on the levels of TK ligands Flt3-L, RANKL and VEGF were measured by ELISA. Expression of Flt3 and development of dendritic cells (DC) was evaluated in the bone marrow and spleen by flow cytometry.

Results: Sunitinib treatment alleviated mBSA-induced arthritis, reducing intensity of synovitis and frequency of bone erosions. This was accompanied by a reduction of mBSA antibodies and marker for bone degradation, CTX-I.

Sunitinib induced a pronounced increase in Flt3-ligand levels, while levels of VEGF and RANKL were changed only slightly, indicating relative specificity on Flt3-signaling. Following sunitinib treatment, the expression of Flt3 was selectively decreased on CD3+ population in bone marrow.

In spleen, sunitinib induced a significant decrease of pDCs as well as cDCs affecting all cDC subsets. However, sunitinib increased CD8+ population in spleen while the populations of B-cells and CD4+ T-cells were unchanged.

Conclusion: Sunitinib blocks TKs through Flt3 pathway alleviating synovial inflammation and bone resorption in antigen induced arthritis. This effect is potentially mediated through downregulation of DCs and decreased antigen presentation.

A Decrease in Neutrophil Counts Following a Single Infusion of Tocilizumab Is Predictive of Low Disease Activity and Remission after 24 Weeks. Jasemine Saech[2], Kathrin Kuhr[1], Matthias Laudes[1], Olaf Schultz[1], Thomas Rath[1], Tobias Roehrs[1] and Andrea Rubbert-Roth[1] [1]University Clinic Cologne, [2]University Clinic of Cologne, Cologne

Background: Tocilizumab, a humanised monoclonal antibody targeting the IL-6 receptor, represents a potent new therapeutic principle for patients with active RA and intolerance or inadequate response to conventional DMARDs and/or TNF-blockers. Given the broad therapeutic armentarium of biologics that is available for RA patients today, predictive parameters before or during the early treatment period are urgently needed to optimize therapeutic strategies.

Method: In our center, 40 patients with active RA were started on tocilizumab 8 mg/kg iv q4w and followed prospectively for 24 weeks. DAS 28 and routine laboratory parameters were obtained at baseline and every 4 weeks subsequently.

Results: 40 patients (25% male, 75% female, mean baseline DAS28 6.09) were treated with tocilizumab 8mg/kg. 15/40 (42%) patients received tocilizumab as monotherapy and 25/40 (58%) with concomitant DMARD treatment. In 26/40 (64%) patients, tocilizumab was used as the first biological.

After 24 weeks, 20 patients achieved low disease activity LDA (DAS 28≤3.2) and 12 were in remission (DAS28≤2,6). CRP, neutrophils or other clinical or laboratory parameters at baseline did not correlate to outcome at week 24.

Patients with a DAS decrease of ≥ 1.2 at week 4 (early responders = ER) were compared to patients with a DAS difference of < 1.2 at week 4 (early non-responders = NR). 64 % of the ER, but only 31% of NR achieved LDA in week 24 (n.s.). More impressively, 52% of the ER, but 11% of the NR achieved remission in week 24 (p=0.02).

CRP levels normalized in all patients at week 4 and did not differ bet-ween ER and NR. Neutrophil counts at week 4 remained within normal limits in all patients. Of note, a decrease in neutrophil counts of ≥25% from baseline to week 4 was observed more frequently in ER (20/31) than in NR (2/9) (p = 0.05). More interestingly, a neutrophil decrease of ≥25% from baseline to week 4 was significantly associated with LDA and remission at week 24 (p=0,03).

Conclusion: Patients who responded to tocilizumab with a DAS 28 decrease of ≥1.2 in week 4 (ER) achieved remission significantly more often in week 24 than patients who do not respond ar week 4. Baseline CRP or normalization of CRP at week 4 did not correlate to ER/NR at week 4 or to LDA/re-mission at week 24. Of note, a decrease in neutrophil counts of ≥25% after a single infusion of tocilizumab (baseline to week 4) was highly predictive for achieving LDA/ remission in week 24.

A Simplified Disease Activity Score (DAS): Validation in the BeSt Trial. Rosanne Koevoets[6], Yvonne Goekoop-Ruyterman[2], Desiree M. Van Der Heijde[5], K. H. Han[7], H. K. Ronday[1], T. W. J. Huizinga[6], P. J. S. M Kerstens[3], B. A. C. Dijkmans[8] and Cornelia F. Allaart[4]. [1]Haga Hospital, Den Hague, [2]Haga Hospital, Den Hague, The Netherlands, [3]JBI, Amsterdam, [4]Leiden Univ Med Ctr, Leiden, The Netherlands, [5]Leiden University Medical Center, Meerssen, The Netherlands, [6]Leiden University Medical Centre, Leiden, The Netherlands, [7]Maasstad Hospital, Rotterdam, [8]VU Medical Centre, Amsterdam, The Netherlands

Background: Implementation of DAS steered treatment is challenging current daily practice. Some feel that using the Ritchie Articular Index for pain in the original DAS is impractical.

Objective: To assess the validity of a simplified version of the original DAS with different versions of the pain component.

Methods: Within the first year of the BeSt trial, a 4 strategies trial in recent RA patients aiming at a DAS≤2.4, the percentage agreement and kappa statistics were calculated for 3 different versions of a simplified DAS compared to the original DAS: DAS with the Ritchie score reduced to a 0–1 score ('DAS 0–1'), DAS with a 53 joint 0–1 count for pain (DAS-TJC53), and a DAS with a 44 joint 0–1 count for pain (DAS-TJC44). At the same time for all alternative DAS versions and the DAS28 the DAS was calculated with the VAS general health (GH) and the VAS for patient's global assessment of disease activity (PGA). To display the difference for the continuous scores Bland-Altman plots were created with the mean versus the mean difference. Percentages agreement and kappa statistics were calculated for classification into remission, low disease activity (LDA) or moderate (MDA) or high (HDA) disease activity for all indices both with PGA and GH.

Results: DAS scores with a separate joint count are in general higher since there are no single counting joint groups created. As by definition the 'DAS 0-1' was lower in few cases; in the majority of the patients the DAS scores were equal (see figure1).

Mean difference between DAS and 'DAS 0–1' was −0.03; (limits of agreement (-0.24;0.18) between DAS and 'DAS-TJC53' 0.18 (-0.33;0.66) and between DAS and 'DAS-TJC44' 0.11 (-0.42–0.64) (figure 1). Compared with the original DAS, the 'DAS 0–1', 'DAS TJC53' and the 'DAS TJC44' agreed on the classification of patients in LDA, MDA or HDA in 99% (κ=0.98), 86% (κ=0.81) and 86% (κ=0.80), which would have resulted in the same treatment decisions in this trial. Although separate VAS scores are not highly correlated (r=0.5–0.8) all indices with PGA showed high chance corrected agreement (κ=0.87–0.94) compared to the corresponding GH score.

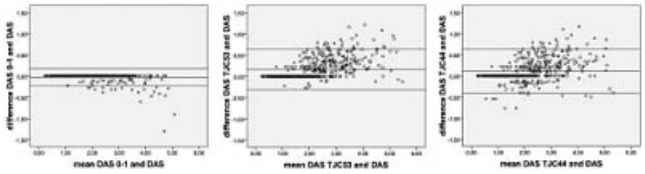

Figure 1. Bland-Altman plots representing the mean of the original DAS and alternative DAS in relation to the difference between both.

Conclusion: There are no important differences between all alternative DAS versions, both with the VAS GH and PGA, and all can therefore be used reliably as alternatives to the original DAS.

296

Aiming To Reach Remission—Is It Worthwhile? Helga Radner[3], Josef S. Smolen[1] and Daniel Aletaha[2]. [1]Krankenhaus Lainz, Vienna, Austria, [2]Medical University of Vienna, Vienna, Austria, [3]Medical University Vienna, Vienna, Austria

Background: Rheumatoid arthritis (RA) is a prevalent chronic inflammatory disease causing disability and a considerable burden for the single patient and society. Remission (REM) is one of the major goals of RA treatment. In this study, we investigated whether in patients with low disease activity aiming for remission is also effective from a socio-economic point of view.

Patients and Methods: In 356 patients with established RA we obtained information about quality of life (Short Form 36, SF-36), utility (Short Form 6D, SF-6D; Euro-Quol 5D, EQ-5D), physical disability (Health Assessment Questionnaire, HAQ), productivity (Work productivity and activity impairment Questionnaire, WPAI), as well as disease activity (Clinical Disease Activity Index, CDAI). In cross-sectional analyses we compared data obtained of patients in REM (n=89) to those in LDA (n=152) using Students T-Test. We also compared patients who stayed in REM (n=34) for a whole year and compared their values with those of patients in LDA (n=66) for the same period.

Results: In the cross-sectional analyses we found statistically significant differences of utilities when comparing patients in REM with those in LDA (SF-6D 0.75 vs. 0.66; EQ-5D 0.89 vs. 0.78), physical disability (HAQ 0.38 vs. 0.75) and productivity (WPAI % overall impairment: 18.1% vs. 33.8%; WPAI % impairment while working: 11.3% vs. 27.2%) (all comparisons: $p<0.05$?). Regarding quality of life we found significant differences in all domains except role emotional and MCS in favor of REM. Though, compared to healthy populations there are still significant differences in all domains except mental health (figure).

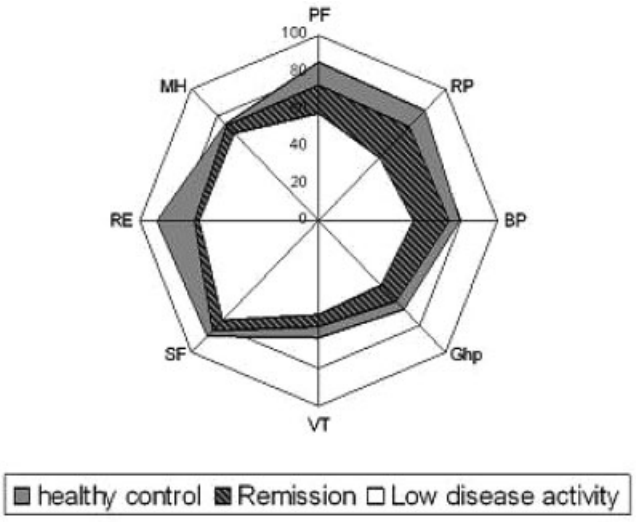

Figure 1. Domains of Short Form 36 in patients within REM compared to LDA and healthy control.
Abbreviations: BP bodily pain; PF physical function; RP role physical, GHP general health perception; SF social function; MH mental health; RE role emotional, VT vitality.

Preliminary longitudinal analyses showed significant differences of outcomes over one year between patients in REM and those in LDA: QALY (SF-6D 0.89 vs. 0.80; EQ-5D 0.80 vs. 0.66), Quality of life over one year (PCS 48.7 vs. 38.0), physical disability over one year (HAQ 0.22 vs. 0.69), and percent of overall activity impairment per year (12.2% vs. 31.0%). No significant difference of percent of activity impairment while working was found.

Conclusion: From a socio-economic perspective including quality of life, disability, and productivity, REM seems to be still superior to any other state of disease, even LDA. Therefore aiming for REM seems worthwhile and should be the major target when treating RA.

Body Weight and Response to Biologics in RA and Spondyloarthritides. Obesity Reduces the Rate of Remission-Response. The GISEA Registry. Gianfranco Ferraccioli[2], Francesco Trotta[5], Leonardo Punzi[11], Clodoveo Ferri[10], Piercarlo Sarzi-Puttini[6], Lisa Maria Bambara[4], Giovanni Triolo[3], Roberto Giacomelli[1], Roberto Gerli[12], Roberto Gorla[7], Angelo Marchesoni[13], Walter Grassi[9] and G. Lapadula[8]. [1]Department of Internal Medicine, University of L'Aquila, L'Aquila, Italy, [2]Division of Rheumatology, UCSC, Rome, Italy, [3]Rheumatology Department, University of Palermo, Palermo, Italy, [4]Rheumatology Department, University of Verona, Verona, Italy, [5]Rheumatology Division, University of Ferrara, Ferrara, Italy, [6]Rheumatology Unit, L Sacco University, Milano, Italy, [7]Rheumatology Unit, Spedali Civili of Brescia, Brescia, Italy, [8]Rheumatology Unit, University of Bari, Bari, Italy, [9]Rheumatology Unit, University of Marche, Jesi, Italy, [10]Rheumatology Unit, University of Modena, Modena, Italy, [11]Rheumatology Unit, University of Padova, Padova, Italy, [12]Rheumatology Unit, University of Perugia, Perugia, Italy, [13]UOC DH of Rheumatology, G. Pini Orthopaedic Institute, Milano, Italy

Background: It is well known that obesity produces inflammation and there are conflicting evidences that obesity determines higher disease activity status in rheumatoid arthritis (RA). Even underweight seems to lead to increased disease activity (cachexia). These possibly related changes between weight and disease activity could affect different responses to therapy. In this study we sought to define whether body weight could lead to different remission/response rate to anti-TNF in rheumatoid arthritis (RA) as well as in seronegative Spondyloarthropathies (SNeSpA).

Materials and Methods: The GISEA registry collect data on all RA and SNeSpA receiving Biologics from 14 Centres in Italy. The data we analyzed regards 580 RA and 392 SNeSpA receiving biologic treatments for at least 12 months. RA patients were 81.4% female, the mean age 56.75 yrs, had a mean DAS28 of 5.36, and ESR of 34.6, an HAQ of 1.31 at entry and a mean disease duration of 13 yrs; SNeSpA were 50 % male, the mean age was 49.5 yrs, the mean BASDAI was 5.48, HAQ 0.98 and dis.dur. 9.95 yrs. In RA 39.9 % were in normal weight, in SNeSpA 39.5 % were in normal weight. In RA 73% received anti TNFa, 27 % others (Rituxan, Abatacept). In SNeSpA 100 % were receiving TNFa blockers.

Results: In RA, DAS28 remission was seen in 18.9 % and in 16.2 % of all patients at the 6° month and 12° month of follow-up respectively. The respective percentages in normal weight RA were 20.3 and 19.4 % at the 6° and 12° month of follow up versus 16.9 % and 6.8% in obese patients ($p=0.018$). In SNeSpA a BASDAI < 3 was seen in 13.5 % and in 9.7 % of all patients at the 6° and 12° month of follow-up. The respective percentages in normal weight SNeSpA were 15.5 and 14.1% at the 6° and 12° month of follow-up versus 7.2 and 3.6% in obese patients ($p=0.03$). The numbers of underweight patients were too low to draw any conclusion.

Conclusions: Data suggest that obesity associates with a lower percentage of success in obtaining DAS28 remission in long standing RA. There is a 2.85 fold lower chance of obtaining remission in obese. In SNeSpA there is a 3 fold lower chance of obtaining a BASDAI of < 3 in obese versus normal weight patients. Two conclusions come along, the need to increase the dose of biologics in obese patients, the need to better control inflammation in obese in order to get control of comorbidities such as cardiovascular complications.

Celecoxib, a Selective COX-2 Inhibitor Improved Upper Gastrointestinal (GI) Adverse Lesions in Patients with Rheumatoid Arthritis on Long-Term NSAID Therapy with Endoscopic Evaluation. Shigeyoshi Tsuji[1], Hirofumi Miyoshi[2], Tetsuya Tomita[3], Takanobu Nakase[2], Masayuki Hamada[2], Takahiro Oomae[2], Chikako Tsumoto[2], Yoshimasa Hirata[2], Muneteka Iguchi[2], Shoko Edogawa[2], Hideo Kawai[2] and Hideki Yoshikawa[4]. [1]Hoshigaoka Kosei-Nenkin Hospital, Hirakata City, Osaka, Japan, [2]Hoshigaoka Kosei-Nenkin Hospital, [3]Osaka Univ Med School, Suita Osaka, Japan, [4]Osaka Univ Med School

Purpose: Nonsteroidal anti-inflammatory drugs (NSAIDs) are widely used for pain relief in patients with rheumatoid arthritis (RA); however, gastrointestinal (GI) adverse events are one of the serious problems of NSAIDs. Selective cyclooxygenase (COX)-2 inhibitors have been proven to be less associated with GI complications than traditional NSAIDs. However,

their effects on the GI tract have not been well studied in patients with preexisting NSAIDs-induced GI complications. Here, we prospectively investigated the effects of celecoxib (CEL) after switching from NSAIDs on the GI tract in RA patients with endoscopically identified GI mucosal injury.

Methods: We conducted upper GI endoscopy to examine GI tract injury in RA patients who had been treated with NSAIDs for 3 or more months with informed consent. GI mucosal injury was evaluated according to the modified LANZA score. Patients with mucosal injury without ulcers were switched from NSAIDs to CEL, while those with ulcers were switched to CEL with famotidine (FAM) on complete ulcer healing with therapy. At 16 week, the extent of GI mucosal injury was endoscopically reevaluated. Disease activity score (DAS28), joint symptoms, and visual analogue scale (VAS; global improvement and pain) were evaluated before and at 8 and 16 weeks after switching to CEL. Wilcoxon signed rank test was used and significance level was set at 0.05.

Results: Eighty-two patients were eligible for the study (69 females), and the average age and affected period were 62.2 (30–83) and 17.5 (1–50) years, respectively. The most prevalently-used NSAID was loxoprofen sodium (49.4%), followed by diclofenac sodium (25.9%), meloxicam (13.6%), and etodolac (11.1%). Endoscopic analysis revealed GI mucosal injury, including 6 ulcers, in 45 of 82 patients (54.9%). LANZA scores were 1, 2, 3, and 4, for 11, 12, 16, and 6 patients, respectively, and the mean score was 2.4 ± 1.0. The incidence ratio of GI mucosal injury was significantly higher in patients using diclofenac sodium ($p<0.05$) compared with those using other NSAIDs. At 16 week, LANZA score and the total number of GI erosions/redness were significantly reduced to 1.6 ± 1.3 and 6.5 ± 6.1, from respective pre-treatment values of 2.1 ± 0.8 and 10.6 ± 8.6, respectively ($p<0.01$). Of the 6 patients achieving complete remission of GI ulcers, 1 exhibited recurrent ulcers at week 16, and was diagnosed as having an *H. pylori* infection. At 16 week, DAS28 (ESR4) and DAS28 (CRP4) were significantly improved to 3.6 ± 1.3 ($p<0.05$) and 3.0 ± 1.1 ($p<0.01$), compared with each pre-treatment value of 3.9 ± 1.3 and 3.3 ± 1.1, and the number of tender and swollen joints were significantly reduced to 2.4 ± 3.7 ($p<0.05$) and 0.8 ± 1.2 ($p<0.01$), compared with each pre-treatment value of 3.1 ± 3.2 and 1.8 ± 2.2, respectively. VAS score was not changed after switching to CEL, suggesting its comparable analgesic effects to other NSAIDs.

Conclusion: In RA patients receiving long-term NSAIDs therapy, we demonstrated for the first time that preexisting NSAID-induced upper GI injury is improved after switching to CEL. Further, Its GI safety profile was accompanied by analgesic effects, suggesting the usefulness of switching to CEL for these patients.

Changes in Lipoproteins Associated with MTX, MTX + Etanercept, and Triple DMARD Therapy among Early RA Patients in the TEAR Trial. Jeffrey R. Curtis[6], Christina Charles-Schoeman[2], Shuo Yang[4], Lang Chen[4], Stacey Cofield[4], George Howard[4], Theresa M. McVie[4], Larry W. Moreland[5], James R. O'Dell[7], Harold E. Paulus[1], Monika Safford[4] and S. Louis Bridges[3]. [1]Encino, CA, [2]UCLA, Santa Monica, CA, [3]Univ of Alabama-Birmingham, Birmingham, AL, [4]Univ of Alabama-Birmingham, [5]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [6]University of Alabama - Brimingham, Birmingham, AL, [7]University of Nebraska Medical Center, Omaha, NE

Background: DMARDs and anti-TNF agents may affect lipid profiles, but past studies in RA patients have generally been small and lacked comparator groups to quantify and compare changes in traditional lipoproteins. We studied early RA patients participating in the Treatment of Early Rheumatoid Arthritis (TEAR) trial randomized to initiate aggressively-titrated methotrexate (MTX) with step-up at 24 weeks to etanercept or triple therapy for patients not in low disease activity; methotrexate + etanercept (MTX+ETA); or triple therapy (TT) [MTX + sulfasalazine (SSZ) + hydroxychloroquine (HCQ)].

Methods: TEAR is a 2-year investigator-initiated, randomized, placebo-controlled trial of 755 DMARD-naïve early RA patients. In this analysis, participants had total serum cholesterol (TC), low-density lipoprotein (LDL), and high-density lipoprotein (HDL) measured at 0, 48, and 102 weeks. LDL was measured quantitatively since samples were collected non-fasting. Changes in lipoproteins at weeks 48 and 102 were compared to baseline and across treatment arms. Change in LDL was correlated with change in CRP at the corresponding time points. Partial results are available based upon samples run to-date; the remaining samples are currently being analyzed.

Results: Characteristics of TEAR participants with lipid lab data (mean ± standard deviation): age 50.7 ± 13.4 yrs; 74% women; body mass index 30 ± 7; RA disease duration 3.5 ± 6.5 months; 87% RF+; 41% glucocorticoid users (mean dose 2.6 ± 4.1 mg/day); 34% current smokers; DAS28 5.8 ± 1.0. At baseline, mean values for total cholesterol were 233 ± 55 mg/dL, LDL 126 ± 39 mg/dL, HDL 54 ± 18 mg/dL. There were no significant baseline differences between treatment groups.

At 48 weeks, there were statistically significant increases in total cholesterol, LDL, and HDL compared to baseline ($p < 0.001$ for all) (see Table). These increases were greater in the MTX + ETA group than in the other treatment groups; only the increase in LDL was significant compared to MTX step-up group ($p = 0.04$). Changes at week 102 were generally similar but quantitatively lower than changes at 48 weeks. There was a low correlation between increase in quantitative LDL and decrease in CRP between 0 and 48 and also between 0 and 102 weeks ($R^2 \leq 0.03$, $p > 0.05$ across all treatment arms at both timepoints).

Changes in lipid profiles at 48 weeks, by randomization to each TEAR treatment arm

		MTX + Etanercept Group		MTX + HCQ + SSZ Group	
Change between 0 and 48 weeks (mg/dL)	Step-Up MTX Group (all pts)		p value versus MTX alone		p value versus MTX alone
Total Cholesterol	35.9 ± 61.1 (n = 137)	49.4 ± 56.2 (n = 89)	0.19	20.1 ± 61.0 (n = 44)	0.23
LDL (Quantitative)	16.2 ± 32.4 (n = 137)	27.3 ± 32.5 (n = 83)	0.04	9.1 ± 39.8 (n = 44)	0.39
HDL	13.1 ± 21.1 (n = 138)	14.6 ± 15.0 (n = 83)	0.62	8.7 ± 22.0 (n = 44)	0.34

Conclusion: Based upon preliminary results available to-date, substantial increases in cholesterol were observed among early RA patients starting MTX, MTX + ETA, and triple therapy. Physicians should be cognizant of optimizing CV risk factors such as lipoproteins in RA patients, particularly in relation to initiation of RA medications.

DAS28 Level at Baseline Best Predicts Which Patients with New Onset Inflammatory Arthritis Will Ultimately Require Biologic Therapy. Vivian P. Bykerk[9], Gilles Boire[6], Boulos Haraoui[3], Carol Hitchon[7], Diane Ferland[2], Carter Thorne[4], Ed C. Keystone[8], Janet E. Pope[5] and CATCH Investogators[1]. [1]Canada, [2]Hopital Maisonneuve Rosement, Montreal, PQ, Canada, [3]Institut de Rhumatologie de Montreal, Montreal, PQ, Canada, [4]South Lake Regional Health Center, Newmarket, Newmarket, ON, Canada, [5]St Joseph Health Care London, London, ON, Canada, [6]Universite de Sherbrooke, Sherbrooke, PQ, Canada, [7]University of Manitoba, Winnipeg, MB, Canada, [8]University of Toronto, Toronto, ON, Canada, [9]University of Toronto, Boston, MA

Background: Use of rapidly escalated higher dose MTX in combination with other DMARDs followed, if needed with biologic therapies, with a goal of reaching remission by 6 months is the current standard of care for patients with new onset rheumatoid arthritis. Whether or not patients with very active new onset inflammatory arthritis should be treated with initial biologic therapies remains controversial amongst most health care providers.

Objectives: To determine what factors at baseline or in the first three months of follow-up of patients with new onset arthritis correctly predict which patients need biologic therapies at one year.

Methods: Data from patients (n=1146) enrolled since July 2007 were collected from the Canadian Early Arthritis Cohort (CATCH) study, a multi-centre observational prospective "real world" cohort of patients with EIA. Inclusion Criteria: age >16, symptom duration 6–52 weeks of persistent synovitis, ≥2 effused joints or 1 swollen MCP/PIP + ≥1 of: +RF, +CCP, AM stiffness >45 minutes, response to NSAIDs, or a painful MTP squeeze test. A regression analysis was performed to determine factors best predict which patients will require biologic therapies at one year. Factors considered for this analysis included age, sex, DAS28 at baseline (BL), DAS28 at 3 months, use of methotrexate at doses of ≥ 20 mg by 3 months, baseline

erosions, socioeconomic status, active smoking status, CCP, RF, higher than normal CRP/ESR, swollen joint count (0–28), tender joint count (0–28), symptom duration. Patients needing and not needing biologics were matched for length of follow up. Patients were treated with ≥ 2 DMARDs prior to being eligible for biologic therapy.

Results: Baseline characteristics: mean age 52±16 years, 73% female, median symptom duration 5.5 months, mean DAS28 ESR 4.9±1.6, 25% already had erosions at baseline. 73% of patients met 1987 criteria for RA.27% treated with oral glucocorticoids, 50% with MTX, 35% with combination DMARDs, 8% with Biologics within 1 year. Patients had a median follow up of 0.75 years with follow up as long as 8 years. Of the variables analyzed the only independent factor predicting the use of biologics at one year was the DAS28 at baseline (OR=1.48, p<0.000001).

Conclusions: Of all the classical baseline factors used to determine prognosis in RA in previous studies, baseline DAS28 was the only independent factor significantly predicting use of biologics at one year.

Decreased Rate of Remission at 1 Year in Menopaused Women with Early Inflammatory Arthritis: The ESPOIR Cohort Study. Cédric Lukas[2], Ihsane Hmamouchi[2], Xavier Le Loet[3], Bruno Fautrel[1] and Bernard Combe[2]. [1]Department of Rheumatology, La Pitie Salpetriere Hospital, Paris, France, [2]Department of Rheumatology, Lapeyronie Hospital, Montpellier, France, [3]Department of Rheumatology, Rouen Hospital, Rouen, France

Background: Remission has become the current aim in the management of rheumatoid arthritis (RA), especially since the advent of biologic antirheumatic agents.

Objectives: To evaluate factors potentially influencing achievement of remission in women with early inflammatory arthritis.

Methods: The ESPOIR cohort study collects data on patients presenting with early arthritis. Remission, defined by a disease activity score (DAS 28) of <2.6, was used as the outcome measure after 1 year of follow-up and standard care. Baseline clinical, laboratory, genetic, and radiographic data were assessed. Logistic regression analysis was performed to determine baseline predictive factors of remission at 1 year, adjusting for patient-, disease- and physician characteristics.

Results: Of the 624 analysed patients, 318 (51%) fulfilled the American College of Rheumatology 1987 revised criteria for the classification of RA after 24 months of follow-up. The mean age was 47±13 years, and the mean symptom duration was 3 months. In the total population, 207 patients (33.2%) were in remission at one year, versus 112 (35.2%) in the RA group. In both populations and after adjustment for age and classical prognostic factors (disease activity at baseline, presence of raised acute phase reactants (CRP >10mg/l), presence of rheumatoid factor or anti-CCP antibodies and functional status), logistic regression analysis showed that the menopausal status had a significant independent pejorative value in achieving a remission status after 1 year of follow-up and usual care: OR=0.47 [95%CI 0.27–0.84], p=0.01 in the total sample, OR=0.54 [95%CI 0.24–1.19], p=0.13 in the patients diagnosed RA after 24 months of follow-up.

Conclusion: In the ESPOIR cohort, about one third of patients achieved remission after 1 year of usual care. Multivariate analysis revealed that beside usual prognostic factors, menopausal status had an independent negative influence on the outcome, with an approximately 50% decreased chance of achieving this favorable status in menopaused women.

Demographic, Disease and Treatment Characteristics of the Rheumatoid Arthritis Population Enrolled in the AMORA Study (Applications for Methotrexate Optimization in Rheumatoid Arthritis) in Evaluating the Avise PG^{SM} Test. Prashanth R. Sunkureddi[1], Judith F. Gendreau[2], Rong Zablocki[3] and Dawn Navis[3]. [1]Clear Lake Rheumatology, Nassau Bay, TX, [2]Cypress Bioscience, Inc, San Diego, CA, [3]Cypress Bioscience, Inc

The study evaluated an assay for RBC methotrexate polyglutamates (MTXPG) in terms of its clinical utility and impact on treatment plans in RA patients experiencing inadequate clinical responses. The study also provided the opportunity to assess the relationships between demographic, treatment and disease characteristics and corresponding MTXPG levels.

Methods: 20 rheumatologists enrolled 146 adult RA patients. Patients were to have been taking MTX for a minimum of 3 months and experiencing an insufficient response to current therapies. Demographic, treatment and disease-related information was collected and the physician completed assessments of the patient's global health status and MTX efficacy. The physicians reported proposed treatment plans before and after MTXPG testing. After receiving the MTXPG result, physicians were surveyed regarding their opinion of the clinical utility of the assay.

Results: Presented in Table 1, 67% of patients were receiving 15 mg MTX or more per week at the time of testing. Almost 77% of patients were on MTX monotherapy; 14% were on biologics in addition to MTX; and 9% were on other non-biologics.

10% of patients had a MTXPG level above 60 nmol/L (the threshold above which previous studies showed an odds ratio of a good clinical response 5-fold higher than levels < 60 nmol/L). 64% exhibited intermediate MTXPG levels (20 – 60 nmol/L) and 27% of patients exhibited subtherapeutic MTXPG levels (< 20 nmol/L, the level below which the odds ratio of a poor response was found to be 3-fold higher than levels > 20 nmol/L). For the population as a whole, increasing MTXPG levels were associated with increases in the mean duration of MTX therapy.

Patients' tender+swollen joint counts tended to decrease as MTXPG levels rose. A similar relationship was seen with the physician's Global Health Assessment, which correlated well (rho = −.5) with patients' combined tender+swollen joint counts.

In 97% of the cases, physicians' rated the overall clinical utility of the MTXPG test as very usefulor somewhat useful. Physicians modified the prospective treatment plans for 45% of their patients after reviewing MTXPG results.

Table 1	MTXPG Results								
	<20 nmol/L N = 39			20-60 nmol/L N = 93			> 60 nmol/L N = 14		
Demographic, Disease and Treatment Variables	Median	Mean	Standard Deviation	Median	Mean	Standard Deviation	Median	Mean	Standard Deviation
Age (years)	53.0	53.6	12.65	62.0	61.4	13.13	71.0	72.9	8.45
MTXPG Result (nmol/L)	12.0	11.9	5.38	37.3	38.6	11.26	67.8	73.3	15.09
Current MTX Dose (mg/week)	15.0	14.2	4.66	15.0	16.0	4.09	15.0	15.3	4.61
Duration of Current MTX Dose (months)	6.0	20.2	40.93	8.0	18.7	24.16	13.0	18.0	18.94
RA Duration (months)	20.0	56.2	85.84	32.0	76.6	101.87	54.5	120.1	121.94
Initial MTX Dose (mg)	8.8	9.3	3.06	10.0	10.4	3.61	10.0	10.6	3.84
Total Duration of MTX Therapy since Initiation (months)	16.0	29.4	41.67	19.0	39.7	53.28	32.0	90.8	106.53
Swollen Joint Count	4.0	8.2	8.39	6.0	7.7	6.39	4.0	5.0	3.21
Tender Joint Count	6.0	8.9	8.16	6.0	7.0	5.68	4.0	4.8	4.12
Physician Assessment of MTX Efficacy (VAS: 0-10)	4.9	4.9	2.34	5.9	5.7	2.15	6.5	6.3	1.96
Physician Assessment of Patient's Global Health (VAS: 0-10)	6.0	5.7	2.21	5.6	5.7	2.04	6.6	6.6	1.27

Conclusion: In the AMORA study, higher MTXPG levels were associated with increasing MTX dose, duration of MTX therapy, and age. Clinical markers of disease activity also trended toward improvement as MTXPG levels increased. Physicians' expressed positive opinions regarding the test's overall clinical utility, and treatment plans were frequently modified after receipt of the MTXPG results (in 45% of cases).

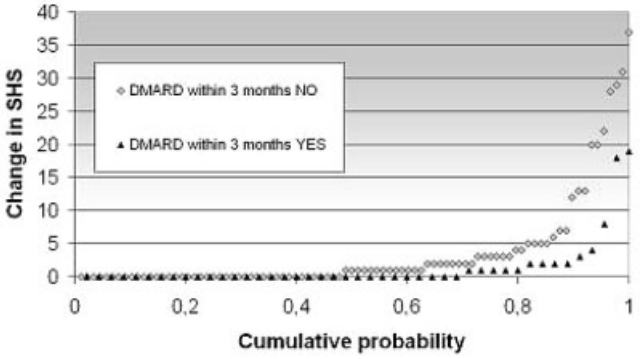
Demonstration of the Structural Efficacy of Very Early DMARD Initiation in Early Inflammatory Arthritis in Clinical Practice: Results of a Propensity Analysis in the ESPOIR. Cédric Lukas[3], Bernard G. Combe[4], Philippe Ravaud[1], Jean Sibilia[2], Robert Landewe[6] and Desiree M. Van Der Heijde[5]. [1]Department of Epidemiology and Biostatistics, Bichat Hospital, Paris, France, [2]Department of Rheumatology, Hautepierre Hospital, Strasbourg, France, [3]Department of Rheumatology, Lapeyronie Hospital, Montpellier, France, [4]Department of Rheumatology, Lapeyronie Hospital, Montpellier, France, [5]Leiden University Medical Center, Meerssen, The Netherlands, [6]Univ Hosp Maastricht, Maastricht, The Netherlands

Background: Despite the consensus recommending early treatment start in patients with early inflammatory arthritis with DMARDs of proven structural efficiency, demonstration of decreased radiographic progression with earlier therapy is scarce.

Objective: To compare radiographic progression in patients treated with a DMARD very early in the course of their disease (within 3 months after the onset of symptoms) and those who were started later on.

Methods: Patients included in the French observational ESPOIR cohort, treated independently of the data collection and without fixed protocol, were followed-up and radiographic progression after 12 months was assessed by Sharp-van der Heijde score (SHS). Propensity score (PS) was obtained by modelling the start of DMARD by logistic regression analysis using baseline disease specific and demographic variables. The influence of a very early DMARD start was evaluated by generalized linear regression, adjusting for PS as continuous covariate.

Results: 661 patients were analysed. Expectedly, patients treated within 6 months (ie with worst prognosis) showed a higher radiographic progression at 12 months ($p=0.026$). After adjustment for PS, the estimated marginal mean was significantly decreased in the early treatment group: 1.11 [0.95;1.27] SHS unit, versus 1.59 [1.48;1.69] ($p<0.001$). Additional analyses showed that this difference was especially pronounced in the groups of patients with a worse prognosis (figure).



Observed radiographic progression in patients with early inflammatory arthritis treated within 3 months after symptoms onset versus later, in the last quintile of propensity score.

Conclusion: Our results confirm for the first time that in a daily clinical practice standard of care of patients with very early arthritis, time to DMARD start clearly influences short-term radiographic outcome. These results strengthen the current recommendations claiming for a very early initiation of specific therapy in patients with early inflammatory arthritis.

Derivation of a Preliminary Administrative Claims-Based Algorithm To Identify Lack of Effectiveness of Rheumatoid Arthritis Medications. Jeffrey R. Curtis[7], Shuo Yang[4], John Baddley[1], Grant W. Cannon[9], Lang Chen[5], Elizabeth Delzell[5], Nivedita M. Patkar[2], Kenneth G. Saag[8], Monika Safford[3], Jasvinder Singh[1] and Ted R. Mikuls[6]. [1]Birmingham VAMC/UAB, [2]Univ of AL at Birmingham, Birmingham, AL, [3]Univ of AL at Birmingham, [4]Univ of Alabama at Birmingham, [5]Univ of Alabama at Birmingham, Birmingham, [6]Univ of Nebraska Med Ctr, Omaha, NE, [7]University of Alabama–Birmingham, Birmingham, AL, [8]University of Alabama-Birmingham, Birmingham, AL, [9]University of Utah, Salt Lake City, UT

Background: Administrative claims data are commonly used to evaluate medication safety. Use of this type of data to study the clinical effectiveness of medications for rheumatoid arthritis (RA) has been limited by lack of a validated effectiveness algorithm. We created and tested a claims-based algorithm to serve as a proxy for a lack of clinical effectiveness of biologics for RA patients (pts).

Methods: Using national administrative claims data from the Veterans Health Administration (VA), we identified all U.S. veterans with RA using ICD9 code 714.X. We linked medical, pharmacy, and laboratory results to the nested subcohort of rheumatologist-confirmed RA patients participating in the longitudinal VA RA registry (VARA). VARA contains clinical and RA-specific information including DAS28 and CDAI. Among VARA enrollees, we identified the date individuals initiated a new biologics (the 'index date'; no use in prior 6 months) who remained under observation $\geq$ 1 year. The gold standard outcome was low disease activity (LDA, DAS28 $\leq$ 3.2) at one year ($\pm$ 2 months), + persistence with therapy. Alternate LDA criteria was CDAI $<= 10$.

The claims-based effectiveness rule defined lack of effectiveness as non-persistence with biologic therapy or increase in biologic dose. Further, treatment was considered not effective for pts not on steroids at baseline if they initiated chronic steroids, and for those on baseline steroids, if their cumulative steroid use 6 months after treatment exceeded the cumulative dose 6 months prior to treatment. Finally, therapy was considered ineffective if pts received $>$ 1 intra-articular or parenteral joint injection after the index date + 90 days. We calculated the performance characteristics of the effectiveness algorithm, with particular interest in the negative predictive value (NPV) as a proxy for lack of clinical effectiveness.

Results: Among 1397 enrolled VARA participants who were linkable to VA administrative claims data, 292 unique patients were eligible for analysis and initiated biologics for 386 treatment episodes. Characteristics of VARA patients in the analysis were mean $\pm$ SD age 64.7 $\pm$ 11.1 years, 91% male, 64% rheumatoid factor positive. At one year, 84% of treatment episodes did not achieve LDA criteria with persistence by DAS28 criterion. The NPV of the effectiveness rule was 82% (77% – 87%) using DAS28 criteria and 65% (58 –72%) using CDAI criteria. Ongoing work is underway to refine the algorithm and maximize its performance characteristics.

Conclusion: Administrative claims data may be useful in identifying lack of effectiveness of medications for RA. Validation in an external dataset will be useful to assess the generalizability and performance of this algorithm in other RA populations.

		Gold Standard: Low Disease Activity (DAS28 $\leq$ 3.2) and Persistent at 1 year		
		+	−	
Claims-Based	+	17 (4.4%)	112 (29.0%)	129 (33.4%)
Effectiveness Rule	−	46 (11.9%)	211 (54.7%)	257 (66.5%)
		63 (16.3%)	323 (83.7%)	386 (100%)

305

Differences in Disease Severity and Response to Biologic Agents in a Racially Diverse US-Based Cohort of Patients with Rheumatoid Arthritis (RA). George A. Karpouzas[2], Rosalinda Moran[2], Soha Dolatabadi[1] and Michael Weisman[1]. [1]Cedars Sinai, [2]Harbor-UCLA

Background: Descriptions of RA behavior and response to therapy originate largely from studies in Caucasians. Additionaly, most subjects in clinical practice do not fulfill inclusion criteria for most RA trials. These observations may question the generalizability of the results of such trials to racially diverse populations. We describe RA clinical, serologic parameters, conventional and biologic DMARD utilization and therapeutic outcomes in a large, minority-enriched cohort from a single academic Center in the US.

Methods: We report on 433 pts fullfiling 1987 ACR criteria for RA and with regular follow-up. Patients were assessed quarterly, and Disease Activity Score (DAS28-3v-ESR) and functional outcomes (HAQ-DI, patient assessment of pain) were recorded. Good EULAR response (DAS28<3.2 and DAS28 change>1.2) was the only acceptable outcome and therapeutic adjustments were aimed at that goal. Continuous variables in unmatched and matched groups were analyzed with ANOVA and Wilcoxon's matched pairs test respectively. Categorical variables were analysed with Chi-square tests.

Results: Hispanics (H) comprised 81%, African Americans (AA) 12%, Caucasians (C) 5.1%, and others 3.8%. H and AA were significantly more female, and H were younger. There was no difference in disease duration, ESR, CRP, Rheumatoid Factor (RF) status and titer, or erosions in any group. ACPA (a-cyclic citrullinated peptide Ab) prevailed in AA (p=0.049). H and AA overall showed higher cross-sectional disease severity compared to C (table-p=0.04). Fewer H and AA achieved DAS28<3.2 than C (p=0.02); to accomplish this, H had higher frequency of biologic utilization than both AA and C (p=0.003). H or AA allocated biologics did not have higher disease severity at biologic onset, nor were they prescribed biologics more frequently than C. Despite a robust and similar change in DAS28 from baseline compared to C, significantly less of biologic treated H and AA achieved DAS28<3.2 (p=0.003).

Conclusion: US-based H and AA with RA have higher cross-sectional disease severity than C. In spite of similar disease activity at biologic onset, this likely reflects inferior response to biologic therapy; significantly fewer biologic-treated H and AA subjects achieved good disease control compared to C. The reasons for these disparities are under investigation.

Table. Patient Characteristics

N (%)	Hispanic = 349 (80.6)	AA = 50 (11.5)	C = 22 (5.1)	*p*-all groups

Disease Activity in Patients with Early Rheumatoid Arthritis Receiving Stable Conventional DMARDs Significantly Influences the Timing of Achieving a Low Disease State and Remission at 3 Versus 6 Months. Pooneh Akhavan[3], Vivian P. Bykerk[3], Ye Sun[4], J. Hochman[7], Janet E. Pope[10], Janet E. Pope[10], Carol A. Hitchon[11], Gilles Boire[8], Boulos Haraoui[2], Diane S. Ferland[6], J. Carter Thorne[9], Deborah A. Weber[5], Ed C. Keystone[12] and All CATCH Investigators[1]. [1]Canada, [2]Institut de Rhumatologie, Montreal, QC, Canada, [3]Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada, [4]Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada, [5]Mt Sinai Hosp, Toronto, ON, Canada, [6]Rheumatology, Hopital Maisonneuve, LaSalle, QC, Canada, [7]Rheumatology, University of Toronto, [8]Sherbrooke University, Sherbrooke, QC, Canada, [9]Southlake Regional Health Care, Newmarket, ON, Canada, [10]St Joseph Health Care London, London, ON, Canada, [11]University of Manitoba, Winnipeg, MB, Canada, [12]University of Toronto, Toronto, ON, Canada

Purpose: To date timing of treatment outcomes and responses have been evaluated mainly in retrospective studies of clinical trials in patients with high disease activity. Studies in real world patient populations with more moderate disease are sparse. We were interested in evaluating these outcomes in such a setting. The primary objective of this study was to evaluate the influence of disease activity on the timing to achieve Low Disease Activity State (LDAS) and remission (REM) in early rheumatoid arthritis (ERA) patients receiving stable treatment. We also explored the effect of baseline disease activity on response to treatment.

Methods: Patients with early RA in the Canadian Early Arthritis Cohort (CATCH), were evaluated. Patients who were receiving stable DMARDS for 6 months (with no dose adjustments after one month of initiating therapy and not receiving oral or parenteral steroids) were included. The majority of patients were receiving methotrexate ± sulphasalazine ± hydroxychloroquine. Patients with baseline moderate disease activity (MDA) (DAS28 >= 3.2 –5.1) (n= 38) versus high disease activity (HDA) (DAS 28 > 5.1) (n= 61) who had not achieved LDAS or REM at 3 months were evaluated for the proportion achieving LDAS or REM at 6 months. DAS 28 responses for these patients was compared at these two time points. We defined a poor therapeutic response by a ΔDAS 28 < 0.6 and good response by a ΔDAS < 1.2.

Results: 108 patients were evaluated with mean age of 50 years and mean disease duration of 6.3 ± 3.0 (mead ± sd) months at baseline. Rheumatoid factor was positive in 60% of patients. The majority of MDA patients achieved LDAS or REM by 3 months with a slightly greater proportion requiring 6 mo to achieve adequate clinical response. At 3 mo 58% of MDA patients achieved LDAS versus 63% at 6 months. Of 16 patients not in LDAS, 31% achieved it by 6 months. At 3 months 47% of MDA patients achieved REM versus 50% at 6 months. Of 20 patients not in REM at 3months 25% achieved it by 6 months.In patients with HDA a substantial number of patients required 6 months to achieve LDAS or REM. In these HDA patients 34% achieved LDAS at 3 months versus 62% at 6 months. Of 40 patients not achieving LDAS at 3 months 48% achieved it by 6 months while of 51 patients not achieving REM at 3 months 43% achieved it by 6 months. Of interest, almost all HDA patients achieved a ΔDAS > 0.6 (93%) or ΔDAS > 1.2 (84%) at 3 months. In contrast 37% of MDA patients failed to achieve a Δ DAS of 0.6 and 53% a change of 1.2 at 3 months. Of MDA patients with a Δ DAS of < 0.6 at 3 months, 36% achieved LDAS and 29% achieved REM at 6 months. Similar results were observed with a Δ DAS < 1.2 at 3months.

Conclusion: Baseline disease activity has a significant effect on timing to achieve an adequate clinical response. In HDA patients particularly consideration should be given to continuing therapy for at least 6 months if LDAS or REM is not achieved at 3 months.

Does Sequence Matter When Switching from One Anti–Tumor Necrosis Factor Agent to Another? O. Baser[3], S. Roy[1], C. Akin[2] and M. A. Cifaldi[1]. [1]Abbott Laboratories, Abbott Park, IL, [2]Brigham and Women's Hospital, Boston, MA, [3]University of Michigan, Ann Arbor, MI

Background: A significant proportion of patients with rheumatoid arthritis (RA) switch from one anti–tumor necrosis factor (anti-TNF) agent to another. This study examines patient characteristics, costs, and outcomes of switching from one anti-TNF to another. Predictors of switching between anti-TNFs are also examined.

Methods: Continuously eligible adult patients in a large commercial administrative claims database with confirmed diagnoses of RA between January 2002 and December 2008 were included if they had initiated new anti-TNF treatment after a 12-month biologic-free period. Disease severity was estimated using a composite Severity Index for Rheumatoid Arthritis (SIFRA), a measure validated for administrative databases. Costs and outcomes were compared between groups 12 months after the switch, after adjusting for baseline differences in patient, disease, and prescriber characteristics through a propensity score-matching technique. Cox regression was used to determine the predictors of time to switch of biologic treatment.

Results: There were 1,567 patients in the study who switched to a second anti-TNF. Of these patients, 48% (n=751) switched to ADA, 19% (n=294) to IFX, and 33% (n=522) to ETN. Patients who were younger (HR=0.40), used methotrexate (HR=0.76), or other DMARDs (e.g. SSZ, HCQ and Gold) at baseline (HR=0.73), and had a low SIFRA severity index (HR=0.85) experienced a shorter time to switching to a second anti-TNF. Patients who started with IFX or ETN switched to a second anti-TNF sooner than those

who started on ADA (HR=0.86 for ETN and 0.85 for IFX vs. ADA). Patients switching from ETN to IFX instead of to ADA had more severe disease (p=0.002), had a greater comorbidity burden (p=0.002), were more likely to use MTX (p=0.0259), and were more likely to have had dose escalation prior to switch. Patients switching from ADA to IFX had a greater comorbidity burden compared with those who switched to ETN. Among switchers from IFX, slightly older patients with higher rates of respiratory infections were switched to ADA, compared with ETN. After adjusting for baseline differences, RA-related total annual health care costs were significantly lower for switches between the subcutaneously injected anti-TNFs (ETN-ADA, p<0.0001 both ways) compared with switches to their infusion counterpart (IFX). Among all possible anti-TNF sequences, RA-related total costs, as well as disease severity were lowest one year after a switch to ADA irrespective of which anti-TNF patients were switched from (table).

Adjusted RA-Related Costs and Disease Severity Outcomes 1 Year After Switch

	ETN to IFX	ETN to ADA	P-Value	IFX to ETN	IFX to ADA	P-Value	ADA to ETN	ADA to IFX	P-Value
Total RA-related cost	$19,523	$15,632	<0.0001	$15,324	$14,986	0.574	$18,652	$24,867	<0.0001
SIFRA	5.15	4.65	<0.0001	5.01	4.71	0.0001	4.74	4.76	0.805

Conclusions: The timing and outcomes of switching were observed to be different based on sequence of anti-TNFs used. Relative to ADA, patients switched sooner to a second anti-TNF if they had started on IFX or ETN. Both cost and disease severity outcomes appear to be better for switches to ADA compared with switches to IFX or to ETN.

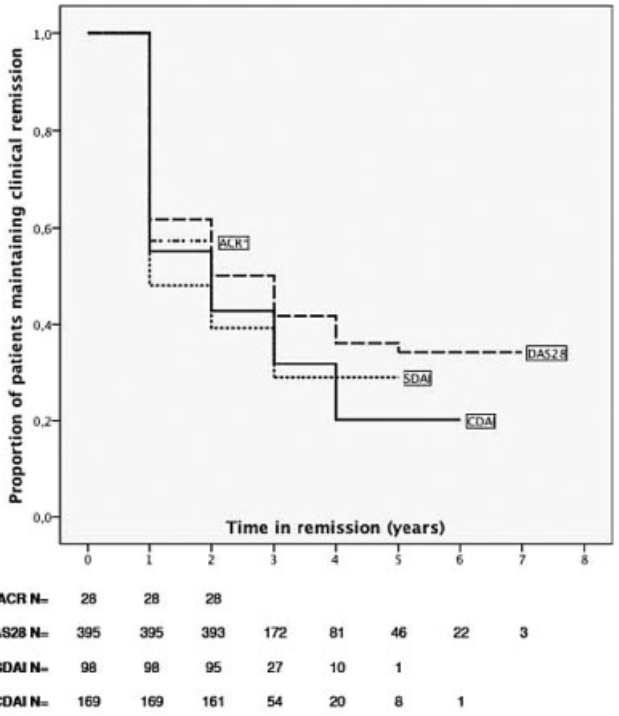
Durability of Clinical Remission in Rheumatoid Arthritis Based on Various Criteria. Femke H. M. Prince[2], Vivian P. Bykerk[2], Nancy A. Shadick[1], Jing Cui[2], Michele Frits[2], Christine K. Iannaccone[2], Michael E. Weinblatt[3] and Daniel Hal Solomon[3]. [1]Brigham & Womens Hospital, Boston, MA, [2]Brigham and Women's Hospital, Division of Rheumatology, Immunology and Allergy, BRASS, Boston, MA, [3]Brigham and Womens Hospital, Boston, MA

Background: The treatment target of Rheumatoid Arthritis (RA) is remission. Clinical remission can be defined by several criteria, but only one incorporates time as a variable. There are few data about the duration of remission by any criteria. The study aim was to describe the duration of remission periods in RA patients enrolled in a cohort from a single academic center, using different remission criteria.

Methods: Data were collected from a prospective, observational, single-center cohort of RA patients. Patients are prospectively followed, and their RA is managed according to the preference of the treating rheumatologist. Disease activity of patients was evaluated annually and remission was defined by: Disease Activity Score 28 (DAS28<2.6), ACR, Clinical Disease Activity Index (CDAI<2.8) and Simplified Disease Activity Index (SDAI<3.3). For the analyses we only included patients with: 1) at least two years follow-up; and 2) at least one remission time-point with subsequently 12 months or more follow-up. First remission time point for each patient was considered baseline. Analyses were performed using Kaplan-Meier survival curves and differences were analyzed using the log-rank-test.

Results: Of the 1095 RA patients in our study cohort, 846 had at least two years follow-up. When we considered the different remission criteria for all 846 patients, 408 were in remission at at least one time-point (with 12 months follow-up) according to the DAS28 (n=395), ACR (n=28), CDAI (n=169), or SDAI (n=98). At entrance of the cohort, median age of the 408 patients was 56 years, 83% were female, 64% were anti-cyclic citrullinated peptide or rheumatoid factor status positive, and median disease duration was eight years. Overall median survival time of remission was two years. Time in remission according to the different remission criteria is shown in the **Figure** (Kaplan-Meier curve). Probability of maintaining remission at the subsequent examination was significantly higher for the DAS28 criteria compared with the CDAI (p=0.029) and SDAI (p=0.030). The difference between duration of remission for DAS28 and ACR criteria was non-significant (p=0.57), however only few patients met the ACR criteria and no data were available for more than two years.



*ACR curve stops at 2 years

Figure. Duration of RA remission based on various remission criteria.

Conclusion: This study shows that approximately 50% of the RA patients who reached clinical remission maintained this state after one year. Even after multiple years in remission, patients can still drop out of remission. Whether patients are considered to be in clinical remission depends on the criteria used.

Effect of Anti-Tumor Necrosis Factor Alpha Therapy on Cardiovascular Events in Rheumatoid Arthritis: A Systematic Review and Meta-Analysis. Cheryl C. M. Barnabe[2], Billie-Jean Martin[1] and William A. Ghali[2]. [1]Libin Cardiovascular Institute, [2]University of Calgary, Calgary, AB, Canada

Background: Rheumatoid arthritis (RA) patients have an increased risk of cardiovascular (CV) events, attributed to both traditional CV risk factors and the inflammatory milieu of inadequately treated RA. Anti-tumor necrosis factor alpha (anti-TNF) therapy has an important role in treating patients with RA resistant to disease modifying therapies, and has been shown to have a positive impact on surrogate biomarkers of CV disease. Our objective was to systematically assess the association of anti-TNF therapy in RA on CV event rates reported in observational cohorts and randomized controlled trials (RCTs).

Methods: A search of PubMed (1950 to November 2009) and EMBASE (1980 to November 2009) was supplemented by manual searches of reference lists and conference abstracts. Observational cohorts and RCTs reporting on CV events (all events, myocardial infarction (MI), congestive heart failure (CHF), and cerebrovascular accident (CVA)) in RA patients treated with anti-TNF therapy were identified to determine the relative risk compared to those patients treated with traditional disease modifying drugs. The systematic review and meta-analysis includes 16 and 13 publications respectively.

Results: In cohort studies (total of 106,202 patients), anti-TNF therapy was associated with a reduced risk for all CV events (pooled adjusted RR 0.46; 95%CI 0.28–0.77), MI (pooled adjusted RR 0.81; 95%CI 0.68–0.96), and CVA (pooled adjusted RR 0.69; 95%CI 0.53–0.89). Cohort study results

for CHF outcomes were not suitable for meta-analysis. Meta-analysis of RCTs (total of 2,126 patients) also produced a point estimate indicating lower risk of CV events but this was not statistically significant (pooled relative risk of 0.85; 95%CI 0.28–2.59).

Conclusions: Anti-TNF therapy is associated with a reduced risk of all CV events, MI and CVA in observational cohorts. The point estimate of effect from RCTs is underpowered with wide confidence intervals, but also demonstrates a trend towards decreased risk. Limitations include heterogeneity among cohort studies and possible publication bias. For the RCT analysis, CV events were secondary outcomes and statistical power was limited.

Effect of Intensive Repletion and Maintenance Vitamin D Therapy in Rheumatoid Arthritis Patients. Uzma J. Haque[1], Kevin Fontaine[2] and Susan J. Bartlett[3]. [1]Johns Hopkins School of Medicine, Lutherville, MD, [2]Johns Hopkins School of Medicine, [3]McGill University, Montreal, QC, Canada

Background: We have previously shown that 60% of rheumatoid arthritis (RA) patients attending an academic rheumatology clinic in Baltimore Maryland were vitamin D deficient. We are not aware of any studies that have evaluated the effectiveness of intensive vitamin D supplementation and maintenance therapy in this population.

Objective: To estimate the effectiveness of intensive vitamin D supplementation and maintenance therapy on 25(OH)D levels in a cohort of RA patients.

Participants: 25(OH)D levels were obtained in 111 persons who met ACR criteria for RA and who were receiving treatment at the Johns Hopkins Arthritis Center between January 2009 and June 2010.

Methods: Patients were consecutively approached during routine clinic visits. 25(OH)D levels were ascertained using the DiaSorin radioimmunoassay. Vitamin D deficiency was defined as 25(OH)D $<$ 30 ng/mL. Patients who were deficient were randomly assigned to 8 weeks of standard intensive repletion therapy (INT= ergocalciferol 50,000 IU /week) followed by up to 16 weeks of maintenance therapy (MT= ergocalciferol 50,000 IU/month) or placebo for 16 weeks (followed by the above vitamin D treatment). Hyperparathyroidism was excluded before initiating vitamin D therapy.

Results: Participants were mostly female (83%) and white (83%) with a mean ($\pm$ SD) age of 53.8 $\pm$ 12.1 yrs. At baseline, mean 25(OH)D was 21.5 $\pm$ 5.9; 70/111 (63.1%) were classified as vitamin D deficient. Patients seen from Oct – June had 7.0 times the odds of being deficient (95% CI 1.4–35.6) as those seen July – Sept. Of 46 patients completing INT, mean increase in 25(OH)D was 18.4 $\pm$ 13.5 ng/mL; 89% were classified as vitamin D sufficient. In summer, INT therapy was associated with significantly higher increases in 25(OH)D levels than those seen in the fall and winter (20.5 $\pm$ 4.5 and 12.3 $\pm$ 3.9 mg/dL, respectively.) However, adequate levels were not maintained with maintenance therapy; in 41 patients who completed 8 weeks of MT, 25(OH)D levels decreased by -9.8 ± 10.7 ng/ml; only 61% were now classified as sufficient. Of 36 persons completing a total of 16 weeks of MT, 25(OH)D decreased an additional -3.7 ± 5.9 ng/mL overall; only 31% were classified as sufficient.

Conclusions: Despite increasing awareness of the importance of vitamin D, deficiency remains common in RA patients. Intensive supplementation therapy with ergocalciferol appears to be effective in significantly increasing vitamin D levels in most RA patients. However, maintenance therapy, as currently used in clinical practice, may not be sufficient to maintain adequate vitamin D levels in these patients over time. Given the importance of optimal vitamin D levels, routine monitoring of may be required to ensure that sufficient levels are maintained. Our data suggest that RA patients may require higher maintenance doses to sustain vitamin D sufficiency.

Effectiveness of Initial Treatment Allocation Based on Expert Opinion for Prevention of Rapid Radiological Progression in a Daily Practice Early RA Cohort. Anne Durnez[2], Geert Vanderschueren[1], Luc Lateur[1], Rene Westhovens[2] and Patrick Verschueren[2]. [1]University Hospital Leuven Radiology, Leuven, Belgium, [2]University Hospital Leuven Rheumatology, Leuven, Belgium

Background: Until now in daily practice initial treatment decisions are essentially based on expert opinion and only informally on prognostic factors. Recently a prediction model for rapid radiographic progression (RRP) was developed using a RA study population(1).

Objective: To evaluate the effectiveness of expert centered treatment selection for early RA and investigate the additional value of a prediction model for RRP in daily practice.

Methods: Consecutive early RA patients were allocated to initial combination therapy with steroids (ICTS) or DMARD monotherapy (IMT), based on informal evaluation of prognostic parameters: joint counts, ESR, CRP, RF, anti-CCP and radiographic damage(2). Subsequently a tight control strategy was applied. Baseline and year 1 radiographs were scored according to Sharp/van der Heijde (SvdH). Changes in SvdH score of more than 5 units at year 1 (=RRP) were documented. Mean change in SvdH scores and proportion of patients with RRP were compared between the ICTS and IMT group. Based on 28-SJC, RF titer and CRP/ESR, each patient was placed in the ASPIRE prediction matrix yielding a theoretical RRP risk for intensive or less intensive initial treatment. The mean risk of the selected treatment was compared between different subpopulations. The numbers needed to treat (NNT) intensively to avoid one RRP after 1 year were calculated based on the matrix model. By roc curve analysis the optimal NNT cut off for RRP prevention was determined.

Results: Patients prescribed ICTS (n=37) had a higher baseline disease activity and more were anti-CCP positive than in the IMT group (n=43). Nevertheless the mean [SD] change in total SvdH score after 1 year was lower in the ICTS group versus the IMT group (-0,95 [2,84] vs. 1,16 [4,11]; NS). There was also less RRP in the ICTS (1/37) compared to the IMT group (4/43). The mean [SD] risk associated with the expert's initial treatment choice was higher in patients with RRP (17,4% [7,7] vs. 12,21% [8,68]). The mean NNT intensively to prevent RRP was lower in the ICTS compared to the IMT group, but also in patients with compared to without rapid progression. The PPV of the NNT for RRP prevention was 12,6%, but the NPV reached 100% (sensitivity 100%, specificity 53,3%) with 9,17 as a cut off in our population.

Conclusion: Also in daily practice ICTS seems more effective for the prevention of RRP than IMT. Treatment allocation based on informal evaluation of risk factors keeps the theoretical risk for RRP under control in most patients with early RA, avoiding over- and under-treatment at group level. After a theoretically more risk full treatment choice only a minority develops RRP at 1 year, probably also thanks to subsequent treatment adaptations. The predictive matrix model would be most helpful for preventing over-treatment in daily practice.

312

ESR, CRP, or RF Status at Presentation Is Only Marginally Predictive of Future Treatments with Methotrexate or Biologic Agents over 25 Years in Two Settings in the United States and in Finland. Tuulikki Sokka[1], Hannu Kautiainen[2] and Theodore Pincus[3]. [1]Jyvaskyla Central Hospital, Jyvaskyla, Finland, [2]Medcare Oy, Annekoski, Finland, [3]New York University Hospital for Joint Disease, Hastings-on-Hudson, NY

Purpose: To analyze the likelihood of initiation of methotrexate (MTX) or anti-tumor necrosis factor alpha (anti-TNFα) biological agents in treatment of 1,892 RA patients in Jyvaskyla, Finland and 478 in Nashville, TN, USA between 1980 and 2004, according to whether rheumatoid factor (RF), erythrocyte sedimentation rate (ESR), or C-reactive protein (CRP) was in normal or abnormal range at presentation.

Methods: Databases maintained from 1980–2004 on all patients with RA seen at Jyvaskyla Central Hospital, Jyvaskyla, Finland and all patients seen by one rheumatologist at Vanderbilt University in Nashville, TN, USA were analyzed. The first recorded ESR and CRP was available for 1,892 RA patients in Jyvaskyla and 478 in Nashville. The proportion of patients in whom MTX or an anti-TNF agent was initiated over the 25 years was analyzed according to baseline values for ESR $<$28 vs. $\geq$28 mm/h, CRP $<$10 vs. $\geq$10 mg/L, and a positive RF test at any time over disease course.

Results: Findings were quite similar at the 2 sites: at baseline, normal ESR $<$28 mm/h was seen in 45% and 47% of patients and normal CRP $<$10 mg/L in 44% and 58%, in Jyvaskyla and Nashville, respectively. RF was negative throughout disease course in 38% and 37%. The only significant

difference in future therapy was seen for RF and MTX treatment in Jyvaskyla, where 69% of patients with positive RF tests were treated with MTX versus 54% of patients with negative tests (p <0.001). MTX treatment was begun in only 5% more patients in Nashville who were RF-positive vs negative (67 vs 62%, NS). Patients with abnormal values at baseline for ESR and CRP were only marginally (<5%) more likely to be treated with MTX than patients with normal values (Table). No differences were seen in likelihood of future treatment with biological agents according to baseline ESR, CRP, or RF status at any time, in either locale (Table).

Percentage of patients with RA treated with MTX or anti-TNF agent during follow-up, according to high or low baseline values for ESR, CRP, and life-time RF in Jyvaskyla, Finland and Nashville, TN.

		Jyvaskyla, Finland					Nashville, TN				
Measure	**Treatment**	**n**	**Total**	**Normal**	**High**	**p**	**n**	**Total**	**Normal**	**High**	**p**
ESR				**<28mm/h**	**≥28mm/h**				**<28mm/h**	**≥28mm/h**	
	MTX	1892	63%	62%	64%	0.41	478	64%	64%	65%	0.76
	Anti-TNF	1892	4.3%	5.2%	3.6%	0.10	478	8.4%	8.4%	8.3%	0.98
CRP				**<10 mg/L**	**≥10 mg/L**				**<10 mg/L**	**≥10 mg/L**	
	MTX	1744	62%	61%	63%	0.41	175	85%	83%	88%	0.43
	Anti-TNF	1744	4.2%	4.7%	3.9%	0.41	175	20%	19%	22%	0.59
RF				**Neg**	**Pos**				**Neg**	**Pos**	
	MTX	1874	63%	54%	69%	<0.001	292	65%	62%	67%	0.36
	Anti-TNF	1874	4.4%	4.4%	4.4%	0.99	292	14%	15%	14%	0.83

Conclusion: Baseline laboratory values for ESR, CRP, and RF have only marginal impact on the likelihood of treatment with MTX or biological agents. At least 30% of patients with RA have a normal ESR or CRP, or negative RF test. A traditional view that an abnormal laboratory test generally is associated with more severe clinical status and higher likelihood of aggressive treatment has not been studied extensively with an evidence-based approach, although insufficient data are available for ACPA (anti-CCP) in this study. Additional data from usual care at other sites could provide further information toward possible reassessment of laboratory tests in usual care of patients with RA.

Invasive Fungal Infections in Seniors with Rheumatoid Arthritis: A Population-Based Study from the Ontario Biologics Research Initiative. Jessica Widdifield[7], Sasha R. Bernatsky[3], J. Michael Paterson[1], Nadia Gunraj[2], Janet E. Pope[6], J. Carter Thorne[5], Alfred A. Cividino[4] and Claire Bombardier[7]. [1]Institute for Clinical Evaluative Science, Canada, [2]Institute for Clinical Evaluative Science, [3]McGill UHC/RVH, Montreal, QC, Canada, [4]McMaster University, Hamilton, ON, Canada, [5]Southlake Regional Health Care, Newmarket, ON, Canada, [6]St Joseph Health Care London, London, ON, Canada, [7]University of Toronto

Purpose: An increased risk of invasive fungal infections has been suggested in rheumatoid arthritis (RA). The Ontario Biologics Research Initiative (OBRI) is an innovative undertaking to promote real-world rheumatic drug surveillance, based in part on Ontario's comprehensive administrative healthcare databases. Our objective was to assess the risk of serious fungal infections in seniors with RA.

Methods: An RA cohort was assembled from Ontario billing and hospitalization data, 1992–2009. Analyses were limited to subjects aged > 65 who filled ≥ 1 prescription for an oral glucocorticoid, disease-modifying agent (DMARD) or biologic. We studied cases of invasive fungal infections (Aspergillosis, Coccidioidomycosis, Histoplasmosis, Blastomycosis, Paracoccidioidomycosis, systemic Candidiasis) identified from the diagnoses most responsible for hospitalizations and/or emergency room visits over 1998–2009. Cases of infection were matched (on age, sex, and date of cohort entry) to up to 5 controls from the same RA cohort. Multivariate conditional logistic regression analyses assessed the independent effects of demographics, comorbidity, medications, and markers of RA severity (number of rheumatology visits, extra-articular RA features, joint replacement).

Results: In 85,458 seniors with RA (contributing 614,915.5 person-years), 57 invasive fungal infections occurred (9.3 events per 100,000 person-years). Cases were more likely than controls (n=285) to be rural (42.1% of cases vs. 19.6% of controls) and to have more co-morbidities especially lung (43.9% vs 24.6%) and renal disease (12.3% vs 4.2%). Cases also had more extra-articular RA features (33.3% vs 21.4%) and more rheumatology visits. Biologic exposures were rare in our cohort, and at the time of infection, no cases were exposed to a biologic agent. In both cases and controls, the most common DMARDs were methotrexate (11.7%) and hydroxychloroquine (6.7%). In contrast, prednisone exposure > 10mg/d occurred in 17.5% of cases, versus 7.0% of controls. Multivariable models demonstrated that risk of invasive fungal infections was higher among rural-versus-urban residents (HR 14.47, 95% CI 4.46, 46.98) and in subjects with more co-morbidities (as assessed by number of distinct drugs used in the year prior, HR 1.24 95% CI 1.12, 1.37). There was a notable trend for greater risk of invasive fungal infection with prednisone doses > 20 mg/d (adjusted HR 6.10 95% CI 0.96, 38.83 (p=0.0556).

Conclusions: Rural residence and greater co-morbidity were associated with increased risk for invasive fungal infections in seniors with RA. Steroids were suggested as an independent risk factor in this population-based sample. Potential limitations of our study include relatively low drug exposure rates, the possibility of incomplete ascertainment of biologic exposures (for individuals receiving drugs through private insurance) and channelling bias (where persons at highest risk for infections may not be prescribed biologics).

Is DAS28 Remission Good Enough? Disease Activity and Functionality in Rheumatoid Arthritis, Results of the DREAM Remission Induction Cohort. Marloes Vermeer[3], Ina H. Kuper[3], Monique Hoekstra[1], Hein J. Bernelot Moens[4], Piet L. C. M. van Riel[2] and Mart A. F. J. van de Laar[3]. [1]Isala Klinieken, Zwolle, The Netherlands, [2]Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, [3]University of Twente and Medisch Spectrum Twente, Enschede, The Netherlands, [4]Ziekenhuisgroep Twente, Almelo/Hengelo, The Netherlands

Background: Remission is the goal of treatment in rheumatoid arthritis (RA). In general, remission is associated with improved functionality. However, it is unclear whether remission according to the Disease Activity Score in 28 joints (DAS28) criteria is good enough to prevent functional disability. The objective of this study was to assess the relation between DAS28 and functionality after 1 year follow-up in very early RA.

Methods: Data of the Dutch Rheumatoid Arthritis Monitoring (DREAM) remission induction cohort were used (1). Disease activity was indexed as remission (DAS28 < 2.6), low (2.6 ≥ DAS28 ≤ 3.2), moderate (3.2 < DAS28 ≤ 5.1) and high (DAS28 > 5.1). Functionality was measured with the Health Assessment Questionnaire Disability Index (HAQ; scale 0 (best) to 3 (worst)) as well as with the SF-36 Physical Functioning Scale (PF-10; scale 0 (worst) to 100 (best)). HAQ ≤ 0.5 was regarded as HAQ remission (2). Primary outcomes after one year were: median HAQ and PF-10 values and percentages of patients reaching a HAQ ≤ 0.5 stratified by DAS28 level and the association between DAS28 and functionality (HAQ, PF-10).

Results: One year data were available for 239 patients. After one year, mean (SD) DAS28 was 2.59 (1.05) and observed DAS28 levels were 56.9% (136/239) remission, 16.3% (39/239) low, 24.3% (58/239) moderate and 2.5% (6/239) high. One year median (IQR) values of HAQ and PF-10 were 0.38 (0.00–0.86) and 75.0 (55.0–90.0) respectively. Median HAQ increased as median PF-10 decreased in parallel to increasing DAS28 levels (Kruskal-Wallis Test, both p<0.001) (Table 1). Higher percentages of HAQ ≤ 0.5 were found in the lowest disease activity groups (Table 1). Percentages of HAQ ≤ 0.5 were similar for age groups (< 55 yrs and ≥ 55 yrs) and gender. Overall, DAS28 correlated with HAQ (Spearman's rho 0.41, p<0.001) and PF-10 (rho −0.32, p<0.001). In patients who were in remission after one year (n=136), DAS28 still correlated with HAQ (rho 0.22, p=0.010) and PF-10 (rho −0.19, p=0.027).

Table 1. DAS28 levels and functionality scores after one year.

DAS28 level	Median (IQR) HAQ	HAQ ≤0.5, n (%)	Median (IQR) PF-10
Remission (n = 136)	0.25 (0.00–0.50)	104 (76.5)	80.0 (65.0–95.0)
Low (n = 39)	0.38 (0.00–0.75)	25 (64.1)	75.0 (55.0–90.0)
Moderate (n = 58)	0.69 (0.25–1.16)	23 (39.7)	65.0 (40.0–80.0)
High (n = 6)	1.33 (0.94–1.91)	1 (16.7)	40.0 (22.5–60.0)

Conclusion: A lower disease activity is related to better functionality in patients with very early RA. Below the DAS28 remission threshold (DAS28 < 2.6), a lower DAS28 is still associated with better functionality scores. The DAS28 is a composite score and the HAQ and PF-10 are patient reported outcomes. Our results emphasize that aiming for remission is

important but aiming at the lowest possible DAS28 is even better as it results in improved functionality, which is relevant for patients.

Low Rate of Rheumatoid Arthritis Remission in Real Life: Might Predictive Factors Explain? Elodie Loppin[2], Ronan Garlantezec[1] and Elisabeth Solau-Gervais[2]. [1]Public Heatlh Department, University Hospital Brest, France, [2]Rheumatology Department University Hospital Poitiers, France

Objective: Remission constitutes the best achievable state in patients with rheumatoid arthritis (RA). Remission rates in usual clinical care are much more lower than the one in randomized clinical trials (1). The objective of the study was to define remission factors in "real life".

Methods: Remission has been assessed retrospectively for records of 364 patients with rheumatoid arthritis receiving usual care. These patients were out and in patients followed in an university hospital with at least one visit in year 2008. Disease activity was evaluated on records according to DAS 28 criteria. Remission was defined by a DAS28 < 2.6.Statistical analysis used Chi-2 and multivariate analysis with the software SAS9.

Results: The evaluation of disease activity was available for 328 patients (90 %). Mean age of the patients was 63 years (+/−13,7) and mean duration of the disease was 13,6 (+/−10,7). Rheumatoid factor and anti-CCP was positive respectively in 79.3% and 73.8 %. Eighty five percent had an erosive disease. The rate of global remission was 28 %. Factors associated statistically with remission in multivariate analyse were (Ors 95% confidence intervals): male sex (0,2-0,8), younger age (0,2-0,9), rheumatoid factor-positive (1,2–6,5) and the absence of concomitant prednisolone treatment (0,3-0,9). Younger age and rheumatoid factor-positive represents more a population with a "higher therapeutic objective" and female sex and older age patients have more a difference in the evaluation of the disease, rather than true differences in RA activity. Moreover, the remission rate was significantly different according to the treatment: 15% without DMARDs or biotherapy, 24% with DMARDs and 47% with anti-TNF alpha treatment. As regards to the three anti-TNF alpha, the remission rate was the lowest for infliximab (18%), than etanercept (43%). Patients treated with adalimumab had the highest rate of remission with 64%. The difference was significant between infliximab and adalimumab (OR: 1.2–101) and between infliximab and etanercept (OR: 1,1–30,15) but not between etanercept and adalimumab.

Conclusion: Male sex, younger age, rheumatoid factor-positive and corticoids free are associated with remission. Assessing remission in clinical practice is possible, and etanercept and adalimumab treatments are associated with higher rate of remission.

Lymphocytopenia and Infection Risk in Rheumatoid Arthritis: A Population Based Analysis. Deana D. Hoganson[2], Eric L. Matteson[1], Patrick D. Fitz-Gibbon[3] and Cynthia S. Crowson[3]. [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, Rochester, MN, [3]Mayo Clinic Rochester

Background: There is an increased susceptibility for infections in patients with rheumatoid arthritis (RA) which contributes to increased mortality. Lymphocytopenia is prevalent in RA patients and may contribute to increased infection risk. The purpose of this study was to examine the association between lymphocytopenia and infection in RA patients during the pre-biologic era and develop a risk score for infections.

Methods: We utilized a population based cohort of patients with incident RA ascertained between 1955 and 1994 that were followed longitudinally through their complete medical records until 1/1/2000. The outcome measures included all objectively confirmed infections (by microbiology or radiology) and serious infections (requiring hospitalization or IV antibiotics). Data were collected on smoking status, leukopenia, lymphocytopenia, comorbidities (alcoholism, diabetes mellitus (DM), chronic lung disease, cardiovascular disease (CVD)), RA disease characteristics (erosions, extra-articular manifestations (ExRA), rheumatoid factor (RF), nodules, erythrocyte sedimentation rate (ESR)) and medication use. Potential predictors were examined using multivariable Andersen-Gill models (a variation of Cox modeling allowing multiple infections per patient) with time-dependent covariates.

Results: Among the 584 RA patients (mean age 58 years; 72% female; median followup 9.9 years), 277 had ≥1 objectively confirmed infection (706 total infections), and 252 had ≥1 serious infection (646 total infections). Significant predictors of both outcomes included age, male sex, leukopenia, lymphocytopenia, alcoholism, DM, chronic lung disease, CVD, ExRA, RF positivity, nodules, ESR and glucocorticoid use. Lymphocytopenia was significantly associated with objectively confirmed (HR=1.7, 95% CI=1.3–2.2; p<0.001) and serious (HR=1.6, 95% CI=1.2–2.2; p<0.001) infections after adjustment for the other risk factors. Using these models, infection risk scores were developed for each outcome. The score discriminated patients with low (5 year risk 13% ± 4.1%), medium (5 year risk 23% ± 7.4%), and high infection risk (5 year risk 40% ± 8.5%) (figure).

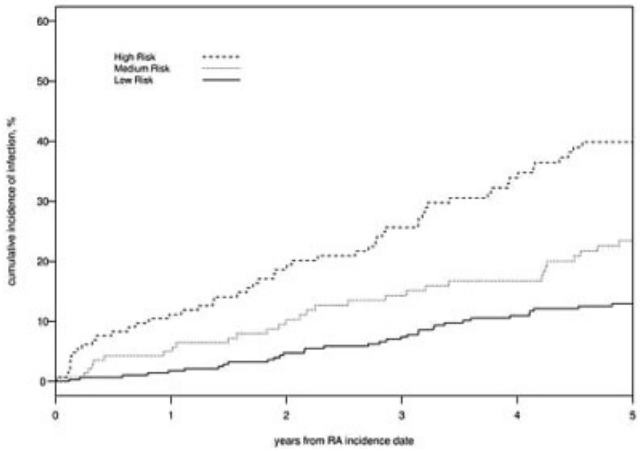

Figure. Cumulative incidence of objectively confirmed infections in RA patients based on risk score.

Conclusions: This study reveals that lymphocytopenia is an independent risk factor for infection in RA patients. A risk score may alert clinicians to the potential occurrence of infection in their RA patients. Further research is needed to examine whether this score accurately estimates the infection risk in patients treated with biologics.

Measures of Disease Activity Provide Various Clinical Decisions in Individual Patients. P. H. P. de Jong[1], J. M. W. Hazes[2], J. J. Luime[2] and A. E. A. M. Weel[3]. [1]Department of Rheumatology, ErasmusMC, Rotterdam, The Netherlands, [2]Department of Rheumatology, ErasmusMC, Rotterdam, [3]Department of Rheumatology, Maasstad Hospital, Rotterdam

Background: Disease Activity Score (DAS) and its modified versions, Simplified Disease Activity Index (SDAI) and Clinical Disease Activity Index (CDAI) are indices used to measure disease activity. Provided thresholds for activity states to adjust therapy on were solely based on rheumatologists' decisions. To achieve disease remission, treatment adjustments based on tight controlled indices is recommended in individual patients, but no preferred index is defined. Moreover, data on reflection of disease state with clinical remission are missing.

Purpose: To investigate the interchangeability of measures of disease activity to base treatment decisions on. To compare remission thresholds of indices with predefined clinical remission.

Methods: For this study data are used of a currently ongoing clinical trial in patients 18 years or older with recent-onset arthritis (tREACH). Treatment decisions to step up or step down are performed every 3 months and based upon the DAS thresholds >2.4 and <1.6. For the present study DAS indices are recalculated, namely DAS 3 variables (no patient Global), DAS-CRP, DAS-CRP 3 variables, same combinations for 28 joints and SDAI and CDAI. Thresholds for remission and active disease for DAS28, SDAI and CDAI are respectively <2.6 and >3.2, <3.30 and >11, and <2.80 and >10. Clinical remission is defined as having: (1) less than 2 swollen joints, (2) no swollen

joints and (3) no swollen and no tender joints. Discriminative ability of thresholds were calculated by sensitivity and specificity analyses using DAS as reference.

Results: 753 disease activity scores per index were available from 344 patients using data of all visits available. Active disease states of various indices compared to DAS have a sensitivity range from 78% to 90%. DAS indices with 44 joints have a specificity above 95%, others are below 90% (Table 1). For remission all DAS indices have a sensitivity above 82% whereas CDAI and SDAI have a significant lower sensitivity of respectively 28% and 26%. For specificity the indices varied not statistical significantly (Table 1).

*Diagnosis Rheumatoid Arthritis according to the ACR classification criteria-1987

SDAI and CDAI have a significant lower sensitivity and high specificity for clinical remission. All DAS indices however have a higher sensitivity but lower specificity (Table 2).

Conclusion: Various indices of disease activity misclassify disease state when compared to the original DAS, which could imply that patients have still active disease in one while not in another. Moreover remission thresholds are also discordant where SDAI and CDAI under detect clinical remission, where DAS indices might misclassify patients to be in clinical remission.

Minocycline and Doxycycline Therapy in Community Patients with Rheumatoid Arthritis (RA): Incidence, Patient-Level Determinants of Use and Side Effects. Christopher J. Smith[2], Harlan R. Sayles[2], Ted R. Mikuls[1] and Kaleb D. Michaud[1]. [1]Univ of Nebraska Med Ctr, Omaha, NE, [2]University of Nebraska Med Ctr, Omaha, NE

Background: Minocycline (MC) and doxycycline (DC) are safe and moderately effective disease-modifying antirheumatic drugs (DMARDs) in the treatment of early, DMARD-naive RA. Little is known about how these medications are used outside the context of clinical trials. We characterize the use of MC and DC in a large community of RA patients by examining associated prescribing patterns, patient-level determinants of use, and the frequency and severity of patient-reported side effects.

Methods: We studied 15,716 patients with RA observed between 1998 and 2009 while participating in a long-term US observational study. Patients were categorized by their use of MC/DC. Patient-reported side effects and their consequences were also evaluated.

Results: MC and/or DC were used 1,407 (9%) patients during their disease course with 480 (3.1%) incident users. Patients were seen by 1,067 rheumatologists, of which 196 (18.4%) prescribed MC/DC with an interquartile range of 1–2 patients per physician. Significant differences between MC/DC users and non-users are shown.

Table. Sociodemographic and disease characteristics of MC/DC users and non-users

	Initiated MC and/or DC (n = 480)	Never Used MC or DC (n = 14,309)	p-value
RA Duration (years)	14.77 (10.92)	13.70 (11.05)	0.036
Age (years)	58.35 (11.60)	59.76 (13.28)	0.021
Caucasian, Non-Hispanic %	93.68	89.72	0.005
Lifetime DMARD	2.90 (1.83)	2.13 (1.54)	<0.001
Lifetime DMARD & Biologics	3.30 (2.10)	2.52 (1.81)	<0.001
Prednisone %	40.08	35.34	0.033
SF-36 PCS (0–100)	35.03 (11.17)	36.39 (11.09)	0.008

In multivariable Cox regression, initiation of MC/DC was significantly associated with an increase in disease activity, comorbidity, previous number of non-biologic DMARDs, and calendar year, and associated with a decrease in previous number of biologic DMARDs and use of MTX, leflunomide or azathioprine. Side effects were reported by 17.8% of MC users and 11.8% of DC users. About 40% of those reporting side effects discontinued the medication. Skin complaints accounted for 54% of MC patient-reported side-effects. The most-commonly effected organ systems for DC were gastrointestinal (35.4%) and skin (33.7%). Dizziness was reported equally by MC (9.5%) and DC (8.2%) users. The majority of side effects were classified as mild or moderate for MC (70.0%) and DC (76.4%).

Conclusion: Rheumatologists have not embraced MC and DC as primary treatment options for RA and reserve their use primarily in patients with long-standing disease refractory to other agents. These drugs are generally well-tolerated with skin complaints, nausea, and dizziness being the most common patient-reported side effects.

Multi-Centre, Cross-Sectional, Observational Study of the Safety of Methotrexate and Leflunomide in Combination in the Treatment of Patients with Rheumatoid Arthritis *The SMILE Study— Safety of Methotrexate In Combination with Leflunomide.* Paul Bird[2], Hedley Griffiths[1] and The Optimising Patient Outcomes in Australian RheumatoLogy [OPAL] Consortium. [1]Barwon Rheumatology Service, Victoria, Australia, [2]Combined Rheumatology Practice (CRP), University of NSW, Sydney, NSW, Australia

Background: The combination of methotrexate and leflunomide is effective in early RA[1] and commonly utilized in Australia. The frequency of use of this combination in Australia is in part due to Federal government legislation, mandating the combination as pre-requisite treatment prior to eligibility for government funded biological therapy. Hepatotoxicity and neutropenia are two of the most common adverse effects associated with this combination.

The primary objective of this study was to assess the safety of treating patients with rheumatoid arthritis with a combination of methotrexate (MTX) and leflunomide (LEF) in comparison to methotrexate monotherapy (MTX).

Methods: Multi-centre, observational, cross-sectional, retrospective, safety study. The study was conducted by the OPAL QUMI (**O**ptimising **P**atient outcomes in **A**ustralian rheumato**L**ogy – Quality Use of Medicines Initiative). Using a clinical audit program, data was sourced from 12 participating rheumatology practices comprising 24 rheumatologists. All data was de-identified to patient, clinic and clinician prior to collection. Approval for the study was granted by the University of New South Wales Human Research Ethics Committee.

Results: In total, 3362 patients were included in the study; 72% female, 27% male, <1% gender unassigned, mean age 62 years (SD 13.8). Distribution of therapy: MTX monotherapy 49.2%, LEF monotherapy 7.6%, MTX/LEF 14.8%, Neither MTX or LEF 28.4%.

Mean MTX dose in the monotherapy group was 14 mg/week (SD 6.7), mean MTX dose in the MTX/LEF combination group 18 mg (SD 17). Mean LEF dose in the monotherapy group was 16.8 mg/day (SD 4.9), mean LEF dose in the MTX/ LEF combination group was 16.0 (SD 5.3). Co-morbid liver disease was reported in less than 5% of patients.

Liver function abnormalities were reported in 12% of the MTX monotherapy group, 16% of the LEF monotherapy group, 14% of the MTX/LEF combination group and 16% of the group taking neither of the drugs. The majority of the AST/ALT abnormalities were in the range less than 1.5 times the upper limit of normal in all four groups.

Neutropenia was reported in 2% of the MTX monotherapy group, 8% of the LEF monotherapy group, 5% of the MTX/LEF combination group and 3% of the group not taking either drug.

Conclusion: Liver function abnormalities and neutropenia in the MTX/LEF combination group were mild and equivalent to reported levels in either MTX monotherapy or LEF monotherapy. Levels of liver function abnormalities in the combination group were lower than those reported in previously published trials.[2] The combination of MTX and LEF was well tolerated, with adverse events comparable to monotherapy and the other non biologic DMARD treatment group.

Multi-Centre, Observational Study Shows High Proportion of Australian Rheumatoid Arthritis Patients Have Inadequate Disease Control. Geoffrey Littlejohn[2] and Kathleen E. Tymms[1]. [1]Canberra Rheumatology, Canberra, ACT, Australia, [2]Monash Medical Centre, Clayton, Victoria, Australia

Background: Contemporary management of rheumatoid arthritis [RA] includes early use of disease modifying drugs with the aim to achieve disease remission. RA management in Australia involves drug algorithms based on disease activity predefined by health care payers. This study used a new methodology in order to evaluate the disease activity and current therapy of RA patients managed in Australia.

Methods: Using a point of care electronic clinical management program, details of RA patients treated in 21 participating Australian clinics were collected at one point in time. This included patient demographics, diagnosis, medications and disease measures. The data was de-identified to patient, clinic and clinician. Analysis of this data was conducted to determine the proportion of RA patients who were in disease remission (DAS28 <2.6), low disease activity (LDA, DAS28 2.6–3.1), moderate disease activity (MDA, DAS28 3.2–5.1) and high disease activity (HDA, DAS28 >5.1), and their respective treatments. Ethics approval was granted by the University of New South Wales Human Research Ethics Committee.

Results: As of the 23rd April 2010, 4766 rheumatoid arthritis patients (73% females; 26% males, <1% gender indeterminate) had been assessed at 21 participating clinics. The mean age was 61.5 (60.5 females, 64.2 males) and mean disease duration was 12.6 years (13.1 females, 11.3 males). DAS28 scores were recorded for 51% of patients with 42% in remission, 20% in LDA, 30% in MDA and 8% in HDA. Of the patients in remission, 20% were being treated with a bDMARD, 77% with methotrexate (MTX), 24% with leflunomide (LEF), and 36% with prednisone. Of the patients in MDA, 23% were being treated with a bDMARD, 80% with MTX, 33% with LEF and 49% with prednisone. Of the patients in HDA, 30% were being treated with a bDMARD, 84% with MTX, 45% with LEF and 65% with prednisone.

Overall, 18% of patients were being treated with a bDMARD and 35% of patients were being treated with prednisone.

Conclusions: Cross-sectional assessment of this large cohort of Australian RA patients, managed in accordance with contemporary practice, shows a large number who have moderate and high disease activity. As disease activity predicts radiological and functional outcomes, this indicates that current RA management practice in Australia will result in significant future health burden in RA patients.

Multiple Courses of Rituximab Produce Sustained Efficacy in Patients with Rheumatoid Arthritis with an Inadequate Response to One or More TNF Inhibitors. Edward C. Keystone[6], Roy M. Fleischmann[5], Paul Emery[2], Maxime Dougados[3], Sarah Williams[4], Matthew D. Linnik[1] and Mark Reynard[4]. [1]Biogen Idec, San Diego, San Diego, CA, [2]Chapel Allerton Hospital, Leeds, United Kingdom, [3]Hospital Cochin, Paris, France, [4]Roche Products Ltd, Welwyn Garden City, UK, [5]University of Texas Southwestern Medical Center, Dallas, Dallas, TX, [6]University of Toronto, Toronto, ON, Canada

Objectives: To assess the efficacy of repeat courses of rituximab (RTX) in patients (pts) with a prior inadequate response to TNF inhibitors (TNF-IR).

Methods: Rheumatoid arthritis (RA) pts recruited into Phase II or III studies with RTX and who previously had an IR to a TNF inhibitor were permitted to receive further courses of RTX in open-label extensions. Eligibility for retreatment included a response to the initial course (at least 20% reduction in swollen and tender joint counts [SJC/TJC]) with subsequent courses given no more frequently than every 16 weeks. Criteria for retreatment included active disease defined as either ≥8 SJC and TJC or DAS28 ≥2.6 (depending on the study). Each course (C) consisted of 2 × 1000mg given as IV infusions 2 weeks (wks) apart. Efficacy was determined 24 wks following each course of RTX with outcomes assessed relative to the pts pre-RTX treatment baseline. Analyses were performed using observed data on all pts, and on all pts with efficacy data at 24 wks following each of their first five courses of RTX (the within pt-within visit [WW] population).

Results: 500 RA TNF-IR pts had been exposed to at least one course of RTX and had efficacy data at Week 24, with 119 evaluable at 24 wks following each course (WW population). Observed efficacy in all pts show higher responses for C2 onwards compared with C1. However, retreatment criteria may cause this population to become enriched for RTX responders, as pts were required to achieve a response to C1. Similar maintained or improved responses were seen in the WW population.

	All patients					Within pt, within visit				
	C1	C2	C3	C4	C5	C1	C2	C3	C4	C5
ACR responses (n)	500	360	289	222	153	119	119	119	119	119
ACR20 (%)	61.0	70.8	70.9	65.8	65.4	68.9	72.3	71.4	67.2	70.6
ACR50 (%)	30.2	41.4	46.4	43.2	42.5	35.3	41.2	45.4	42.9	44.5
ACR70 (%)	12.0	18.9	25.3	22.5	20.3	16.0	18.5	23.5	21.0	22.7
EULAR responses (n)	489	355	288	215	149	112	112	112	112	112
Good response (%)	15.7	25.4	33.3	28.8	28.2	10.7	20.5	25.9	23.2	30.4
DAS28 LDA (%)	16.2	25.6	33.7	28.8	28.2	11.6	20.5	25.9	23.2	30.4
DAS28 remission (%)	8.4	14.4	17.7	17.2	16.1	6.3	8.9	9.8	15.2	15.2
Change in DAS28										
Mean change	−2.15	−2.64	−2.93	−2.88	−2.93	−2.29	−2.63	−2.83	−2.85	−3.08
SD	1.43	1.43	1.46	1.59	1.73	1.32	1.46	1.46	1.67	1.66

LDA = DAS28 ≤3.2; remission = DAS28 <2.6

From C1 to C5, the proportion of pts in the WW population achieving DAS28 low disease activity (LDA) or remission doubled. Safety over repeat courses did not show any unexpected findings, with consistent rates of infection and serious infection.

Conclusion: In TNF-IR pts with an initial response to RTX, repeated courses of RTX were associated with sustained levels of efficacy.

National Trends in Drug Use, Health Status and Costs in Older Americans with Rheumatoid Arthritis. Leslie R. Harrold[3], Becky Briesacher[4], Daniel Peterson[1] and Jerry H. Gurwitz[2]. [1]Meyers Primary Care Institute, [2]Meyers Primary Care Institute/UMass Medical School, [3]UMass Medical Schl, Worcester, MA, [4]UMass Medical School

Introduction: Little is known about the recent adoption of the nonbiologic and biologic disease modifying anti-rheumatic drugs (DMARDs) in older patients with rheumatoid arthritis (RA), or the potential impact of these drugs on health status and costs.

Method: We identified a nationally-representative sample of RA patients in the Medicare Current Beneficiary Survey linked to Medicare claims data (unweighted unique n of 221 to 258 patients annually; initial response rate ~85%) and tracked DMARD use and health status during the years 2000–2006. RA patients were identified using a combination of ICD-9 diagnoses (714.XX); self-reported RA diagnosis, and use of biologic and nonbiologic disease modifying anti-rheumatic drugs (DMARDs). DMARD use was identified based on self-reported use of adalimumab, etanercept, hydroxychloroquine, infliximab, methotrexate, and sulfasalazine as well as procedure codes for infliximab infusions. Health status was assessed using validated, self-reported measures of functional status (the Nagi, activities of daily living, and instrumental activities of daily living) and general health status. Total costs (in 2006 dollars) for all prescription medications and medical care, as well as the proportion of all medical costs attributable to prescription medications, were examined over time. Tests for trends were conducted using weighted regressions.

Results: From 2000 to 2006, the use of any biologic in the Medicare population with RA increased almost 300% (from 4.6% in 2000 to 13.2% in 2006; p=0.01). Use of cytotoxic DMARDs occurred in 28.5% in 2000 as compared to 34.1% in 2006 (p=0.23). Use of noncytotoxic DMARDs remained at a stable rate of 21.3–25.2%. During this period, the proportion of RA patients rating their health as excellent/good increased by 29% (from 43.0% in 2000 to 55.6% in 2006; p=0.007). Significant improvements in functional status occurred in 2 of the 3 measures (ADL and Nagi). Total costs for prescription medications increased by 77% ($2645 in 2000 to $4685 in 2006, p=0.0001). Total medical costs increased but the trend was not significant. In 2000, the mean proportion of medical costs attributable to prescription medications was 30.2% as compared to 37.5% in 2006 (p=0.001).

Table 1. National trends in drug use, health status and costs in older rheumatoid arthritis patients (only even years shown)

	2000	2002	2004	2006	P values
RA patients (N)	225	258	254	247	
Medication use (%)					
Noncytotoxic DMARDs*	25.2	21.4	22.0	23.2	0.900
Cytotoxic DMARDs**	28.5	26.9	32.6	34.1	0.226
Any biologic use***	4.6	6.7	7.7	13.2	0.007
Self-Reported Health Status (%)					
Excellent/good	43.0	44.0	48.7	55.6	0.005
Functional status, mean					
Nagi	3.56 (0.11)	3.51 (0.12)	3.30 (0.10)	3.16 (0.10)	0.045
IADL	1.65 (0.12)	1.83 (0.12)	1.46 (0.11)	1.51 (0.12)	0.142
ADL	1.35 (0.12)	1.63 (0.11)	1.16 (0.12)	1.12 (0.13)	0.017
Costs					
Prescription costs (mean; 2006 dollars)	2645	3270	3726	4685	0.0001
Total medical care costs (mean; 2006 dollars)	16563	18310	17783	19510	0.296
Mean propostion of medical care costs due to prescription drugs (%)	30.2	31.9	36.6	37.5	0.001

* hydroxychloroquine and sulfasalazine
** methotrexate and leflunomide
*** adalimumab, etanercept and infliximab

Conclusions: Between 2000 and 2006, the use of biologic agents for RA substantially increased in older adults with RA. During the same period, there were concurrent improvements in self-reported health status and functional status. However, these gains were offset by an increase in total prescription medication costs.

Pandemic H1N1 Influenza Vaccination Responses in Rheumatid Arthritis and Systemic Lupus Erythematosus Patients: An Association with Serum IL17 and CXCL13 Level. Sung-Hoon Park[1], Hwa-Jeong Lee[2], Hyun-Hee Kwon[2], Seong-Kyu Kim[2] and Jung-Yoon Choe[2]. [1]Catholic University of Daegu, School of Medicine, Arthritis and Autoimmunity Research Center, Daegu, Korea, Republic of, [2]Catholic University of Daegu, School of Medicine, Arthritis and Autoimmunity Research Center

Background: Infections are the main cause of morbidity and hospitalization in immunocompromised host. With the worldwide outbreak of pandemic H1N1 2009 influenza, many patients in rheumatology department comprised a target group for prophylaxis by vaccination. We investigated an efficacy and safety of pandemic H1N1 vaccine in rheumatoid arthritis(RA) and systemic lupus erythematosus(SLE) patients, and evaluate its correlation with serum cytokine level.

Methods: This is a prospective, case-controlled study. The blood samples drawn from selected patients before vaccination and in post-vaccination weeks 4 were assayed in one session to measure titres of antibodies against haemagglutinin specific for influenza virus strains: A/New Caledonia/20/99(H1N1). Serum IL17 and CXCL13 level were measured in the same session by enzyme-linked immunosorbent assay according to the recommendations of the manufacturer's instructions(R&D Systems, Minneapolis, MN, USA). The association of serum cytokine level with anti-influenza antibody titer and mean fold increase(MFI) was investigated. Each specific side effects after vaccination were monitored in both patients and control groups.

Results: A total of 43 RA patients, 31 SLE patients were enrolled in the study and were compared with age, sex-matched 40 helathy controls(HC). The geometric mean antibody titer(GMT) for pre- and post-vaccination week 12 was not significantly different between RA and HC, SLE and HC. The seroconversion rate in HC and RA was not significantly different, while the seroprotection rate is 82.5% in HC, and 55.8% in RA, is significantly higher in HC. MFI in HC was 19.65 and 6.00 in RA, 6.06 in SLE patients, and was significantly higher in HC. The seroprotection/seroconversion rate of SLE patients were not significantly different from HC. Serum IL17 level was 6.28±2.89pg/ml and 7.56±3.34pg/ml in pre-, post-vaccination SLE patients, 33.85±15.62pg/ml and 38.04±18.60pg/ml in RA patients and was significantly lower in SLE patients. Serum CXCL13 level was 518.73±729.29pg/ml and 431.53±601.23pg/ml in pre-, post-vaccination SLE patients, which was significantly higher than HC(149.64±248.81pg/ml and 147.36±213.92pg/ml in each pre-, post-vaccination) and was not significantly different with the level of RA patients. In SLE patients, serum CXCL13 level was positively correlated with post-vaccination antibody titer(Pearson's correlation coefficient 0.44, $p<0.05$). No serious vaccination-related adverse event or disease flare was observed in HC and the patient groups.

Conclusion: The increase in post-vaccination antibody titer is weaker in both RA and SLE patients group than HC. Post-vaccination antibody titer was positively correlated with B lymphocyte chemoattractant, CXCL13 in RA, not in SLE patients.

Patient Preferences for Biologic Agents in Rheumatoid Arthritis: A Discrete Choice Experiment. David A. Navarta[2], Federico Augustovski[3], Andrea Beratarrechea[3], Vilma Irazola[3], Fernando Rubinstein[3], Pablo Tesolin[3], Juan M. Gonzalez[6], Veronica Lencina[4], Marina Scolnik[2], Christian Wainmann[5], Gustavo Citera[4] and Enrique R. Soriano[1]. [1]Hospital Italiano de Buenos Aires, and Fundacion PM Catoggio, Buenos Aires, Capital Federal, Argentina, [2]Hospital Italiano de Buenos Aires, and Fundacion PM Catoggio, Buenos Aires, Argentina, Argentina, [3]Institute for Clinical Effectiveness and Health Policy, Buenos Aires, Argentina, [4]Instituto Rehabilitacion Psicofisica, Buenos Aires, Argentina, [5]Instituto Rehabilitacion Psicofisica, Buenos Aires, Argentina, [6]RTI Health Solutions, NC

Background: Rheumatoid Arthritis (RA) is a chronic condition which requires a substantial degree of adherence to different recommendations. RA patients' preferences among available treatment options have been previously explored using different approaches. Discrete choice experiments (DCEs) allow systematic assessment of preferences by asking respondents to choose between scenarios with different attributes. We conducted a DCE to elicit RA patients' preferences regarding treatment with Biologic Agents (BA).

Methods: We designed a DCE, in which RA patients had to choose between hypothetical drug profiles that could differ in seven treatment attributes (with three to four levels each): effectiveness, route of administration, frequency of admin-

istration, local and systemic adverse effects, severe infections and out-of-pocket costs. We included RA patients older than 18 years who had never received BA from one private and one public hospital in Buenos Aires, Argentina. A Multinomial probit regression model (MNP) was used to analyze the relative importance of treatment attributes, and their willingness to pay (WTP).

Results: 240 RA patients were included. Mean age was 56.2 (SD: 13.5) years, 87% were women, and median disease duration was 9 years. All patients were receiving conventional DMARDs (84.5% Metotrexate); median Clinical Disease Activity Index was 7.5 (interquartile range [IQR]: 3.5–16), and median HAQ was 0.5 (IQR: 0–1.225). Mean family monthly income was 645 US dollars ($). All the attributes showed to be significant factors affecting choice of treatment. Most attributes levels showed coefficients with the expected signs and were statistically significant. Attributes importance ranking was in the following order: cost, systemic adverse events, frequency of administration, efficacy, route of administration, local adverse events and serious infection.

Table. Model main results. Results expressed the mean distance and CI 95% of the most favored level and the least favored level of each attribute.

Attribute	Mean	Lower limit 95% CI	Upper limit 95% CI
Cost	0.8058	0.6884	0.9245
Systemic adverse events	0.6654	0.5696	0.7573
Frequency of administration	0.6145	0.5164	0.7124
Efficacy	0.4174	0.3253	0.5094
Route of administration	0.4129	0.3053	0.5208
Local adverse events	0.3981	0.3068	0.4875
Serious infection	0.2938	0.2190	0.3701

Patients had relatively high monthly WTP for treatments that significantly reduced the risk of systemic adverse events: mean 331 (95% CI: 212–499) US dollars ($) for a reduction from 30% to 10%; of decreasing dose frequency: mean $ 302 (95% CI: 183–461) for going from weekly to monthly administration; increasing treatment efficacy: mean: $ 386 (95% CI:285–532) for 40 vs 20 mm reduction in patient global assessment VAS, and also for switching from an intravenous to an oral therapy: mean $ 262 (95% CI: 262–555).

Conclusion: Different treatment attributes had a significant and different influence in RA patients choice of BA. The results of the DCE indicated that most respondents would be willing to pay for treatments that importantly reduced the risk of systemic adverse effects, dose frequency, with increased treatment efficacy, and with an oral route of administration.

Patient Risk Perception of Teratogenicity of Disease Modifying Anti-Rheumatic Drugs. Eliza F. Chakravarty[3], Megan E. Clowse[2], Karen H. Costenbader[1], Christina Chambers[4] and Kaleb Michaud[5]. [1]Brigham and Womens Hospital, [2]Duke University, Durham, NC, [3]Stanford University, [4]University of California, San Diego, [5]University of Nebraska

Purpose: Women with chronic diseases often require long term therapy with disease modifying agents. Some of these medications are known or suspected teratogens (methotrexate has an estimated 10% risk of teratogenicity) while others have fewer pregnancy risks (hydroxychloroquine has an estimated risk of teratogenicity similar to the background rate of 3–5%) and can be safely used during pregnancy. Although counseled to avoid pregnancy while taking potentially teratogenic medications, women with chronic disease occasionally become pregnant and antenatal exposure occurs. Little is known about women's perception of teratogenic risks of immunosuppressive medications.

Methods: A comprehensive reproductive history questionnaire was mailed to women diagnosed by a rheumatologist with RA (n=870), SLE (n=237), or fibromyalgia (n=164) participating in a US longitudinal observational study of rheumatic diseases. Women were asked to estimate the risks of birth defects occurring in the general population, in women with their disease taking no medications, and after exposure to a variety of anti-inflammatory and immunosuppressive medications. Regression models were generated to identify disease, demographic, medication, treating physician, or reproductive variables that may be associated with perceived risk of teratogenicity among patients with RA.

Results: 589 (68%) women with RA, 85 (36%) women with SLE and 96 (59%) women with fibromyalgia completed the risk perception portion of the reproductive history questionnaire.

Variable	RA	SLE	Fib
n	589	85	96
Age	58.6 (12)	53.0 (10)	53.3 (10)
Disease Duration	20 (13)	18 (13)	18 (13)
Reported side effect to any drug	49%	49%	50%
Never pregnant	14 (2.4%)	1 (1.2%)	0
No Children	14 (2.4%)	3 (3.5%)	1 (1%)
Number of children	2.5 (1.4)	2.3 (1.1)	2.3 (1.1)
Ever had child with birth defect	77 (13%)	8 (9.4%)	12 (12.5%)
Risk of birth defect			
In healthy women	1.00%	0.86%	0.41%
In women with your disease	1.14%	1.09%	0.49%
With NSAIDs	1.61%	1.74%	1.19%
With prednisone	4.15%	2.25%	2.60%
With plaquenil	2.63%	2.04%	2.15%
With methotrexate	6.51%	7.28%	3.30%
With leflunomide	5.05%	9.75%	6.23%
With TNF inhibitor	4.83%	4.95%	4.05%

Mean age at questionnaire completion was 53–59 years. Almost all women had children and up to 13% reported a child with a birth defect. Only 1.5% of respondents correctly estimated the risk of birth defects in the general population, whereas 96.2% underestimated risks and 2.3 % overestimated risks. Women underestimated teratogenic risks for all categories, but identified methotrexate or leflunomide as the agents with the highest risk of teratogenicity (see table). No variables were found to correlate with level of risk perception, including: age, education, past medication use, smoking, age of disease onset, number of children, child with birth defect, side effects of medication, menopause, physician gender, or recall of discussion about teratogenicity with provider.

Conclusions: Women with RA, SLE, and fibromyalgia tend to underestimate risks of birth defects and teratogenicity in the general population as well as from chronic disease modifying agents. Educational efforts should emphasize discussions of teratogenicity and pregnancy-related risks of medication use.

Post-Treatment Changes in Serum C-Reactive Protein Levels and Clinical Response in Rheumatoid Arthritis. Paul Emery[8], Eric L. Matteson[6], Mark C. Genovese[7], Sarah Sague[1], Elizabeth C. Hsia[3], Mittie K. Doyle[4], Hongtao Fan[2], Michael Elashoff[5] and Mahboob U. Rahman[4]. [1]Centocor Research and Development, Inc., Malvern, PA, [2]Centocor Research and Development, Inc., [3]Centocor Research and Development, Inc./Univ of Pennsylvania School of Medicine, Malvern, PA, [4]Centocor Research and Development, Inc./Univ. of Pennsylvania School of Medicine, Malvern, PA, [5]Elashoff Consulting, [6]Mayo Clinic, Rochester, MN, [7]Stanford Universit, Sunnyvale, CA, [8]University Leeds, Leeds, United Kingdom

Background: With the availability of many effective therapies for RA, biomarker(s) that can reliably predict response to a treatment (tx) would be useful in clinical practice. Serum CRP levels have been known to be associated with disease activity including radiographic progression. It is however not clear if early changes in serum CRP levels in response to tx can predict sustained clinical response at later time points.

Objectives: To evaluate if early post-tx changes in CRP can reliably predict clinical response, we evaluated the association of early post-tx changes in serum CRP levels with clinical response at a later time point.

Methods: Sera were collected at wk0, 4 & 24 from GO-BEFORE (MTX naïve RA pts; 477 golimumab[GLM]+/−MTX, 160PBO+MTX), GO-FORWARD (active RA pts despite MTX; 311GLM+/−MTX, 133PBO+MTX) and GO-AFTER (active RA pts previously tx with TNF inhibitors; 304GLM, 155PBO) studies. Samples were tested for CRP levels using Roche Tinaquant assay. CRP levels at baseline (BL), wk4 & 24 in GLM±MTX and PBO+/−MTX pts achieving and not achieving multiple measures of clinical response (ACR & EULAR/DAS response criteria) were evaluated. Logistic regression models were used to test for marker associations with clinical endpts. Positive predictive value (PPV) & Negative predictive value (NPV) were calculated.

Results: The figure shows CRP levels at wk0, 4&24 among remission (DAS28-ESR<2.6) achievers and non-achievers at wk24 (as a representative data; data for other clinical measures of response were similar but not shown). Pts

achieving remission tend to have lower CRP at BL, wk4&24, compared to pts not achieving remission, & pts treated with GLM had in general lower CRP levels than pts treated with MTX or PBO. Changes from BL in CRP levels were analyzed in 3 RA populations and decreases from BL at wk4 in pts with BL CRP>1 mg/dL were significantly associated with remission at wk24 in GLM±MTX pts from GO-BEFORE (OR=1.4; p<0.002; PPV=67%; NPV=53%), GO-FORWARD (OR=2.1; p<0.000;PPV=70%; NPV=68%) and GO-AFTER (OR=1.3; p=0.06; PPV=51%; NPV=64%). Reductions from BL CRP of >50% at wk4 in these pt subsets were also signif. associated with multiple measures of clinical response including remission (data not shown).

Conclusion: While changes in CRP levels associate with clinical response and may be a good measure of disease activity in RA at any time point, it is not a reliable predictor of clinical response to tx.

Practice Patterns of US Rheumatologists Related to Diagnosis and Assessment of Disease Activity as Well as Switching Biologic Therapies in Rheumatoid Arthritis. Marco DiBonaventura[2], Sanjoy Roy[1], Jochen Ertl[2] and Mary A. Cifaldi[1]. [1]Abbott Laboratories, Abbott Park, IL, [2]Kantar Health, New York, NY

Background and Purpose: This study investigated measures used by US rheumatologists to diagnose RA and assess disease activity. We also describe the treating rheumatologists' practice patterns for switching biologic therapies for patients who discontinued anti–tumor necrosis factor (anti-TNF) agents for any reason.

Methods: A sample of US rheumatologists (N=110) from the All Global physician panel were surveyed online. The All Global physician panel is an opt-in, actively managed, online panel of several hundred thousand physicians in the US and Europe. Respondents were asked for demographic and practice information, as well as, about RA diagnostic and disease severity measures they were aware of and how often they used those measures. Responses for awareness and frequency of use were measured on a 5-point scale, where 1=never use and 5=always use.

Results: Physicians were mostly men (n=81, 74%), fairly equally distributed between urban and suburban practices (suburban: n=58, 53%). The mean number of years in practice (post-residency) was 15.9, and the mean number RA patients seen per month was 143.1. The anti–cyclic citrullinated peptide antibody (anti-CCP) test had the greatest awareness and frequency of use as a diagnostic measure (97% of physicians aware of the test; mean frequency of use score±SD, 4.5±0.9). Regarding awareness and use of assessments of disease activity, swollen joint count was the most common (SJC; 89% of physicians aware; mean use±SD, 4.2±1.4). C-reactive protein (CRP) concentration, erythrocyte sedimentation rate (ESR), and tender joint count (TJC) were among the other measures with high awareness and frequent use. Magnetic resonance imaging (MRI) and Disease Activity Score (DAS), used as measures for diagnosis or assessment, had the largest discordance between high awareness and low use. White blood count (WBC) had the largest discordance between low awareness and high use, both as a diagnostic and an assessment measure. Assessment of their switching behavior showed that rheumatologists switched biologic therapies for 25% of their patients; 67% were switched to a second anti-TNF agent; the remainder were switched to a non-TNF biologic therapy. Approximately 75%, 69%, and 52% of patients were switched to a second anti-TNF agent when the first was etanercept, adalimumab, and infliximab, respectively.

Conclusions: The anti-CCP test and SJC were the most well-known and the most frequently used measures to diagnose RA and assess disease activity. MRI and DAS were well-known but rarely used in routine practice, whereas WBC was used relatively frequently despite low awareness of its value as a diagnostic tool. Rheumatologists switched therapy for a quarter of their patients who received biologic therapy, and the switch to a second anti-TNF was more frequent for subcutaneous anti-TNF agents compared with agents administered by intravenous infusion.

Disclosure: M. DiBonaventura: Kantar Health (contractor for Abbott), 3; **S. Roy:** Abbott Laboratories, 1, 3; **J. Ertl:** Kantar Health (contractor for Abbott), 3; **M. A. Cifaldi:** Abbott Laboratories, 1, 3.

Predictors of Successful Cessation of TNF Blockers in Patients with RA. M. van den Broek[4], N. B. Klarenbeek[5], L. Dirven[5], A. A. Schouffoer[1], H. M. J. Hulsmans[2], P. J. S. M Kerstens[3], T. W. J. Huizinga[5], B. A. C. Dijkmans[6] and C. F. Allaart[5]. [1]Groene Hart Hospital, Gouda, The Netherlands, [2]Haga Hospital, The Hague, The Netherlands, [3]Jan van Breemen Instituut, Amsterdam, The Netherlands, [4]LUMC, Leiden, The Netherlands, [5]LUMC, Leiden, The Netherlands, [6]VU Medical Centre, Amsterdam, The Netherlands

Objective: To observe disease activity after cessation of infliximab (IFX) and to identify predictors of persistent low disease activity.

Methods: In the BeSt study, 120 patients with recent onset RA were treated with initial methotrexate (MTX)+IFX combination therapy, and 109 other patients started MTX+IFX after failing (DAS>2.4) on 3 previous treatment steps. If DAS remained ≤ 2.4 for at least 6 months, IFX was tapered and finally stopped. In these patients, possible predictors for a rise in DAS > 2.4, resulting in reintroduction of IFX were examined using Cox regression analysis.

Results: IFX was discontinued in 76/120 patients from the initial and

27/109 from the delayed treatment group. Median DAS at time of discontinuation was 1.39 (IQR 0.84–1.70). Over a median period of 81 months (range 16–97) follow up, 54% of patients had a persistent DAS ≤ 2.4. In 47 patients, IFX was reintroduced after a median duration of 14 (IQR 3–44) months. After a median duration of 3 months, 85% of these patients, 25/31 from the initial and 15/16 from the delayed IFX treatment group, again had a DAS ≤ 2.4. Two (4%) patients did not achieve a DAS ≤ 2.4 after reintroduction of IFX, 3 again stopped IFX because of adverse events and 2 at patient's request.

Smoking, IFX treatment duration, physician's assessment of disease activity (VAS) and yearly damage progression were predictors of reintroduction of IFX ($p<0.01$). Shared epitope (SE), erosion score and treatment group showed a trend ($p= 0.01$). Separate analyses for both treatment groups showed similar effect sizes, with the exception of smoking in the delayed treatment group. In the multivariable model, which included treatment group, smoking (Hazard rate 2.17, 95% CI 1.11–4.26), treatment duration ≥18 months (HR 2.28, 95% CI 1.01–5.12) and SE (HR 3.41, 95% CI 1.19–9.81) were independently associated with reintroduction of IFX after cessation.

Conclusion: IFX could be discontinued successfully in more than half of patients. The majority of patients who did have a disease flare quickly regained low disease activity after reintroduction of IFX. Smoking, positive shared epitope status and long IFX treatment duration (≥18 months) were independent predictors of reintroduction of IFX after cessation.

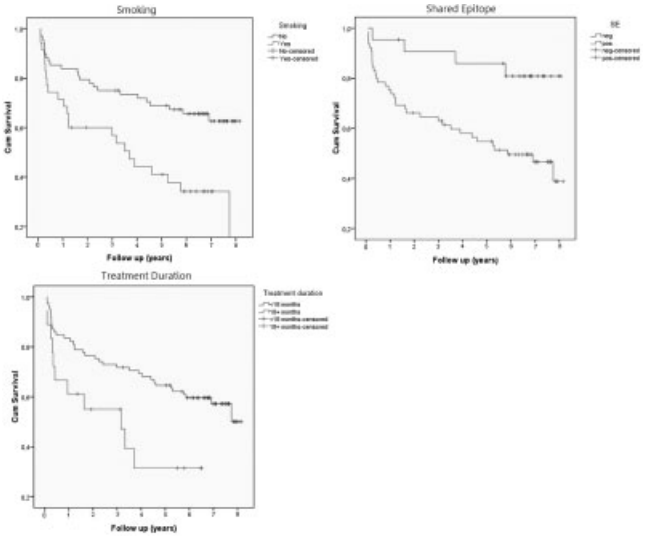

Figure: Kaplan Meier curves depicting reintroduction of IFX over time per risk factor.

Prevalence of Reactivation of Hepatitis B Virus Replication in Rheumatoid Arthritis Patients. Dai Tanaka[2], Yukitomo Urata[4], Ryoko Uesato[3], Kenji Kowatari[3], Yoshihide Nakamura[1] and Taisuke Nitobe[3]. [1]Department of Orthopaedic Surgery, Hirosaki University Graduate School of Medicine, [2]Department of Orthopaedic Surgery, Seihoku Chuo Hospital, Gosyogawara, Aomori, Japan, [3]Department of Orthopaedic Surgery, Seihoku Chuo Hospital, [4]Departments of Rheumatology, Seihoku Chuo Hospital, Gosyogawara, Japan

Purpose: Reactivation of hepatitis B involves the reappearance of active necroinflammatory liver disease after an inactive hepatitis B surface antigen (HBsAg) carrier state or resolved hepatitis B, occurring during or after immunosuppression therapy or chemotherapy. We prospectively investigated the reactivation rate for hepatitis B virus (HBV)-DNA replication in cases of rheumatoid arthritis (RA) with resolved hepatitis B.

Methods: HBV markers were evaluated in 428 RA patients. Patients with positive findings of HBsAg or HBV-DNA at enrolment were excluded from this study. Subjects comprised 422 RA patients, with resolved hepatitis B diagnosed in 135 patients based on HBsAg-negative and anti-hepatitis B core antibody/anti-hepatitis B surface antibody-positive results. HBV-DNA was measured every 3 months in this group, and if HBV-DNA became positive after enrolment, measurement was repeated every month.

Results: HBV-DNA became positive (≥3.64 log copies/mL) in 7 of 135 patients for 12 months. Use of biologic agents was significantly more frequent in patients who developed reactivation of HBV-DNA replication (85.7%) than in patients who did not (36.0%, $p=0.008$). Hazard ratios for use of biologic agents and etanercept were 10.9 ($p=0.008$) and 6.9 ($p=0.001$), respectively.

Conclusions: RA patients with resolved hepatitis B need careful monitoring when receiving biologic agents, regardless of HBV-DNA levels.

Table 1. Distribution of HBsAb and HBcAb results among HBsAg-negative and -positive patients

	HBsAg-negative		HBsAg-positive	
	HBsAb-positive	HBsAb-negative	HBsAb-positive	HBsAb-negative
HBcAb-positive	85	38	3	3
HBcAb-negative	12	0	0	0

Table 2. Comparison of HBV replication-positive and HBV replication-negative patients for baseline demographic, clinical and laboratory characteristics

Baseline demographic, clinical and laboratory characteristics	HBV replication (+)	HBV replication (−)	*P*
n	7	128	
Age, years (mean)	63.3 ± 12.9 (64.7)	65.8 ± 11.8 (66.8)	0.695

Primary Anti-TNF Failures Experience Better Clinical Responses but Similar Health Care Utilization to a Second Anti-TNF Agent Than Secondary Failures: Analysis of the Alberta Rheumatoid Arthritis Biologics Registry. Walter P. Maksymowych[2], Arto Ohinmaa[1], Liam Martin[3], Anthony S. Russell[2], Susan G. Barr[3], Dale Sholter[2], Chris J. Penney[3], Charles Yan[1] and Philip Jacobs[1]. [1]Institute of Health Economics, Edmonton, AB, Canada, [2]University of Alberta, Edmonton, AB, Canada, [3]University of Calgary, Calgary, AB, Canada

Purpose: Meta-analysis of anti-TNF switching data from observational cohorts has concluded that responses are inferior in those switching due to primary as compared to secondary anti-TNF failures but limitations include small sample size of individual studies, failure to define response, and selection bias. We assessed the impact of switching anti-TNF agents at different time points in the Alberta Biologics Registry, an observational cohort of RA patients starting anti-TNF therapy in 2004, where collection of outcome data on all patients is requested by the Provincial pharmaceutical formulary.

Methods: The Alberta Biologics Registry collects clinical, employment, and health economic data at baseline, 3 months, and every 6 months thereafter. Patients must attain either an ACR20 or EULAR response ($\geq$1.2) plus a HAQ response of $\geq$ 0.22 units by 12 weeks and maintain this at each subsequent visit to continue to receive anti-TNF agent. Health-related quality of life is measured with the EQ-5D and self reported health care utilization is measured for the six months prior to each visit. We analyzed responses according to time of switch (3 month versus subsequent time points) and according to specific anti-TNF agent switches.

Table. Change in health outcomes from baseline to 27 months of anti-TNF therapy.

	HAQ change	DAS change	EQ-5D change
Non-switcher	−0.82 (p<0.001)	−2.84 (p<0.001)	0.30 (p<0.001)
1° failure switcher	−0.70 (p<0.01)	−2.59 (p<0.001)	0.30 (p<0.001)
2° failure switcher	−0.41 (p<0.01)	−1.70 (p<0.001)	0.20 (p<0.01)

Results: From 1,222 patients in the registry, 649 patients had 27 month follow up assessment and 498 (76.7%) of these remained on the first anti-TNF during the study period. There were 28 (4.3%) primary failures and 123 (19%) secondary failures who switched a median of 15 months from baseline. The response rate to the second anti-TNF was somewhat better in the primary versus the secondary failures (p=NS) at 3 months after initiation of the second anti-TNF for HAQ, DAS, EQ-5D. By 27 months, switchers due to primary failures had attained comparable reductions in outcomes to non-switchers while changes in secondary failures were from 50% (HAQ) to 68% (EQ-5D) lower compared to non-switchers (p<0.05). Health care utilization was significantly reduced in four measured parameters over 27 months: number of rheumatologist visits (-0.31 visits, p<0.001), family physician visits (-0.95, p<0.001), % having $\geq$1 outpatient visit (-0.22, p<0.001), and % having day surgery (-0.026, p<0.001). This reduction was comparable between patients switching amongst different anti-TNF agents and non-switchers.

Conclusion: The results from this mandatory registry show that primary failures to anti-TNF show similar responses to patients responding to their first anti-TNF agent. Clinical responses in secondary failures are less optimal. Despite this, there is no significant difference between primary and secondary failures in the significant reduction in the health care utilization while receiving their second anti-TNF agent over the course of the 27 month follow up period.

331

Rate of Remission in Clinical RA Patients by ACR/EULAR Criteria. Shadi H. Shahouri[3], James D. Anderson[5], Ruth E. Busch[2], Timothy S. Shaver[4], Shirley Y. Wang[3], David N. Weidensaul[1], Martin J. Bergman[6], Kaleb D. Michaud[8] and Frederick Wolfe[7]. [1]ARCKArthritis & Rheum Clinics KS, Wichita, KS, [2]Arthritis & Rheum Clinic, Wichita, KS, [3]Arthritis & Rheum Clinic of KS, Wichita, KS, [4]Arthritis & Rheum Clinics KS, Wichita, KS, [5]Arthritis & Rheum Clinics KS, Leawood, KS, [6]Arthritis and Rheumatology, Ridley Park, PA, [7]Natil Data Bank for Rheumatic, Wichita, KS, [8]Univ of Nebraska Med Ctr, Omaha, NE

Purpose: Remission is the most desirable outcome of RA treatment, but a multiplicity of definitions has hampered the measured of remission in the community. The ACR/EULAR remission committee has recently made recommendations for RA clinical trials, and also provided possible alternatives for clinical practice. We explored the clinic practice suggestions and determined the rate of remission in a large multicenter RA clinical practice.

Methods: From 1,350 consecutive RA patients seen in clinical practice between January 2007 and March 2010 during 12,801 visits, we studied 1,079 patients with ESR data during 5,289 clinical visits. ESR missing data was primarily a function of patient medical insurance. We calculated a series of remission measures according to the ACR/EULAR recommendations.

Name	Definition
ACR/EULAR-3	SJ28 $\leq$1 & TJ28 $\leq$1 & Pt global $\leq$1
ACR/EULAR-4	SJ28 $\leq$1 & TJ28 $\leq$1 & Pt global $\leq$1 & MD global $\leq$1
ACR/EULAR CDAI	(SJ28 + TJ28 + Pt global + MD global) $\leq$ 2.8
ACR/EULAR-3 + ESR	SJ28 $\leq$1 & TJ28 $\leq$1 & Pt global $\leq$1 & (ESR <30 mm [women] or < 10 mm [men])
ACR/EULAR-3 + Low ESR	SJ28 $\leq$1 & TJ28 $\leq$1 & Pt global $\leq$1 & (ESR <22 mm [women] or <11 mm [men])

Each patient contributed an average of 4.9 observations (range 1–24). We determined the rate of remission by modeling all observation using general estimating equations. We also included ACR/EULAR-3 to define the limit of remission without ESR and we used ACR/EULAR-3 + Low ESR to explore a more restrictive ESR limit based on the distribution of ESR in the community.

Results: Patients' age and RA duration were 58.8 (SD 13.9) years and 10.0 (10.1) years, and 75% of patients were women.

Name	Rate (95% CI)	Biologic effect (On vs. not on)
ACR/EULAR-3	8.4% (7.2, 9.6)	9.3% vs. 7.7%, p = 0.068
ACR/EULAR-4	5.1% (4.2, 6.1)	6.7% vs. 4.0%, p <0.001
ACR/EULAR CDAI	7.5% (6.4, 8.7)	10.3% vs. 5.6%, p <0.001
ACR/EULAR-3 + ESR	6.0% (4.9, 7.0)	6.4% vs. 5.5%, p = 0.229
ACR/EULAR-3 + Low ESR	4.0% (3.2, 4.9)	4.3% vs. 3.8%, p = 0.408

The rate of remission ranged from 5.1% to 7.5% according to the ACR/EULAR recommendation. The rate rose to 8.4% from 6.0% when ESR was eliminated and fell to 4.0% when ESR limits were tightened. In the ACR/EULAR-3 and the ESR criteria, the rate of remission was not higher in biologic treated patients, but was higher in all criteria that included MD global (ACR/EULAR-4 and ACR/EULAR CDAI).

Conclusions: Overall, the rate of remission using contemporary RA treatment in the community is between 5.1% to 7.5%. These rates are substantially lower than reported in clinical trials using DAS-28 criteria. Criteria that include physician global tend to find more benefit with biologic therapy than criteria that do not include physician measures.

Rituximab Alters the HDL Particle from a Pro-Inflammatory into an Anti-Inflammatory Property in Good Responding Rheumatoid Arthritis Patients. Hennie G. Raterman[2], Han H. M. Levels[1], Alexandre E. Voskuyl[2], Willem F. Lems[2], Ben A. C. Dijkmans[2] and Michael T. Nurmohamed[2]. [1]Academical Medical Center, The Netherlands, [2]VU University Medical Center, Amsterdam, The Netherlands

Background: Rheumatoid arthritis (RA) patients suffer from an increased prevalence and incidence of (non)fatal cardiovascular diseases (CVD). A well known risk factor for CVD is an atherogenic lipid profile and, interestingly, a high inflammatory state is associated with an unfavourable lipid profile in RA patients. Moreover, an inflammatory state alters the HDL into a more proatherogenic composition as the particle loses its anti-inflammatory features. Effective anti-inflammatory treatment with TNF blocking agents improves the lipid profile, but data about effects of novel biological agents like rituximab on lipid profile is limited in RA patients.

Objective: To investigate the changes in HDL protein composition in rituximab treated RA patients.

Methods: In 12 RA patients (6 good responding and 6 non responding patients), who participated in an ongoing observational study of consecutive rituximab treated RA patients, serum and EDTA plasma samples were collected at baseline, 3 months and 6 months and stored at − 80°C. In these

samples lipid levels (including total and HDL cholesterol, triglycerides and apolipoproteins (ApoA-I and ApoB)) were assessed in a single run. After anti apo A-I immunocapture, HDL protein profling was carried out using surface-enhanced laser desorption/ionization time-of-flight mass spectrometry (SELDI-TOF MS) analysis. GEE analyses were used to determine disease activity marker and lipid changes in time.

Results: At baseline DAS28 was significantly higher in EULAR non responders compared to responders (see table, p = 0.001). Other baseline characteristics did not differ significantly between responders and non responders. As expected, after 6 months treatment significant changes in DAS28 and CRP were observed in responders versus non responders. No other significant changes were observed after 6 months treatment. SELDI-TOF MS analysis revealed a significant decrease in density of the mass charge (m/z) marker 11,743, representing serum amyloid A (SAA)-1, in good responding rituximab patients when compared to non responding patients. Moreover, 7 other markers (i.e. 3,893, 7,065, 8,647, 9,401, 9,764, 15969 and 87,407 m/z ($p<0.05$)) changed significantly in the good responding patients. In these patients no significant changes in HDL, ApoA-1 and ApoB levels were observed, although triglycerides were significant lower in good responding patients during treatment.

Table. Characteristics of rituximab treated RA patients.

	Responders baseline	Non responders baseline	Responders t = 6 months	Non responders t = 6 months
DAS28	5.0 ± 0.7	6.6 ± 0.5*	2.8 ± 0.6#	6.3 ± 0.3*
CRP, mg/l	7.5 (4–14)	16 (10–64)	2.6 (2.5–6.3)	22 (4–60)
total cholesterol, mmol/l	4.72 ± 0.92	5.22 ± 1.2	5.10 ± 1.4	5.05 ± 1.2
HDL cholesterol, mmol/l	1.64 ± 0.4	1.55 ± 0.5	1.68 ± 0.5	1.50 ± 0.3
total: HDL cholesterol	2.97 ± 0.6	3.59 ± 1.1	3.09 ± 0.6	3.38 ± 0.66
Triglycerides, mmol/l	1.03 ± 0.3	1.49 ± 0.4	1.08 ± 0.3	1.68 ± 0.8
LDL, mmol/l	2.62 ± 0.7	3.0 ± 1.0	2.93 ± 1.1	2.79 ± 1.0
ApoA-I, mmol/l	1.62 ± 0.3	1.66 ± 0.4	1.64 ± 0.3	1.64 ± 0.2
ApoB, mmol/l	0.65 ± 0.1	0.77 ± 0.2	0.71 ± 0.2	0.72 ± 0.2
ApoB: ApoA-I ratio	0.42 ± 0.1	0.48 ± 0.1	0.44 ± 0.1	0.44 ± 0.1

*$p < 0.05$ compared with responders. #$p < 0.05$ compared with baseline

Conclusions: In good responding rituximab treated RA patients the qualitative changes in the HDL protein composition reflect the change in disease activity, giving circumstantial evidence that next to quantitative changes in lipid levels during anti-inflammatory therapy the HDL particle seems to alter into a less proinflammatory and anti-atherogenic composition.

Rituximab-Reduced Immunoglobulin Free Light Chains in RA Correlate with Disease Suppression: A Novel Mechanism of Action of Rituximab. J. Tekstra[3], T. Groot Kormelink[2], R. Thurlings[1], M. Boumans[1], K. Vos[1], P. P. Tak[1], J. W. J. Bijlsma[3], F. P. J. G. Lafeber[3], F. A. Redegeld[2] and J. A. G. van Roon[3]. [1]Clinical Immunology & Rheumatology, Academic Medical Center/University of Amsterdam, The Netherlands, [2]Pharmacology and Pathophysiology, Utrecht Institute for Pharmaceutical Sciences, Fac. Science, Utrecht, the Netherlands, [3]Rheumatology & Clinical Immunology, University Medical Center Utrecht, The Netherlands

Background: Immunoglobulin kappa and lambda free light chains (FLCs) are produced physiologically and levels are increased in several inflammatory diseases like asthma, inflammatory bowel disease and rheumatoid arthritis (RA). FLCs are short-lived products of B lymphocytes and have been shown to promote inflammation by activation of mast cells.

Objective: To investigate the expression levels of local and systemic levels of FLCs and their correlation with disease activity and to study whether FLC changes upon B cell targeted therapy in RA patients correlate with changes in disease activity.

Methods: FLC expression levels were measured in synovial fluid (SF) and synovial tissue (ST) of RA and OA patients (SF n=68 vs n=24; ST both n=10). 50 RA patients with active disease were treated with rituximab. Clinical response was defined according to the EULAR criteria. FLC kappa and lambda concentrations were measured at baseline and 3 and 6 months after treatment. At these time points, total immunoglobulin concentrations, rheumatic factor (RF) and anti-CCP levels were also measured.

Results: Strongly increased FLC concentrations were found in SF from inflamed joints (mean 24 vs 144 mg/L, $p<0.0001$) that correlated with disease parameters (ESR, both kappa and lambda FLC $p<0.001$). Increased FLC expression was also detected in ST of RA patients. Serum FLC levels also correlated with DAS 28 ($p=0.006$ for kappa and $p=0.04$ for lambda) and ESR and CRP (all $p<0.01$). Over time, kappa and lambda FLC concentrations decreased after rituximab treatment ($p<0.001$ for baseline vs 3 months and $p<0.01$ for baseline vs 6 months after treatment for both kappa and lambda FLC). Patients without clinical response to rituximab showed no significant reduction of FLC concentrations, whereas patients who responded clinically did show a significant decrease in FLCs (both $p<0.001$). Changes in FLC concentrations, 3 and 6 months after treatment, showed a highly significant ($P<0.001$) correlation with the changes in ESR. As described previously, RF levels and, to a lesser extent, anti-CCP antibody levels decreased after rituximab treatment (45% and 26%, resp). In contrast to FLC concentrations, these decreases did not discriminate clinical responders from non-responders. Total IgG, IgA and IgM concentrations remained within normal limits.

Conclusion: Rituximab significantly reduced FLC levels that are increased in RA patients. Changes in FLC concentrations significantly correlate with the clinical response. Our study suggests that inhibition of FLCs may represent a novel anti-inflammatory mechanism of Rituximab treatment.

Seven Year Results of DAS Steered Treatment in the BeSt Study: Clinical and Radiological Outcomes. L. Dirven[5], M. van den Broek[5], N. B. Klarenbeek[5], M. V. van Krugten[1], P. A. H. M. van der Lubbe[2], P. J. S. M. Kerstens[3], T. W. J. Huizinga[5], B. A. C. Dijkmans[6] and C. F. Allaart[4]. [1]Admiraal de Ruyter Hospital, [2]Haga Hospital, [3]Jan van Breemen Institute, [4]Leiden Univ Med Ctr, Leiden, The Netherlands, [5]Leiden University Medical Center, [6]VU Medical Centre, Amsterdam, The Netherlands

Objective: To compare clinical and radiological outcomes of four treatment strategies after 7 years DAS-steered treatment in recent onset rheumatoid arthritis.

Methods: 508 recent onset RA patients were randomized into four treatment strategies: 1. sequential monotherapy, 2. step up combination therapy, 3. initial combination with prednisone, 4. initial combination with infliximab. Treatment adjustments were made every three months based on DAS measurements (if DAS >2.4: dose increase/switch next treatment step, if DAS ≤ 2.4 during ≥6 months: taper to maintenance dose, next if DAS <1.6 during ≥6 months: stop anti-rheumatic treatment). Functional ability (HAQ) was analyzed with a linear mixed model (LMM) with time, treatment and time*treatment as independent variables. Joint damage progression (Sharp-van der Heijde Score (SHS)) was assessed on X-rays of baseline and year 2, 4, 5, 6, 7 and scored by two independent readers in random order, blinded for patient identity.

Results: After 7-years follow-up, 130 patients (26%) dropped out the study. At t=7 year, 79% had a DAS ≤2.4 and 46% DAS <1.6 (remission), equally distributed among the four groups (table). Sixteen, 16, 17 and 17% of the patients in groups 1–4 were in drug free remission with a median (mean) duration of 36 (31) months. Ten patients lost and six new patients achieved drug free remission in year 7. Four patients with prolonged drug-free remission dropped out. The initial improvement of function, which occurred earlier in groups 3 and 4 than in groups 1 and 2, was maintained without deterioration over 7 years time in all groups. Over time (LMM), patients in group 4 have significantly better functional ability compared to groups 1 and 2 (mean HAQ: 0.70, 0.71 and 0.57 respectively). After initial differences between the 4 groups, yearly radiological damage progression rates were similar between all groups, reflecting the efficacy of DAS-steered therapy. Differences in total damage after 7 years are no longer statistically significant. Mean SHS progression in patients in sustained drug free remission was 0.3 (median (IQR) 0 (0–0.2)) per person year drug-free. Toxicity was comparable between the groups.

Conclusion: With continued DAS steered treatment aiming at DAS ≤2.4, functional improvement was maintained and radiological progression as well as percentages in remission and in drug free remission were stabilized. Over 7 years time, patients treated with initial combination therapy with infliximab had better functioning than patients treated with initial monotherapy.

Surveillance of Surgical Site Infection in Patients with Rheumatoid Arthritis. Kengo Harigane[1], Yuichi Mochida[2], Katsushi Ishii[2], Naoya Taki[2], Naoto Mitsugi[2] and Tomoyuki Saito[3]. [1]Yokohama City University Medical Center, Yokohama, Kanagawa, Japan, [2]Yokohama City University Medical Center, [3]Yokohama City University School of Medicine

Introduction: After introducing the guideline of Centers for Disease Control and Prevention in 1999, clinical concern about SSI has been increasing. Recently, the guideline is widely recognized as the basics for prevention protocols of SSI. Although rheumatoid arthritis (RA) is listed as a risk factor for SSI in the guideline, few studies were reported about the disease specific surveillance with RA.

Objectives: The aims of current study were to examine the incidence and to identify risk factors of SSI in patients with RA.

Methods: The clinical records of 779 patients (female 710 cases and male 69 cases) with RA who underwent orthopaedic surgeries in our hospital between January 1999 and October 2009 were carefully reviewed and the occurrences of SSI were investigated. SSI was strictly determined using the definitions of the guideline of CDC. The associations of SSI with administration of steroids and MTX, and with the presence of diabetes mellitus were also analyzed.

Results: Seventeen cases were recognized as SSI (2.2%); nine cases were superficial and eight cases were deep infections. The incident rate of SSI in arthroplasty cases was 2.9%, which was higher than the rate in non-arthroplasty cases (1.4%), however the p-value did not reach statistical difference ($p=0.2$). Steroids administration showed a statistically significant risk of SSI ($p=0.04$), on the other hand, methotrexate administration was a negative risk factor of SSI ($p=0.047$). The dose of oral steroids at the time of surgery clearly showed a positive dose-dependent correlation with the rate of SSI ($p=0.01$). There was no significant correlation between SSI and the presence of diabetes mellitus.

Conclusion: After introducing the strict guideline of CDC, reported incidences of SSI became higher (approximately 2%). In those reports, more than half cases of SSI occurred in superficial lesions. The results of current study were similar to recent reports. The incident rates of SSI showed no statistical difference between arthroplasty and non-arthroplasty cases. As for risk factors, the administration of steroids was a risk of SSI, in contrast, administration of MTX was a negative risk factor of SSI.

Sustained Remission in Early RA: Results from SONORA Study. Claire Bombardier[3], Pooneh Akhavan[2], Maggie Chen[1] and Xiuying Li[1]. [1]University Health Network, [2]University of Toronto, University Health Network, [3]University of Toronto, University Health Network, Mount Sinai Hospital, Toronto, ON, Canada

Purpose: Remission constitutes the best achievable state in patients with rheumatoid arthritis (RA). Current measures of Disease Activity - such as the DAS28 - define the patient's remission status at a given point in time. While, for the patient, sustained remission over time is the ultimate goal. The purpose of this study is to assess the frequency and predictors of sustained remission in a large cohort of early RA patients in regular clinical practice.

Methods: A total of 994 patients diagnosed as early RA (symptoms ≥3 and ≤12 months) by a board-certified rheumatologist across North America were recruited in this study. We analyzed remission and sustained remission in 851 patients who had two-year complete follow up information. Remission was defined as less than 2.6 for DAS28 and sustained remission was defined as consecutive remission at year 1 and year 2. Univariate logistic regressions were used to explore the predictors for sustained remission and multivariate logistic regression were used to estimate the remission probabilities controlling for significant factors.

Results: The mean age of patients was 53 years (SD, 14.8), with 72% female and 90% Caucasian. The mean RA symptom duration was 170 days (180), 61% were seropositive for rheumatoid factor and 43% anti-CCP positive (>20 unit/ml) at baseline. Seventy-four percent of patients had received DMARDs at baseline compared to 90% at year 1 and, 87% at 2. Two percent of the subjects were on Biologics at baseline compared to 15%, 23% at year 1 and 2. Remissions at any one of the two visits were seen in 238 (28%) patients. Among them, 68 (8%) patients achieved sustained remission. The univariate logistic regression showed that low baseline DAS28 score, HAQ score, disease duration and CRP are significant predictors for sustained remission. The multivariate logistic regression showed that HAQ is no longer significant when other factors (low baseline DAS28, low CRP and short disease duration) are in the model. The final model therefore excludes HAQ as a predictor.

Table 1.

	Odds ratio	95% CI	P-value
Baseline DAS28	0.660	(0.536, 0.813)	<0.0001
Disease duration (in months)	0.878	(0.796, 0.968)	0.0091
CRP	0.834	(0.723, 0.962)	0.0126

Conclusions: Low sustained remission rates were observed in this early RA cohort recruited before the wide use of biologics. The multivariate model predicts the probability of sustained remission using easily accessible clinical and laboratory variables. These identified factors can help guide rheumatologists in making treatment decisions for early RA patients.

Disclosure: C. Bombardier: None; **P. Akhavan:** None; **M. Chen:** None; **X. Li:** None.

Sustained Remission, a Realistic Target in Early Rheumatoid Arthritis Patients Treated with Conventional DMARDs. Irazú Contreras-Yáñez, Marina Rull-Gabayet and Virginia Pascual-Ramos. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Ciudad de México, DF, Mexico

Background: A remission-like state has become the treatment goal of patients with early rheumatoid arthritis (≤12 months, ERA).

Objectives: To describe sustained outcomes in an ERA cohort of patients treated with conventional disease modifying anti-rheumatic drugs (DMARDs) in whom long-standing follow-up is performed in a real clinical setting. To identify associated predictors.

Patients and Methods: 101 ERA with at least 2 years of follow-up were included. Standard baseline and consecutive assessments (2 monthly apart for the first 2 years and every 2, 4 or 6 months, thereafter) included swollen and tender joint counts, patient-reported outcomes, acute reactant phase determinations, disease activity score-28 joints evaluated (DAS28),

comorbidity and treatment evaluations. At baseline, socio-demographic data, rheumatoid factor (RF) and antibodies to cyclic citrullinated peptides (a-CCP) were recorded and determined. *Permanent sustained remission* (*PSR*) was defined when patients achieved sustained remission (SR=at least 3 consecutive 2 monthly apart DAS28≤2.4) and maintained it until last follow-up, *lost sustained remission* (*LSR*) when patients achieved SR but within follow-up DAS28 was >2.4 and *persistent disease activity (PDA)* when patients never achieved SR. Cumulative treatment and comorbidity were defined prior to outcomes.

Statistics: X^2, t-Student, ANOVA and Cox regression analysis were used.

Results: At baseline, 88 (87.1%) patients were females, 78 (77.2%) had RF and 71 (71%) a-CCP; their (mean±SD) age was of 38.2±13.5 years, disease duration of 5.2±2.7 months, DAS28 of 6.1±1.3 and health assessment questionnaire (HAQ) of 1.5±0.9. Seventy-one patients (70.3%) received aggressive treatment (≥3 combined DMARDs). At last follow-up (49±13.8 months), 34 patients (33.7%) achieved PSR, 54 (53.5%) achieved LSR and 13 (12.9%) had PDA.

Patients with favorable outcomes (persistent or lost sustained remission) had less frequently baseline RF and a-CCP (p≤0.07) and lower clinical (p=0.07) and serological (p≤0.004) disease activity at baseline than persistently active patients. Patients with PSR achieved sooner their state than patients with LSR (p=0.008). Persistently active patients received more frequently corticosteroids at any time (p≤0.07) and a more aggressive DMARDs treatment at baseline (p=0.02) than both groups of patients who achieved sustained remission.

To identify predictors of favorable outcomes, patients with PSR were compared to LSR patients. Early (within the first year of follow-up) sustained remission was the only predictor of permanent sustained remission (HR: 3.5, 95%CI: 1.6–7.6, 0=0.001) after controlling for baseline RF, aggressive DMARD treatment and disease duration. Similar results were obtained when patients with PDA and LSR were combined and compared to patients with PSR (HR: 4.15, 95%CI: 1.93-0.95, p≤0.001) after controlling for baseline RF and ESR, aggressive DMARD treatment and baseline number of DMARDs/patient.

Conclusions: Sustained remission is achieved by most of the ERA who received DMARDs. Patients who achieve early a sustained remission state show an excellent longstanding outcome.

Disclosure: I. Contreras-Yáñez: None; **M. Rull-Gabayet:** None; **V. Pascual-Ramos:** None.

Switching Patterns for Biologic Drugs among Patients with Rheumatoid Arthritis Who Have Previously Failed at Least One Biologic Agent. Stephen Johnston[2], Sarika Ogale[1], Nicole Princic[3], Bong-Chul Chu[3] and Tripthi Kamath[1]. [1]Genentech USA, Inc., [2]Thomson Reuters, Washington, DC, [3]Thomson Reuters

Background: There is limited real-world observational data on switching patterns for biologic disease modifying antirheumatic drugs (DMARDs) in patients with rheumatoid arthritis (RA) who have previously failed at least one biologic DMARD.

Methods: Retrospective observational study using healthcare claims from the Thomson Reuters MarketScan® Research Databases.

Selected patients were aged 18 or older and initiated a biologic DMARD (abatacept, adalimumab, etanercept, infliximab, or rituximab) between 3/1/2006–9/30/2008 (initiation date = index) with evidence of at least one different biologic DMARD during the 12 months prior to index. Patients were required to have at least one medical claim with an ICD-9-CM diagnosis code for RA (714.0x) within 12-months prior to index; patients with diagnoses for other conditions in which biologic DMARDs are indicated were excluded.

A 12-month pre-index baseline period was used to measure patient characteristics and a minimum 12-month post-index period was used to measure time-to switch (days from index until the first occurrence of a switch to a different biologic DMARD or censoring at disenrollment). The Kaplan Meier product-limit method of survival analysis and a log-rank test was used to test the statistical significance of differences in time-to switching.

Results: Table 1 displays demographic and clinical characteristics for the 3,049 patients who were selected for study.

Table 1. Baseline demographic and clinical characteristics of RA patients initiating a subsequent biologic DMARD after failing at least one biologic DMARD

	Abatacept N = 620	Adalimumab N = 1,073	Etanercept N = 609	Infliximab N = 424	Rituximab N = 323
Age, mean (SD)	58.4 (12.4)	56.6 (11.8)	55.7 (12.1)	55.6 (12.0)	57.2 (11.9)
Female, %	82.3%	81.7%	78.3%	77.1%	75.2%
Northeast region, %	7.6%	10.2%	11.5%	8.5%	7.7%
North Central region, %	27.7%	27.4%	29.6%	25.0%	32.8%
South region, %	46.6%	40.5%	39.9%	50.0%	44.9%
West region, %	17.6%	21.3%	18.4%	16.3%	14.2%
Deyo-Charlson Comorbidity index, mean (SD)	1.6 (1.1)	1.5 (1.1)	1.6 (1.0)	1.6 (1.0)	1.8 (1.3)
Prior methotrexate, %	56.9%	61.2%	63.7%	70.3%	62.5%
Unique 3-digit ICD-9-CM diagnosis codes, mean (SD)	13.2 (8.0)	11.5 (7.2)	11.9 (7.6)	12.1 (7.2)	13.7 (8.9)
Unique medications, mean (SD)	18.5 (11.2)	18.4 (10.8)	17.5 (9.6)	19.1 (10.1)	19.7 (10.8)

Switch rates per 1,000-person years were: abatacept = 243; adalimumab = 208; etanercept = 170; infliximab = 285; rituximab = 171. Figure 1 displays survival curves for the time-to switch for patients initiating each biologic agent.

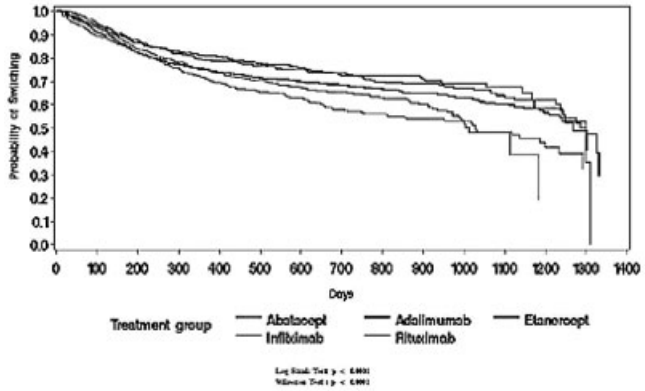

Figure 1. Kaplan Meier survival curve for time-to-switching among RA patients initiating a subsequent biologic DMARD after failing at least one biologic DMARD.

Conclusions: Switching of RA biologics may occur due to inadequate response to the current biologic, burden of side effects, or other variables. In this analysis, switch rates per 1,000 person-years were the lowest among patients initiating rituximab and etanercept and highest among patients initiating infliximab. Time-to switch was significantly different across the groups (p<0.001), and was longest in patients initiating rituximab and etanercept and shortest in patients initiating infliximab.

Systemic Immunosuppressives and the Risk of Diabetes in Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA). Daniel Hal Solomon[3], Elena M. Massarotti[1], Raj Garg[2], Claire Canning[2], Jun Liu[2] and Sebastian Schneeweiss[2]. [1]Brigham & Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, [3]Brigham and Womens Hospital, Boston, MA

Background: Several inflammatory conditions, including RA and PsA, have been linked with insulin resistance and diabetes mellitus (DM). The underlying inflammation and use of oral glucocorticoids are two possible causes. Prior investigations demonstrate an improvement in insulin resistance with several TNF inhibitors (TNFi), and hydroxychloroquine (HCQ) has been shown to reduce the risk of diabetes in a large observational RA cohort. We compared the risk of incident DM among subjects diagnosed with RA or PsA based on their use of a variety of DMARDs.

Methods: Our study cohort was drawn from two data sources—a population-based cohort from a Canadian province and a large commercial insurance plan. Patients with at least two diagnoses of RA or two diagnoses of PsA who have no evidence of DM (no diagnoses and no diabetes medication use) were eligible for the study cohort at the time they switched or added an immunosuppressive. DMARD regimens were categorized into four mutually exclusive groups: 1) TNFi with or without other DMARDs, 2) methotrexate (MTX) without a TNFi or HCQ, 3) HCQ without MTX or a

TNFi, or 4) other DMARD without a TNFi, MTX or HCQ. The primary outcome was incident DM, defined as a diagnosis and start of a DM-specific medication. Incidence rates for DM were compared across exposure groups. In addition, adjusted hazard ratios were calculated in Cox regression with other DMARD considered the reference exposure. Adjusted analyses included covariates for age, gender, Charlson comorbidity score, oral glucocorticoid use, topical glucocorticoid use, prior DMARDs, calendar year, plus several other health service indicators. Secondary analyses focused on different periods during follow-up and on oral glucocorticoid users.

Results: The study cohort consisted of 22,493 subjects with RA or PsA starting one of the four groups: 4,623 TNFi, 8,195 MTX, 5,682 HCQ, and 3,993 another DMARD. Mean follow-up was 6 months. The four groups' characteristics were similar with respect to age, gender, distribution of underlying rheumatic disease, and health services utilization, but differed by oral steroid use with the TNFi group having more prior steroid use. The incidence rates for DM were as follows: total cohort 24.6 per 1,000 person-years, TNFi 19.7, MTX 23.8, HCQ 22.2, and another DMARD 50.2. Adjusted hazard ratios for DM were 0.62 (95% CI 0.42 – 0.91) for TNFi, 0.77 (95% CI 0.53–1.13) for MTX, and 0.54 (95% CI 0.36–0.80) for HCQ (see Figure). Secondary analyses exhibit consistent findings.

Adjusted Cox Proportional Hazards for Risk of Diabetes Mellitus in RA and PsA

	Non-biologic DMARD	Hydroxy-chloroquine	Methotrexate	TNF inhibitor
Model 1	1.00	0.58 (0.39–0.85)	0.63 (0.45–0.88)	0.72 (0.50–1.03)
Model 2	1.00	0.58 (0.39–0.85)	0.62 (0.44–0.87)	0.76 (0.53–1.09)
Model 3	1.00	0.54 (0.36–0.80)	0.77 (0.53–1.13)	0.62 (0.42–0.91)

Notes: Model 1: Adjusted for diagnosis and data source. Model 2: Adjusted as Model 1 + age and gender. Model 3: Adjusted as Model 2 + Charlson Score, dermatologist visits, dermatology indicator, generics, number of hospital visits, number of MD visits, prior but no current HCQ, prior but no current MTX, prior but no current NBDMARD, prior but no current oral steroids, prior but no current TNFA, prior oral steroids, prior topical steroids, number of rheumatology visits, number of dermatologist visits, and year of index.

Conclusions: Among subjects diagnosed with RA or PsA, the adjusted risk of incident DM appeared reduced for persons starting a TNFi or HCQ compared with another DMARD. This result was robust across secondary analyses and suggests that a treatment trial testing the effects of specific DMARDs on incident DM would be warranted.

The Belgian MIRA (MabThera in Rheumatoid Arthritis) Registry: Clues for the Optimization of Rituximab Treatment Strategies. Bert Vander Cruyssen[2], Patrick Durez[1], Rene Westhovens[5], Ilse Hoffman[3], M. J. Kaiser[4] and Filip De Keyser. [1]Cliniques Universitaires Saint-Luc, Brussels, [2]Ghent University Hosptial, [3]GZA St-Augustinus Hospital Antwerp, Belgium, [4]University Hospital Liege, Liege, Belgium, [5]University Hospitals KULeuven, Leuven, Belgium

Background: The Belgian MIRA registry aims to record safety and efficacy data of rituximab treatment. In Belgium, RA patients are eligible for treatment with rituximab if they failed at least 1 anti-TNF and have a baseline DAS28 > 3.7. From week 24 on, patients can be retreated if they have a moderate or good EULAR response at week 16, and a current DAS28 score of at least 3.2.

Methods: All Belgian rheumatologists could participate in the study. Patients entered the registry as from November 2006 and the entry is still open. All patients were treated with 2 infusions per course of rituximab (2 × 1000 mg week 0 and 2) in combination with 100 mg of methylprednisolone and MTX. Baseline patient's characteristics were recorded as well as DAS28-variables every 2 months.

Results: By mid may 2010, 497 patients had entered the registry with a mean follow-up time of 84 weeks. Patients (mean age of 59 years, 77 % female) had a mean disease duration of 12 years.

Rituximab therapy decreased the overall mean disease activity from DAS28-ESR 5.9 (SE = 0.1) at baseline to 4.1 (SE = 0.1) at week 16. 83% of patients fulfilled the EULAR good or moderate response criteria. Further decrease of DAS was observed at the end of year 1 and year 2 with a mean DAS28-ESR of 4.0 (SE = 0.2) and 3.7 (SE = 0.2) at these respective time points.

342 and 188 patients received a 2nd and 3rd course of rituximab respectively. The median time to retreatment was 32 weeks after the first course.

At the start of each treatment course, the DAS28-ESR values were lower compared to values at the start of the previous treatment course. The values reached a minimum at week 16 of each respective treatment course, and then increased slightly, until the start of the following treatment course. Paired analysis of DAS28 scores 6 months after the first and second course suggests that lower DAS scores are obtained after the second course (mean diff = −0.6, SE =0.2, p <0.001).

This further decrease of DAS28 scores between the first and second course was especially seen in those patients who did not flare (increase of DAS28>1.2) between week 24 and their second course (mean diff = −1.1, SE = 0.2 vs. mean diff −0.08, SE = 0.4, p = 0.002).

85 patients discontinued treatment: 62 stopped due to inefficacy and 18 stopped due to safety issues (infusion reactions in 6 patients, infections in 5, other reasons in 7 patients). 2 Patient died. Only 33 patients were lost to follow-up.

Conclusions: The efficacy of rituximab in refractory RA patients is confirmed in this daily practice cohort. DAS28 response was observed in the large majority of our cohort and a sustained DAS 28 decrease was observed during the following course, especially in patients who didn't show an obvious flare. These elements suggest that treatment of RA patients with rituximab could be optimized by earlier retreatment in patients who developed flares.

The Incidence of Herpes Zoster in Seniors with Rheumatoid Arthritis. Jessica Widdifield[7], Sasha R. Bernatsky[2], J. Michael Paterson[1], Nadia Gunraj[1], Janet E. Pope[5], J. Carter Thorne[4], Alfred A. Cividino[3] and Claire Bombardier[6]. [1]Institute for Clinical Evaluative Science, [2]McGill UHC/RVH, Montreal, QC, Canada, [3]McMaster University, Hamilton, ON, Canada, [4]Southlake Regional Health Care, Newmarket, ON, Canada, [5]St Joseph Health Care London, London, ON, Canada, [6]University of Toronto, Toronto, ON, Canada, [7]University of Toronto

Herpes zoster (HZ) is a painful cutaneous eruption caused by varicella-zoster reactivation. It results in substantial morbidity, particularly in elderly and/or immunocompromised patients. Recent literature suggests that patients with rheumatoid arthritis (RA) are at particular risk for HZ. The Ontario Biologics Research Initiative (OBRI) conducts real-world surveillance through administrative database linkage with primary data collection, based in Canada's largest province (population > 13 million).

Purpose: To study risk and risk factors for HZ, using a case-control sample nested within a cohort of seniors with RA.

Methods: An RA cohort was assembled from Ontario billing, hospitalization and prescription data, 1992–2008. Analyses were limited to subjects aged >65 who filled ≥ 1 prescription for a disease-modifying agent (DMARD), oral corticosteroid, or biologic. We studied cases of HZ identified from physician billing and hospitalization diagnoses over 1998–2009. RA controls (age, sex and time matched) were randomly selected by risk-set sampling. Multivariate conditional logistic regression assessed the independent effects of concomitant drug treatments on HZ, adjusted for demographics, comorbidity, and markers of RA severity (rheumatology visits, extra-articular RA features, joint replacement).

Results: A total of 3,999 cases of HZ were recorded among 85,458 seniors with RA during 614,915 person-years (6.5 events/1000 person-years). Comparing these HZ cases to 19,995 RA controls, 21.9% of cases versus 10.8% of controls were exposed to prednisone at the time of infection. Multivariate models demonstrated that risk of HZ was higher among current and past use of all DMARD groups. There was a notable increasing trend for higher risk of HZ with increasing steroid doses. Due to low rates of biologic drug exposures in our sample, the estimated effects of these agents were imprecise, but also consistent with a higher risk.

Drug Exposure	Adjusted Odds Ratio [95% Confidence Interval]

Steroid Use [REF = None]	
Low ≤5 mg prednisone equivalent/day	**1.66 [1.45 1.91]**
Medium 6–9 mg/day	**1.91 [1.46 2.50]**
High 10–19 mg/day	**1.99 [1.67 2.37]**
Very High ≥ 20 mg/day	**3.22 [2.66 3.89]**
Past use	**1.29 [1.17 1.42]**

Conclusions: Our estimates emphasize an association of anti-rheumatic therapies with the occurrence of HZ. Potential limitations of our study include the possibility of incomplete ascertainment of biologic exposures (private insurance is not represented in public payer database; but this is uncommon) and channelling bias (where persons at highest risk for infections may not be prescribed biologics).

The Influence of Systemic Glucocorticoid Therapy upon the Risk of Non-Serious Infection in Patients with Rheumatoid Arthritis. William G. Dixon[3], Abbas Kezouh[2], Sasha R. Bernatsky[1] and Samy Suissa[2]. [1]McGill UHC/RVH, Montreal, QC, Canada, [2]McGill University, [3]The University of Manchester, Manchester, United Kingdom

Background: Glucocorticoid (GC) therapy is a strong risk factor for serious infections in patients with RA. However, the association between GCs and non-serious infections (NSI) is not well studied. Although NSIs are not life-threatening, they are common: respiratory infections alone account for up to 400 general practice consultations annually per 1000 patients. Even a modest increase in relative risk due to GCs may represent a large increase in the attributable risk and a significant health burden.

Methods: Using data from Quebec health administrative databases from 1985–2003, we assembled a cohort of 16,207 patients with RA aged >65. GC and DMARD therapy were identified from drug dispensing records. NSI cases were defined as the first occurrence of either a community physician billing code for infection or community-dispensed anti-infectives. The incidence of NSI was estimated in the whole cohort. The incidence of NSI in GC-exposed and GC-non-exposed person time was calculated in a cohort analysis to enable estimation of the attributable risk. A nested case-control analysis was performed, matching each case to 5 controls. Matching was done on entry date and time in cohort, using risk set sampling. Analysis considered drugs dispensed within 45 days prior to the index date (date of infection for each case-control set), adjusting for age, sex, markers of disease severity, DMARDs and co-morbidity. Oral GC therapy was considered together, then categorised into 5 dose bands. Conditional logistic regression was used to calculate the odds ratio, interpretable as a relative risk.

Results: 13,634 first-episode NSI occurred during 28,695 person years (pyrs), generating an incidence rate of 475 events/ 1000 pyrs. The rate of NSI in GC exposed and unexposed person time was 524 and 388/1000 pyrs, respectively. The attributable risk was therefore 135 events/ 1000 pyrs. In the case-control analysis, GC therapy was associated with an adjusted relative risk (aRR) of 1.20 (95% CI 1.15, 1.25). A positive dose response was seen between risk and GC dose. Methotrexate (MTX) was the most commonly used DMARD, and was associated with a no increased risk of NSI (aRR 1.00 (0.95, 1.04)). Patients currently prescribed sulfasalazine or anti-malarials had a lower rate of infection than patients not prescribed those drugs. Cyclophosphamide was associated with a higher risk of infection (aRR 2.14 (1.51, 3.03)). The results for anti-TNF therapy were inconclusive given the small number of patients exposed to them. All GC risk estimates (including 0–5mg/day) were higher than that seen for MTX.

	Cases n = 13,634	Controls n = 68,170	Adjusted RR* (95% CI)
Oral GC exposure within last 45 days	37.9	32.5	1.20 (1.15, 1.25)
Average daily dose of oral GC therapy			
• <5 mg PEQ	3.2	3.1	1.10 (0.99, 1.22)
• 5–9.9 mg PEQ	17.8	17.1	1.10 (1.04, 1.16)
• 10–14.9 mg PEQ	9.5	7.9	1.25 (1.17, 1.34)
• 15–19.9 mg PEQ	2.7	2.1	1.26 (1.12, 1.42)
• >=20 mg PEQ	4.7	2.3	1.85 (1.68, 2.05)
Any GC: oral or injection	39.2	33.7	1.19 (1.14, 1.24)
Current DMARD use			
• Methotrexate	33.3	33.0	1.00 (0.95, 1.04)
• Sulfasalazine	2.4	3.0	0.79 (0.70, 0.89)
• Leflunomide	0.3	0.3	1.00 (0.71, 1.39)
• CQ/HCQ	29.4	30.7	0.93 (0.89, 0.98)
• Azathioprine	1.9	1.5	1.05 (0.91, 1.22)
• Cyclophosphamide	1.7	0.7	2.14 (1.51, 3.03)
• Gold	7.1	6.5	1.08 (0.99, 1.18)
• Anti-TNF therapy	0.1	0.1	1.48 (0.87, 2.52)
• Others**	1.8	1.7	1.07 (0.92, 1.25)

GC = glucocorticoid, PEQ = prednisolone equivalent, RR = relative risk
*Adjusted for age, sex, markers of disease severity, and co-morbidity
**Includes ciclosporin, mycophenolate mofetil, and D-penicillamine

Conclusion: GC therapy is associated with an increased risk of NSI. The magnitude of the risk increases with dose, and is higher than that seen with MTX (although residual confounding may exist). Whilst the RR is low at 1.20, the absolute risk is high, with one additional infection seen for every 8 patients treated for 1 year.

Three Months of Therapy with DMARDs Is an Inadequate Period of Time To Alter the Treatment in Patients with Early Rheumatoid Arthritis When Treating to a Target of Low Disease State or Remission. Results from Canadian Early ArThritis CoHort (CATCH).

Pooneh Akhavan[4], Vivian P. Bykerk[5], Ye Sun[6], J. Hochman[12], Janet E. Pope[9], Carol A. Hitchon[1], Gilles Boire[10], Boulos Haraoui[2], Diane S. Ferland[7], J. Carter Thorne[8], Deborah A. Weber[5], Ed C. Keystone[11] and CATCH Investogators[3]. [1]Arthritis Center, University of Manitoba, Winnipeg, MB, Canada, [2]Institut de Rhumatologie, Montreal, QC, Canada, [3]M, Canada, [4]Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada, [5]Mt Sinai Hospital, Toronto, ON, Canada, [6]Mt Sinai Hospital, Toronto, ON, Canada, [7]Rheumatology, Hopital Maisonneuve, Rosement, University of Montreal, LaSalle, QC, Canada, [8]Southlake Regional Health Care, Newmarket, ON, Canada, [9]St Joseph Health Care London, London, ON, Canada, [10]Universite de Sherbrooke, Sherbrooke, QC, Canada, [11]University of Toronto, Toronto, ON, Canada, [12]University of Toronto, Toronto, ON

Objective: The objective of this study was to evaluate the concept of therapy alteration in patients with early rheumatoid arthritis (ERA) not achieving an adequate response by 3 months in a prospective cohort.

The study was designed to assess whether 3 months was an adequate time for decision-making regarding altering therapy in ERA patients who have been on stable DMARDs for 6 months and have not achieved low disease activity state (LDAS) or remission (REM).

Methods: Patients with ERA were studied in the Canadian Early Arthritis Cohort (CATCH), a prospective cohort where data was collected according to a standardized protocol. Patients who were on stable DMARDs therapy (with no dose adjustments after one month of initiating therapy and not receiving oral or parenteral steroids) for 6 months were evaluated. Patients not achieving LDAS or REM by 3 months were examined for the proportion of those achieving LDAS or REM by 6 months. We also evaluated patients achieving LDAS or REM by 6 months who had not achieved these outcomes by 3 months.

Results: 108 patients were evaluated with the baseline mean age of 50 years and disease duration of 6.3 months. Mean patient global assessment of disease activity, pain score and HAQ-DI were 61.2, 65.0 and 1.0 respectively at baseline. At 3 months, 46% and 31% of patients achieved LDAS or REM respectively, while 65% and 52% achieved these states by 6 months. Of 58 patients not in LDAS at 3 months, 26 (45%) achieved LDAS by 6 months. Of 74 patients not in REM by 3 months, 29 (40%) achieved REM by 6 months. Of 56 patients who achieved REM by 6 months, only 27 (48%) achieved it by 3 months.

Although baseline swollen joint count, tender joint count and CRP levels were not significantly different in two groups, patients who achieved LDAS at 6 months had higher pain (71±17 vs 47±32, $p<0.05$) and patients global assessment (77±18 vs 53±32, $p<0.05$) scores at baseline compare to those achieved this state at 3 months. In patients with delayed remission (at 6 months) in addition to the above outcome measures, HAQ-DI (0.6±0.6 vs 1.1±0.6, $p=0.003$) was higher at baseline when compared to patient who achieved remission at 3 months.

Conclusion: While remaining on a stable therapy through 6 months, a substantial proportion of patients who had not achieved an adequate clinical response (LDAS or REM) by 3 months achieved these states by 6 months. Attention should be given to patient reported outcomes when assessing patients with ERA for risk of delayed remission. The data in this real world setting suggest that in a significant number of patients, 3 months was not an adequate period of time to decide on altering therapy based on whether an adequate clinical response had been achieved. Our results support recent guidelines suggesting that a 3 to 6 month time frame is required for optimal treatment decision making when treating to an LDAS or REM target.

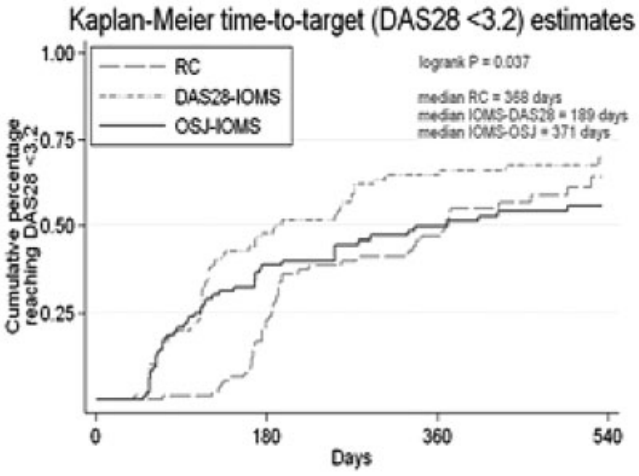
Treating to Target with TNFi in Active Established Rheumatoid Arthritis Results in Longer Drug Survival Than Routine Care with TNFi: Results from the Optimization of Humira RCT.

Janet E. Pope[4], J. Carter Thorne[3], Boulos Haraoui[2] and John Sampalis[1]. [1]Montreal, ON, Canada, [2]Institut de Rhumatologie, Montreal, QC, Canada, [3]Southlake Regional Health Care, Newmarket, ON, Canada, [4]St. Joseph's Health Care, London, ON, Canada

Background: This randomized trial in active RA receiving adalimumab was done to determine if targeted outcomes yielded better results than routine care in established RA and to determine if treating to no swollen joints (0SJC) would be more effective than treating to a DAS<3.2. Drug survival was studied, as the withdrawal rate for TNFi in RA is 20 to 30% annually for the first two years; then decreases thereafter.

Methods: The Optimization of Humira trial was a real-life 18 months RCT in patients with established active RA.; with randomization to: routine care (RC), or treating to clinical target (low DAS28<3.2 or 0/28 SJC). The primary outcome measure was the change in DAS28 at 12 months. Sample size was calculated to show a difference between RC and more intensive (targeted) care, allowing 20% to be previously TNFi experienced.

Results: 309 patients were enrolled. Mean age was 54 years, 80% were female, mean baseline DAS28 was 5.9 and the mean number of previous DMARDs used was 2.7. There were no between groups differences at baseline except for past number of DMARDS used (RC=2.6, DAS=2.9, 0SJC=2.5, $p=0.02$) and 0SJC was younger (51.5). More medication changes for RA (#/100 pt-months) occurred in 0SJC group: 3.3 in RC, 5.1 in DAS and 6.2 in 0SJC, $P<0.035$). 91% of completers were satisfied with treatment at 12 months. Targeted treatment resulted in faster improvement, but RC eventually caught up. At 6 months the change in DAS was −1.9 in RC, =2.4 in DAS and −2.0 in 0 SJC. At 12 months it was −2.4, −2.7 and −2.2 and 18 months: −2.5, −2.7. −2.1. The drop out was 52% in routine care, 27% in the DAS and 22% in the 0 SJC ($p=0.001$). Drop out due to adverse events was 8% in RC, 12% in DAS and 4% in 0SJC ($p=0.018$). The median time to DAS<3.2 was 368 in RC, 189 days in DAS and 371 days in 0SJC. Median time to good/moderate EULAR response was 185 days for RC, 76 days for DAS and 93 days for 0SJC ($p=0.0002$). More in intensive care achieved DAS<2.6 (p=NS). The figure shows time to DAS<3.2. The table demonstrates the markedly different drop outs between routine care and intensive care.



RESULTS		RC	DAS	0 SJC	P-value
# of patients at baseline		109	100	99	
Total # of patients discontinued		57 (52.3)	27 (27)	22 (22.2)	
# of patients discontinued according to visit: n (%)	Visit 2	1 (0.9)	4 (4.0)	0 (0.0)	Overall: *P<0.001* RC vs. DAS: *P<0.001* RC vs. 0 SJC: *P<0.001* DAS vs. 0 SJC: P=0.434
	Visit 4	9 (8.3)	3 (3.0)	2 (2.0)	
	Visit 6	10 (9.2)	11 (11.0)	6 (6.1)	
	Visit 9	7 (6.4)	1 (1.0)	7 (7.1)	
	Visit 12	20 (18.3)	8 (8.0)	7 (7.1)	
	Unknown	10 (9.2)	0 (0.0)	0 (0.0)	
# of patients discontinued according to visit: n (%)	Lost to Follow-up	19 (17.4)	3 (3.0)	5 (5.1)	Overall: *P=0.018* RC vs. DAS: *P=0.014* RC vs. 0 SJC: *P=0.130* DAS vs. 0 SJC: P=0.177
	Withdrawal of Consent	6 (5.5)	5 (5.0)	6 (6.1)	
	Adverse Event	9 (8.3)	12 (12.0)	4 (4.0)	
	Protocol Violation	1 (0.9)	0 (0.0)	2 (2.0)	
	Other	22 (20.2)	7 (7.0)	5 (5.1)	

Conclusions: Treating to target with the same TNFi therapy in established RA may not alter the outcomes vs. routine care for DAS<3.2 by 18 months for those continuing treatment but the drop out rate with treating to a target is very low. A, low disease state occurs earlier in targeted care. The target of 0SJC may be feasible in established RA starting antiTNF treatment but does not look superior to DAS target.

Tumor Necrosis Factor-α Inhibitor Use Does Not Affect Lipid Profiles in Patients with Rheumatoid Arthritis. Stephanie J. Morris[1], Jana L. Antohe[1], Jennifer Sartorius[2], H. Les Kirchner[2], Sorina Dancea[1], Mary Chester Wasko[3] and Androniki Bili[1]. [1]Geisinger Health System, Danville, PA, [2]Geisinger Health System, [3]Univ of Pittsburgh, Pittsburgh, PA

Background: Patients with rheumatoid arthritis (RA) have increased risk of cardiovascular disease (CVD). In some studies of RA patients, tumor necrosis factor-alpha (TNF-α) inhibitors and other biologic agents have been associated with adverse lipid profiles, a risk factor for CVD.This study examined the association of TNF-α inhibitor use with lipid levels in an RA inception cohort in a rural, tertiary health system using Electronic Health Record (EHR).

Methods: Patients diagnosed with RA (ICD-9 code 714.0 at ≥2 office visits with a rheumatologist) from 1/1/2001 – 5/1/2009 were identified through the EHR (n=1539). The RA diagnosis was validated against the American College of Rheumatology criteria by manual review of 100 random charts with 97% concordance. Analysis was restricted to patients with at least one post-RA lipid result (n=706). Outcomes were lipid level results over time by TNF-α inhibitor usage status (infliximab, etanercept, and adalimumab). The lipid panel included low density lipoprotein (LDL), high density lipoprotein (HDL), total cholesterol (TC), and triglycerides. In addition, LDL/HDL and TC/HDL (the atherogenic index) were included as outcomes. Each patient's TNF-α inhibitor use status was evaluated at each lipid measurement date. Body mass index (BMI), erythrocyte sedimentation rate, C-reactive protein, rheumatoid factor (RF), anti-cyclic citrullinated peptide (CCP) antibodies, diabetes, hypertension, use of glucocorticoids, nonsteroidal anti-inflammatory medications, hydroxychloroquine, methotrexate, and lipid-lowering medications, were controlled for in a random effects, linear regression model. Time is represented as time since RA diagnosis to each lipid result date in years.

Results: 706 incident RA patients with 2851 lipid results were identified and were included in the analysis. The majority of patients were female (69%), and 98% were Caucasian, with median age of 65 years and BMI 29.8 kg/m^2. RF and anti-CCP were positive in 79% and 42% (of the patients who had results recorded in the EHR) respectively. Of the 706 patients, 182 (25.8%) were ever on TNF-α inhibitors. In the regression models, use of TNF-α inhibitors was associated with the following estimated average changes in lipids over time: LDL increase of 0.49 mg/dl (p=0.811), HDL decrease of 0.51 mg/dl (p=0.517), TC increase of 1.64 mg/dl (p=0.505), triglycerides increase of 5.11 mg/dl (p=0.388), LDL/HDL increase 0.063 (p=0.224), and TC/HDL increase of 0.104 (p=0.132).

Conclusions: Use of TNF-α inhibitors in this inception RA cohort was not associated with significant changes in total cholesterol, LDL, HDL, LDL/HDL, or TC/HDL. These results are reassuring, given the widespread use of TNF inhibitors and increased risk of CVD in this patient population.

Urinary Tract Infections in Rheumatoid Arthritis. Colin C. Edgerton[1], Kaleb D. Michaud[3] and Frederick Wolfe[2]. [1]Eisenhower Army Medical Center, Evans, GA, [2]Natilonal Data Bank for Rheumatic Disease, Wichita, KS, [3]Univ of Nebraska Med Ctr, Omaha, NE

Purpose: Recent interest in urinary tract infections in rheumatoid arthritis (RA) has stemmed from the assessment of risk of infection with biologic agents. There have been little data about community acquired urinary tract infections (UTI) until a recent report gave an incidence rate (IR) of ~3% (1). By contrast, an epidemiology study in the general population reported an IR at 10.8% (95% CI 9.4. 12.1) in women (2). We used a large prospective data bank to investigate these differences and to understand risk factor for UTI in RA.

Methods: We used general estimating equations to evaluate the risk of UTI in 17,139 RA patients and 107,546 semiannual observations. Patients self-reported the number of urinary tract infections in the previous 6 months. We evaluated the role of age, sex, antirheumatic drug use, education, BMI, household income, smoking, comorbidity, and the tendency to over-report symptoms. We also calculated the misclassification rate for self-reported events based on 76,493 cases that evaluated for validation.

Results: The estimated IR for UTI, adjusted for 10% overreporting, was 8.9% (8.6, 9.2) overall and 11.4% (11.0, 11.8) in women and 3.3% (2.9, 3.7) in men. Serious events, resulting in hospitalization or requiring intravenous antibiotics was reported in 0.39%. In multivariable analyses, UTI was associated with diabetes, OR 1.2 (95% CI 1.0, 1.3), corticosteroid use OR 1.1 (1.0, 1.2), but not to biologic use, OR 1.0 (0.9, 1.1). Among other factors, UTI was associated with less household income and multiple comorbidities, but not with smoking, BMI, education level or estrogen use. When the study variables were applied to serious infection, the OR increased for prednisone use, 1.9 (1.6, 2.4) and diabetes, 2.0 (1.5, 2.6), but remained non-significant, 0.9 (0.7, 1,1) for biologics. Overall, prednisone was used at 34.9% of observations and biologics at 38.2%.

Conclusions: Based on increased risk associated with prednisone and comorbidity, as well as increased IC compared with the community epidemiology study, we estimate that UTI is slightly increased in RA. These results are 3 times higher than a previous study (1). The Observed rate of serious urinary tract infection was consistent with data from the British Biologics registry (3).

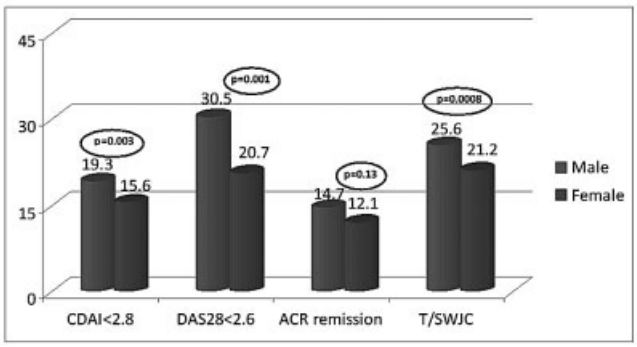
Women with RA Achieve Remission Less Frequently Than Men, Using the CORRONA Database among 6668 Patients. Daniel E. Furst[5], Veena Ranganath[4], Joel M. Kremer[1], James Louie[4], Dinesh Khanna[4], Lawrence Rasouliyan[2] and Jeffrey D. Greenberg[3]. [1]Albany Medical College, [2]ICON, [3]NYU, [4]UCLA, [5]University of California Los Angeles Medical School, Los Angeles, CA

Background: Remission is a commendable and achievable goal for RA patients but it is not clear whether the RA remission rate is different between women and men.

Objectives: To examine the large CORRONA database for differences between remission rates in women and men.

Methods: Logistic regression compared women and men using CDAI<2.8, DAS28<2.6 and ACR remission. Independent variables included: age, gender, disease duration, OA, erosions, RF, Jt tenderness, mHAQ, ethnicity, depression and medications.

Results:



6668 RA pt's were included for CDAI; 1412–1956 for the DAS28 and ACR remission. Women achieved remission less frequently than men. Ethnicity had no effect. Other differences were not clinically significant (eg. W-0.5 more JTC; 0.06 were in HAQ, 2–3 mm worse pain and global VAS). Men had more co-morbidities (eg. diabetes W-6.4%;M-9.0%; MI/CVA-W:33%;M:9.3%)

Conclusion: In the CORRONA database, the remission rate for women was lower than for men.Ethnicity had no effect.

A Novel Splicing Regulatory Mechanism in Generating a Truncated Human Death Receptor 3 (*DR3*) Gene Product That Contributes to the Pathogenesis of Rheumatoid Arthritis. Masaru Mizuhara[2], Akira Hashiramoto[3], Kohsuke Yoshida[1] and Shunichi Shiozawa[4]. [1]Department of Biophysics, Kobe University Graduate School of Health Science, Kobe, Hyogo, Japan, [2]Department of Biophysics, Kobe University Graduate School of Health Science, Kobe, Japan, [3]Department of Biophysics, Kobe University Graduate School of Health Science/Department of Medicine, Kobe University Graduate School of Medicine/The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Hyogo, Japan, [4]Department of Biophysics, Kobe University Graduate School of Health Science/Department of Medicine, Kobe University Graduate School of Medicine/The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan

Purpose: Death Receptor 3 (DR3), a member of tumor necrosis factor receptor superfamily, transmits both apoptosis and NFκB activation signalings. We previously reported a new DR3 haplotype containing 4 single-nucleotide polymorphisms (SNPs) and one 14-nucleotide deletion within exon 5 and intron 5 (GenBank accession Nos. AB051850 to DR3 and AB051851), which resulted in insertion of a portion of intron 5 into the coding sequence to generate a premature stop codon. Based on these mutations, we identified a mutant type of *DR3* gene (*mtDR3*) encoding a truncated *DR3* lacking tramsmembrane domain and death domain as the candidate disease gene for Japanese-Korean patients with rheumatoid arthritis (RA). In this study, we show a specific binding of splicing regulatory proteins on intron 5 in the *mtDR3* gene, which leads to generation of a truncated *DR3* lacking death domain molecule contributing to the pathogenesis of RA.

Methods: The wild type (wt) exon 2, wt intron 5 and mutant intron 5 pre-mRNA were synthesized from *wtDR3* and *mtDR3* genes, respectively, using PCR and DNA transcription and were incubated with nuclear proteins extracted from jurkat cells. The nuclear protein bound to intron 5 pre-mRNA was collected, separated on SDS-Polyacrylamide gels and analysed by silver staining, mass spectrometric and western blotting.

Results: We previously identified that the mutation of *DR3* gene, the polymorphism is: d: g.2590A>T (rs3138155) from the first base of ATG, enhances insertion of a portion of intron 5. As to the cause of exon insertion at intron 5, we have detected 3 nuclear proteins with molecular weight, 100kDa, 70kDa and 60kDa which bound to the mutant type intron 5, but not to wild type intron 5, of DR3 mRNA under silver staining. Mass spectrometric and western blotting identified them as splicing factors, proline- and glutamine-rich (SFPQ), heterogeneous nuclear ribonucleoprotein L (hnRNP L) and non-POU domain-containing octamer-binding protein (NONO), respectively.

Conclusion: As to the cause of exon insertion at intron 5, the truncated *DR3* lacking death domain molecule contributes to the pathogenesis of RA. We have identified 3 splicing regulatory proteins, SFPQ, hnRNP L and NONO, that specifically bound to the intron 5 *mtDR3* to generate a truncated *DR3* gene product.

BAFF Expression on the Surface of RA Synovial Fibroblasts (RASFib) Facilitates B Cell Responses to IL-15. Yolanda Garcia-Carmona, Marta Benito-Miguel, Alejandro Balsa, Emilio Martin-Mola and Maria Eugenia Miranda-Carus. Hospital La Paz, Madrid, Spain, Hospital La Paz, Madrid, Spain, Hospital La Paz, Madrid

Background: We previously described that IL-15 expressed on RASFib significantly contributes, by a cell-contact dependent mechanism, to the anti-apoptotic action of RASFib on B cells. In addition, whereas exogenous recombinant IL-15 (rhIL-15) has a minimal effect on isolated B cell survival, it significantly potentiates the anti-apoptotic effect of RASFib on B cells. This is attributable to an RASFib-mediated upregulation of the B cell IL-15 receptor.

Objectives: BAFF, a B cell survival factor expressed on RASFib, was tested as a potential candidate involved in upregulating B cell IL-15R.

Methods: Magnetically sorted peripheral blood memory B cells from 20 healthy subjects (CD19+CD20+CD27+, purity >96%) were cultured in the presence or absence of rhIL-15, recombinant human BAFF (rhBAFF), or a combination of both. In addition, B cells were cocultured with RASFib from synovectomy or arthroplasty specimens (n= 10) in the presence or absence of rhIL-15, with or without BAFF neutralizing agents.

Results: Survival of isolated B cells cultured for 6 days in plain medium was below 1% (annexin V-7AAD and JC-1 staining). RhIL-15 had a minimal effect on isolated B cell survival. In contrast, culture of B cells in the presence of rhBAFF resulted in significantly increased survival (22.3+/−3.2% viable cells at 6 days, $p<0.001$) together with upregulation of all three IL-15R chains; in parallel, rhIL-15 potentiated the anti-apoptotic effect of BAFF (32.7+/−4.4% viable cells at 6 days, $p<0.05$).

Flow cytometry of RASFib detached with PBS-EDTA demonstrated surface expression of BAFF together with surface IL-15. In parallel, coculture with RASFib dramatically prolonged B cell survival (55.3+/−8.1% viable cells at 6 days, $p<0.01$) and at the same time upregulated B cell expression of IL-15Ra, b and g chains. RhIL-15 potentiated the anti-apoptotic effect of RASFib (75.1+/−5.2% viable cells, $p<0.05$). In the presence of BAFF neutralizing agents (an anti-BAFF MoAb or a BAFFR-Fc), the effect of RASFib on both B cell survival and B cell expression of IL-15 R was significantly attenuated (28.1+/−4.5 or 27.3 +/−3.8 viable cells, respectively, $p<0.05$). In parallel, rhIL-15 had a lower effect on the survival of B cells cocultured with RASFib in the presence of BAFF neutralizing agents (62.3+/−8.2% viable cells, $p<0.05$ vs conditions without BAFF neutralization). IL-15 blocking agents were not additive with BAFF neutralization in Bcell/RASFib cocultures (28.3+/−4.2% viable cells). In contrast, in the absence of BAFF antagonists, neutralization of IL-15 (with an anti-IL-15 MoAb or an antagonistic IL-15 mutant/Fcg2a fusion protein) was effective at decreasing the antiapoptotic effect of RASFib on B cells (35.5+/−6.2% or 32.8+/−5.7% viable cells, respectively, $p<0.01$). Isotype control MoAbs or Fc fusion proteins used as negative controls had no effect. This indicates that constitutive surface IL-15 expression on RASFib contributes to extending the survival of cocultured B cells when constitutive BAFF activity is spared.

Conclusion: The antiapoptotic effect of RASFib surface IL-15 on cocultured B cells is facilitated by RASFib surface BAFF, through an upregulation of IL-15Ra, b and g chain expression.

Characterization of Fibrinogen-Specific CD4 T Cells Using Peptide-MHC Tetramers. Laura F. Su[1] and Mark M. Davis[2]. [1]Stanford, Mountain View, CA, [2]Stanford

Purpose: Rheumatoid arthritis (RA) is one of the most common debilitating systemic inflammatory conditions. To date, little is known about which autoantigens are involved in RA and how T cells recognizing self-proteins may become pathogenic in disease. Fibrinogen is a common target of autoantibodies in RA patients and a putative T cell autoantigen involved in disease development. The short-term aim of this study is to identify and characterize fibrinogen-specific CD4 T cells in healthy individuals, with the goal of extending the analysis to patients with RA.

Method: Autoantigen-specific T cells were identified directly ex vivo using peptide-MHC tetramers. HLA-DR4 monomers with a tethered thrombin cleavable CLIP peptide were purified from the culture supernatant of a stable HLA-DR4 transfectant cell line by antibody affinity chromatography. The purified monomers were then biotinylated, thrombin cleaved, loaded with peptides, and oligomerized onto a streptavidin backbone labeled with a fluorophore. To identify individuals carrying the HLA-DRB1*0401 (DR4) allele, HLA typing was performed on healthy blood donors and RA patients using sequence-specific primer PCR. Individuals with DR4 allele(s) were selected for T cell repertoire analysis. To identify antigen-specific T cells, blood from DR4 positive individuals were enriched for CD4 cells by rosettasep/ficoll centrifugation. Tetramer staining was performed at room temperature for 1 hour using 10nM of tetramers loaded with peptides from hemagglutinin (HA) and fibrinogen. Memory phenotyping was performed using antibodies against the protein tyrosine phosphatase, CD45RO, and the chemokine receptor, CCR7. Tetramer tagged cells were magnetically enriched and analyzed by flow cytometry.

Results: We are able to identify fibrinogen-specific CD4 T cells in healthy individuals without expansion in culture. The frequency of lymphocytes recognizing fibrinogen is between 0.3 to 22 cells per million CD4 T cells. There does not appear to be significant gender- or age- dependent differences, with similar frequency of fibrinogen-specific lymphocytes seen in male and female, and between young and the older individuals.

Phenotypic characterization of antigen-specific cells using antibodies against CD45RO and CCR7 reveals a memory population that recognizes fibrinogen in most people without an autoimmune disease. The presence of antigen-experienced cells recognizing fibrinogen indicates that the immunological self is not ignorant of these epitopes and suggests that active regulatory mechanisms is involved in preventing inappropriate T cell activation.

Conclusion: Rare antigen-experienced fibrinogen-specific CD4 T cells can be detected in the peripheral blood of healthy individuals. Study is currently ongoing to evaluate the role of regulatory T cells in modulating the activity of fibrinogen-specific T cells and to extend the analysis to patients with RA.

Defective ERK Signaling in Hematopoietic Progenitor Cells in Rheumatoid Arthritis. Ines Colmegna[2], Sergei Pryschep[1], Hisashi Oishi[3], Jorg J. Goronzy[3] and Cornelia M. Weyand[3]. [1]Georgia Institute of Technology, [2]McGill University, Montreal, QC, Canada, [3]Stanford University

Background: The main functional property of hematopoietic progenitor cells (CD34+ HPC) is their proliferative response to hematopoietins. HPC from patients with rheumatoid arthritis (RA) are hypo-responsive to growth factor stimulation leading to a decreased cell cycle entry and progression and thus to a restricted expansion capacity. Kinase-based signal transduction pathways are key integration points that link extracellular stimuli to proliferation, differentiation and cell survival. We tested the hypothesis of whether a defect of the extracellular signal-regulated kinase (ERK) pathway underlies the proliferative defect of RA HPC.

Methods: CD34+ cells from patients with rheumatoid factor-positive RA and demographically matched healthy controls were MACS sorted from PBMC. A minimum of 12 RA samples and 12 matched controls were included per experiment. The surface expression of cytokine receptors (IL-3 and IL-6 receptor subunits, c-kit and FLT3) was evaluated by FACS. Baseline and post-cytokine (IL-3, IL-6, FLT3-L and SCF) activation phosphorylation states of ERK 1/2 were determined by flowcytometric single-cell phosphoprotein analysis (Phospho-Flow). Transcripts of ERK target genes (c-Myc and Cyclin D) were quantified by RT-PCR. The co-localization of K-Ras/Raf-B, proximal events in the activation of ERK, was assessed by confocal microscopy in CD34+ cells.

Results: The frequency and density of cytokine receptor expression was similar in RA and controls CD34+ cells. Baseline and post-cytokine activation phosphorylated ERK (pERK) was decreased in RA CD34 compared to demographically matched controls (baseline $p=0.04$, 10' activation $p=0.005$, 15' activation $p=0.006$). Transcripts of ERK modulated genes involved in cell cycle progression (Cyclin D3, and c-Myc) were significantly reduced in RA ($p<0.02$). Confocal microscopy studies demonstrated significantly lower cytokine-induced Ras/Raf colocalization in RA CD34+ cells than in controls. ($p=0.04$) implicating proximal events in the defective ERK activation.

Conclusions: Cytokine evoked signaling responses of the ERK signaling pathway, a key integration network linking extracellular stimuli to proliferation, are defective in RA HPC. Insufficient clustering of K-Ras and Raf-B complexes, decreased phosphorilation of ERK and downregulation of the expression of ERK dependent genes involved in proliferative responses are all consistent with a defect in the ERK pathway.

Human STEAP4 (Six-Transmembrane Epithelial Antigen of Prostate 4) Regulates Inflammatory Cytokines and the Proliferation of Fibroblast-Like Synoviocyte in Patients with RA. Yoko Tanaka, Isao Matsumoto, Naoto Umeda, Kayo Yamamoto, Yuki Tanaka, Asuka Inoue and Takayuki Sumida. University of Tsukuba

Background: We recently demonstrated that TNFα-induced- adipose related protein (TIARP) plays a crucial role in TNFa-dependent arthritis model such as glucose-6-phosphate isomerase (GPI) -induced arthritis. STEAP4 mRNA and protein expression was reported to be upregulated by TNFα in a dose-dependent manner by using human adipose tissue, however, the function of STEAP4 in other tissue is still unclear. The purpose of this study is to clarify the function of STEAP4 in fibroblast-like synoviocyte (FLS) from RA patients and the relationship between STEAP4 and RA.

Methods: 1) To unravel localization of STEAP4, the expression of EEA1 (known to be a endosome marker) or CD68 in FLS was examined by fluorescence immunohistochemistry (IF). 2) FLS obtained from RA synovium were treated with TNFα (2ng/ml), and the fluctuation of STEAP4 was evaluated by Western blot analysis (WB). 3) FLS obtained from RA was transfected by siRNA specific for STEAP4, and cultured for 24 h. IL-6 mRNA was quantified by real time PCR. 4) GFP-STEAP4 or GFP-empty plasmid DNA were transfected to FLS, then cultured for 24 h with TNFα. Secretion of IL-6, IL-8, MMP3, and GM-CSF was examined by ELISA. 5) Proliferation and apoptosis of GFP-STEAP4 transfectant were investigated by BrdU assay or flow cytometry. 6) The expression of STEAP4 in PBMC was measured before and after therapy with infliximab ($N=40$).

Results: 1) STEAP4 was co-localized with CD68 in the FLS obtained from RA patients. STEAP4, EEA1 and CD68 were clearly co-localized in cytoplasm (endosome and lysosome) of the synovium. 2) In vitro analysis, the expressions of STEAP4 protein in FLS was up regulated by TNFα stimulation confirmed by WB. 3) The expression of IL-6 mRNA was up regulated by STEAP4 siRNA ($p<0.05$). 4) The amount of IL-6, IL-8, GM-CSF secretion were down-regulated by overexpression of STEAP4 ($p<0.05$), although MMP3 were upregulated after TNFα stimulation. 5) Proliferation was decreased and apoptotic cells were increased in GFP-STEAP4 transfectant compared to GFP-empty transfectant. 6) The expression of STEAP4 was decreased after infliximab treatment especially in good responder ($p<0.05$).

Conclusion: STEAP4 expression was observed in rheumatoid synovium, was clearly up regulated by TNFα stimulation, and controlled inflammatory cytokines and proliferation of FLS. In addition, the expression of STEAP4 in PBMC was upregulated by TNF antagonist in RA, suggest that it may play a potential role in the pathogenesis of TNF-α- induced arthritis.

IL-15 Promotes Osteoclastogenesis Via Phospholipase D Signaling Pathway in Rheumatoid Arthritis. Ji-Min Kim[1], Mi-Kyung Park[2], Mi-La Cho[2], Yong-Geun Jung[1], Su-Jin Moon[1], Seung-Ki Kwok[1], Ji-Hyeon Ju[1], Kyung-Su Park[1], Ho-Youn Kim[1] and Sung-Hwan Park[1]. [1]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic of, [2]Rheumatism Research Center, Catholic Research Institute of Medical Science, The Catholic University of Korea, Seoul, Korea, Republic of

Background: Osteoclast plays an important role in the joint destruction in rheumatoid arthritis (RA). Osteoclast formation is enhanced in the presence of receptor activator of nuclear factor κ B ligand (RANKL) and macrophage colony-stimulating factor (M-CSF). Interleukin 15 (IL-15) has also been reported to stimulate the osteoclast differentiation. This study was undertaken to investigate novel signaling molecules essential for the IL-15-mediated osteoclastogenesis.

Methods: Expression of phospholipase D1 (PLD1), RANKL, mitogen-activated protein kinases (MAPKs) and nuclear factor-κB (NF-κB) was determined by immunohistochemistry in the RA synovial tissue. Whether or not IL-15 modulates the expression of various molecules in the RA fibroblast-like synoviocyte (FLS) was examined by quantitative polymerase chain reaction and western blotting. In order to evaluate the effect of IL-15 and phosphatidic acid (PA; active product of PLD metabolism) on the osteoclast formation, peripheral blood monocytes from RA patients were cultured with or without FLS in the presence of M-CSF and RANKL, the traditional osteoclast differentiation condition.

Results: The expression of IL-15, PLD and phosphorylated extracellular signal-regulated kinase (ERK), c-Jun N-terminal kinase (JNK), inhibitor of κB was enhanced in the RA synovial tissue. Expression of RANKL and PLD1 was significantly upregulated by IL-15 in the FLS from RA patients. PA enhanced the RANKL expression, which was inhibited by the blockade of PA production by 1-butanol or PLD1 siRNA. IL-15 and PA also stimulated the osteoclastogenesis through the phosphorylation of NF-κB as well as MAPKs such as ERK and JNK. Regardless of the presence of RA FLS, IL-15-induced osteoclastogenesis in the monocytes cultured with M-CSF and RANKL was suppressed by the blockade of PA production.

Conclusions: PLD1 activation by IL-15 contributed to RANKL-mediated osteoclastogenesis via NF-kB and MAPK signaling pathway in FLS of RA patients. Taken together, our data suggest that PLD1 may be an important mediator of IL-15-induced osteoclastogenesis and can be considered as a new therapeutic target in RA.

IL-17A and IL-17F Contribute to the Progression of Rheumatoid Arthritis by Inducing a CXCR4-Dependent Invasive Phenotype in Synoviocytes. Arnaud Hot[2], Saloua Zrioual[1], Vanina Lenief[1] and Pierre Miossec[1]. [1]Hospital Edouard Herriot, Lyon, Lyon, France, [2]Immunogenomics and Inflammation Research Unit and Department of Immunology and Rheumatology, Hospital Edouard Herriot, Lyon, France

Objectives: Rheumatoid arthritis (RA) synovium undergoes histological changes characterized by angiogenesis, immune cell infiltration and hyperplasia of synovial lining cells. Among the inflammatory mediators expressed in RA synovium, IL-17 is emerging as a key mediator. The aim of our study was to assess the role IL-17A and IL-17F in synoviocytes migration and invasion.

Methods: IL-17A and IL-17F induced mRNA expression in RA synoviocytes was analyzed using microarrays (Affymetrix, U133 +2) and qRT-PCR. The capacities of IL-17 and IL-17F alone or in combination with TNF-α to induce synoviocyte migration and invasion were tested using Boyden chambers and using transwell matrigel invasion chambers. The specific contribution of CXCR4, the SDF-1 receptor was analyzed using neutralizing antibody. As Hypoxia Induced Factor 1 (HIF1-α) regulates CXCR4 expression, a functional assay (binding DNA assay) was used to evaluate the role of both cytokines in the regulation of HIF1-α expression and activation. To evaluate the role of Hypoxia pathway in RA, 40 RA patients and 20 healthy volunteers (controls) were enrolled for determination of gene expression profiles in whole peripheral blood using U133A Affymetrix microarrays.

Results: IL-17A and IL-17F induced a molecular pattern characterized by inflammation- (LIF, IL-11, IL-23p19, FGF-2) and hypoxia-related genes (SLCA1, CA9, CXCR4). In particular, IL-17A and IL-17F alone or combined with TNF-α induced CXCR4 mRNA in synoviocytes (289 fold for IL17A, 34 fold for IL-17F, 450 fold for the combination of IL-17A with TNF-a). Using immunofluorence microscopy, the expression of CXCR4 at the surface of synoviocyte was confirmed. Moreover, IL-17A and TNF-α induced synoviocyte migration and invasion through a CXCR4-dependent mechanism with a synergistic effect, (6 vs 67 migrated cells/HPF, p≤0,05). The blockade of CXCR4 led to a decrease of synoviocyte migration (- 10 fold, P<0,05). The combination of IL-17A and TNF-α, as the combination of IL-17F and TNF-α in a lesser manner was able to promote the activation of HIF1-α in synoviocytes (2 fold, P=0,0034), and this association was synergic to induce VEGF mRNA expression. To confirm the role of hypoxia pathway in RA, the expression of HIF1-α induced genes was measured in blood of RA patients, and control subjects. Six hypoxia related genes were overexpressed in blood of RA patients as summarized in table 1.

Conclusion: Both IL-17A and IL-17F may contribute to the progression of RA, notably through their effect on synoviocyte aggressiveness. Part of this effect results from a mediated CXCR4/SDF1 pathway and the induction of hypoxia pathway.

Table 1: The observed data from a set of 40 RA patients and 20 controls demonstrated an upregulation of HIF1α-dependent genes.

In Rheumatoid Arthritis, Naïve B Cells Prevail in the Peripheral Blood, Whereas Memory B Cells Accumulate in the Joint Compartment, Express ZAP-70 and Characterize the Aggregate Pattern. Alessandro Michelutti[2], Elisa Gremese[2], Barbara Tolusso[2], Francesca Morassi[1], Rosalia Privitera[2], Silvia Canestri[2], Giusy Peluso[2], Silvia L. Bosello[2] and Gianfranco Ferraccioli[2]. [1]Division of Histopathology, Catholic University of Sacred Heart, Rome, Italy, [2]Division of Rheumatology, Catholic University of Sacred Heart, Rome, Italy

Statement of Purpose: To analyse B cell subsets in the peripheral blood of RA, non-RA patients and Healthy Controls (HC) and in the synovial compartment in order to understand whether there is a compartmentalization of some subsets. To examine the phenotypic characteristics of the B cells in the synovial fluid and tissue and their possible relationship with disease activity and with synovial tissue cells and their pattern of distribution.

Materials and Methods: Twelve patients with RA and 15 non-RA arthritides (4 UA, 3 MCA-microcrystal arthritis, 1 SpA, 1 SLE, 4 MOA-monoarthritis, 2 PsA) were examined for B cell subsets in the peripheral blood (PB) and in the synovial fluid (SF) and underwent synovial biopsy. Ten HC matched for sex and age, were enrolled in the study as control group.

Results: The percentage of B cells was similar in RA and in non-RA patients, both in peripheral blood and in the synovial compartment.

Considering the peripheral blood compartment, the percentage of CD19+ B cells (8.0 ± 4.8%), as well as the eBm5 (12.4 ± 5.6%) were lower in RA than in HC (CD19+%: 10.8 ± 3.6%, *p=0.003;* eBm5%: 16.0 ± 7.1%; p=0.06). On the other hand, the percentage of CD19+Zap-70+ B cells were higher in RA than in HC (6.1 ± 5.5%-median 5.0 vs 3.9 ± 3.1%- median 3.1% in HC; *p=0.05*), whereas no differences were seen between RA and non-RA patients (4.1±0.3%, p *=0.22*).

In the SF of RA patients, the percentage of Bm2 +Bm2' were significantly lower than in the PB (3.2 ± 3.2% vs 41.3 ± 20.5% in peripheral blood, *p=0.001*); on the contrary Bm5 were significantly higher in the SF than in the PB (67.9 ± 11.4% vs 21.3 ± 21.1%, *p=0.001*). These data have been confirmed by a significant increase of CD27+ B cells in the SF vs the PB (58.8 ± 18.1% vs 25.1 ± 14.9%, *p=0.001*). More particularly, the percentage of CD27+IgD- was significantly higher in SF (54.7 ± 16.7%) compared to PB (11.1 ± 7.9% in PB, *p=0.001*).

Dividing RA patients with high disease activity (DAS44 > 3.7) from those with a DAS< 3.7, the analysis revealed that Bm1 in the SF were higher in active RA (18.9 ± 8.4% vs 10.7 ± 5.3%, *p=0.04*), whereas eBm5+Bm5 B cells were lower in active RA (75.4 ± 9.4% vs 85.9 ± 6.4%, *p=0.03*). ZAP-70+ B cells correlated with the total number of leukocytes (r=0.32, *p=0.04*), inversely with Bm2+Bm2'%(r=-0.56, *p=0.05*), and with the Bm2+Bm2'/eBm5+Bm5 ratio (r=-0.54, *p=0.05*).

Moreover, the IHC analysis of CD68, CD3, CD20, CD27-CD20, CD38-CD20 and CD138 positive cells in the synovial tissue showed an increased trend in RA vs non-RA synovial tissues (p=ns). ZAP-70+ B cells correlated significantly with CD38+ B cells (r=-0.79, *p=0.04*). Considering the RA synovial biopsies with the aggregate and diffuse patterns, CD27+ B cells characterized the pseudo-follicular/aggregate pattern (128.6 ± 89.3/hpf vs 40.7 ± 31.9/hpf; *p=0.03*).

Conclusions: There is a characteristic accumulation of memory B cells in the joint compartment, with CD27 characterizing the aggregate pattern. In addition, data suggested that these cells are ZAP-70+, which was previously shown to confer to B cells a longer life span. The synovial fluid of patients with active disease contained more "naïve" Bm1 and Bm2-Bm2' cells than patients with less active disease.

Influence of TNF-α, MMP-3, TIMP-3 and HLA Class II Genes Polymorphisms in the Rheumatoid Arthritis Articular Damage. Renata T. Alarcon[5], Artur R. C. Fernandes[5], Geraldo R. C. Pinheiro[3], Magali J. G. Usnayo[3], Luis C. M. Porto[4], Juliana Cardoso-Oliveira[3], Gustavo M. Fabricio-Silva[3], Ieda M. M. Laurindo[1], Manoel B. Bertolo[2], Mario Yazbek[2], Mariana G. Soares[5], Neusa P. Silva[5], Kaline M. C. Pereira[5] and Luis E. C. Andrade[5]. [1]Universidade de Sao Paulo, Sao Paulo, SP, Brazil, [2]Universidade Estadual de Campinas, Campinas, SP, Brazil, [3]Universidade Estadual do Rio de Janeiro, Rio de Janeiro, RJ, Brazil, [4]Universidade Estadual do Rio de Janeiro, Rio de Janeiro, RF, Brazil, [5]Universidade Federal de Sao Paulo - UNIFESP, Sao Paulo, SP, Brazil

Background: The recent availability of drugs that may alter the course of rheumatoid arthritis (RA) has emphasized the need for predictors of disease outcome in order to assign patients to appropriate treatment. HLA-DRB1 and extra-HLA genes are implicated in the predisposition and progression of RA and polymorphism in some of those may serve as modulators of disease severity. TNF-alpha, matrix metalloproteinase-3 (MMP3) and tissue inhibitor of metalloproteinases-3 (TIMP-3) are integrated in the pathway of joint destruction in RA. Genetic studies of patients with RA can supply data that contribute to define more precisely the groups of patients with good and bad disease progression.

Objective: To evaluate possible associations between cumulative articular damage and polymorphisms in HLA-DRB1, TNF-alpha (-308G/A), MMP3 (-1171 5A/6A) and TIMP3 (-899T/A, -915A/G and -1296T/C) genes in a sample of Brazilian patients with RA.

Methods: We selected 440 RA patients from three university centers in southeast Brazil (São Paulo, Rio de Janeiro, and Campinas). DNA was obtained from peripheral leukocytes. The regions of interest for TNF-alpha, MMP-3 and TIMP-3 were amplified by PCR. Amplicons were digested with appropriate restriction enzymes and the resulting fragments were resolved in agarose gel electrophoresis (RFLP). HLA-DRB1 alleles were determined by PCR using sequence-specific oligonucleotide probes (PCR/SSO) and DRB1*04 alleles by PCR sequence-specific primers (PCR/SSP). Sharp's index was scored in hands and feet X-rays by an experienced blinded radiologist. Derivative Sharp scores were developed according to the mathematical division of hands/feet scores (Sharp-h/f), fingers/wrists scores (Sharp-f/w), and erosion/space narrowing scores (Sharp-e/sn).

Results: There was no ethnic association except for a higher prevalence of MMP3 allele 6A in blacks (83.3%) compared to other races (60%) (p<0.001). There was no association between the studied polymorphisms and total Sharp score. However, patients with predominant feet damage (Sharp-h/f < 1.67) had higher frequency of TIMP3 –1296T (72.6% vs 52.6%, p=0.001) and TIMP3 –915A (71.4% vs 55.5%, p=0.009) alleles as compared with those with predominant hand damage. Predominance of space narrowing (Sharp-e/sn <1.67) was associated with −899 TIMP3 allele A (7.8% vs 0.5%, p=0.007). Sharp-f/w score was not associated with polymorphism in the studied genes. The derived Sharp scores were not associated with HLA-DRB1, weight, height, and BMI.

Conclusions: TIMP-3 polymorphism was significantly associated with the preferential topography of joint destruction and with the predominant type of radiographic changes (erosion versus space narrowing) in rheumatoid arthritis.

Inhibition of the Recycling of Polyamines Restores DNA Methylation in Rheumatoid Arthritis Synovial Fibroblasts. Emmanuel Karouzakis[1], Christoph Kolling[2], Renate E. Gay[1], Beat A. Michel[1], Steffen Gay[1] and Michel Neidhart[1]. [1]Center of Experimental Rheumatology and Zurich Center of Integrative Human Physiology (ZIHP), University Hospital Zurich, [2]Schulthess Clinic, Zurich

Objective: Global DNA hypomethylation in rheumatoid arthritis synovial fibroblasts (RASF) contributes to their intrinsic activation that leads to cartilage and bone destruction. S-adenosylmethionine (SAM) is the methyl donor during DNA methylation—mediated in somatic cells by DNA methyltransferase 1 (Dnmt1). SAM is also used as substrate in the biosynthesis and recycling of polyamines and metabolized utilizing the key enzymes adenosylmethione decarboxylase (AMD) and spermidine/spermine acetyltransferase (SSAT) resulting in the production of diacetylpolyamines. SSAT recycles spermidine and spermine into putrescine that in turn up-regulate AMD thereby accelerating the consumption of SAM. The aim of this study is to investigate whether the increased recycling of polyamines is associated with the global DNA hypomethylation in RASF.

Methods: RASF (n = 12) and osteoarthritis synovial fibroblasts (OASF, n = 6) were stained for AMD, SSAT, polyamine modulated factor binding protein 1 (PMF-1/PMFBP1), Dnmt1 and analyzed by flow cytometry. 5-methylcytosine (5-MeC) was measured by flow cytometry, diacetylspermine (DASp) in cell culture supernatants and cell extracts was determined by ELISA. S-Adenosylmethionine (SAM) was measured in cell extracts by fluorometry. Small interfering RNAs (siRNA) were used to down-regulating AMD and/or SSAT and diminazene aceturate (DA) was employed to inhibit the activity of SSAT.

Results: The intracellular levels of AMD, SSAT and PMFBP1, as well as the level of DASp in cell culture supernatants, were significantly increased in RASF, compared to OASF (AMD/RASF: 36 ± 5, OASF: 23± 4, p < 0.005; SSAT/RASF: 34 ± 8, OASF: 17 ± 3, p< 0.001; PMFBP1/RASF: 79.0 ± 27.7; OASF: 49.7 ± 7.2 mean fluorescence [mf], p< 0.05). On the other hand, the levels of SAM in cell culture extracts, as well as the amount of Dnmt1 and 5-MeC, were significantly decreased in RASF, compared to OASF (SAM/RASF: 0.95± 0.94, OASF: 3.10±0.25 nM/mg protein, p<0.001; Dnmt1/RASF: 7.2±1.3, OASF: 13.3±1.0 mf, p < 0.001; 5-MeC/RASF: 0.98±0.26, OASF: 2.52±0.37 mf minus background, p<0.001). A significant association was found between the amount of SAM in the cell extracts and the 5-MeC in nuclei (r = 0.69, p<0.005); in addition, parameters of the catabolism and/or recycling of polyamines negatively correlated with SAM, Dnmt1 and 5-MeC (from r = −0.50 to r = −0.83, p < 0.01 to < 0.001). Furthermore, siRNA to SSAT can reduce the expression of AMD (controls: 35.5 ± 10.7, siRNA against SSAT: 27.9 ± 4.8 mf, p= 0.18, n = 4). Similarly, inhibition of SSAT activity by DA significantly reduced the expression of AMD (controls: 33.3 ± 6.6, DA: 19.2 ± 4.8 mf, p<0.05, n = 4). A 2 weeks treatment with DA restored the DNA 5-MeC content of RASF (control: 1.41, DA: 2.75 mf, pool of 4 patients) to levels measured in OASF (2.68 mf, pool of 4 patients).

Conclusion: Intrinsic elevations of PMFBP1 and SSAT enhance the catabolism and recycling of polyamines in RASF. A high consumption of SAM by this pathway is an important factor contributing to the global DNA hypomethylation in these cells. Decreasing SSAT transcription or activity could represent a new therapeutic strategy in RA.

Interleukin-6 Promotes Pathological Angiogenesis by Modulating Angiopoietin Expression in Rheumatoid Arthritis. Ken Kayakabe[1], Takashi Kuroiwa[2], Noriyuki Sakurai[2], Hidekazu Ikeuchi[2], Akito Maeshima[2], Keiju Hiromura[2] and Yoshihisa Nojima[2]. [1]Department of Medicine and Clinical Science, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan, [2]Department of Medicine and Clinical Science, Gunma University Graduate School of Medicine

Background: Angiogenesis is a part of important factors in the pathogenesis of RA. Pathological angiogenesis is characterized by endothelial proliferation accompanied by increased permeability, in which vascular endothelial growth factor (VEGF) plays a dominant role. Angiopoietin-1 (Ang-1) rather facilitates vessel stabilization by keeping endothelial cell adhesion and has a natural antagonist, Ang-2. Previous studies have shown that interleukin-6 (IL-6) promotes angiogenesis in RA but the precise mechanism is not well determined. In this study we sought to examine whether IL-6 promoted angiogenesis in RA by modulating VEGF/angiopoietin expression.

Methods: Fibroblast-like synovial cells derived from RA patients (FLS) were cultured overnight to confluent. Then, human umbilical vein endothelial cells (EC) were added and co-cultured for 6 days in the presence or absence of recombinant human IL-6 (together with soluble IL-6 receptor), VEGF, or Ang-1. EC were stained with anti-CD31 antibody, and EC proliferation was determined by CD31-positive area analyzed by Image-J (NIH). Cell-cell adhesion of EC was assessed by immunofluorescent staining of CD31. Synovial fluids (SF) were collected from patients with RA (n=25) and osteoarthritis (OA) (n=7), who undertook therapeutic SF aspiration. The levels of VEGF, IL-6, Ang-1, and Ang-2 in culture supernatants or SF were determined by ELISA. Quantitative real-time PCR was performed to examine mRNA expression of Ang-1.

Results: Compared with medium control, IL-6 stimulation at 100 ng/ml in co-culture induced 2.5-fold increase of EC proliferation. VEGF at 10 ng/ml also induced 2.2-fold increase. EC stimulated with IL-6 exhibited irregular shape and decreased cell-cell adhesion, suggesting pathological angiogenesis with increased permeability. In the supernatants of co-culture, IL-6 up-regulated expression of VEGF compared with medium control (81 vs 31 pg/ml) and Ang-2 (5304 vs 1726 pg/ml), while decreased Ang-1 (32 vs 99 pg/ml). Interestingly, adding recombinant Ang-1 in co-culture protected EC from shape change and decrease of cell-cell adhesion induced by IL-6, indicating the critical role of angiopoietins in pathological angiogenesis. In the culture of either FLS or EC alone, we found that cellular source of Ang-1 and VEGF was FLS and that of Ang-2 was EC. In FLS, IL-6 reduced Ang-1 expression compared with medium control, both in protein and mRNA levels, by 75% and 60%, respectively. In ELISA, IL-6 also induced 2.5-fold increase of VEGF expression in FLS and 1.7-fold increase of Ang-2 in EC. In SF, expression of IL-6 (5059 vs 262 pg/ml), VEGF (3137 vs 1715 pg/ml), Ang-1 (104 vs 36 pg/ml) and Ang-2 (9216 vs 1494 pg/ml) were significantly higher in RA than in OA. In RA, IL-6 expression was positively correlated with VEGF (r=0.516, p=0.008), while VEGF negatively with Ang-1 (r=-0.515, p=0.008).

Conclusion: IL-6 not only up-regulates VEGF but also down-regulates Ang-1 signaling. This synergistic effect may play a critical role in the pathological angiogenesis in RA.

MicroRNA and mRNA Integrated Analysis in Rheumatoid Arthritis Synovial Macrophages. Jong Dae Ji[3], Bit-Na-Ra Lee[5], Tae-Hwan Kim[5], Jae-Bum Jun[5], Dae-Hyun Yoo[5], Kyung-Sun Na[2], Jin-Hyun Woo[4], Sung Jae Choi[4], Young Ho Lee[4], Jeongwon Sohn[1] and Gwan Gyu Song[4]. [1]Department of Biochemistry, College of Medicine, Korea University, Seoul, Korea, [2]Kim's Clinic, Seoul, Korea, [3]Rheumatology, College of Medicine, Korea University, Seoul, Korea, Republic of, [4]Rheumatology, College of Medicine, Korea University, Seoul, Korea, [5]The Hospital for Rheumatic Diseases, Hanyang University, Seoul, Korea

Dysregulated expression of microRNAs (miRNAs) has been shown to be a hallmark of human diseases, and recent studies provide growing evidences that miRNA dysregulation might be play important roles in the pathogenesis of rheumatoid arthritis. Abnormal expression of certain miRNAs was found in peripheral blood mononuclear cells, synovial fibroblasts and synovial tissue from patients with rheumatoid arthritis. To investigate whether abnormal expression of miRNA in rheumatoid arthritis could account for dysregulated expression of certain genes, we compared different expressions of miRNAs and mRNAs in rheumatoid synovial fluid macrophages to normal peripheral blood monocytes, using gene expression oligonucleotide microarray and microRNA microarray.

Comparative analysis of mRNA profiles showed significant different expressions (defined as 2-fold change and $P<0.05$) of 430 genes in RA synovial macrophages, of which 303 (70%) were upregulated and 127 (30%) were downregulated, compared to normal PB monocytes. Among the biological process class, highly represented genes included those involved in cell adhesion, immunity and defense, nucleic acid metabolism and signal transduction. Among molecular function class, highly represented genes included those involved in cell adhesion molecule, defense/immunity protein, receptor, nucleic acid binding and transcription factor. We identified 13 differentially expressed miRNAs in RA synovial macrophages, compared with normal PB monocytes. Out of 13 miRNAs, 9 miRNAs were upregulated and 4 miRNAs were downregulated in RA synovial macrophages. Total 62 genes were predicted as target genes of 13 differentially expressed miRNAs in RA synovial macrophages. Out of these 62 genes, 28 genes were upregulated and 34 genes were downregulated. Among 62 miRNA-targeted dysregulated genes, few genes such as GSTM1, VIPR1, PADI4, CDA, IL21R, CCL5, IL7R, STAT4, HTRA1 and IL18BP have been reported to be associated with rheumatoid arthritis. We validated the differential expression of these genes in RA synovial macrophages using quantitative real time PCR.

In the present study, we observed that several miRNAs are differentially expressed in RA synovial macrophages, and suggest that these dysregulated miRNAs may regulate expressions of several genes associated with the pathogenesis of RA.

Mitochondrial Mutagenesis in Synovial Tissue Is Associated with *In Vivo* Hypoxia, Inflammation and Oxidative Damage. Monika Biniecka[2], Edward Fox[1], Chin T. Ng[2], Len Harty[2], Ursula Fearon[2], Douglas J. Veale[2] and Jacintha O'Sullivan[2]. [1]Department of Pathology, University of Washington, Seattle, WA, [2]Translation Research Group, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Co. Dublin, Ireland

Background: Mitochondrial components are highly susceptible to attack by oxygen radicals due to their close proximity to the electron transport chain and the presence of polyunsaturated fatty acid rich membranes. Oxidative damage to mitochondrial DNA (mtDNA) itself can affect genes encoding respiratory chain complexes and transcription, which may lead to further mitochondrial DNA mutations. Moreover, ROS induced oxidative damage could potentially be a major source of mitochondrial genomic instability leading to respiratory chain dysfunction. The aim of this study was to examine the relationship of random mitochondrial DNA point mutations to *in vivo* synovial tissue oxygen level (tpO_2), synovial inflammation and lipid oxidative damage in the inflamed joint of inflammatory arthritis patients.

Method: Oxygen partial pressure in synovial tissue (tpO_2) was measured *in vivo* using a combined oxygen/temperature Licox probe. Synovial membrane biopsies were obtained from the site of the oxygen tension measurement under direct visualization at the time of arthroscopy. The newly validated mitochondrial Random Mutation Capture assay was used to quantitatively evaluate alterations of the mitochondrial genome in synovial tissue biopsies. Expression of inflammatory cell specific markers (CD68 of macrophages and CD3 of T cells) and lipid peroxidation (4-HNE) were quantified by immunohistochemistry.

Results: Twenty subjects were recruited prior to starting therapy with biologic agents (14 patients with RA and 6 patients with PsA). The median synovial tissue pO_2 level was profoundly hypoxic at 25.47mmHg, equivalent to an ambient oxygen tension 3.3%. The mutations detected were mainly transitions i.e. AT>GC and CG>TA, characteristic of mutation following oxidative stress. A statistically significant increase in the frequency of point mutations was detected in synovial biopsies in patients with tpO_2<20mmHg compared to patients with tpO_2>20mmHg ($p<0.05$). Higher *in vivo* tpO_2 was significantly associated with a decrease in the frequency of mtDNA point mutations (p=0.05; r=-0.38). Significantly greater mitochondrial mutation burden correlated with high expression of CD68 (p=0.026; r=0.44) and CD3 (p=0.047; r=0.29) positive cells in the sublining layer of synovial tissue. Higher frequency of random mitochondrial DNA mutations was also significantly associated with higher synovial 4-HNE cytoplasmic expression in lining and sublining layers of the synovium (p=0.04; r=0.46 and p=0.03; r=0.44 respectively).

Conclusion: Higher frequency of random mitochondrial mutations was significantly associated with reduced *in vivo* oxygen level, with higher microscopic inflammation and oxidative stress. This data implicates that alterations in the mitochondrial genome may be a consequence of severe hypoxic levels in the inflamed joint.

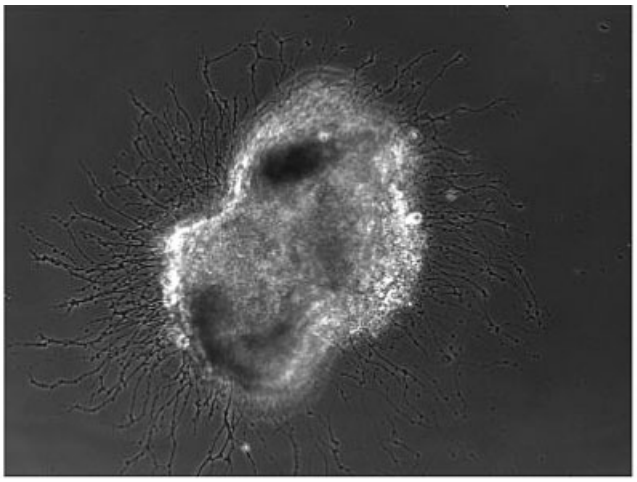
Nerve Fiber Repulsion by Semaphorins—More Redundancy Than Expected in the Rheumatoid Arthritis Joint. Susanne Klatt, Alexander Fassold and Rainer H. Straub. University Hospital Regensburg, Regensburg, Germany, University Hospital Regensburg, Regensburg, Germany

Background: The loss of sympathetic nerve fibers (SNF) is a general principle in inflammatory diseases. Since sympathetic neurotransmitters exert antiinflammatory effects at increased concentrations, their loss in inflamed tissue is reasonable to overcome infection and ensure proper wound healing. However, this mechanism is unfavorable in chronic autoimmune diseases like rheumatoid arthritis (RA). It is generally accepted that semaphorins are the major factors which are involved in guidance and repulsion of nerve fibers, respectively. Additional factors that might influence sympathetic nerve fiber repulsion need to be investigated. Recent findings indicate increased concentrations of norepinephrine, dopamine and 17beta-estradiol in synovial tissue of patients suffering from RA. The aim of this project was to test the effects of these substances on growth and repulsion of sympathetic nerve fibers in vitro.

Methods: In order to study the effect of different factors on nerve fiber repulsion a neurite outgrowth assay was established. In this assay the behavior of nerve fibers from sympathetic trunk ganglia of postnatal mice could be investigated using time-lapse microscopy.



Results: Both investigated semaphorins 3F and 3C induced a repulsion of SNF. Semaphorin 3F repelled 80 % to 100 % of sympathetic nerve fibers, whereas Semaphorin 3C only repelled 30 %. Interestingly, TNF repelled nerve fibers with variable effects (from 10% to 100%) although the variability is unexplained. High concentrations of dopamine and norepinephrine (10^{-6}M) induced significant, but slight nerve fiber repulsion up to 20 % in comparison to controls. Stimulation with low concentrations of 17beta-estradiol (10^{-10}M) led to repulsion of sympathetic nerve fibers. Lower concentrations of norepinephrine (10^{-8}M) seemed to favour nerve fiber outgrowth.

Conclusions: The outgrowth assay enabled us to study the influence of pathogenetically relevant factors which may be involved in nerve fiber growth and repulsion. We assume that not only specific axon guidance molecules like semaphorins, but rather the interplay of other factors, which are elevated in inflamed tissue predominantly influence nerve fiber growth and repulsion during the course of rheumatoid arthritis.

Phosphoinositide 3-Kinase Delta (PI3Kδ) Regulation and Function in RA. Beatrix Bartok[2], David Boyle[2], Christian Rommel[1] and Gary S. Firestein[3]. [1]Intellikine, [2]UCSD, San Diego, [3]UCSD

Purpose: Phosphoinositide-3 kinases (PI3K) are emerging as drug targets to treat inflammation and autoimmune diseases. Expression of PI3Kγ and PI3Kδ isoforms is relatively selective for leukocytes and regulate innate and adaptive immune responses. They belong to Class I PI3Ks which also include PI3Kα and β isoforms. Unlike PI3Kγ and PI3Kδ, the a and b isoforms are ubiquitously expressed which limits their targeting potential for rheumatic disease. Analysis of genetically modified mice that lack PI3Kγ or δ activity revealed complementary but nonredundant functions in leukocytes. Recently, PI3Kδ expression was observed in cultured fibroblast-like synoviocytes (FLS). The goal of our study was to assess the potential role of PI3Kδ and its downstream target Akt in synovial inflammation.

Methods: Immunohistochemistry (IHC) was used to analyze PI3Kδ expression in RA FLS and synovial tissue. Quantitative real-time PCR (qPCR) was used to determine PI3Kδ mRNA levels and protein expression was quantified with Western blot analysis. PI3K mediated activation of Akt and GSKb was detected using Western blot analysis using phospho-specific antibodies. A selective PI3Ka, PI3Kb and panPI3K inhibitors were used in FLS cultures. An MTT assay was used to quantify cell survival in response to H_2O_2.

Results: PI3Kδ was detected in RA synovial tissue by IHC, with the greatest intensity in the intimal lining layer, which contains FLS. Modest sublining staining was also observed in scattered mononuclear cells. PI3Kδ expression was confirmed in cultured FLS in chamber slides by IHC and by Western blot analysis of FLS extracts (n=4). PI3Kδ mRNA level was 2.5-fold greater in RA compared with OA synovium (n=6 each, $p < 0.05$). PI3K pathway activation in cultured FLS was analyzed by evaluating Akt and GSKb phosphorylation. Only low levels of P-Akt and P-GSKβ were detected in response to IL-1, TNF, LPS or TGFβ. However, a rapid and sustained 140-fold increase in Akt phosphorylation and 3-fold increase in GSKβ phosphorylation was induced by PDGF. To determine relative contribution of PI3Kδ to Akt and GSKβ activation, FLS were pre-incubated with PI3Ka, b, δ or pan PI3K inhibitors. Based on the inhibition of P-Akt, PI3Kδ contributed 55±5% and PI3Kα was responsible 40±5% of Akt phosphorylation. PI3Kδ inhibition had no effect on P-GSKβ levels. We also assessed the effect of PI3Kd inhibition on FLS proliferation and cell death in vitro compared to PI3Kα and pan PI3K inhibition. PDGF stimulation decreased FLS cell death by 50% in response to H_2O_2 and was completely reversed by PI3Kδ inhibition.

Conclusions: PI3Kδ is expressed in the rheumatoid synovial intimal lining. It also plays a novel role in FLS survival, which could contribute to synovial lining hyperplasia. PI3Kδ inhibitors in RA could provide anti-inflammatory effects in RA due to suppression of leukocyte function as well as novel disease modifying effects by decreasing FLS survival.

Platelet Microparticle Proteome: Insight into Role of Microparticles under Different Stimulatory Conditions. Roopa Shree Subbaiah[5], K. C. Sekhar Rao[1], Peter Nigrovic[2], David Lee[4], Masaru Miyagi[1], Eric Boilard[3] and Reuben Gobezie[6]. [1]Case Center for Proteomics and Bioinformatics, School of Medicine, Case Western Reserve University, Cleveland, OH, [2]Center for Adults with Pediatric Rheumatic Illness (CAPRI), Pediatric and Adult Rheumatology, Children's Hospital Boston, Brigham and Women's Hospital, Boston, MA, [3]Department of Rheumatology and Immunology, CHUL, QC, Canada, [4]Division of Rheumatology, Immunology and Allergy, Brigham & Women's Hospital, Boston, MA, [5]The Department of Orthopaedic Surgery, Case Western Reserve University, School of Medicine, University Hospitals of Cleveland, Cleveland, OH, [6]The Department of Orthopaedic Surgery, Case Western Reserve University, School of Medicine, University Hospitals of Cleveland, Cleveland, OH

Background/Purpose: Platelets are well known for their role in thrombosis, but they contribute also to other physiologic and pathologic functions including inflammation. Our recent work demonstrated that platelets can contribute to joint inflammation through the release of small membrane vesicles called microparticles, which are frequently the most abundant cellular element in inflammatory synovial fluid. Generated upon contact with extracellular matrix via the platelet collagen/laminin receptor glycoprotein VI (GPVI), platelet microparticles (pMP) promote inflammation via interleukin 1 and potentially other mechanisms. Since GPVI is not the only stimulus that can induce pMP production, we employed a quantitative proteomic approach to determine whether pMPs remain identical across multiple pathways of platelet activation, or whether diverse activating stimuli engender production of microparticles that are biologically distinct.

Methods: Platelets from a healthy donor were stimulated by three different agonists, collagen-related peptide (CRP, a synthetic GPVI agonist), thrombin and adenosine diphosphate (ADP). Formed pMP were purified and analyzed using high throughput mass spectrometric analysis through a quantitative proteomic approach. Unstimulated platelets were used as control. The Mascot search engine was used for protein identification. Data analysis was done using Genego software.

Results: Mass spectrometry data analysis of the three different proteome sets indicated important differential effect of major agonists in the generation of pRPs. Microparticles generated via GPVI ligation were rich in molecules pertaining to

lipid mediators, strongly suggesting an inflammatory function, while MPs from thrombin possessed multiple procoagulant molecules. In addition, MPs from CRP stimulation contained additional molecules that further activate the immune system as compared to thrombin stimulated MPs. ADP stimulated pathway was observed in all three datasets. Ongoing studies are being carried out to confirm and extend these results.

Conclusions: Our results provide evidence for the differential functions of microparticles released by platelets under various stimulation conditions. In particular, a proteomic approach substantiates the proinflammatory nature of pMPs produced upon contact with collagen, while other pathways may elicit pMP with prothrombotic or other functions. These findings represent a novel observation in fundamental platelet biology and support the possibility that blockade of GPVI may represent a promising therapy for inflammatory arthritis while leaving intact the important hemostatic activity of platelets.

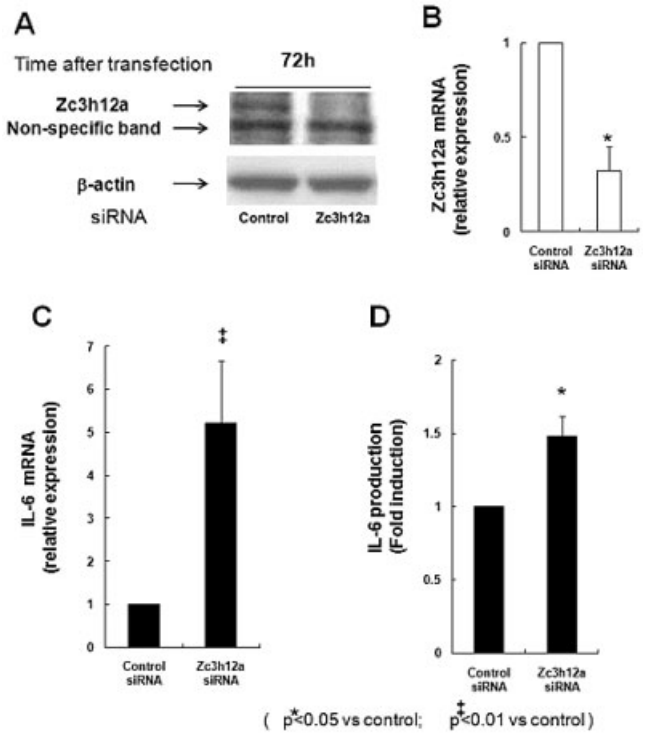
Post-Transcriptional Regulation of IL-6 Production by Zc3h12a in Fibroblast-Like Synovial Cells. Tomohiro Koga, Satoshi Yamasaki, Akitomo Okada, Shin-ya Kawashiri, Hideki Nakamura, Atsushi Kawakami and Katsumi Eguchi. Nagasaki University, Nagasaki, Japan, Nagasaki University, Nagasaki, Japan

Objective: Zc3h12a is a RNA binding protein with a CCCH-type finger motif, known to regulate mRNA metabolism. Previous reports suggest that Zc3h12a acts as a negative regulator of inflammatory processes because it is engaged in the degradation of IL-6 We investigate the effect of Zc3h12a on IL-6 production in fibroblast-like synovial cells (FLS) from rheumatoid arthritis (RA) patients.

Methods: The expression of Zc3h12a in FLS was determined by western blot and polymerase chain reaction. To knock down the expression of Zc3h12a in FLS, siRNA for Zc3h12a was transfected by lipofection method. The supernatants were collected after the siRNA transfection for the quantification of IL-6 production. Cell proliferation was analyzed by the Cell Counting Kit-8 assay after Zc3h12a knock down.

Results: Protein and mRNA for Zc3h12a were demonstrated in all the FLS from RA patients. Zc3h12a transcripts were induced by LPS and IL-1β in FLS. The production of IL-6 as well as its transcripts expression was significantly increased by knocking down of Zc3h12a. Proliferation of Zc3h12a knocked down FLS was significantly promoted in the presence of recombinant soluble IL-6 receptor (sIL-6R). Knocking down of Zc3h12a also induced the activation of signal tranducer and activator of transcription 3 (STAT3).



Conclusion: Our data suggests that Zc3h12a is a novel IL-6 regulator in FLS, which may be involved in the progression of RA.

Role of IL-17 in Pannus Formation and Osteoclastogenesis in Rheumatoid Arthritis. Hiroshi Ito[2], Hidehiro Yamada[3], Toshiko Nozaki Shibata[2], Hirofumi Mitomi[2], Kiyomi Matsuo[2], So Nomoto[1] and Shoichi Ozaki[4]. [1]Department of Orthopaedic Surgery and Rheumatology, Saiseikai Yokohama Tobu Hospital, [2]Division of Rheumatology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan, [3]Division of Rheumatology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan, [4]Division of Rheumatology, St. Marianna University School of Medicine, Kawasaki, Japan

Objectives: IL-17 plays a critical role in the pathogenesis of murine model of arthritis. There are, however, controversies whether IL-17 plays as a pro-inflammatory mediator in rheumatoid arthritis (RA). We studied an exact role of IL-17 in RA using a human cellular model of pannus.

Methods: Inflammatory cells that infiltrated synovial tissue (ST) from patients with RA were collected without enzyme digestion, and designated as ST-derived inflammatory cells as previously reported in Arthritis Rheum 2007;56:2875-85. ST-derived inflammatory cells were cultured in the presence or absence of IL-17 and/or indomethacin, and the morphologic change was observed for 4 weeks. Cytokines produced in the culture supernatants were measured by ELISA kits. Osteoclastic activity was assessed by the development of resorption pits in calcium phosphate-coated slides.

Results: Primary culture of the ST-derived inflammatory cells resulted in a 3-dimensional macroscopic tissue growth, during which TNF-alpha, M-CSF and MMP-9, but not IL-17, were produced in the supernatant. Culture of ST-derived inflammatory cells on calcium phosphate-coated slides resulted in the development of a numerous number of resorption pits. ST-derived inflammatory cells produced IL-17 when stimulated with exogenous Toll-like receptor (TLR) ligands. Exogenous addition of IL-17 dramatically enhanced production of IL-6 and PGE2 from ST-derived inflammatory cells in a dose dependent manner. When endogenous PGE2 production was blocked by indometacin, IL-17 enhanced pannus-like tissue growth, the production of TNF-alpha and M-CSF, and the development of resorption pits, while exogenous addition of PGE1 suppressed their activities.

Discussion: The present study suggests that IL-17 induces negative feedback regulation through the induction of PGE2, while it stimulates pro-inflammatory pathways such as inflammatory cytokine production, pannus formation and osteoclastogenesis in RA. The study also suggests that stimulations of innate immunity via TLR induces and/or exacerbates rheumatoid synovitis mainly through induction of IL-6.

Role of Raf Kinase Inhibitor Protein in Cytokines, Matrix Metalloproteinases Regulation and Invasiveness of Rheumatoid Fibroblast-Like Synobiocytes. Joong Kyong Ahn[1], You Sun Lee[2], Eun-Jung Park[3], Ji-Won Hwang[3], Ji-Min Oh[3], Jaejoon Lee[3], Chan-Hong Jeon[4], Eun-Mi Koh[3] and Hoon-Suk Cha[3]. [1]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, [2]Masan Samsung Hospital, Sungkyunkwan University School of Medicine, [3]Samsung Medical Center, Sungkyunkwan University School of Medicine, [4]Soonchunhyang University College of Medicine

Objective: Raf kinase inhibitor protein (RKIP) is a protein that directly interacts with the kinase domain of Raf-1, and has been shown to modulate many processes, including Alzheimer's disease, diabetes and cancer. RKIP negatively regulates the Raf/MEK/ERK pathway by interfering with the activity of Raf-1. Also, RKIP-1 interferes with the activity of the IKK complex and prevents the movement of NF-κB to the nucleus. The role of RKIP in rheumatoid fibroblast-like synoviocytes (FLS) is not known. The present study was performed to investigate the expression and function of RKIP in rheumatoid arthritis (RA) FLS.

Methods: RKIP expression was measured in synovial tissue (ST) and FLS by Western blot analysis. Plasmid containing RKIP or control vector, RKIP small interfering RNA (siRNA), or control siRNA were transfected into FLS using the Amaxa system. Expression of cytokines and matrix metallo-

proteinases (MMPs) mRNA were examined by quantitative real-time PCR. Phosphorylated MAP kinases were measured in RA FLS by Western blot analysis. NF-κB EMSA was performed after TNFa stimulation in RKIP-overexpressed FLS. In vitro cell invasion assay was performed to measure the invasiveness of RA FLS according to RKIP silencing.

Results: RKIP protein was detected in RA ST and FLS, which was similar to osteoarthritis ST and FLS (n=4 each). RKIP overexpression decreased IL-6, IL-8, MMP-1, and MMP-3 mRNA expression (40.76±24.38%, 32.16±18.93%, 31.25±25.09%, and 30.39±14.16% inhibition, respectively) in TNF-α-stimulated RA FLS (n=4), but these results did not reach statistical significance except the result of IL-6 mRNA (p=0.001). RKIP silencing by siRNA resulted in significantly increased MMP-1 and MMP-3 mRNA expression (1.8±0.4 and 2.3±0.8 fold increase, respectively) in TNF-α-stimulated RA FLS (n=3, p=0.01 for each). RKIP silencing also increased IL-6 and IL-8 mRNA expression (1.4±0.3 and 2.1±0.8 fold increased, respectively) in TNF-α-stimulated RA FLS (n=3), but it's not statistical significant. RKIP overexpression suppressed TNF-α-induced ERK phosphorylation. However, p38 and JNK phosphorylation by TNF-α were not affected by RKIP overexpression. RKIP overexpression also suppressed TNF-α-induced NF-κB activation measured by EMSA. RKIP silencing resulted in significantly higher invasion index in TNF-α-stimulated RA FLS compared to controls (10.33±1.45 vs. 4.00±0.58, n=3, p=0.02).

Conclusion: RKIP plays an important role in inflammatory cytokine and MMP production by regulating ERK and NF-κB activation in RA FLS. These results suggest that RKIP might be a potential therapeutic target for RA.

Sublining CD79a+ B Cell Correlates with Joint Destruction in Rheumatoid Arthritis. Ying-qian Mo[2], Lie Dai[1], Dong-hui Zheng[3], Lang-jing Zhu[2], Xiu-ning Wei[4] and Bai-yu Zhang[2]. [1]Department of Rheumatology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China, [2]Department of Rheumatology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China, [3]Department of Rheumatology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China, [4]Department of Rheumatology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China., China

Objectives: The potent efficacy of B cell-depletion therapy (rituximab) in the treatment of patients with RA has revitalized interest in the pathogenic role of B cells. Recent data indicated the importance of understanding which B cell was critical to RA pathogenesis in designing therapeutic strategies to target B cells. Thus, we aimed to evaluate the distribution and densities of synovial B lineage cells in a large and well-documented cohort of Chinese RA patients, and to determine which type of these B cells correlate with disease activity and joint destruction in RA.

Methods: Synovium was obtained from 69 patients with active RA (defined as $DAS_{28} \geq 3.2$) by needle biopsy and controlled with 14 patients with osteoarthritis (OA) and 15 with orthopedic arthropathies (Orth.A). Serial sections from paraffin blocks were stained for CD68 (macrophage), CD3 (T cell), CD20 (B cell), CD38 (plasmocyte), CD79a (B lineage cell from pre-B cell to plasmocyte stage), CD21 (follicular dentritic cell) and CD34 (endothelial cell) by immunohistochemistry. Quantitative analysis was performed to evaluate cell densities. Radiographic joint destruction of both hands was evaluated by standard Sharp score.

Results: (1) Sublining CD79a+ cell density in RA group (1381.8±1328.2/mm^2) was significantly higher than those in OA group (335.9±727.3/mm^2, $p<0.001$) or Orth.A group (417.9±548.3 /mm^2, $p=0.003$). Receiver operating characteristic curve (ROC) analysis showed high synovial expression of CD79a differentiated RA well from OA ($p=0.001$) or Orth.A ($p=0.003$); (2) Spearman's rank order correlation test showed significant correlation of sublining CD79a+ cell density in RA synovium with synovitis score ($r=0.714$, $p<0.001$) or CD3+ T cell density ($r=0.714$, $p<0.001$); (3) Sublining CD79a+ cell density was significantly higher in long-standing RA patients (disease duration>2 years, n=45, 1633.5±1443.9/mm^2) than those in early RA patients (disease duration≤2 years, n=24, 891.1±912.2/mm^2, $p=0.045$); and correlated significantly with CRP ($r=0.281$, $p=0.033$); (4) Sublining CD79a+ B cell density in RA group correlated significantly with total joint space narrowing score ($r=0.444$, $p=0.002$), erosion score ($r=0.485$, $p=0.001$) and Sharp score ($r=0.458$, $p=0.001$) and Erosive RA showed higher sublining CD79a+ cells density (n=42, 1527.6±1374.9/mm^2) compared with non-erosive RA (n=27, 771.3±919.3/mm^2, $p=0.028$).

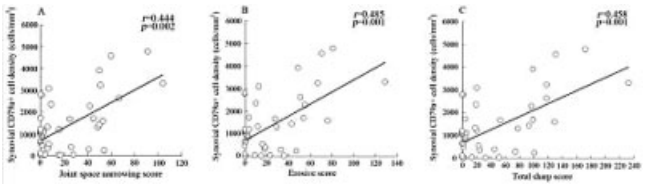

Fig. 1. Spearman's rank correlation analysis for sublining CD79a+ B cell density and radiological Sharp score in RA. A, Correlation between sublining CD79a+ B cell density and joint space narrowing score; B, Correlation between sublining CD79a+ B cell density and erosion score; C, Correlation between sublining CD79a+ B cell density and total Sharp score. (RA: rheumatoid arthritis)

Conclusions: Our results indicate that synovial B lineage cells play a vital role in the maintenance of immune response in rheumatoid synovitis via interaction with T cells and sublining CD79a+ B cell may be involved in the pathogenic process of joint destruction in RA.

SUMO-2/3 Regulates Apoptosis and MMP Expression in RA Fibroblast-Like Synoviocytes. Svetlana Frank[3], Simon Strietholt[3], Christine Seyfert[2], Thomas Pauly[1], George Kollias[4], Thomas Pap[5] and Marvin A. Peters[3]. [1]Department of Nephrology and Rheumatology, Heinrich-Heine University, [2]Department of Orthopaedic Surgery, Zeisigwaldkliniken, Chemnitz, Germany, [3]Institute of Experimental Musculoskeletal Medicine, University of Muenster, Muenster, Germany, [4]Institute of Immunology, Biomedical Sciences Research Center, Vari, Greece, [5]University Hospital Münster, Münster, Germany

Background: Posttranslational modification through SUMOylation has emerged as an important way by which proteins can be modified to change their intracellular localization, stability and gene expression. Previous data have shown that the overexpression of SUMO-1 contributes to the activation of RA fibroblasts like synoviocytes (RA-FLS) through a SUMO-1/SENP1 dependent mechanism. Based on these data, we investigated the expression of SUMO-2/3 in human RA and in hTNFtg mice and studied its role in regulating both apoptosis and the expression of disease specific MMPs

Methods: Synovial tissue samples were obtained from RA and osteoarthritis (OA) patients at joint replacement surgery and used for histological analysis as well as for the isolation of fibroblast like synoviocytes. Using specific antibodies in immunohistochemical and Western blot analyses, we studied the expression of SUMO-2/3 in fibroblasts from the human samples as well as from hTNF-tg and wt mice. Knockdown of SUMO-2/3 was performed using specific siRNA against both SUMO-2 and -3. The apoptotic response of the fibroblasts was measured using a Caspase-3/7 assay after induction of cell death with 100ng/ml Fas ligand over 13h. MMP-1 and MMP-3 production in FLS from RA and OA patients was measured by ELISAs.

Results: Immunohistochemistry and Western blot analyses revealed a clear upregulation of SUMO-2/3 expression in all RA synovial tissue samples and in RA-FLS compared to OA control samples. These data were confirmed in tissue sections of hTNFtg mice, as well as in FLS from these mice. Knockdown of SUMO-2/3 by siRNA sensitized RASF to Fas-mediated apoptosis. Furthermore, TNF-alpha and IL-1β induced upregulation of MMP-3 was significantly stronger after knockdown of SUMO-2/3 in RA- and OA-FLS. Interestingly, the expression of MMP-1 was not affected.

Conclusions: Our results demonstrate that the posttranslational modification of target proteins by SUMO-2/3 and specifically increased levels of SUMO-2/3 in RA-FLS contribute to the resistance of these cells against Fas-mediated apoptosis. Moreover, our data indicate that SUMO-2/3 is involved in the regulation and TNF-alpha stimulated production of MMP-3. Therefore, we hypothesize that SUMO-2/3 are novel players contributing to the specific activation of RASF and, thus, to the disease process of RA.

The 6-O Extracellular Endosulfatases as Novel Regulators of Synovitis. Yoon Hoon Hong[1], Shuhei Otsuki[1], Shugeru Miyaki[1], Beatriz Caramez[2], Noboru Taniguchi[1] and Martin Lotz[1]. [1]The Scripps Research Institute, La Jolla, CA, [2]The Scripps Research Institute, La Jolla, CA

Purpose: As receptors or co-receptors, the heparan sulfate proteoglycans (HSPG) modulate the binding and signaling of various ligands to their specific receptors. The sulfation pattern of HSPG is critical in determining binding or release of ligands. The recently identified extracellular sulfatases (Sulf-1, -2) exert novel signaling mechanisms by regulating the binding of ligands to the 6-O sulfate on HSPG and thereby can modulate several signaling pathways that are involved in inflammation. The aim of this study was to analyze expression patterns of Sulf-1 and Sulf-2 and their role in experimental arthritis.

Method: Sulf expression in normal and arthritic human and murine knee joints and in cultured human fibroblast-like synoviocytes (FLS) were analyzed by real-time PCR, immunohistochemistry and western blotting. The role of Sulf in arthritis pathogenesis was analyzed by using the antigen-induced arthritis (AIA) model in wild-type, Sulf1−/− and Sulf2−/− mice. IL-6, an important mediator in arthritis, was measured by ELISA in FLS subjected to Sulf silencing or over-expressing with siRNA or cDNA transfection.

Results: Synovial tissues from humans with rheumatoid arthritis (RA) and mice with AIA showed increased expression of Sulf-1 and Sulf-2 than tissues from human osteoarthritis (OA) or surgically-induced OA in mice or normal knee. Cultured FLS from RA patients showed higher Sulf-1 and Sulf-2 expression as compared to FLS from OA patients. Treatment of FLS with IL-1β or TNFα increased Sulf-1 expression was more prominently than Sulf-2. The severity of AIA was significantly reduced in Sulf1−/− but not in Sulf2−/− mice and this was associated with reduced synovial leukocyte infiltration and pro-inflammatory cytokine expression such as IL-1β and IL-6. Sulf-1 over-expression in FLS enhanced and Sulf-1 silencing reduced IL-6 expression but did not alter the basal or IL-1β induced expression of Cox-2, MMP-3 or MMP-13.

Conclusion: Increased Sulf expression is observed in arthritic synovium and in IL-1β or TNFα activated FLS. Sulf-1 plays an important role in arthritis pathogenesis and this is at least in part mediated by the controlling IL-6 production. Thus, Sulf-1 represents a novel therapeutic target for inflammatory arthropathies.

The Critical Role of STAT3 in the Th17 Differentiation of RA Synovial T Cells. Ji Hyeon Ju, Mi-La Cho, Ji Min Kim, Yong-Geun Jeong, Seung-Ki Kwok, Kyung Su Park, Sung-Hwan Park and Ho-Youn Kim College of Medicine, The Catholic University of Korea

Objective: STAT3, a signal transduction molecule of inflammatory cytokines such as IL-6, IL-21 and IL-23, plays an important role during the differentiation of CD4+ T cell into Th17 cells (Th17). Since Th17 is the pathogenic cell in autoimmune arthritis, STAT3 has also been suspected to be closely involved in the pathophysiology. This study aims to investigate the mechanism of rheumatoid arthritis (RA) related to the differentiation of Th17 and to identify the role of STAT3.

Method: Cytokine levels in the peripheral blood and synovial fluid of RA patients were measured with ELISA. Immunohistochemical staining of RA synovium was performed to investigate the relationship between synovitis and the expression of STAT3. CD4+ T cells, isolated from peripheral blood and synovial fluid of normal individuals and RA patients, were respectively stimulated with factors leading to Th17 differentiation (anti-CD3 1 μg/ml, anti-CD28 1 μg/ml, IL-23 5 ng/ml, TGF-β 2 ng/ml, IL-6 10 ng/ml, anti-IFN-γ 10 μg/ml, anti-IL-4 μg/ml) or regulatory T cells (Treg) differentiation (anti-CD3 1 μg/ml, anti-CD28 1 μg/ml, TGF-β 20 ng/ml, IL-2 5 ng/ml), as known. STAT3 siRNA was transfected to CD4+ T cells during the differentiation of Th17 cells, which was followed by FACS, RT-PCR and ELISA analyses in order to investigate the impact of STAT3 in Th17 and Treg differentiation.

Result: IL-6, a Th17 related cytokine, was significantly increased in RA synovium ($P<0.01$). The number of Th17 cells in the synovial tissue was significantly higher in RA patients than in normal population. STAT3 and p727S-STAT3 expressions were significantly increased in RA synovium, and their expressions were positively related to the severity of synovitis such as infiltration of inflammatory cells and synovial proliferation ($r=0.68$, $P<0.05$). When STAT3 siRNA was transfected to the CD4+ T cell differentiation in normal individuals, IL-17 and IL-22 expressions and Th17 population decreased, whereas TGF-β expressions and Treg population increased ($P<0.05$). In contrast to the STAT3 inhibition, when STAT5, the transcription factor for Treg, was inhibited, the number of Th17 was increased and that of Treg was decreased ($P<0.05$). Similar findings were observed in the CD4+ T cells isolated from peripheral blood of RA patients. Notably, T cells from RA synovial fluid were significantly decreased in differentiating into Th17 (RASF 0.2% < RAPB 0.5% < HCPB 0.7%, $P<0.05$) while increasing the proportion of Treg (RASF 20% > RAPB 10%, HCPB 11%, $P<0.05$).

Conclusion: The downstream signaling of STAT3 plays a critical role in CD4+ T cell differentiating into Th17 as well as Treg. Inhibition of STAT3 in CD4+ T cells of RA synovium effectively attenuated the differentiation of Th17. By simultaneously achieving Th17 inhibition and Treg stimulation, the regulation of STAT3 promises a novel strategy for RA treatment.

TNFα-Driven IL-32 Expression in Rheumatoid Arthritis Synovial Tissue Amplifies an Inflammatory Cascade. Bas Heinhuis[4], Marije I. Koenders[4], Piet L. van Riel[2], Charles A. Dinarello[3], Mihai G. Netea[1], Wim B. van den Berg[4] and Leo A. B. Joosten[1]. [1]Department of Medicine, Radboud University Nijmegen Medical Centre, Nijmegen the Netherlands, [2]Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, [3]Division of Infectious Diseases, University of Colorado Denver, Aurora, CO, [4]Rheumatology Research & Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen the Netherlands

Statement of Purpose: To investigate the interplay between IL-32 and TNFα in chronic inflamed synovial tissue and to assess whether anti-TNFα treatment of RA patients modulates synovial IL-32 expression.

Methods: To study the interplay between IL-32 and TNFα, we first investigated the induction of IL-32γ by TNFα stimulation in human synovial fibroblasts donated by arthritis patients and compared it with other stimuli such as TLR ligands or IL-1β. Second, we investigated the production of TNFα through intracellular overexpression of IL-32γ followed by LPS stimulation in human THP1 cells. Additionally, we determined the induction of IL-1β, IL-6, and CXCL8. Third, the role of endogenous IL-32 was studied by silencing IL-32γ in human synovial fibroblasts and subsequently IL-6 and CXCL8 levels were determined. Fourth, overexpression of intracellular IL-32γ using an adenovirus expressing human IL-32γ followed by TNFα stimulation was done in synovial fibroblasts to investigate induction of proinflammatory cytokines. Fifth, modulation of TNFα mRNA stability was investigated in human THP1 cells transduced with an adenoviral vector expressing human IL-32γ. IL-1β, IL-6, and CXCL8 mRNA stability was determined. Finally, immunohistochemistry was applied to study IL-32 expression in synovial biopsies from RA patients.

Summary of the Results: Synovial fibroblasts stimulated with TNFα showed potent induction of IL-32γ expression when compared to IL-1β, TLR ligands or medium. Moreover, TNFα induced IL-32γ expression is specific since IL-1β stimulation induced primarily IL-6 and CXCL8. Of high interest, overexpression of intracellular IL-32γ in human THP1 cells followed by LPS exposure resulted in significant production of TNFα, IL-1β, IL-6, and CXCL8. Furthermore, silencing of endogenous IL-32γ showed potent down-regulation of IL-6 and CXCL8 whereas overexpression of IL-32γ resulted in enhanced production of IL-6 and CXCL8 in human synovial fibroblasts. To investigate the mechanism how IL-32γ is capable of amplifying the inflammatory cascade resulting in a self perpetuating loop between IL-32γ and TNFα, we studied mRNA stability. Enhanced expression of intracellular IL-32γ resulted in delayed TNFα, IL-1β, and CXCL8 mRNA decay. In contrast, IL-6 mRNA stability was not regulated by IL-32γ. Of high interest, treatment of RA patients with anti-TNFα resulted in significant reduction of IL-32 protein expression in synovial tissue.

Conclusions: TNFα is a potent specific inducer of endogenous IL-32 expression and IL-32 itself contributes to a prolonged TNFα production. This results in a self perpetuating loop between IL-32γ and TNFα resulting in potent induction of several proinflammatory cytokines and chemokines. This auto-inflammatory loop can potentially be intervened by silencing IL-32 or anti-TNFα treatment. Targeting IL-32 might be a novel therapy to counteract the auto-inflammatory cascade of TNFα-IL-32-TNFα present in chronic inflamed synovial tissue of RA patients.

Underexpression of TIM-3 and Blunted Galectin-9-Induced Apoptosis of CD4+ T Cells in Rheumatoid Arthritis. Jaejoon Lee[4], Ji-Min Oh[6], Ji Won Hwang[6], Eun-Jung Park[6], Eun-Kyung Bae[3], Joong Kyong Ahn[1], Yoo Sun Lee[2], Eun-Mi Koh[5] and Hoon-Suk Cha[4]. [1]Kangbook Samsung Hospital, Sungkyunkwan University School of Medicine, [2]Masan Samsung Hospital, Sungkyunkwan University School of Medicine, [3]Samsung Biomedical Research Institute, [4]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [5]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [6]Samsung Medical Center, Sungkyunkwan University School of Medicine

Purpose: T cell immunoglobulin- and mucin-domain-containing molecule-3 (TIM-3) is a novel transmembrane protein involved in the negative regulation of Th1 cell-mediated immunity by interacting with its ligand galectin-9. Galectin-9 has been shown to induce apoptosis of TIM-3 expressing Th1 cells in vitro and in vivo. We have previously demonstrated that, in rheumatoid arthritis (RA) patients, TIM-3 is expressed in the synovial tissues and that TIM-3 mRNA expression in the peripheral mononuclear cells is inversely correlated with disease activity as measured by DAS28. We hypothesize that galectin-9 induced apoptosis of Th1 cells in RA is impaired because of aberrantly low TIM-3 expression which may lead to augmented Th1 response. This study was therefore undertaken to investigate the expression of TIM-3 from CD4+ T cells and galectin-9-mediated apoptosis of CD4+T cells from RA patients and healthy controls.

Methods: CD4+T cells from RA patients and healthy controls were isolated from peripheral blood mononuclear cells and then were activated. The expression of TIM-3 mRNA in CD4+T cells was measured using real-time PCR. After CD4+T cells were activated in the presence of graded doses of galectin-9 or control, galectin-9 induced cytotoxicity and apoptotic activity of CD4+ T cells were analyzed using MTT assays and annexin V staining, respectively.

Results: TIM-3 mRNA expression was significantly lower in CD4+T cells from RA patients compared to those in healthy controls ($p=0.028$). CD4+T cell survival as measured by MTT assay when incubated with galectin-9 (15nM) was significantly higher in RA patients than in healthy controls ($p=0.002$). The increased survival trend of CD4+ T cells from RA patients was maintained at higher dose of galectin-9 (50nM), but did not reach statistical significance ($p=0.078$). Apoptotic activity of CD4+ cells from healthy controls as measured by annexin V staining increased with graded doses of galectin-9 (0nM vs. 30nM, 0nM vs. 90nM, $p=0.016$ each). However, apoptotic activity of CD4+T cells from RA patients did not change despite the stimulation with galectin-9.

Conclusion: Galectin-9-mediated apoptosis of CD4+ T cells is dysfunctional in RA patients. Blunted galectin-9-mediated apoptosis may be exerted through underexpression of TIM-3 that negatively regulates Th1 response. Our data suggest that TIM-3 and its interaction with galectin-9 may play an important role in the pathogenesis of RA and may represent a potential therapeutic target.

Appearance of Non-Rheumatoid Arthralgia after Tocilizumab Treatment in RA Patients with High Disease Activity. Osamu Saiki[2] and Hiroshi Uda[1]. [1]Sakai Onshinkai Hospital, Sakai, Japan, [2]Shiraishi Hospital, Imabari, Japan

Purpose: Tocilizumab, IL-6 receptor antagonist, is one of essential biologics to treat RA patients and several side reactions have been reported, but appearance of non-rheumatoid arthralgia after tocilizumab injection has not been discussed. We experienced several RA patients who developed additional non-rheumatoid somatic arthralgia after tocilizumab treatment. We conducted this study to examine which patients develop non-rheumatoid arthralgia and to clarify how the pain is appeared and how we should take care of these patients.

Patients and Method: We treated RA patients with tocilizumab who had not responded to MTX and/or TNF inhibitors. When we treated RA patients with tocilizumab, we examined CRP and other blood tests in addition to clinical symptoms. Serum levels of IL-6 and TNF-α were also examined before and after tocilizumab treatment.

Results: Sixty-eight RA patients were treated with 8mg/kg tocilizumab every 4 week. Among 68 RA patients, 25 patients developed non-rheumatoid arthralgia. They suffered from severe pains of large joints such as shoulder pain and lumbago, and the quality and the site of pain was quite different from those of RA. The pain started one day after receiving tocilizumab injection and lasted for one week or longer. The magnitude of pain reduced time by time. When the non-rheumatoid arthralgia was appeared, the levels of CRP had fallen down from high levels (more than 50 mg/L) to low levels (under 5mg/L). In the patients experienced non-rheumatoid arthralgia, the serum CRP levels before tocilizumab therapy were significantly higher (113 ± 57 mg/L) than those in patients without non-rheumatoid arthralgia (31 ± 18 mg/L) and the serum levels of IL-6 were very high at 28 days after first tocilizumab treatment and they were significantly higher than in those without non-rheumatoid arthralgia. But the serum levels of high sensitive TNF-α were less than 2.8 pg/mL in both patients.

Conclusion: In tocilizumab treatment, RA patients with high disease activity develop non-rheumatoid arthralgia more frequently than those with low disease activity. In the patients who developed non-rheumatoid arthralgia, the levels of IL-6 but not CRP or TNF-α were selectively high suggesting that the pain would preferentially relate to IL-6 rather than CRP or TNF-α. The elevation of IL-6 levels is due to blocking of IL-6 receptor by tocilizumab treatment. However, the relationships between appearance of non-rheumatoid arthralgia and the high levels of IL-6 were remained to uncertain.

Are Venous Thrombotic Events (VTE) Increased in Patients with Rheumatoid Arthritis (RA) Treated with Anti-TNF Therapy? Results from the British Society for Rheumatology Biologics Register (BSRBR). Rebecca Davies, James Galloway, Kath D. Watson, Mark Lunt, BSRBR Control Centre Consortium, Deborah P. M. Symmons, Kimme L. Hyrich and on Behalf of the British Society for Rheumatology Biologics Register. University of Manchester

Background: Case reports have shown that TNF decreases platelet activation and inhibits thrombus formation, and so blocking TNF may contribute to thrombus formation. Research looking at the role of such therapies on venous thrombotic events (VTE) in RA patients has produced conflicting results with more recent studies documenting an increased risk, particularly in post-orthopaedic surgery patients. The aims of this analysis were (1) to compare rates of VTE in RA patients treated with anti-TNF vs. non-biologic disease modifying anti-rheumatic drugs (nbDMARDs) alone and (2) to compare the rates between each individual anti-TNF and nbDMARDs.

Methods: To 31/10/2009, 11,881 anti-TNF and 3,673 biologic-naive nbDMARD control patients had been recruited to the BSRBR, a UK national register of active RA patients on biologic therapy. All patients were followed by regular hospital and patient questionnaires. This on-drug analysis, limited to first biologic only, followed all patients until first VTE (defined as deep venous thrombosis or pulmonary embolism), death, treatment discontinuation or last follow-up date, whichever came first. Cox proportional hazards models were used to compare rates of VTE between cohorts. Inverse probability of treatment weighting (IPTW) was used to adjust for the confounding effect of baseline differences between groups, including age, gender, diabetes, steroid use, smoking, BMI, hypertension, disease duration, severity and year of entry into the study. Surgery was entered into the model as a time-varying covariate, with patients viewed as being at increased risk for 90 days post-procedure. Missing baseline data were accounted for using multiple imputation.

Results: The anti-TNF cohort was younger (mean 56 v 60 years), had a higher proportion of females (76 v 72%) and more severe disease (mean DAS28/HAQ: anti-TNF 6.6/2.0, nbDMARD 5.1/1.5). The median duration of follow up was 4.3 years (IQR 2.9, 5.4) in the anti-TNF cohort, and 3.0 years (IQR 1.7, 4.2) in the nbDMARD cohort.

A total of 204 first VTE's were reported (160 anti-TNF, 44 nbDMARD). 13% of anti-TNF and 7% of nbDMARD VTE events were reported within 90 days of hip or knee replacement. Overall there was no difference in the rate

of VTE between anti-TNF and nbDMARD treated patients (adjusted HR 0.9 (95% CI 0.5, 1.6). The risk was similar across all anti-TNF agents.

Conclusion: Anti-TNF therapy is not associated with an increased risk of VTE in RA patients. There is also no difference in VTE risk between the anti-TNF drugs.

Table: Patient characteristics and incidence of VTEs.

	nbDMARD	All anti-TNF	ETN**	INF**	ADA**
Subjects (n)	3673	11881	4139	3475	4267

Assessment of Cardiovascular Markers after 24 Weeks of Abatacept or Rituximab Therapy in Patients with Rheumatoid Arthritis. Sylvain Mathieu[3], Gauthier Szymanski[1], Jean-Jacques Dubost[2], Natacha Mrozek[4], Geoffroy Marceau[1], Jean-Michel Ristori[4] and Martin Soubrier[4]. [1]Biochimie, CHU Gabriel Montpied, Clermont-Ferrand, France, [2]Humatologie, CHU Gabriel Montpied, Clermont-Ferrand, France, [3]Rhumatologie, CHU Gabriel Montpied, Clermont-Ferrand, France, [4]Rhumatologie, CHU Gabriel Montpied, Clermont-Ferrand, France

Background: Increased incidence of cardiovascular disease has been observed in rheumatoid arthritis (RA). Several studies have attributed this excess cardiac risk to biological inflammation. Effective control of inflammation may be of benefit in reducing cardiovascular risk in RA patients.

Objectives: To investigate the effects of abatacept and rituximab treatment in active RA on markers of atherosclerosis: arterial stiffness measured by augmentation index (AIx) and pulse wave velocity (PWV), lipoproteins, pro-brain natriuretic peptide (pro-BNP) and soluble levels of Receptor for Advanced Glycation Endproducts (sRAGE).

Methods: PWV, AIx, clinical status, lipoproteins, systemic inflammation, pro-BNP and s-RAGE were assessed at baseline and after 24 weeks of abatacept and rituximab therapy.

Results: Thirty RA patients, including 27 women, with a mean age of 58.0 ± 11.6 years and a longstanding disease of about 11 years received rituximab therapy. Of these 30 patients, 90% had rheumatoid factor, 80% anti-CCP antibody and 93.3% were erosive. Nineteen patients had failed to respond to TNF alpha inhibitor treatments.

Seventeen RA patients (14 female), with a mean age of 60.6 ± 14.1 years were treated by abatacept. Of these 17 patients, 47.1% had positive rheumatoid factors, 76.5% had positive anti-CCP antibody, and all were erosive. Twelve patients were non-responders to TNF alpha inhibitor treatments and 7 (41.1%) to rituximab treatment.

1) Arterial stiffness. After abatacept treatment, no change was observed in PWV (8.6 ± 4.2 vs. 9.4 ± 3.1 m/s; p=0.09) and AIx (29.9 ± 10.6 vs. 30.1 ± 9.3%; p=0.98). With rituximab, an improvement in AIx was obtained (AIx: 29.1 ± 8.0% vs. 31.7 ± 10.5%; p=0.024) but not to a level of significance for PWV (7.9 ± 2.7 vs. 8.1 ± 3.4 m/s; p=0.620).

2) Lipoproteins and other cardiovascular risk markers. After both treatments, a significant increase in the level of apolipoprotein A1 (apoA1) and a tendency to a decrease in the apolipoprotein B/apoA1 ratio were obtained. No change was found in levels of pro-BNP, sRAGE or apoB.

3) Disease activity. DAS28 ESR and DAS28 CRP were significantly improved after both rituximab and abatacept. We found a decrease in parameters of biological inflammation, significant after rituximab and not significant after abatacept.

Conclusion: This study shows that arterial stiffness, occurring in RA, was not improved after 6 months of abatacept or rituximab therapy, nor pro-BNP and s-RAGE. However, the treatment did have a beneficial effect on lipid profile and so it would be interesting to have an assessment over a longer period, especially since abatacept and rituximab are not anticytokine therapies.

376

Before Beginning Anti-TNF, a Better Targeted Screening and a Twice Decrease Frequency of Latent Tuberculosis (TB) with IFN gamma Release Assays (IGRA) Compared with Tuberculin Skin Test. Results in 396 Patients from the ETAT Study. Xavier Mariette[3], Gabriel Baron[3], Frédéric Lioté[3], Philippe Goupille[4], René-Marc Flipo[1], Bernard Combe[2], Florence Tubach[3], Dominique Emilie[3], Dominique Salmon[3], Marc Leman[3], Guislaine Carcelain[3] and Philippe Ravaud[3]. [1]Lille University, [2]Montpellier University, [3]Paris University, [4]Tours University

Background: In spite of screening for latent tuberculosis (TB) with tuberculin skin test (TST), reactivation of TB remains a non rare severe complication in patients treated with TNF blockers, mainly with monoclonal antibodies. Great hope came from a more efficient screening of latent TB with specific IFN gamma release assays (IGRA).

Objective: To compare TST and 2 IGRA in a large cohort of patients with different immune mediated inflammatory diseases (IMID) before introduction of anti-TNF.

Methods: 396 patients with IMID were screened for latent TB with TST and with 2 IGRA, Quantiferon Gold and T-Spot TB, before beginning anti-TNF. 126 patients (32%) had rheumatoid arthritis, 178 (45%) had spondyloarthritis and 92 (23%) had Crohn's disease. 238 patients (60%) received an immunosuppressive treatment and 144 (36%) received steroids.

Results: 138 patients (35%) had positive skin test (> 5mm) and 66 (17%) had positive IGRA (either Quantiferon Gold or T-Spot TB), p< 0.0001. Interestingly, 122 patients (31%) had discordant results between TST and IGRA, 97 (25%) with positive TST and negative IGRA and 25 (6%) with negative TST but positive IGRA. The discordant results in the different diseases are indicated in the table.

		IGRA + in all patients (n = 396)			IGRA + in RA patients (n = 126)			IGRA + in SpA patients (n = 178)			IGRA + in CD patients (n = 92)		
		No	Yes	Tot	No	Yes	Tot	No	Yes	Tot	No	Yes	Tot
TST + (> 5 mm)	No	233	25	258	79	13	92	85	7	92	69	5	74
	Yes	97	41	**138 (34.9%)**	24	10	**34 (27.0%)**	58	28	**86 (48.3%)**	15	3	**18 (19.6%)**
	Tot	330	**66 (16.7%)**	396	103	**23 (18.3%)**	126	143	**35 (19.7%)**	178	84	**8 (8.7%)**	92
P (IGRA + vs TST+			<0.0001			0.07			<0.0001			0.03	

Proportion of positive results was higher with T-Spot TB than with Quantiferon Gold: 59/396 (15%) versus 39/396 (10%), p= 0.0006.Concordance between the 2 IGRA tests was good: 91% [88–94], kappa= 0.61 [0.49–0.73].

In multivariate analysis, the factors influencing positivity of IGRA (one or the other) were to be born in a TB endemic area (OR=2.9 [1.5–5.7]) and not to be vaccinated with BCG (OR=3.7 [1.3–10.8]).

The number of indeterminate results was greater with T-Spot TB than with Quantiferon Gold TB: 29/396 (7.3%) versus 11/396 (2.8%), p=0.002. Among the 29 indeterminate tests with TsSpot TB, 25 were negative with Quantiferon Gold, 3 were positive and 1 was indeterminate. Among the 11 indeterminate tests with Quantiferon Gold, 8 were negative with TsSpot TB, 0 were positive and 3 were indeterminate. No factor influences an indeterminate result of IGRA, and in particular neither steroid use nor immunosuppressant use.

All the patients were treated with antibiotics depending of the IGRA tests (1 or the other). No patient developed TB with 1 year of follow-up.

Conclusion: In this large series of almost 400 patients assessed for latent TB before anti-TNF, IGRA are positive in twice less cases than TST and 31% of the patients had discordant results between TST and IGRA, ¾ with positive TST and negative IGRA and ¼ with negative TST and positive IGRA. Using IGRA for screening of latent TB seems more effective than TST for better targeting the population at risk of TB with anti-TNF treatment but

the sensitivity and the specificity of each of the tests will have to be assessed in the sub-group of patients with certain latent TB on clinico-radiological arguments independently of the results of the tests.

Better Results Are Achieved with Switching Directly to Biologics Than Switching Via DMARD Combinations in RA Patients Who Have Failed Methotrexate as Their Initial DMARD: Real Life Data from NOR-DMARD. Elisabeth Lie[2], Till Uhlig[2], Knut Mikkelsen[3], Synøve Kalstad[5], Erik Rødevand[4], Cecilie Kaufmann[1] and Tore K. Kvien[2]. [1]Buskerud Central Hospital, Norway, [2]Diakonhjemmet Hospital, Norway, [3]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway, [4]St. Olavs Hospital, Norway, [5]University Hospital of Northern Norway, Norway

Background: Combination of methotrexate (MTX) with an anti-TNF agent is generally considered more effective than combinations with synthetic DMARDs in RA pts who have failed MTX. Many countries require use of at least two DMARDs before start of a biologic agent and the relative benefit of these different strategies in real life is not clarified. The objective of this study was to examine the value of switching via MTX+DMARD combinations vs switching directly to MTX+aTNF after failing MTX mono.

Methods: The NOR-DMARD registry includes pts >18 yrs of age with inflammatory arthropathies starting treatment with DMARDs or biologicals in 5 centres. Pts are consecutively included and followed longitudinally. For the current analyses we included RA pts with <5 yrs disease duration who had failed on MTX (but no other DMARDs), and who were started on MTX+aTNF (group I) or MTX+DMARDs (group IIa). From group IIa we identified a subgroup of pts who received MTX+anti-TNF after failure of the MTX+DMARD combination (i.e. failed ≥2 DMARDs) (group IIb). We compared effectiveness and disease states between group I and group IIa and between group I and group IIb. Survival analyses (Kaplan-Meier) were based on 1- and 2-yr data.

Results: Group I included 85 pts (37 etan(ercept), 25 infl(iximab), 23 ada(limumab)) and group IIa 125 pts (56 MTX+sulfasalazine, 43 triple, 24 MTX+antimalarials, 2 MTX+leflunomide). In groups I/IIa 73%/70% were RF pos (p=0.60), 61%/69% were female (p=0.25), mean age was 50/53 yrs (p=0.15), median(IQR) disease duration was 1.2(0.6–2.3)/1.1(0.5–1.8) yrs (p=0.24). Baseline disease activity was similar (mean DAS28 4.94/4.97, MHAQ 0.79/0.70, SF6D 0.57/0.58, all differences N.S). 6-month disease activity states and responses were superior for group I vs group IIa (table). 1- and 2-yr drug survival were superior for group I vs group IIa (p<0.001/ p=0.001). 31 of the 125 pts who received MTX+DMARDs were later started on secondary MTX+aTNF (group IIb; 11 etan, 12 infl, 8 ada). These pts (68% female, 81% RF pos) were at baseline not significantly different from the remaining pts in group IIa. At start of MTX+aTNF mean DAS28/MHAQ/SF6D were 5.46/0.74/0.59. On average group IIb pts reached a less favourable disease activity state than group I (table). Mean 6-month change in SF6D was 0.13 for group I vs 0.02 for group IIb (p<0.001). Drug survival was superior for group I vs group IIb at 1 yr (p=0.09) and 2 yrs (p=0.02).

*group I vs. group IIa; **group I vs. group IIb

Conclusion: In these pts who were MTX failures, MTX+anti-TNF was superior to MTX+DMARDs in terms of disease states reached, response and remission rates, and retention to therapy. Furthermore, the subgroup of pts receiving MTX+aTNF after failing the MTX+DMARD combination reached less favourable disease activity states and a lower remission rate than pts receiving MTX+aTNF after having failed MTX only. These data may suggest that delayed initiation of TNF inhibitor can reduce the achieved clinical benefit.

Characterization of Laboratory Parameters in Long-Term Extension Studies of Tocilizumab in Rheumatoid Arthritis. William Rigby[3], Daniel E. Furst[8], Warren Rizzo[1], Alexandra Balbir-Gurman[5], Moshe Zilberstein[6], Emma Vernon[7], Joel M. Kremer[2], Andrea Rubbert-Roth[9] and Ronald F. van Vollenhoven[4]. [1]Advanced Arthritis Care, Scottsdale, AZ, [2]Albany Medical College, Albany, NY, [3]Dartmouth Medical School, Lebanon, NH, [4]Karolinska University Hospital, Stockholm, Sweden, [5]Rambam Health Care Campus, Haifa, Israel, [6]Roche, Nutley, NJ, [7]Roche, Welwyn, UK, [8]UCLA Medical Center, Los Angeles, CA, [9]University of Cologne, Cologne, Germany

Purpose: Tocilizumab (TCZ) is a fully humanized monoclonal antibody that targets interleukin-6-receptor signal transduction. Efficacy and safety of TCZ in patients with RA have been demonstrated in 7 phase 3 studies. The objective of this analysis was to assess the effects of TCZ on laboratory parameters in patients with RA using pooled data from clinical trials (OPTION, TOWARD, RADIATE, AMBITION, and LITHE) and ongoing long-term extension studies.

Methods: This was a pooled analysis of patients who received ≥1 TCZ dose (in OPTION, TOWARD, RADIATE, AMBITION, LITHE, GROWTH95, and GROWTH96) from initial exposure through August 28, 2009. Data were examined using descriptive statistics.

Results: A total of 4009 patients received TCZ with a median (mean) treatment duration of 3.1 (2.7) years and a total observation time of 10,994 patient-years (PY). Mean CRP levels decreased from 2.43 mg/dL at baseline to 0.17 mg/dL at first assessment (week 2) and have remained at or near normal levels (0.13 mg/dL at week 192). Mean ESR decreased from 46 mm/h at baseline to 17 mm/h at week 2 and to 8 mm/h at week 192. Mean hemoglobin/albumin levels increased from 134.0/38.1 g/L at baseline to 143.0/41.6 g/L at week 6 and to 149.0/42.1 g/L at week 192. Clinically significant decreases in neutrophil counts occurred in 4.5% (grade 3: ANC = 0.5-<1.0 × 10^9/L) and 0.7% (grade 4: ANC = <0.5 × 10^9/L) of patients, and there was no apparent correlation between decreased neutrophil counts and serious infections. Continued exposure to TCZ was not associated with increased incidences of CTC grade 3/4 decreases in neutrophil counts. A decrease in platelet counts to ≥25 to <50 × 10^9/L occurred in 0.4% of patients and to <25 × 10^9/L in 0.5% of patients. There was no apparent correlation between decreased platelet count and serious bleeding event. Increased ALT/AST levels from normal at baseline to >3 to 5× ULN and >3× ULN occurred in 7.9%/2.7% and 10.3%/3.3% of patients. Most transaminase elevations >3× ULN were single, transient occurrences. An increase in LDL from <130 mg/dL at baseline to ≥130 mg/dL at last observation was reported in 22.6% (63/279) of patients who were receiving lipid-lowering medication and in 37.4% (761/2033) of patients who were not receiving lipid-lowering medication. Lipid profile changes were not associated with increased cardiovascular events over a median duration of 3.1 (range, 0–4.6) years.

Conclusions: Treatment with TCZ led to marked improvements in CRP levels and ESR as early as week 2. Among patients with increases in lipid levels, hepatic transaminases, neutrophil counts, or platelet counts, no clear increase in associated clinical events was noted; this could have been a result of monitoring and treatment adjustments that occurred in this longitudinal study. Regular monitoring of these parameters should be employed during routine use of TCZ in patients with RA.

Disease Activity, Calendar Year, and Physician Preference Are Associated with Switching of Biologic Agents for Reasons of Inadequate Efficacy. Jeffrey R. Curtis[3], Ying Shan[4], Joel M. Kremer[2], Jeffrey D. Greenberg[1] and George Reed[4]. [1]Millburn, NJ, [2]The Center for Rheumatology, Albany, NY, [3]University of Alabama - Brimingham, Birmingham, AL, [4]University of Massachusetts

Background: As new biologic agents have become available, the impact of having additional options on the decision to switch is unclear. We evaluated factors associated with switching biologic medication regimen in a large U.S. registry of rheumatoid arthritis (RA) patients.

Methods: Using CORRONA data through 12/31/2009, eligible patients had RA newly treated with an anti-TNF agent with ≥ 6 months of follow-up. The outcome was discontinuing or switching to a different biologic within one year due to inadequate efficacy. Individuals switching for other reasons were excluded.

Factors associated with switching for lack of efficacy were evaluated using logistic regression, with a focus on CDAI and calendar year. Clustering at the physician level was estimated using random effects. We tested the hypotheses that switching would be more likely as new biologics were available over time after controlling for disease activity, and that physician preference for switching would be significant even after adjustment.

Results: Among 3,351 patients initiating an anti-TNF medication, 1,328 were eligible for analysis. Baseline characteristics were mean±SD 46.2 years, 80% women, 90% RF+, mean RA duration 9.5±9.2 years, mean CDAI 21.9±14.5, mean MD global 34±22, mean DAS28 4.5±1.5, 37% steroids, 62% 1st biologic, 30% 2nd biologic, 8% 3rd biologic.

Among these, 125 switched their biologic regimen for lack of efficacy; 44 (35%) switched within 6 months. Numerous factors were different among patients who switched versus those persistent: CDAI (22.4 vs. 12.5, $p < 0.001$), change in CDAI (−2.7 vs. −9.7, $p = 0.002$), MD global (−7.6 vs. −14.4, $p = 0.04$), change in swollen joints (−0.1 vs. −3.3, $p = 0.001$), change in patient global (0.1 vs. −11.8, $p = 0.008$).

As shown (Table), calendar year was associated with switching even after controlling for disease activity. Patients with moderate disease activity (CDAI 10–21) were even more likely than low or high disease activity to be switched over time (p value for interaction between moderate disease activity × calendar year = 0.03). There was a small but significant effect of clustering by physician in the decision to switch for lack of efficacy (OR=1.2, 95%CI 1.1–66.5).

Factors Associated with RA Patients Switching Their Biologic Medication Regimen for Lack of Efficacy

	Odds Ratio (95% CI)
Clinical Disease Activity Index (CDAI)	
<10 (referent)	1.0
10–21	4.0 (2.3–6.9)
> = 22	7.7 (4.6–14.7)
Change in CDAI	
>=10 unit improvement (referent)	1.0
Improvement between 1 and 10 units	1.3 (0.8–2.2)
No improvement, or worsening	1.6 (0.9–2.6)
Calendar Year	
2002–2005 (referent)	1.0
2006–2007	2.0 (1.1–3.7)
2008–2009	3.4 (1.9–6.0)
Number of prior biologics used	
1 (referent)	1.0
2	1.7 (1.1–2.6)
3	1.4 (0.7–2.7)

Conclusion: The availability of new biologic agents in recent years has increased the likelihood of switching for reasons of lack of efficacy, especially for patients with moderate disease activity, and after controlling for clinical response. Physician preference also was significantly associated with the decision to switch. The future availability of new agents will likely further motivate medication switching.

Early Clinical Response to Treatment Predicts Long-Term Outcome in RA Patients: 5 Year Follow-Up Results of a MTX-Based Tight Control Strategy (CAMERA). M. F. Bakker[1], J. W. G. Jacobs[1], P. M. J. Welsing[1], S. A. Vreugdenhil[4], C. van Booma-Frankfort[2], S. P. Linn-Rasker[3], E. Ton[1], F. P. J. G. Lafeber[1] and J. W. J. Bijlsma[1]. [1]Rheumatology & Clinical Immunology, University Medical Center Utrecht, The Netherlands, [2]Rheumatology, Diakonessenhuis Utrecht, the Netherlands, [3]Rheumatology, Meander Medical Center Amersfoort, the Netherlands, [4]Rheumatology, St. Antonius Hospital Nieuwegein, the Netherlands

Background: The CAMERA trial showed that an intensive, tightly controlled MTX-based strategy after 2 years of treatment is more effective in early RA when compared to a conventional MTX-based strategy. The aim of this investigation was to compare the long-term effects of the intensive strategy in CAMERA with those of the conventional strategy in early RA and to investigate the predictive value of an early response for long-term outcome.

Methods: The clinical (DAS28) and radiographic (mean yearly radiographic progression rate) outcome at 5 years was compared between strategies and tested with independent t-tests. Patients of the CAMERA trial were classified as early good-, moderate- or non-responders after 6 months of treatment according to the EULAR criteria. Whether early response to treatment had additional predictive value to that of established baseline predictors (rheumatoid factor, joint damage and disease activity) was investigated by multivariate linear regression analysis, taking into account the 2 treatment strategies.

Results: Of the 299 patients, 5 years data were present of 205 (102 intensively, 103 conventionally treated) patients. Analysis showed no indication for missing data due to selective drop-out. The mean (SD) DAS28 at 5 years of treatment was 2.68 (1.0) and 2.75 (1.3) for intensively and conventionally treated patients respectively. The median (IQR) radiographic progression rates at 5 years were 1.4 (0.1–3.6) and 0.8 (0.0–3.2), respectively. There was no significant difference for clinical and radiological outcomes between the initial treatment strategies. According to the EULAR criteria, 68, 84, and 45 patients had an early good-, moderate-, and non-response, respectively. Patients with an early good-, moderate- or non-response respectively had a mean DAS28 at 5 years of 2.39 (1.2), 2.69 (1.1), and 3.11 (1.2) and a median radiographic progression rate of respectively 0.6 (0.0–2.2), 1.5 (0.2–3.6), and 2.5 (0.5–6.2). Early good-responders showed significantly better results for clinical (p=.09 and p=.001) and radiological (p=.013 and p=.001) outcomes at 5 years when compared to those with early moderate- and non-response, respectively. About 2/3 of the early good-responders and 1/4 of the early non-responders had been allocated to the intensive treatment strategy. The multivariate regression analysis with inclusion of known predictors showed that early response to treatment is an independent predictor of long-term outcome, both within the tight control and conventional strategy.

Conclusions: The difference in effect between treatment strategies diminished over the years. An early good-response to treatment independently predicts significantly better long-term outcomes irrespective of the treatment strategy. Effects of continuation of tight control in those patients who still have active disease needs further study.

Early Development of Antibodies Against Infliximab Predicts Withdrawal Due to Adverse Drug Reactions in Patients with Rheumatoid Arthritis. Sophine B. Krintel[2], Veit Peter Grunert[4], Merete L. Hetland[1], Julia S. Johansen[3], Matthias Rothfuss[4] and Ursula Klause[4]. [1]DANBIO Registry and Department of Rheumatology at Copenhagen University Hospital, Hvidovre and Glostrup, Hvidovre, Denmark, [2]DANBIO Registry and Department of Rheumatology at Copenhagen University Hospital, Hvidovre and Glostrup and Department of Medicine at Copenhagen University Hospital, Herlev, Valby, Denmark, [3]Medicine and Oncology at Copenhagen University Hospital, Herlev, Denmark, [4]Roche Diagnostics GmbH, Penzberg, Penzberg, Germany

Background: Some patients with rheumatoid arthritis (RA) treated with TNFalpha inhibitors develop adverse drug reactions (ADR) or secondary treatment failure. The objectives were to investigate the frequency of

antibodies against infliximab in patients with RA during treatment with infliximab, and to determine if development of such antibodies was associated with withdrawal due to early ADR and/or treatment failure.

Methods: Between October 1999 and August 2008 serum samples were collected from 218 Danish patients with RA (80% females, median age = 56 years, disease duration = 10.1 years, 65% RF positive, median DAS28(CRP) = 5.0 (IQR =4.2–5.9)) who initiated treatment with infliximab according to national guidelines. The levels of anti-infliximab antibodies (AB) were determined pre-infusion at baseline (week 0), weeks 6 and 14 (or at withdrawal) by the IMPACT Indirect Assay (Roche Diagnostics). Based on 100 blood donors and all 218 baseline samples, a preliminary cutoff for the assay was defined. A sample was considered positive (AB+) if the signal was at least two fold above the highest signal seen in any blood donor or baseline sample, otherwise as negative (AB-).

Clinical assessments were performed at weeks 0, 2, 6, and then every 8th week until termination of treatment. Clinical evaluation (including tender and swollen joint counts (28 joints), CRP, DAS28(CRP) score, and reason for withdrawal) was obtained from the DANBIO Registry. ADR was defined as any adverse event leading to withdrawal of infliximab treatment. Lack of efficacy (LOE) was defined as withdrawal due to high disease activity despite adequate treatment.

Results: In total 28 (13%) patients withdrew due to ADR before week 50 and 46 (21%) due to LOE (median DAS28 4.9 (IQR= 4.35 – 5.65)). Among patients withdrawn due to ADR, 18 withdrew due to infusion reactions. At week 6, 31 patients were AB+, and 15 (48%) of those withdrew due to ADR before week 50. Only 12 (13%) of the 94 AB- patients at week 6 withdrew due to ADR before week 50. Compared to AB- patients, the AB+ patients had a HR of ADR of 5.06 at week 6 ($p<0.0001$), see Table. Patients who withdrew due to infusion reaction were primarily AB+ at week 6 (n=15; 83%). After 14 weeks of treatment, 43 patients were AB+ and 16 (37%) of those withdrew due to ADR before week 50. Compared to AB- patients, the AB+ patients had a HR of ADR of 3.30 at week 14 ($p=0.0009$), see Table. There was no association between development of AB at week 6 and 14 and withdrawal due to LOE, see Table.

	Reason for withdrawal	
	ADR	LOE
Week 6	31/15 vs. 94/12*	27/11 vs. 112/31*
	5.06 (2.36–10.84), p < 0.0001#	1.70 (0.85–3.38), p = 0.13#
Week 14	43/16 vs. 88/12*	40/13 vs. 109/33*
	3.30 (1.56–6.99), p = 0.0009#	1.17 (0.62–2.29), p = 0.63#

*: Number of AB+/withdrawals vs. AB−/withdrawals
#: Hazard Ratio (95% CI), p-value

Conclusions: Early development of antibodies against infliximab predicted withdrawal due to adverse drug reactions in patients with RA within the first year of infliximab treatment. The findings suggest that anti-infliximab antibody measurement 6 weeks after start of treatment represents a promising approach to identify which RA patients that are at increased risk of developing adverse drug reactions.

Effect of Switching Anti–Tumor Necrosis Factor Agents on Clinical Outcomes for Patients with Rheumatoid Arthritis. Amir Goran[2], Sanjoy Roy[1], Marco DiBonaventura[2], Jochen Ertl[2] and Mary Cifaldi[1]. [1]Abbott Laboratories, Abbott Park, IL, [2]Kantar Health, New York, NY

Background and Purpose: Tumor necrosis factor antagonists (anti-TNFs) have led to better management of rheumatoid arthritis (RA), and their efficacy is well-established for patients who have failed disease-modifying antirheumatic drugs (DMARDs). The utility of switching to a second anti-TNF agent, after the first fails, is therefore a topic of immense clinical interest. We assessed outcomes of switching from 1 anti-TNF agent to another on a range of clinical measures.

Methods: Data were extracted from medical charts of patients with RA who were treated with an anti-TNF agent and then switched to a second biologic DMARD by rheumatologists in the United States. Outcomes frequently used in clinical practice were assessed: swollen and tender joint counts (SJC and TJC), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), and physician-reported severity. Mixed models assessed improvements over time, from initiation to discontinuation of the first and then the second anti-TNF agent, controlling for age, sex, time on and between treatments, years since diagnosis, concomitant use of methotrexate, psychiatric comorbidity, and Charlson Comorbidity Index. Subgroups were also analyzed by reason for switching in the following order: lack of/inadequate response to the first agent, side effects/tolerability issues, or other reasons (eg, compliance or cost).

Results: Data were analyzed for 399 patients with RA who switched to a second biologic agent after a mean (SD) of 1.6 (1.7) years on the first therapy. Of 215 who switched to a second anti-TNF agent, 148 switched for lack of/inadequate response, 31 for intolerability, and 36 for other reasons. Mean age was 51.3 years, mean RA duration was 6.5 years, 71.2% were women, and 80.9% were white. After failure on the first anti-TNF agent, patients treated with a second anti-TNF agent for a mean (SD) of 1.3 (1.6) years achieved overall improvements of 65.6%, 69.5%, and 25.5% for TJC, SJC, and severity, respectively (all $p<0.001$); improvements were significantly greater with the second anti-TNF agent compared with the first. CRP (54.2%) and ESR (46.5%) showed similar overall improvements (both $p<0.001$), but there was no difference before and after switching to the second anti-TNF agent. Continued improvement after switching anti-TNF therapies was observed for all patients, except for those who switched due to other reasons. For patients who switched due to inadequate response, significantly greater improvement on all measures was observed during therapy with the second anti-TNF agent compared with the first, whereas the intolerability group experienced steady and significant improvements on both the first and second anti-TNF agent.

Conclusions: For patients with RA who failed a first anti-TNF agent, including those who failed because of lack of response or tolerability issues, significant improvements on SJC, TJC, ESR, CRP, and disease severity were observed after switching to a second anti-TNF agent. Overall improvements were similar or better than those observed in most randomized, controlled trials of an anti-TNF agent as the first biologic therapy, thus demonstrating the value of switching to a second anti-TNF when the first fails.

Efficacy and Safety of Ocrelizumab in Patients with Active Rheumatoid Arthritis Who Had an Inadequate Response to Methotrexate: Results from the Phase III STAGE Trial. William F. C. Rigby[2], Hans Peter T. Tony[7], Kurt R. Oelke[5], Bernard G. Combe[8], Andrew J. Laster[1], Helen Travers[6], Carlos A. Von Muhlen[4], Elena Fisheleva[6], Carmen Martin[6] and Wolfgang Dummer[3]. [1]Arthritis & Osteoporosis Consultants of the Carolinas, Charlotte, NC, [2]Dartmouth Medical School, Lebanon, NH, [3]Genentech Inc, San Francisco, CA, [4]Pontifical Catholic University of Rio Grande do Sul, Porto Alegre, Brazil, [5]Rheumatic Disease Center, Glendale, WI, [6]Roche, Welwyn Garden City, UK, [7]Universitätsklinikum Würzburg, Wuerzburg, Germany, [8]Université Montpellier, Montpellier, France

Purpose: B-cell targeted therapy using anti-CD20 antibodies has demonstrated clinical benefit in patients (pts) with rheumatoid arthritis (RA). This phase III study investigated the efficacy and safety of ocrelizumab (OCR), a humanized anti-CD20 antibody, + methotrexate (MTX) vs MTX alone in pts with active RA who have had an inadequate response to MTX.

Methods: STAGE was a phase III, international, randomized, placebo (PBO)-controlled, parallel-group study, consisting of a 48-wk double-blind PBO-controlled period and open-label extension. A total of 1015 pts with active RA (revised 1987 ACR criteria) with SJC ≥4, TJC ≥4, CRP ≥0.6 mg/dL, RF+ and/or anti-CCP+, and on stable MTX (7.5–25 mg/wk) were randomized (1:1:1) to PBO (n=324), OCR 200 mg × 2 (n=344), or OCR 500 mg × 2 (n=347). Pt baseline characteristics were generally well balanced between treatment groups (means: age 51 yr; SJC 17; TJC 27; CRP 2.4 mg/dL; DAS28 6.4; RA duration 7.4 yr). Two OCR/PBO courses (each consisting of 2 infusions given 14 days apart) were given at days 1/15 and wks 24/26, with methylprednisolone 100 mg iv as premedication. Co-primary endpoints were ACR20 response at wk 24 and at wk 48. Secondary endpoints included change in van der Heijde-modified total Sharp score (mTSS) and ACR50/70 responses at 24 and 48 wks. Pts were allowed to continue the same corticosteroid dose from baseline.

Results: Key efficacy and safety data are shown in Table 1.

	PBO (n=319)	OCR 200 mg x 2 (n=343)	OCR 500 mg x 2 (n=343)
Efficacy[a], %			
Wk 24			
ACR20	35.7	56.9 (p<0.0001)	54.5 (p<0.0001)
ACR50	16.3	31.8 (p<0.0001)	31.2 (p<0.0001)
ACR70	5.6	14.3 (p=0.0002)	12.2 (p=0.0023)
Wk 48			
ACR20	27.6	58.3 (p<0.0001)	62.1 (p<0.0001)
ACR50	12.9	39.9 (p<0.0001)	36.7 (p<0.0001)
ACR70	6.6	20.7 (p=0.0001)	22.4 (p=0.0001)
Radiographic[b]			
Mean change in mTSS, 48 wks	1.74	0.26 (p<0.0001)	-0.03 (p<0.0001)
Safety 48 wks, pts with at least one event (%)			
	[n=320]	[n=343]	[n=343]
AEs	79.4	82.2	83.7
SAEs	11.6	7.6	11.1
Infections	54.1	54.8	56.6
SIEs	3.1	3.2	6.1
IRRs	9.7	20.1	23.3
Serious IRRs	0	0.3	0.6
Deaths, n	1	0	3
Serious infection rates			
Total pt-years	287.08	310.59	311.88
Serious infections[c]	10	11	27
Serious infections/100 pt-yrs (95% CI)	3.48 (1.67, 6.41)	3.54 (1.77, 6.34)	8.66 (5.71, 12.60)

All comparisons (OCR vs PBO) using Cochran-Mantel-Haenszel test, stratified for rheumatoid factor (RF) status and region (US/RoW).
[a]Missing data set to non responder.
[b]Van Elteren test: mITT (pts with 1 BL and at least 1 post-BL X-ray): n=305 for PBO, n=322 for OCR 200 mg x 2, and n=329 for OCR 500 mg x 2. Missing data were extrapolated/interpolated.
[c]Multiple occurrences of the same event in one individual counted multiple times.

Both OCR doses showed statistically significant improvements (vs PBO) in ACR20/50/70 at wks 24 and 48. At wk 48, both OCR doses showed statistically significant ($p<0.0001$) inhibition of progression of joint damage (PJD; change from baseline in mTSS) relative to PBO (85% and 100% inhibition for 200 mg and 500 mg, respectively). Frequency of AEs, serious AEs, and overall infections were comparable. Serious infectious events (SIEs) were reported with similar frequency with OCR 200 mg and PBO (pts with at least 1 SIE: 3.2% and 3.1%, respectively), but were more frequent with OCR 500 mg (6.1%). Two opportunistic infections were reported (1 *Mycobacterium kansasii* infection with OCR 200 mg; 1 fungal esophagitis infection with OCR 500 mg). Four deaths were reported (1 rheumatoid vasculitis with PBO; 3 [1 respiratory failure, 1 sepsis, 1 myocardial infarction] with OCR 500 mg).

Conclusions: Both OCR doses met the primary efficacy endpoints and significantly improved the signs and symptoms of RA at wks 24 and 48. The efficacy of both doses of OCR was generally comparable. Both OCR doses showed inhibition of PJD. More SIEs were reported with OCR 500 mg compared with OCR 200 mg and PBO.

First Experiences with Pregnancies in RA Patients (pts) Receiving Tocilizumab (TCZ) Therapy. Andrea Rubbert-Roth[4], Philippe M. Goupille[1], Shahrzad Moosavi[3] and Antony Hou[2]. [1]Hopital Trousseau, Tours, France, [2]Inland Rheumatology Clinical Trials, Upland, CA, [3]Roche, Nutley, NJ, [4]University of Cologne, Cologne, Germany

Purpose: TCZ, an IL-6 receptor inhibitor, reduces signs and symptoms of RA and inhibits joint damage progression in RA pts. Women of childbearing potential were required to use a reliable contraception method in TCZ clinical trials. However, pregnancies did occur during TCZ use in clinical studies. TCZ has an FDA label of pregnancy category C (no adequate and well-controlled studies in humans; should be used in pregnant women only if potential benefit justifies potential risk to fetus). The purpose of this analysis was to describe pregnancies and their outcomes in RA pts receiving TCZ in clinical studies.

Methods: The analysis included all pregnancies reported in RA pts who received TCZ in one phase 1 study, five phase 3 trials (OPTION, TOWARD, RADIATE, AMBITION, LITHE), and 2 ongoing open-label extension studies (GROWTH95/96). Pts received 1 dose of TCZ 10 mg/kg in the phase 1 study, TCZ 4 or 8 mg/kg Q4W in phase 3 trials, and TCZ 8 mg/kg Q4W in extensions. Cutoff date was August 28, 2009.

Results: A total of 4009 pts (10,994 pt-years) were included. Thirty-three pregnancies were reported in 32 pts, despite a requirement for contraceptive use. All pts had received TCZ 8 mg/kg, except 1 pt who received TCZ 4 mg/kg. Of 32 pts, 26 received TCZ + MTX and 6 received TCZ monotherapy or a concomitant DMARD other than MTX. Most of the 32 pts conceived while using a condom as a primary or secondary contraception method followed by hormonal contraceptive. Some pts used more than one method. Two patients did not use any contraceptive method. Pt age at conception was 19 to 42 y; 10 were ≥35 y. In pts who continued their pregnancies, TCZ and MTX were stopped when the pregnancy was known. Thirteen of 33 pregnancies were therapeutically aborted, 7 (3 pts were ≥35 y) spontaneously aborted, and 11 resulted in term delivery. Outcome was unknown for 2 pregnancies (1 lost to follow-up; 1 outcome not confirmed). Of 7 spontaneous abortions, all occurred within ~2 months of conception; all pts received TCZ 8 mg/kg, and 5 received concomitant MTX at conception. Of 11 term deliveries, 10 were of healthy newborns (1 infant died of ARDS 3 days after emergency cesarean section for intrapartum fetomaternal hemorrhage due to placenta previa). All mothers who delivered to term had received TCZ 8 mg/kg; 9 had received concomitant MTX, and 2 had received TCZ monotherapy.

Conclusions: The amount of clinical trial data about pregnancy outcomes in women exposed to TCZ during pregnancy is limited. The low number of cases and the high rate of therapeutic abortions, as well as concomitant medication use, limit the conclusions that can be drawn regarding the safety of TCZ during pregnancy. Physicians should be aware of the pregnancy information in local prescribing information and advise women of childbearing potential to use reliable methods of contraception before initiating treatment with TCZ. Hormonal contraceptives are substrates of CYP450, and the effect of TCZ on the reliability of hormonal contraceptives is being assessed in a separate clinical trial. A pregnancy registry is being established to assess pregnancy outcomes in women exposed to TCZ during pregnancy.

Golimumab and Cardiovascular Disease Markers in Inflammatory Arthritides. Bruce Kirkham[3], Mary C. Wasko[8], Joan M. Bathon[4], Elizabeth C. Hsia[2], Roy M. Fleischmann[6], Mark C. Genovese[7], Eric L. Matteson[5], Hongjuan Liu[1] and Mahboob U. Rahman[2]. [1]Centocor Research and Development, Inc., [2]Centocor Research and Development, Inc./Univ. of Pennsylvania School of Medicine, Malvern, PA, [3]Guy's and St. Thomas' Hospital, London, United Kingdom, [4]Johns Hopkins Univ., School of Medicine, Baltimore, MD, [5]Mayo Clinic, Rochester, MN, [6]Rheumatology Associates, Dallas, TX, [7]Stanford University, Sunnyvale, CA, [8]Univ. of Pittsburgh

Purpose: To assess the effect of golimumab (GLM), a human anti-tumor necrosis factor (TNF) agent, +/− methotrexate (MTX), on serum lipid profiles and inflammatory markers associated with cardiovascular disease (CVD).

Methods: Serum lipids, including LDL subfractions and inflammatory CV markers (e.g., high sensitivity [hs]CRP, VEGF, ICAM-1, SAA, fibrinogen, IL-6) and markers of insulin sensitivity (fasting glucose, fasting insulin, HbA1c, HOMA-IR, QUICKI) were assessed in 2 phase 3 GLM trials in RA pts (MTX-naïve in GO-BEFORE and MTX inadequate responders [IR] in GO-FORWARD). Changes from baseline to wk14 or 24 were compared between the PBO+MTX (n=293) and combined GLM (50&100 mg)+MTX (n=496) groups (grps).

Results: In GO-FORWARD, total cholesterol (TC), high-density lipoprotein (HDL) and low-density lipoprotein (LDL) levels increased in the GLM+MTX compared with PBO+MTX grp, whereas atherogenic ratios (TC/HDL, LDL/HDL, Apo B1/A1) were not substantially changed. Favorable changes in LDL subfractions (increase in large, decrease in small LDL, increase in mean LDL particle size) were seen in GLM grps. In GO-BEFORE, increases in TC and LDL and favorable changes in LDL subfractions were seen in both the MTX and GLM

grps; in contrast, HDL increase and Apo B/A1 decrease were observed in GLM but not MTX grp. Most inflammatory CV markers improved significantly with GLM+MTX vs PBO+MTX in both studies (hsCRP and ICAM-1 shown in table as representative data). Markers of insulin sensitivity remained unchanged at wks14/24 in patients treated with GLM.

Conclusion: This is the first demonstration of favorable changes in LDL subfractions with anti-TNF therapy. Despite increases in TC and LDL, atherogenic indices remained stable and CV-related inflammatory markers improved with GLM treatment. These findings are consistent with published epidemiologic data suggesting, a beneficial effect of anti-TNF agents on CV events. No significant changes in insulin sensitivity parameters were observed.

Golimumab and Cardiovascular Disease: Carotid Artery Ultrasound Evaluation and Cardiovascular Adverse Events. Joan M. Bathon[5], Mary Chester Wasko[7], Bruce Kirkham[4], Pierre-Jean Touboul[6], Elizabeth C. Hsia[3], Weichun Xu[2], Jiandong Lu[1] and Mahboob U. Rahman[3]. [1]Centocor Research and Development, Inc., Malvern, PA, [2]Centocor Research and Development, Inc., [3]Centocor Research and Development, Inc./Univ. of Pennsylvania School of Medicine, Malvern, PA, [4]Guy's & St. Thomas' Hospital, London, United Kingdom, [5]Johns Hopkins University, Baltimore, MD, [6]Paris-Diderot University, London, United Kingdom, [7]University of Pittsburgh, Pittsburgh, PA

Objective: To evaluate the effect of golimumab on changes in ultrasound measurements of carotid arteries in an exploratory study of patients with rheumatoid arthritis (RA), and to evaluate cardiovascular (CV) adverse events (AEs) in 5 large randomized, controlled studies of golimumab in patients with RA, ankylosing spondylitis (AS), or psoriatic arthritis (PsA).

Methods: Carotid ultrasound measures were performed at baseline and weeks 24 and 52 in a subset of the GO-BEFORE study, in which patients with RA & naïve to methotrexate (MTX) were randomized to subcutaneous injections every 4 weeks of placebo (PBO) + MTX, golimumab 100 mg + PBO, golimumab 50 mg + MTX, or golimumab 100 mg + MTX. Common carotid artery (CCA) intima-media thickness (IMT), distensibility coefficient (DC), interadventitial (IA) diameter, and plaque counts were determined. CCA-IMT measurements were done by automated edge detection using M'ATH software. Carotid ultrasound analyses included only those subjects (n = 392) with a non-missing measurement at baseline and a follow-up time point. CV events reported as serious AEs by investigators (not adjudicated) from the GO-BEFORE, GO-FORWARD (RA), GO-AFTER (RA), GO-REVEAL (PsA), and GO-RAISE (AS) randomized, controlled studies, in which golimumab (50 mg and 100 mg) with or without MTX was compared with PBO with or without MTX, were compiled through week 100 or 104.

Results: In the ultrasound analyses (n = 77 to 96 per group), mean (±standard error) changes in CCA-IMT for the golimumab groups were not statistically significantly different from PBO + MTX except for the 100 mg + MTX group at week 24 and the 50 mg + MTX group at week 52, suggesting a trend of increase in CCA-IMT with golimumab treatment, albeit variable over time (Figure). There was a trend of improvement in DC in GLM + MTX groups; however, changes in DCs and IA diameters for the golimumab groups were not statistically significantly different from PBO + MTX. No changes were observed in the number of plaques detected. In the 5 golimumab studies, 639 patients received PBO (for 339 patient years [py]), 1245 patients received 50 mg (for 1626 py), and 1377 patients received 100 mg (for 2069 py). Sudden death, myocardial infarction, or stroke occurred in 2 patients on PBO (0.59 events per 100 patient-years [95% confidence interval: 0.07, 2.13]), 4 patients on 50 mg (0.25 [0.07, 0.63]), and 10 patients on 100 mg (0.48 [0.23, 0.89]). Ischemic CV events occurred in 4 patients on PBO (1.18 [0.32, 3.02]), 7 patients on 50 mg (0.43 [0.17, 0.89]), and 11 patients on 100 mg (0.53 [0.27, 0.95]).

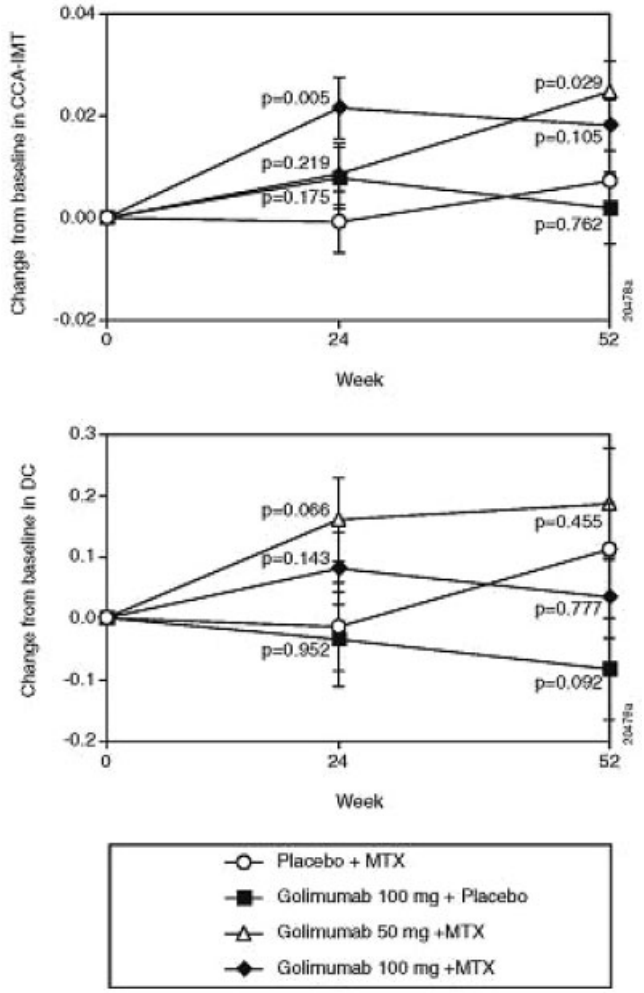

Figure. Changes (mean ± standard deviation) from baseline to weeks 24 and 52 in CCA-IMT and DC.

Conclusion: Changes in subclinical measures of CV disease in response to GLM +/− MTX over 52 weeks were variable, in that trends towards worsening

of CCA-IMT, but improvement in DC, were observed. Because patients receiving GLM did not appear to have an increased incidence of CV events through two years, the clinical relevance of the carotid ultrasound results are unclear.

Hepatitis B Virus Reactivation in Rheumatoid Arthritis and Ankylosing Spondylitis Patients Using Anti-TNFα Agents: A Retrospective Analysis of 52 Cases with or without Anti-Viral Prophylaxis. Han Hee Ryu[5], Eun Young Lee[5], Kichul Shin[4], In Ah Choi[5], Chul Kim[5], Yoon Jong Lee[5], Bin Yoo[7], Min-Chan Park[6], Yong-Beom Park[6], Sang-Cheol Bae[1], Wan Hee Yoo[3], Sung Il Kim[2], Jun Wan Kim[5], Eun Bong Lee[5] and Yeong Wook Song[5]. [1]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, [2]Division of Rheumatology, Department of Internal Medicine Pusan National University Hospital Institutes, Busan, Korea, [3]Division of Rheumatology, Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, Korea, [4]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic of, [5]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, [6]Divsion of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, [7]Divsion or Rheumatology, Department of Internal Medicine, University of Ulsan, Asan Medical Center, Seoul, Korea

Background: Anti-TNFα agents are widely used in the treatment of inflammatory arthritis such as rheumatoid arthritis (RA) and ankylosing spondylitis (AS). However, TNFα is also an important mediator contributing to the normal host immune response against infectious agents, in particular intracellular microorganisms. It is noteworthy that there are a number of case reports describing hepatitis B virus (HBV) reactivation in otherwise asymptomatic carriers under anti-TNFα treatment. Nevertheless, there is no established consensus describing whether this subset of patients would benefit from HBV anti-viral prophylaxis.

Objectives: To investigate the incidence and characteristics of HBV reactivation in HBsAg carriers with RA and AS after initiating anti-TNFα agents.

Methods: We retrospectively collected clinical data from 52 cases of HBsAg carriers with RA or AS who initiated anti-TNFα treatment at 7 centers nationwide. Periodic data of liver function tests and HBV DNA titers were utilized to assess HBV reactivation by 1) elevated HBV DNA level by ≥1 log10 compared with baseline, and 2) increase of AST or ALT above 2 times of the upper normal limit at the same period. YMDD mutation was checked in lamivudine-treated patients who developed HBV reactivation.

Results: Four patients were excluded from the analysis (three with high baseline transaminase, one died due to hepatocellular carcinoma). Among the 48 patients, 19 patients began anti-viral prophylaxis (14 lamivudine, 5 entecavir) with or shortly after starting anti-TNFα treatment. The remainder 29 patients without prophylaxis were treated with anti-viral agents if needed at the discretion of the clinician. The median duration of anti-TNFα treatment was 72 weeks in both groups. Of the 29 patients who did not receive primary prophylaxis, 2 patients (6.9 %) developed viral reactivation within a year of anti-TNFα treatment. In the prophylaxis group, 1 patient developed viral reactivation (5.2 %) at week 64 of anti-TNFα therapy. This single case of viral reactivation among the prophylaxis group was owing to YMDD mutation under lamivudine. There was not one case of reactivation in 5 patients who received entecavir as primary prophylaxis during the study period.

Conclusions: The rate of HBV reactivation in patients under anti-TNFα therapy without anti-viral prophylaxis was 6.9 % among the study population. Anti-viral prophylaxis did help preventing HBV reactivation, except for 1 case of YMDD mutation after using lamivudine. A larger prospective study is warranted to elucidate whether long-term anti-viral prophylaxis would be crucial in HBsAg carriers starting anti-TNFα treatment.

Individual Dose Response Relation for MTX: Prediction of the Optimally Effective Dose in Patients with Early Rheumatoid Arthritis. Paco M. J. Welsing[1], Marije F. Bakker[2] and Johannes W. G. Jacobs[2]. [1]Rheumatology & Clinical Immunology and Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, The Netherlands, [2]Rheumatology & Clinical Immunology, University Medical Center Utrecht, The Netherlands

Background: In early RA, disease activity should be controlled as soon as possible. MTX is the DMARD of first choice and the dose is usually stepwise increased from a low (insufficient) dose until optimal disease control. Clinical intuition is that the optimally effective dose is different for each individual patient. The aim of this investigation was to determine the MTX dose needed for optimal response in individual patients and to explore whether this 'lowest optimally effective MTX dose (LOED)' and the level of disease activity reached can be predicted, to aid optimal MTX-based treatment.

Methods: Within the CAMERA trial the efficacy of a tight control and conventional MTX-based strategy in early RA were compared. Oral MTX was up-titrated from 7.5mg/wk until 30mg/wk (or maximal tolerable dose), if necessary. Per patient a power curve was fitted through the DAS28 measurements over time to control for natural variation in disease activity. Using the individual curves the highest MTX-dose which still resulted in a clinically relevant improvement in disease activity, defined as a decrease >0.15 DAS28 units per month, was determined.

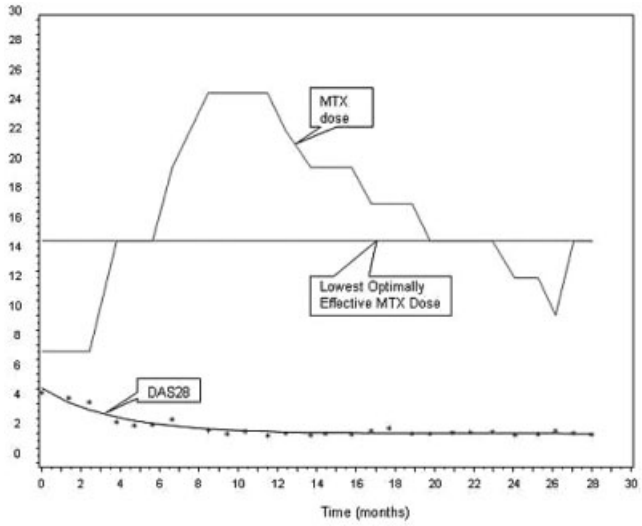

Figure 1. Shows an example of one patient's dose response curve and the LOED.

Using multinomial logistic regression the association of demographic and clinical characteristics at baseline with LOED was studied. Further, using linear regression, the association of demographic and clinical characteristics, including LOED, with the level of disease activity reached was investigated. All models were corrected for treatment strategy. A sensitivity analysis varying the definition of clinically relevant improvement was performed.

Results: For 290 of 299 patients a dose response curve could be estimated; the fit of the curves was found to be adequate. In 208 patients a LOED could be determined. The most common LOEDs were 7.5mg, 15mg, 20mg, and 25mg; higher LOEDs were found more frequent in the tight control strategy arm of the trial. Patients with a LOED of 7.5mg usually only showed an initial improvement in DAS28, probably due to 'regression to the mean'. The highest MTX dose reached was higher than the average LOED. Higher baseline disease activity and higher body height were predictive of higher LOEDs. A lower DAS28 reached was related to a higher LOED next to male gender and a lower DAS28 at baseline. Sensitivity analyses did not change these results.

Conclusion: Different 'optimally effective MTX doses' (after which no further clinically relevant improvement occurs) can be determined for different RA patients and might be predicted by

baseline patient and disease characteristics. The level of disease activity reached is related to this optimally effective MTX dose next to baseline characteristics. Usual dosing strategies with MTX monotherapy might result in over- and undertreatment. Based on these results, a starting dose of at least 15 mg/wk MTX might be a good choice.

Long-Term Effect of Anti TNF-Alpha Therapies on Insulin Resistance, Body Composition and Adipokines in Rheumatoid Arthritis Patients. Esmeralda Delgado-Frias[3], Vanesa Hernández-Hernández[2], Iván Ferraz-Amaro[1], Juan Carlos Quevedo[1], Jose R. Muñiz, Maria T. Arce-Franco, Judith Lopez-Fernandez, Andres Franco-Maside and Federico Diaz-Gonzalez. [1]La Laguna, S/C Tenerife, Spain, [2]La Laguna, S/C Tenerfe, Spain, [3]Hospital Universitario de Canarias, Tenerife, La Laguna, S/C Tenerife, Spain

Introduction: It has been suggested that tumor necrosis factor alpha (TNFalpha), a cytokine that plays a key role in rheumatoid arthritis (RA) pathogenesis, may act as a link between inflammation and cardiovascular disease apparently through several effects including the induction of insulin resistance (IR). The purpose of this study was to clarify if long-term modulation of inflammatory activity by TNFalpha inhibitors has some influence on insulin sensitivity, and if this effect is related to changes in body fat distribution, body composition, physical activity or levels of adipokines (cytokines secreted by adipocytes) in active RA patients.

Methods: Sixteen patients with RA (mean age 50.8±14.6 years, mean duration of disease 6.3±2.7 years) who were receiving anti-TNFalpha agents in addition to methotrexate because of active disease were followed up during one year. Disease activity was assessed by DAS28 (Disease Activity Score), IR was determined by using Homeostatic Model Assessment-2, body composition was evaluated by multifrequency bioelectric impedance analysis, physical activity by accelerometry, abdominal fat distribution by magnetic resonance imaging, and serum level of several key adipokines were quantified by ELISA. All examination and assessments were done at baseline (prior to TNF-alpha treatment) and after 3 and 12 months of treatment.

Results: Body mass indices had increased significantly after one year (25.7±3.2 vs 28.06±4.5 kg/m2, p=0.02) of treatment with anti-TNFalpha. Body composition in terms of fat and fat-free mass had not changed between visits except for a significant elevation of body cell mass (25.5±4.6 vs 26.6±3.1 kg, p=0.02). Values of visceral intraabdominal and subcutaneous abdominal adipose tissue were not modified due to treatment. In spite of a significant improvement in DAS28, patients' physical activity remained stable during the follow up. Basal levels of insulin resistance, beta cell function production or insulin sensitivity did not change along the study. Only insulin sensitivity exhibited a significant increase after 3 months (110[94–138] vs 118[107–156] %, p=0.045) but no longer by the end of the study. Basal levels of adiponectin, visfatin, leptin, ghrelin, resistin, and apelin did not change in response to anti-TNFalpha treatment; only retinol binding protein 4 showed a significant change (51.7±32.7 vs 64.9±28.4 μg/mL, p=0.03) at the end of the study.

Conclusions: Insulin resistance, adiposity, body composition, and adipokine serum levels are not significantly affected by long-term inhibition of TNFalpha in RA patients. Our findings question the suggested beneficial role of anti-TNFalpha treatments in insulin resistance.

Long-Term Safety of Abatacept: Integrated Analysis of Clinical Program Data of up to 7 Years of Treatment. Marc C. Hochberg[7], Rene Westhovens[4], Richard Aranda[2], Sheila M. Kelly[2], Nadar Khan[2], Keqin Qi[2], Ramesh Pappu[2], Ingrid Delaet[2], Allison Luo[2], Anne Torbeyns[3], Larry W. Moreland[6], Roger B. Cohen[5], Sheila Gujrathi[2] and Michael E. Weinblatt[1]. [1]Brigham & Womens Hospital, Boston, MA, [2]Bristol-Myers Squibb, Princeton, NJ, [3]Bristol-Myers Squibb, Braine-l'Alleud, Belgium, [4]Catholic University of Leuven, Leuven, Belgium, [5]Fox Chase Cancer Center, Philadelphia, PA, [6]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [7]University of Maryland, Baltimore, MD

Background: Integrated analyses of clinical trial data are important to assess long-term (LT) safety and detect rare events. Here the authors present an integrated analysis of safety data from the abatacept RA clinical trial program up to December 2009, including 12,132 patient–years (p–y) of exposure.

Methods: Data from eight abatacept RA clinical trials were classified into short-term (ST) and LT periods and analyzed. ST data included six double-blind (6- or 12-month), placebo-controlled periods, one non-randomized Phase II study and one non-randomized Phase III study. The LT data included the open-label (OL) periods of these eight studies. Safety assessments, presented for all patients receiving ≥1 dose of abatacept, included adverse events (AEs), serious AEs (SAEs), mortality and events of clinical interest. Incidence rates (IRs) per 100 p–y with 95% CIs were calculated for the ST, LT and cumulative (ST+LT) periods.

Results: The cumulative period included 4149 patients with 12,132 p–y of exposure; 1165 had ≥5 years' exposure. Mean (range) exposure was 35.6 (1.9–104.2) months. The ST period included 3173 patients (2331 p–y) and the LT period included 3256 patients (9752 p–y). IRs for the ST, LT and cumulative periods are presented (Table). Annual IRs (95% CIs) per 100 p–y for SAEs did not increase with increasing abatacept exposure: Year 1, 19.13 (17.67–20.67); Year 2, 14.39 (12.80–16.11); Year 3, 12.82 (11.09–14.74); Year 4, 10.53 (8.76–12.57); Year 5, 10.18 (8.11–12.62); Year 6, 7.09 (4.54–10.55); Year 7, 8.90 (4.74–15.22). During the cumulative period, the IR (95% CI) of hospitalized infection was 2.64 per 100 p–y (2.35–2.95). The IRs (95% CIs) for the most common serious infections were; pneumonia: 0.46 (0.34–0.59); urinary tract infection: 0.20 (0.13–0.30); cellulitis: 0.18 (0.11–0.28). There were few opportunistic infections (0.36 [0.27–0.49]), with only eight cases of tuberculosis (0.07 [0.03–0.13]) observed overall. The IRs (95% CIs) for non-melanoma skin cancer and solid tumors in the cumulative period were 0.73 (0.58–0.90) and 0.59 (0.46–0.75) per 100 p–y, respectively.

Table. Safety events during the short-term, long-term and cumulative periods

		ST (n = 3173)	LT (n = 3256)	Cumulative (n = 4149)
P-y exposure		2331	9752	12,132
Deaths	Patients with event, n	12	60	73
	Incidence rate*	0.51 (0.27–0.90)	0.62 (0.47–0.79)	0.60 (0.47–0.76)
Overall SAEs	Patients with event, n	400	1086	1373
	Incidence rate*	18.15 (16.41–20.02)	14.31 (13.47–15.18)	14.61 (13.85–15.41)
Serious infections†	Patients with event, n	85	260	332
	Incidence rate*	3.68 (2.94–4.55)	2.79 (2.46–3.15)	2.87 (2.57–3.19)
Malignancies (excluding NMSC)	Patients with event, n	16	72	88
	Incidence rate*	0.69 (0.39–1.11)	0.74 (0.58–0.93)	0.73 (0.58–0.89)
Lung cancer	Patients with event, n	5	13	18
	Incidence rate*	0.21 (0.07–0.50)	0.13 (0.07–0.23)	0.15 (0.09–0.23)
Lymphoma	Patients with event, n	1	8	9
	Incidence rate*	0.04 (0.00–0.24)	0.08 (0.04–0.16)	0.07 (0.03–0.14)
Autoimmune events	Patients with event, n	48	NP	232
	Incidence rate*	2.07 (1.53–2.75)	NP	1.99 (1.74–2.26)
Acute infusional events‡	Patients with event, n	225	NP	377
	Incidence rate*	11.61 (10.14–13.22)	NP	3.90 (3.52–4.32)

*Data show incidence rates per 100 p-y (95% confidence interval); in only six studies ST period, n = 2368, period, n = 3755: ST = short term; LT = long term; SAE = serious adverse event; NMSC = skin cancer; NP = analyses not performed

Conclusions: The integrated safety data from 4149 patients with 12,132 p–y of exposure up to 7 years demonstrate that abatacept is generally well tolerated. No new safety events were identified over time, and the types and IRs of safety events (including events of clinical interest) in the LT and cumulative periods were generally consistent with those in the ST period, indicating that the abatacept safety profile remains stable with increasing duration of exposure.

Long-Term Safety of Rituximab: Follow-Up of the Rheumatoid Arthritis Clinical Trials and Retreatment Population. Ronald van Vollenhoven[5], Paul Emery[2], Clifton O. Bingham[4], Edward C. Keystone[9], Roy M. Fleischmann[8], Daniel E. Furst[7], Katherine Macey[6], Marianne Sweetser[1], Patricia Lehane[6], Pam Farmer[3] and Simon G. Long[6]. [1]Biogen Idec Inc, [2]Chapel Allerton Hospital, Leeds, United Kingdom, [3]Genentech Inc, [4]Johns Hopkins University, Baltimore, MD, [5]Karolinska Institute, Stockholm, Sweden, [6]Roche Products Ltd, [7]University of California Los Angeles Medical School, Los Angeles, CA, [8]University of Texas Southwestern Medical Center, Dallas, TX, [9]University of Toronto, Toronto, ON, Canada

Objective: To evaluate the long-term safety of rituximab (RTX) in rheumatoid arthritis (RA) patients (pts) in clinical trials.

Methods: Pooled observed case analysis of safety data from pts treated with RTX plus methotrexate (MTX) in a global clinical trial program. Pts were offered RTX retreatment based on physician decision of clinical need and the criteria for retreatment included assessment of active disease (defined as either SJC and TJC ≥8 or DAS28 ≥2.6). Pts who received placebo during placebo-controlled study periods were pooled to provide a placebo population.

Results: As of September 2009, 3189 pts had been treated with RTX providing 9342 pt-yrs exposure. The analysis includes >9 yrs of follow-up with up to 15 courses of RTX. More than 1500 pts were followed for >3 yrs and 587 pts for >5 yrs with 1724, 1392, 1036 and 656 pts receiving ≥3, ≥4, ≥5 and ≥6 courses, respectively. Other than infusion-related reactions (IRR), the safety profile of RTX was similar to the placebo population or general RA populations. In the RTX group, the most frequent adverse event (AE) was IRR; most were CTC grade 1 or 2 and occurred after the first infusion of the first course (23.0%), with 0.5% considered serious (over all courses). Rates of serious AEs (SAEs) and infections generally remained stable over time and over multiple RTX courses, and in patients in long-term follow-up (>5 yrs).

	All exposure (n = 3188) 9342 pt-yrs	Long term (>5 yrs) (n = 587) 3386 pt-yrs	Pooled placebo (n = 818) 575 pt-yrs
AE rate/100 pt-yrs (95% CI)	309.4 (305.9–313.0)	285.1 (279.5–290.9)	353.1 (341.5–365.0)
SAE rate/100 pt-yrs (95% CI)	16.2 (15.4–17.0)	15.5 (14.2–16.9)	15.5 (13.2–18.2)
Infection rate/100 pt-yrs (95% CI)	94.3 (92.3–96.3)	83.2 (80.2–86.3)	100.8 (94.7–107.3)
Serious infection rate/100 pt-yrs (95% CI)	4.35 (3.94–4.79)	3.19 (2.64–3.85)	4.29 (3.17–5.80)

The overall serious infection rate was 4.35 events/100 pt-yrs (3.19 events/100 pt-yrs in pts treated for >5 yrs) and was comparable to that observed in the placebo population (4.29 events/100 pt-yrs). The most frequent serious infections were of the lower respiratory tract, predominantly pneumonia (2%). Serious opportunistic infections were rare with the rate comparable to the placebo population (0.04/100 pt-yrs in RTX all exposure compared to 0.1/100 pt-yrs in pooled placebo). Rates of myocardial infarction (0.49 events/100 pt-yrs) and stroke (0.25 events/100 pt-yrs) were consistent with rates in the general RA population (0.34–0.59 events/100 pt-yrs and 0.112–0.76 events/100 pt-yrs, respectively).[1–4]

Conclusions: In long-term follow-up of RA pts treated with RTX in clinical trials, no new safety signals were observed in all exposed pts, or in pts with >5 yrs exposure. RTX has remained generally well tolerated over time and over multiple courses, with a safety profile similar to that of the pooled placebo population and consistent with published data on pts with moderate to severe RA.

Low-Dose Glucocorticoid Chronotherapy of Rheumatoid Arthritis: 12 Week Efficacy and Safety of Modified-Release (MR) Prednisone. Frank Buttgereit[2], Daksha P. Mehta[3], John R. Kirwan[1], Jacek Szechinski[7], Maarten Boers[12], Rieke Alten[10], Jerzy Supronik[8], István Szombati[9], Ulrike Römer[4], Stephan Witte[5], Amy Grahn[6] and Kenneth G. Saag[11]. [1]Bristol Royal Infirmary, Bristol, United Kingdom, [2]Charite University Med-Berlin, Berlin, Germany, [3]Ctr Arthritis & Osteoporosis, Elizabethtown, KY, [4]Horizon Pharma GmbH, Mannheim, Germany, [5]Horizon Pharma GmbH, Mannheim, Germany, [6]Horizon Pharma, Inc., Northbrook, IL, [7]Med. University Dept. of Rheumatology, Wroclaw, Poland, [8]NZOZ Centrum Medyczne, Bialystok, Poland, [9]OEC, Budapest, Hungary, [10]Schlosspark-Klinik, UnivMed, Berlin, Germany, [11]University of Alabama-Birmingham, Birmingham, AL, [12]VU University Medical Center, Amsterdam, The Netherlands

Background: In patients with rheumatoid arthritis (RA), nocturnal increases in proinflammatory cytokines are implicated in the typical early morning symptoms, joint stiffness and pain. Glucocorticoid (GC) chronotherapy with a novel modified-release (MR) prednisone tablet enables delivery of prednisone during the night to specifically target the nocturnal rises in inflammatory mediators and symptoms. This novel approach has shown clinically relevant reduction of morning stiffness (MS) compared to conventional, immediate-release (IR) prednisone, thereby improving the benefit-risk ratio of GC therapy. Here we present efficacy and safety data of low-dose prednisone chronotherapy in patients with RA, not adequately controlled by disease-modifying antirheumatic drug (DMARD) therapy.

Methods: In this 12-week, double-blind, placebo (PBO)-controlled study, patients (n=350) were randomized 2:1 to receive MR prednisone 5 mg or PBO once daily in the evening in addition to their standard RA therapy. The primary endpoint was the percentage of patients achieving a 20% improvement in RA signs and symptoms according to American College of Rheumatology criteria (ACR20) at week 12. A key secondary objective was the relative reduction of MS at week 12. Secondary efficacy endpoints included ACR50 and ACR70 responses, and other measures of clinical efficacy, inflammatory markers, adverse events (AEs) and other safety parameters.

Results: Compared to PBO + DMARD, MR prednisone + DMARD treatment produced a higher ACR20 response (48.5% vs 28.6%, P<0.001), a higher ACR50 response (22.7% vs 9.2%, P<0.003) and ACR 70 response (7.0% vs 2.5%, P<0.1) at week 12. Greater improvements were also seen in morning symptoms and in individual RA core set measures in the MR prednisone group vs. PBO group at week 12. The incidence of adverse events (AEs) on MR prednisone was similar to PBO (43% vs 49%), with more AEs related to RA signs and symptoms (arthralgia and RA flare) in the PBO arm than in the MR prednisone arm (29.4 % vs 16.9 %). There were no clinically relevant differences between treatment groups in vital signs, hematology, biochemistry values or in markers for bone turnover, osteocalcin and urine CTX I.

Conclusion: Even at 5 mg per day, low-dose prednisone chronotherapy is effective in the treatment of signs and symptoms of RA with a short-term safety profile similar to placebo.

Metanalysis on the Effect of TNF-Inhibitors on Lipid Profile. Claire Immediato Daien[1], Yohan Duny[3], Thomas Barnetche[2] and Jacques Morel[1]. [1]Département de Rhumatologie, Hôpital Lapeyronie, Montpellier, France, [2]Département de Rhumatologie, Hôpital Pellegrin, Bordeaux, France, [3]Institut Universitaire de Recherche Clinique, Service de Biostatistiques, Epidémiologie et Santé Publique, Montpellier, France

Background: Patients with Rheumatoid arthritis (RA) have an increased risk for cardiovascular diseases. Lipidic changes related to inflammation have been described in RA. TNF inhibitor (TNFi) therapy is an effective treatment that controls inflammation.

Objective: To assess modification of lipid levels after initiation of TNFi in RA patients.

Methods: The search strategy used Medline database until March 2010 and abstracts of 2009 EULAR/ACR congress. The Mesh terms used were: ("Lipids"[Mesh] OR "Dyslipidemia"[Mesh]) AND "Arthritis, Rheumatoid-"[Majr:NoExp] AND ("TNFR-Fc fusion protein"[Substance Name] OR "infliximab"[Substance Name] OR "adalimumab"[Substance Name] OR "anti-TNF"). Values of total cholesterol (TC), LDL, HDL, triglycerides (TG), atherogen index (AI), and apoB/A were collected before and after TNFi initiation. Three time-points were defined as following: short term from 2 weeks to 2 months, mid-term at 3 months and long term from 6 to 12 months. Paired-data statistic analysis was performed with the logiciel Comprehensive Metanalysis®. Standardized mean differences were obtained using fixed or random effects model (Peto and Dersimonian & Laird method respectively). Random effects model was used when there was evidence of heterogeneity. The percentage of variability beyond chance was estimated using the I^2 statistic. Publication biais was assessed using the Egger's test. The Trim and Fill Analysis for publication biais was performed using Duval and Tweedie's method.

Results: The search led to 31 articles and 1 ACR abstract. Sixteen articles were excluded as they were out of topic or reviews/comments. Three other articles were also excluded because of missing p-values and/or confidence intervalls. Thus, 13 studies were included for the different meta-analyses. Ten of them included patients only treated with monoclonal antibodies, 1 with etanercept and two with respectively 47 and 21% of soluble receptors. The follow-up varied from 2 weeks to 2 years. TNFi were found to increase HDL levels at short term (+0.4 mmol/L; CI95% 0.3–0.5; p<0.0001; I2 4.4%), mid-term (+0.4 mmol/L, CI95% 0.2–0.6; p<0.0001; I2 0%) and long term (+0.3 mmol/L; CI95% 0.1–0.4; p<0.0001; I2 36%) as well as TC (short term: +0.4mmol/L; CI95% 0.3–0.5; p<0.0001, I2 0%; mid-term: +0.2 mmol/L; CI95% 0.1–0.3; p=0.002; I2 34%; long term: +0.2; CI95% 0.0–0.3; p=0.02; I2 25%). At short term, LDL levels were also increased (+0.4mmol/L; CI95% 0.3–0.6; p<0.0001; I2 0%) but not at mid-term (p=0.88; I2 55%) or long term (p=0.83; I2 72%). AI did not variate at short (p=0.3; I2 38%) and long term (p=0.3; 47%). TG levels increased at short term (+0.2; CI95% 0.0–0.3; p=0.009, I2 0%) and long term (+0.2; CI95% 0.1–0.3; p=0.03; I2 55%). ApoB/A tended to decrease at mid-term (−0.1; CI95% −0.3–0.0; p=0.08; I2 50%) and decreased at long term (-0.3 mmol/L; CI95% −0.5 –0.1; p<0.0001; I2 0%). No publication biais were found except for 4 analyses. These analyses remained significant after performing Duval and Tweedie method.

Conclusion: Initiation of TNFi led to a persistant increase of TC and HDL. LDL and AI remained unchanged at long term. TG were increased and apoB/A decreased at long term after initiation of TNFi.

Methothrexate Directly Inhibits RANKL Expression and Osteoclasts Formation in Very Early Arthritis. Shankar Revu, Petra Neregård, Erik Afklint and Anca Irinel Catrina Department of Medicine, Rheumatology Unit, Karolinska University Hopsital and Karolinska Institute, Stockholm, Sweden

Objective: Methotrexate (MTX) is one of the most widely used therapies in rheumatoid arthritis (RA). However, in the long term, patients treated with methotrexate may experience joint deterioration and subclinical inflammation even after clinical remission. Bone biology is governed by the RANKL/RANK/OPG system that determines the balance between bone formation by osteoblasts and bone resorbtion by osteoclasts. Herein we investigated MTX effects on the RANKL/RANK/OPG system in vivo and in vitro.

Methods: 16 patients with newly diagnosed RA (mean disease duration 1 week) were started on MTX 10 mg once a week and increased with 10 mg each week until a stable dose of 20 mg once a week was reached. Patients were naïve for other disease modifying anti rheumatic drugs. Synovial biopsies were obtained by needle arthroscopy at baseline and 8 weeks after initiation of therapy. X-ray of hands and feet were obtained at baseline and 1 year after diagnosis. Immunohistochemical analysis was performed to detect RANKL, RANK and OPG in the synovial biopsies. We further investigated the in vitro effect of MTX on synovial fluid derived mononuclear cells, SFMC (by immunohistochemistry), osteoblasts (by rtPCR and Western blot) and osteoclasts formation (tartrate-resistant acid phosphatase staining and dentine pit formation assay). Statistical analysis was performed using the Wilcoxon and Mann Whitney test when appropriate.

Results: 9 patients (56%) were responders to therapy according to EULAR criteria. 2 patients were having erosions at inclusion and 5 more developed erosions at 1 year follow-up in both the responder and non responder group. MTX treatment decreased synovial inflammation with a significant reduction of synovial cellularity. In parallel MTX decreased synovial RANK expression and the RANKL/OPG ratio, mainly in the subgroup of RA patients with no radiological progression at 1 year follow up. We confirmed the effect on RANK expression in SFMC cultured in vitro with MTX. A decrease of the RANKL/OPG ratio was also observed in cultured osteoblasts as demonstrated both at the mRNA and protein levels. MTX blocks osteoclastogenesis from PBMC despite presence of M-CSF and RANKL indicating that MTX directly inhibits osteoclastogenesis.

Conclusions: MTX directly affects the RANKL/RANK/OPG system and inhibits osteoclasts formation providing an explanation for the bone-sparing effect of MTX observed in a subgroup of RA patients.

Non-Infectious Pulmonary Complications of Biologic Agents for Rheumatic Diseases—A Systematic Literature Review. Andreas Hadjinicolaou[2], Shweta Bhagat[1] and Andrew Ostor[1]. [1]Rheumatology Research Unit, Addenbrooke's Hospital, Cambridge, Cambridge, United Kingdom, [2]University of Cambridge, United Kingdom

Background: Systemic inflammatory diseases, such as rheumatoid arthritis (RA) as well as their treatment with disease modifying anti-rheumatic drugs (DMARDS) and anti-TNFα agents may be complicated by a variety of pulmonary disorders. Due to the influx of new biologic agents, we undertook this systematic literature review (SLR) to identify if any of these were associated with non-infectious lung disease.

Methods: A SLR was conducted in PubMed, the Cochrane Library and EMBASE for reviews, meta-analyses, randomized controlled trials(RCT), clinical trials, case series and reports published up to and including May 2010 using the terms "rituximab" "anakinra" "certolizumab" "golimumab" "tocilizumab" "abatacept" and "efalizumab" in the advanced search option. Search results were assessed by two independent reviewers. Meeting abstracts from the European League Against Rheumatism and the British Society of Rheumatology annual meetings were included. We manually reviewed references of all the selected publications to complement our search with published data not identified in the initial search or with unpublished data from the Food and Drug Administration (FDA), the European Agency for the Evaluation of Medicinal Products (EMEA) and manufacturers. Identified articles were included if they reported a possible relationship of biologic agents with lung toxicity, excluded other potential causes or failed to exclude drug-induced causality. A total of 9 RCTs, 15 clinical studies, 10 case series, 35 case reports were identified.

Results: This SLR revealed possible relationships between some biologic agents and interstitial lung disease (ILD) and other drug-related pulmonary toxicities. No cases of pulmonary toxicity were found with golimumab, certolizumab and efalizumab.

Rituximab(RTX) appeared to have a higher reported rate of ILD as we identified 65 papers reporting at least one case of pulmonary toxicity (148 cases in total). However, RTX was given for a rheumatic disease only in 7 of these studies. In 3 studies in RA and lupus, out of a total of 403 patients involved, there were 3 cases of lung toxicity (1 of ILD and 2 of interstitial

pneumonitis, 1 of which was fatal). 4 case reports of RTX (3 given for RA and 1 for lupus) reported 2 cases of Bronchiolitis Obliterans Organising Pneumonia and 2 of ILD with1 death.

3 RCTs of Tocilizumab enrolling a total of 589 patients reported 6 pulmonary adverse events (2 - ILD, 1 - allergic pneumonitis, 3 - interstitial pneumonia). There was 1 case report of fatal exacerbation of RA induced ILD with tocilizumab.

2 RCTs with a total of 1596 patients on Anakinra for RA refractory to DMARDS reported 3 cases of ILD with 2 fatalities.

In all the non-fatal cases, lung pathology was reversible with drug discontinuation and administration of high dose steroid treatment.

Conclusion: Although the number of reports of pulmonary complications with the newer biologic agents is small, the associated morbidity and mortality is substantial. Drug discontinuation is essential and treatment should be instituted expediously in order to optimise outcomes. Clinicians should remain vigilant for non-infectious pulmonary disease in any patient treated with biologic agents.

396

Parenteral MTX as an Initial Treatment Strategy for Early Rheumatoid Arthritis: Results from a Nationwide Cohort. Vivian P. Bykerk[2], David S. Rowe[3], Janet E. Pope[5], CATCH Scientific Advisory Committee[1], Ashley Bonner[1] and J. Carter Thorne[4]. [1]Canada, [2]Mt Sinai Hospital, Toronto, ON, Canada, [3]Saba University School of Medicine, Stouffville, ON, Canada, [4]Southlake Regional Health Care, Newmarket, ON, Canada, [5]St Joseph Health Care London, London, ON, Canada

Background: Previous studies have established the value of prompt diagnosis and intervention in patients with Early Rheumatoid Arthritis (ERA). While there is a growing body of literature on parenteral administration of methotrexate (pMTX) at optimal doses (≥ 20 mg weekly) there is still no clear recommendation for a standard route and dosage. The Canadian early Arthritis Cohort (CATCH) is a multi-centre observational prospective "real world" cohort for patients with early inflammatory arthritis. With CATCH, there is an opportunity to evaluate the relative effectiveness of different therapeutic strategies in ERA.

Objectives: 1. Compare effectiveness of early optimal doses of pMTX (≥ 20 mg weekly within 100 days of baseline) with other treatment strategies

2. Assess achievement of clinical outcomes: a) DAS28-defined remission (DAS28<2.6) during 12 months; b) LDAS (DAS28<3.2) during 12 months; and "sustained remission" (CATCH target outcome of 2 consecutive visits with DAS28<2.6) at 6 and 12 months.

Methods: CATCH is a study of usual care in over 20 sites across Canada. Patients were selected from the available cohort (n = 898). Only those with baseline DAS28 scores ≥ 2.6 and available data at 6 and/or 12 months were chosen for analysis. At time of abstract submission, 593 patients were eligible. Patients receiving early optimal pMTX (n=126) and those receiving all other treatment regimens (n=467) were compared for achievement of clinical outcomes within the first year as above. Baseline clinical and demographic characteristics were evaluated and compared. Nonparametric analysis and binary logistic regression models were used to assess outcomes between groups.

Results: Patients receiving early optimal pMTX were more likely to achieve LDAS (67% vs. 52%) and DAS28 <2.6 (53% vs. 40%) within the first year ($p<0.05$). Patients in the early optimal pMTX group were also more likely to be on Combination DMARDs during this time ($p<0.01$). Parenteral MTX was found to be a significant predictor of good clinical outcomes in a binary logistic regression model. Baseline differences between groups were assessed - overall, patients on early optimal pMTX were more likely to have baseline predictors of poor clinical outcomes, though were less often seropositive at baseline (50% vs. 65%).

Conclusions: The data are compelling that pMTX ≥ 20 mg should be considered as 1st line therapy in ERA. Results will be reported with updated data at time of conference.

Polymorphisms in the Folate Metabolism Gene MTHFR (C677T and A1298C) Are Not Associated with Methotrexate Adherence: Findings from the Veteran's Affairs Rheumatoid Arthritis (VARA) Registry. Lisa A. Davis[2], Grant W. Cannon[5], Roger Wolff[6], Leah Haverhals[3], Ted R. Mikuls[7], Andreas M. Reimold[1], Gail S. Kerr[8], John S. Richards[8], Dannette S. Johnson[4] and Liron Caplan[2]. [1]Dallas VAMC, Dallas, TX, [2]Denver VAMC, Aurora, CO, [3]Denver VAMC, [4]Jackson VAMC, Jackson, MS, [5]Salt Lake City VAMC, Salt Lake City, UT, [6]Salt Lake City VAMC, [7]Univ of Nebraska Med Ctr, Omaha, NE, [8]Washington, D.C. VAMC, Washington, DC

Background: Methylenetetrahydrofolate reductase (MTHFR) polymorphisms have been associated with specific toxicities of methotrexate (MTX) in rheumatoid arthritis patients. The most commonly studied polymorphisms MTHFR A1298C and C677T (CC and TT homozygotes respectively) have been associated with the occurrence of liver function abnormalities, alopecia, and headache, though other studies are equivocal. These polymorphisms are more common in Caucasians than in other ethnic groups. To examine whether these polymorphisms influence treatment, we studied the relationship of MTHFR A1298C and C677T genotypes with the MTX medication possession ratio (MPR), a measure of medication adherence.

Methods: Quantitative Real-Time PCR was used to genotype 1,054 randomly selected VARA registry participants for MTHFR A1298C and C677T polymorphisms. Patients' medication histories were abstracted from the VA Pharmacy Benefits Management (PBM) database to determine patients' MPR for MTX. Of the 1,054 subjects, MTX MPR data was available on 826. The average weighted MPR (awMPR, outcome variable) was calculated as the proportion of treatment time that the patient had drug available, weighted by course duration. Significant time gaps were defined as greater than 90 days. Linear regression was used to examine the associations of the MTHFR polymorphisms with MTX awMPR. Covariates included in the initial model were patient baseline demographics (age, race, education, co-pay requirements) and markers of RA activity and severity (mean DAS28, mean MDHAQ, aCCP status, nodules [ever], erosions [ever]). Model selection was based on a variation of the backward stepwise procedure that examined groups of conceptually-related variables simultaneously, with a p-value < 0.05 required for inclusion into the final model. The MTHFR A1298C and C677T homozygous genotypes were forced into the final model. A similar linear regression was performed restricted to Caucasian subjects.

Results: MTHFR A1298 and C677T homozygotes were 11.5% and 9.81% of the population, respectively. These MTHFR polymorphisms were not associated with MTX awMPR. In the linear regression model of all patients, older age was associated with an increase in awMPR (see table). In the model limited to Caucasians, no significant predictor of awMPR was found.

Conclusions: Although MTHFR polymorphisms may play a role in specific toxicities related to MTX, we found no evidence that MTHFR status influences patients' medication adherence.

Pooled Analysis of Observational Studies on Lymphoma Incidence among Rheumatoid Arthritis (RA) Patients Initiating Etanercept Therapy. Peter McCroskery[2], Virgil C. Dias[2], Scott Stryker[3], Bojena Bitman[3], Sean Z. Zhao[2] and Debra J. Zack[1]. [1]Amgen Inc, Thousand Oaks, CA, [2]Amgen Inc., Thousand Oaks, CA, [3]Amgen Inc.

Background: There have been several studies suggesting an association between tumor necrosis factor (TNF) inhibitors, including etanercept, and the development of lymphoma in RA patients. Other studies have noted a 2- to 4-fold increase in reported lymphomas in biologic-naïve RA patients compared with the general population (Askling et al, Ann Rheum Dis 2009,68: 648–653), and suggested the increased risk may be attributable to the underlying disease, particularly in patients with chronic active disease. We now present a surveillance analysis of the incidence of lymphoma in patients conducted as a post-marketing commitment to the US Food and Drug Administration.

Methods: The data used in this analysis were from 2 Amgen-sponsored long-term extension studies in patients with late/early and early RA, 2 US registries (RADIUS 1/2) and 3 EU registries (BSRBR and RABBIT, which enrolled patients receiving any biologic drugs and conventional disease modifying antirheumatic drugs, and ARTIS, which enrolled patients receiving any biologic drug). Crude incidence rates and age- and sex-adjusted standardized incidence ratios (SIRs) of lymphoma were estimated based on total patient-years (pt-yrs) of follow-up (since first etanercept exposure) and total pt-yrs of etanercept exposure (through 30 days after last etanercept exposure) using country-specific lymphoma rates.

Results: This study collected data from 24,266 RA patients who accumulated a total 93,260 pt-yrs of observation since the first date of etanercept exposure. The mean exposure to etanercept was 2.7 years. Sixty-two lymphomas were reported, compared with the expected number of 27.3 from country-specific rates, yielding an overall SIR of 2.3 (95% confidence interval [CI]: 1.7 to 2.9), in the total follow-up period. The data from the etanercept exposure period yielded an SIR of 3.0 (CI: 2.3 to 3.9). Variability in the SIRs for lymphoma in the US studies and the EU registries was noted.

Studies	Total Pt-Yrs	Observed Count/ Expected Count	SIR (95% CI)
Lymphoma Incidence in Total Follow-up Period			
US Studies	28818	27/10.5	2.6 (1.7 to 3.9)
RADIUS I and II	21443	13/7.7	1.7 (0.9 to 2.9)
016.0018	4440	7/1.7	4.2 (1.7 to 8.6)
016.0023	2935	7/1.1	6.3 (2.5 to 13.0)
EU Registries	64442	35/16.8	2.1 (1.5 to 2.9)
BSRBR Registry	32427	26/9.1	2.9 (1.9 to 4.2)
RABBIT Registry	4177	1/0.9	1.1 (0.0 to 5.9)
ARTIS Registry	27838	8/6.8	1.2 (0.5 to 2.3)
Total	93260	62/27.3	2.3 (1.7 to 2.9)
Lymphoma Incidence in Etanercept Exposure Period			
US Studies	21218	21/7.6	2.8 (1.7 to 4.2)
RADIUS I and II	13869	10/4.8	2.1 (1.0 to 3.8)
016.0018	4427	6/1.7	3.6 (1.3 to 7.8)
016.0023	2921	5/1.1	4.5 (1.5 to 10.6)
EU Registries	43720	35/11.1	3.2 (2.2 to 4.4)
BSRBR Registry	19286	26/5.2	5.0 (3.2 to 7.3)
RABBIT Registry	4054	1/0.9	1.1 (0.0 to 6.3)
ARTIS Registry	20380	8/5.0	1.6 (0.7 to 3.2)
Total	64938	56/18.7	3.0 (2.3 to 3.9)

CI, Confidence interval; Pt-Yrs, Patient-Years

Conclusions: Overall, the data from the long-term Amgen extension studies and both US and EU registries appear to show a 2- to 4-fold increased risk of lymphoma in RA patients receiving etanercept, though there was variability in SIRs from different sources. This analysis, combined with the observation that the risk of lymphoma in biologic-naïve and biologic-exposed RA patients is similar, supports the interpretation that there is no additional risk for lymphoma in patients receiving etanercept above the already increased risk of lymphoma in RA patients.

Post-Marketing Surveillance Program of Tocilizumab for RA in Japan – Interim Analyses of 3,881 Patients. Takao Koike[2], Masayoshi Harigai[8], Shigeko Inokuma[3], Naoki Ishiguro[6], Junnosuke Ryu[7], Tsutomu Takeuchi[5], Syuji Takei[4], Yoshiya Tanaka[10], Hisashi Yamanaka[9] and Kyoko Ito[1]. [1]Chugai Pharmaceutical Co.Ltd, [2]Hokkaido University, Japan, [3]Japanese Red Cross Medical Center, [4]Kagoshima University, Kagoshima City, Japan, [5]Keio University, Toyko, Japan, [6]Nagoya University, [7]Nihon University, [8]Tokyo Medical and Dental University, Tokyo, Japan, [9]Tokyo Womens Med Univ, Shinjuku-ku, Tokyo, Japan, [10]U Occupa & Environ Hlth, Kitakyushu, Japan

Purpose: An all-cases post-marketing surveillance (PMS) program has been implemented to investigate the safety and efficacy of tocilizumab (TCZ) in Japanese patients with rheumatoid arthritis (RA).

Methods: The PMS study has enrolled all patients with RA who were treated with TCZ in Japan after its launch in April 2008 with a tracking period of 28 weeks for each patient. All adverse events (AEs) and adverse drug reactions (ADRs) during the tracking period and disease activity score 28 (DAS28) at week 0 and week 24 were collected. AEs and ADRs were classified using MedDRA, ver11.1. The present analysis included 3,881 patients whose case report forms were completed by 15th July 2009.

Results: Baseline data of the patients were as follows: mean age, 58.5 y/o (range 16.0–87.0, 36.2% of them were ≥65 y/o); mean disease duration of RA, 10.7 yrs. (38.3% of them were ≥10 yrs); respiratory, cardiac, or hepatic comorbidities, 13.5%, 4.7%, or 4.5%, respectively; previous TNF inhibitors, 62.0%; concomitant methotrexate and glucocorticoid, 50.0% and 75.1%, respectively. Incidences of total and serious ADRs were 35.5% and 7.2%, respectively. The most frequent ADR and serious ADR were infection and infestation with an incidence of 9.6% and 3.4%, respectively. Among serious infections, bacterial pneumonia was the most frequently reported (1.4%). Regarding opportunistic infections, 4 cases of tuberculosis (3 pulmonary and 1 peritoneal tuberculosis) and 6 cases of *Pneumocystis jirovecii* pneumonia were reported. Logistic regression analysis identified risk factors for the development of serious infection (odds ratio, 95% confidence interval): presence of respiratory comorbidities (2.970, 1.959–4.502), higher prednisolone dose at the baseline (>5 mg/day) (2.297, 1.299–4.061), older age (≥65 y/o) (1.762, 1.170–2.651) and longer disease duration (>10 yrs.) (1.561, 1.032–2.361). The malignancies as AE were reported in 17 patients (0.4%) without any specific patterns. Gastrointestinal disorders were reported in 3.0% of cases with 5 cases (0.1%) of gastrointestinal tract perforations. All these patients recovered. Anaphylactic shock/reactions were reported in 8 patients (0.2%). Although dyslipidemia and elevated liver function tests were reported in 5.9% and 6.6% of the patients, respectively, these laboratory test abnormalities accompanied neither serious cardiovascular diseases nor serious hepatic disorders. Twenty-eight out of 3,881 patients died with causes of death in the following order of occurrence (expressed as a percentage): infection, 32%; respiratory disease, 20%; cardiovascular disease, 24%; cerebrovascular disease, 12%. The standardized mortality rate (SMR), with Japanese general population in 2008 as a control, was 1.66, which was similar to those reported in the Japanese cohort study [1].

Conclusions: The results from the interim analysis of the PMS study revealed that TCZ was well tolerated in the real world for Japanese patients with RA.

Predictive Risk Factors of Severe Infections in RA Patients Treated with Abatacept in Real Life: Results from the Orencia and Rheumatoid Arthritis (ORA) Registry. Jacques-Eric Gottenberg[11], Philippe Ravaud[5], Thomas Bardin[7], Patrice Cacoub[6], Aain Cantagrel[12], Bernard Combe[9], Maxime Dougados[3], René-Marc Flipo[8], Bertrand Godeau[4], Loic Guillevin[3], Eric Hachulla[8], Xavier Le Loët[10], Thierry Schaeverbeke[2], Jean Sibilia[11], Gabriel Baron[5] and Xavier Mariette[1]. [1]Bicetre Hospital, [2]Bordeaux Hospital, [3]Cochin Hospital, [4]Henri Mondor Hospital, [5]Hotel Dieu Hospital, [6]La Pitié Hospital, [7]Lariboisière Hospital, [8]LIlle Hospital, [9]Montpellier Hospital, [10]Rouen Hospital, [11]Strasbourg Hospital, [12]Toulouse Hospital

Objective: Little data is available regarding the rate and predicting factors of severe infections in patients with rheumatoid arthritis treated with abatacept (ABA) in daily practice. We therefore addressed this issue using real-life data from the "Orencia and Rheumatoid Arthritis" (ORA) registry.

Methods: ORA is an independent registry promoted by the French Society of Rheumatology dedicated to RA patients with abatacept. At baseline, 3, 6 months and every 6 months or at disease relapse, during 5 years, standardized information are prospectively collected by trained clinical nurses in each center. Central reviewing of charts of patients with SAEs is performed by the two coordinators of the study.

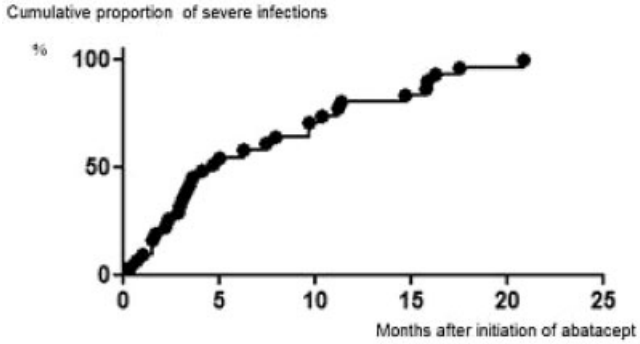
Results:

- Baseline characteristics and comorbidities

1036 patients (78.9% of women) were included. Median age of patients was 58 years and median disease duration was 12 years. 5.8% of patients had a history of cancer, 33.6% a record of severe infection, and 11.4% had diabetes. Follow-up was 557 patient/years on April 30th, 2010.

-Rate of severe infections

35 severe infections occurred, including 31 severe infections during treatment with ABA and/or within the 6 months following ABA discontinuation. Thus, 5.6 severe infections/100 patient-years were observed. No opportunistic infection was observed. Severe infections occurred after a median duration of 4.6 months (range: 2.4–11.2 months) after abatacept initiation.



- Predicting factors of severe infections

The analysis was carried out on the 709 patients who already had at least 1 follow-up visit (at least 3 months of follow-up). On univariate analysis, age, history of cancer, record of previous severe infections, diabetes, a higher number of previous synthetic DMARDs and a lower number of previous anti-TNF were associated with a higher risk of severe infection. Previous treatment with rituximab, disease activity or low IgG levels at initiation of abatacept were not significantly associated with an increased risk of severe infection. On multivariate analysis, history of cancer (OR 3.7 CI95% [1.0–13.9], P=0.05), record of severe infections (2.7 [1.1–6.7], P= 0.03) and diabetes (3.5 [1.3–9.7], P= 0.01) were significantly associated with a higher risk of severe infection.

Conclusion: In ORA registry, severe infections in patients treated with abatacept were slightly more frequent than in clinical trials. This might be related to the fact that a high proportion of patients with comorbidities, who would have been excluded from controlled trials, are treated with ABA in real life. The greatest risk of severe infections occurs within the first 6 months after ABA, as it was also reported with anti-TNF or rituximab. In patients treated with abatacept, predicting factors of severe infections include history of cancer, record of severe infections and diabetes.

Pregnancy Outcomes in Patients with Autoimmune Diseases Treated with Rituximab. Eliza F. Chakravarty[1], Elaine Murray[2], Ariella Kelman[2] and Pamela Farmer[3]. [1]Mountain View, CA, [2]Genentech, South San Francisco, CA, [3]Genentech

Background: Rituximab is a monoclonal antibody to CD20 causing CD20+B-cell depletion. It is approved for treatment of adults with moderately-to severely-active rheumatoid arthritis (RA) with inadequate response to TNF antagonists, and has been studied in other autoimmune diseases. Despite counseling to avoid pregnancy, some women may become pregnant after rituximab treatment. Almost half of all U.S. pregnancies are unplanned, including those in women with underlying medical conditions. Data on pregnancy outcome following rituximab treatment is important when counseling women who inadvertently become pregnant, or are pregnant and need to assess therapeutic options for severe disease.

Methods: Utilizing the rituximab global drug safety database, we reviewed all reports of pregnancy following rituximab use (spontaneous reporting or during clinical trials) among women treated for autoimmune conditions (RA, systemic lupus erythematosus (SLE), idiopathic thrombocytopenia purpura (ITP), and multiple sclerosis). Patients may have received concomitant treatment with known teratogens and abortifacients such as methotrexate.

Results: Of 172 pregnancy reports identified through February 2010, 16 were ongoing, 11 reported paternal exposure, and 40 did not report pregnancy outcomes. Eight patients received rituximab during an established pregnancy for the treatment of profound autoimmune hematologic disease. Of the 105 reports with known outcomes, 56 (53%) resulted in live births, 27 (26%) in spontaneous abortion, and 20 (19%) pregnancies were terminated. One maternal death occurred from an intracerebral hemorrhage in a woman treated for ITP; and one pregnancy ended in fetal demise at 20 weeks from an umbilical knot. There was one neonate death at six weeks of life of an infant delivered to a rituximab treated woman with SLE, who also received mycophenolate mofetil and warfarin while pregnant. Mean gestational age at delivery was 37.3± 2.5 weeks. 73% of live births were full term, and 27% were prior to 37 weeks gestational age. One congenital malformation was reported: clubfoot in one of a set of twins. Six infants had hematological abnormalities at birth: 3 with transient leucopenia, and 3 with thrombocytopenia. Most were mild and transient, although one infant, born to a mother treated with rituximab during the third trimester for profound ITP, had a cerebral hemorrhage of unreported severity. Three neonatal infections were reported: febrile illness at 3 weeks of age, chorioamnionitis, and vertical transmission of CMV; none occurred in infants with cytopenias.

Conclusions: Women should continue to be counseled to avoid pregnancy after rituximab exposure; however, inadvertent pregnancy can occur. Few congenital malformations or infections were seen among exposed neonates, and it is difficult to determine if rituximab, concomitant medications, underlying diseases, or other factors contributed. This data provides information that can be used to counsel women in making decisions during pregnancy.

Pulmonary Function in Patients with Rheumatoid Arthritis Treated with Anti-TNF Biologic Agents. Andrew J. Odden[1], Ann J. Impens[2], Elena Schiopu[2], Kevin Flaherty[1] and Kristine Phillips[2]. [1]University of Michigan, [2]University of Michigan, Ann Arbor, MI

Background: Initiation of anti-tumor necrosis factor (TNF) therapy has been associated with a range of pulmonary pathology in patients with rheumatoid arthritis (RA), including usual interstitial pneumonitis and granulomatous lung disease. It has been suggested that preexisting interstitial lung disease may predispose patients with rheumatoid arthritis treated with anti-TNF agents to the development of worsening pulmonary disease. There have been no known quantitative studies of lung function in patients with RA-associated interstitial lung disease treated with anti-TNF biologics.

Method: This retrospective cohort study identified patients at a single large referral center who were diagnosed with rheumatoid arthritis, had

coexisting interstitial lung disease, and were treated with anti-TNF therapy. Data recorded included demographics, comorbidities, mortality, chest CT, lung biopsy results, and pulmonary function tests including spirometry and DLCO. Patients were included who had spirometry measurements within one year prior to and within six months after initiating anti-TNF therapy. The baseline FEV1 and FVC were compared with FEV1 and FVC six months after therapy using the paired samples test.

Results: Seventy-four patients were identified with rheumatoid arthritis and interstitial lung disease and had been treated with anti-TNF biologic therapy. Demographic, treatment, and PFT data were gathered for this cohort. Of these, 23 had spirometry measured at least one year prior to starting anti-TNF therapy and again within six months after initiation of therapy. There was no statistically significant difference in FEV1 (2.067 liters vs. 2.097 liters, paired difference 0.030 liters, 95% CI −0.104 to 0.164) or FVC (2.664 liters vs. 2.668 liters, paired difference 0.004 liters, 95% CI −0.141 to 0.150) from baseline to six months after starting anti-TNF therapy.

Conclusion: In this retrospective cohort study, there was no statistically significant change in either FEV1 or FVC from baseline to six months after initiation of anti-TNF biologic therapy. Our study suggests that the use of anti-TNF therapy, an important component of the management of patients with rheumatoid arthritis, does not worsen pulmonary function with short term treatment (six months) in patients with pre-existing lung disease. This study is limited by its small sample size and the short interval between baseline and follow-up spirometry, both of which may have limited our ability to detect a clinically significant difference in lung function. Larger prospective studies are needed to determine the safety of using anti-TNF agents in patients with rheumatoid arthritis and interstitial lung disease.

403

Rate of Serious Infections in RA Patients Who Subsequently Receive Other Biologic Therapies after Discontinuing Rituximab Treatment. Mark C. Genovese[8], Ferdinand Breedveld[4], Paul Emery[2], Stanley B. Cohen[6], Ed C. Keystone[9], Eric L. Matteson[5], Laura Burke[7], Akiko Chai[3], William Reiss[3], Marianne Sweetser[1] and Tim Shaw[7]. [1]Biogen Idec, [2]Chapel Allerton Hospital, Leeds, United Kingdom, [3]Genentech, [4]Leiden Univ, [5]Mayo Clinic, Rochester, MN, [6]Rheumatology Associates, Dallas, TX, [7]Roche, [8]Stanford Univ, Sunnyvale, CA, [9]University of Toronto, Toronto, ON, Canada

Purpose: Rituximab (RTX) selectively targets CD20+ B-cells and is approved for treatment of RA patients (pts) who had an inadequate response to ≥1 TNF-inhibitor(s) (TNFi). The pharmacodynamic effect of RTX may be long lasting. The safety of treatment with other biologic disease-modifying antirheumatic drugs (BDMARDs) during this period of peripheral B-cell depletion in pts who have discontinued RTX is an important clinical question. The purpose of this analysis is to describe the rate of serious infection events (SIEs) in pts treated with RTX, who subsequently received a BDMARD.

Methods: Pts with moderately-to-severely active RA who received RTX + methotrexate within an international clinical trial program were included. Following completion or withdrawal from their studies, pts entered safety follow-up (SFU) and peripheral B-cell counts were monitored for ≥48 wks. During SFU, pts were permitted to receive BDMARDs. All SIEs, defined as serious adverse events or infections that required IV antibiotics, were collected.

Results: As of Sept 2009, 3189 RA pts had received ≥1 course of RTX providing 9365 pt-yrs of follow-up (SIE rate / 100 pt-yrs: 4.34 [95% CI: 3.93, 4.78]). Of pts who entered SFU, 283 pts were subsequently treated with BDMARD (median time 8.5 mo [range: 0.1–52] after last RTX infusion). 87 (30.7%) pts received their BDMARD < 6 mo of their last RTX infusion. 230 of the 283 pts received TNFi after RTX. Median follow-up time after receipt of the subsequent BDMARD was 11 mo (7—17). At the time of receiving further BDMARD treatment, 83% had peripheral B-cell counts below lower limit of normal (LLN) (<80 cells/μL). During treatment with RTX and prior to receipt of the BDMARD, the 283 pts had 6.01 SIEs / 100 pt-yrs (Table). Following initiation of BDMARD, the SIE rate was 4.97 / 100 pt-yrs. Median time to SIE after initiating BDMARD was 11 mo (range: 2—21). In 43 pts who received abatacept (ABA) as their 1st subsequent BDMARD post RTX, there was 1 SIE before and 1 after receiving ABA (97.7 total pt-yrs). Overall, the infections were variable and typical for RA pts, with no opportunistic or fatal infections. In subgroup analysis of 174 patients with CD19+ counts <20 cells/ μL at the time of receipt of their next BDMARD, SIE rate / 100 pt-yrs was 6.28 (3.79, 10.42). In pts who received BDMARD <6 mo (n= 87) or ≥6 mo (n= 196) post RTX, SIE rates were 5.04 (2.26, 11.22) and 4.94 (2.66, 9.18), respectively.

Table. Rate of SIEs in Pts Receiving Biologic DMARDs following RTX

	All Pts Receiving Any Biologic after RTX (n = 283)		Pts Receiving a TNFi after RTX (n = 230)	
	Before Biologic	After Biologic	Before TNFi	After TNFi
Total exposure, pt-yrs	365.83	321.84	282.16	265.89
# SIEs	22	16	17	12
SIE per 100 pt-yrs (95% CI)	6.01 (3.96, 9.13)	4.97 (3.05, 8.12)	6.03 (3.75, 9.69)	4.51 (2.66, 7.95)

CI – confidence interval

Conclusion: In this updated analysis, the use of other BDMARDS in RA pts previously treated with RTX was not associated with an increase in the rate of serious infections. The rate of serious infections is consistent with rates seen in long-term safety analyses.

Rates of Tuberculosis and Nontuberculous Mycobacterial Disease among Rheumatoid Arthritis Patients Who Use Anti-Tumor Necrosis Factor alpha Therapy; from the SAfety of Biologic ThERapy (SABER) Study. K. L. Winthrop[2], John Baddley[4], Lang Chen[4], Liyan Liu[1], Carlos G. Grijalva[8], Nivedita M. Patkar[3], Fenlong Xie[4], Elizabeth Delzell[4], Timothy Beukelman[6], Lisa J. Herrinton[1], Kenneth G. Saag[7] and Jeffrey R. Curtis[5]. [1]Kaiser-Permanente, [2]OSHU, [3]Univ of AL at Birmingham, Birmingham, AL, [4]Univ of AL at Birmingham, [5]University of Alabama-Birmingham, Birmingham, AL, [6]University of Alabama-Birmingham, Birmingham, AL, [7]University of Alabama-Birmingham, Birmingham, AL, [8]Vanderbilt

Background: Rheumatoid arthritis (RA) patients who use anti-tumor necrosis factor alpha therapies (anti-TNF) are at increased risk for tuberculosis. Serious infections due to environmental nontuberculous mycobacteria (NTM) have also been reported in such patients. In the United States, there is no population-based data for patients with rheumatic diseases estimating the risk of TB and NTM.

Methods: We identified new users of anti-TNF therapy among a cohort of rheumatoid arthritis (RA) patients during the years 2000–2007 from three data sources: Kaiser-Permanente Northern California, MAX + 'dual eligible' (MAX + Medicare) data from the national Centers of Medicare and Medicaid Services (years 2000–2005), and Tennessee Medicaid. We used validated electronic medical record (Kaiser) and administrative claims data (CMS and Tenncare) algorithms to identify and describe cases of TB and NTM within this cohort. We calculated incidence rates using total anti-TNF exposure time (current use required) for each patient during the study time-period. We compared TB incidence rates with the rate of TB reported by the US Centers for Disease Control in the United States general population during this same time-period.

Results: Among 29500 new users of anti-TNF therapy for RA, we identified 24 NTM and < 11 TB cases and calculated incidence rates of 66.7 (40–93) and 45.9 (14–78) per 100,000 patient-years respectively. The rate of TB in the US general population was 5.1/100,000 during the same study time-period. 80 (%) and 93 (%) of NTM and TB patients were female respectively, with median age in 5 year increment (range) of 50 (25–75 and 55 (25–80+). NTM patients were more likely to be white (50%) than TB patients (40%). Pre-existing chronic obstructive pulmonary disease or bronchiectasis was more frequent among NTM patients (35%) than among TB patients (33%).

Conclusion: In the United States, a region of low TB prevalence, the rate of TB among RA patients who start anti-TNF therapy is 9 fold higher than the general US population. However, NTM disease was more common than tuberculosis among these RA patients. Rheumatologists should continue to screen for latent TB infection prior to prescribing anti-TNF therapy and remain vigilant for NTM disease, particularly in those with a history of underlying lung disease.

Real Life Analysis of the Romanian Experience in Switching from Anti-TNF Based Therapy to Rituximab. Ioan Ancuta[1], Catalin Codreanu[2], Ruxandra Maria Ionescu[4], Horatiu Bolosiu[5], Magda Parvu[3] and Lia Georgescu[6]. [1]"Dr. I. Cantacuzino" Hospital, Bucharest, Romania, [2]"Dr. I. Stoia" Center for Rheumatic Diseases, Bucharest, Romania, [3]"N. Gh. Lupu" Clinical Hospital, Bucharest, Romania, [4]"Sfanta Maria" Clinical Hospital, Bucharest, Romania, [5]Rheumatology Clinic, Cluj - Napoca, Romania, [6]Rheumatology Clinic, Tirgu-Mures, Targu - Mures, Romania

Background: The rheumatoid arthritis is a chronic disorder affecting physical function and patient's quality of life, and its treatment carries therefore important costs for the National Health Insurance House (NHIH). In case of an inadequate response with the first anti-TNF medication, a largely used option is currently to continue the treatment with drugs from the same class, either by modifying dosage/frequency of the initial ones, or by prescribing different anti-TNF. Using the available data from NHIH, we researched if continuing with a second anti-TNF brings both the expected benefits for the patients and is reasonably cost effective for NHIH, versus switching to rituximab (RTX) after the initial medication, instead of using again anti-TNF drugs.

Methods, Materials and Analytical Procedures Used: The analysis was performed for 200 patients (78% women with an average age of 55 and 22% men, average age 54) who were all prescribed in the first stage anti-TNF alpha medication. In the second stage, 102 patients were treated with RTX for 3 courses (after one anti-TNF-IR), while 98 of them received a 2nd anti-TNF medication and after an inadequate response to that were treated with 3 courses of RTX. The median time for follow-up was 1.5 years for each arm. We evaluated the effectiveness of the 2 treatment approaches by calculating the Δ between DAS28 measured after and before each stage of the therapy. The financial efficiency was computed as ratio of average cost per DAS28 point for each strategy.

Summary of the Results: Patients had a good response to the first anti-TNF alpha medication, the medium duration of the treatment being 2.43 years. Average DAS28 before treatment was found 6.43, and 3.88 after (medium ΔDAS28 = −2.55). For the 98 patients having a second anti-TNF alpha therapy we noticed an increase of DAS28, the medium ΔDAS28 reaching 0.96, evidencing development of resistance to the anti-TNF medication. For the 102 patients that switched to RTX in the second treatment stage, DAS28 decreased, reaching ΔDAS28 = −2.39. Over the 3 RTX cycles, DAS28 decreased consistently for all patients but reached its lowest value for the patients having RTX after the first anti-TNF, (ΔDAS28 = −3.9).

Conclusions: Repeating anti-TNF alpha medication after an initial a-TNF inadequate response did not bring benefits to the patients, as DAS28 increased during the second stage of the treatment. The incomplete immunosuppression caused by the first anti-TNF medication could lead to development of resistance to treatment which becomes significant during the next stage. Introducing RTX right after the first anti-TNF inadequate response proved to be the most effective option, leading to cumulating of clinical benefits and to consolidation of lower DAS28 response with each following RTX cure. This strategy is also more efficient, as the cost per DAS28 point decreased compared with introducing RTX only after the second anti-TNF. Therefore the balance cost-benefits is clearly in favor of initiating a RTX medication immediately after the first anti-TNF therapy and this shall be our recommendation for NHIH.

Real Life Treatment with Rituximab in TNF Blocker Non-Responders Is Superior to Treatment with a Second TNF Blocker. Joern Kekow[4], Ulf Müller-Ladner[2], Hendrik Schulze-Koops[1], Ralf Link[3], Steffen Breuer[3] and Monika Kobialko[3]. [1]Division of Rheumatology, University of Munich, Germany, [2]Justus-Liebig University Giessen, Kerckhoff Clinic, Bad Nauheim, Germany, [3]Roche Pharma AG, Grenzach-Wyhlen, Germany, [4]Specialized Hospital for Rheumatology & Orthopaedics, Vogelsang-Gommern, Vogelsang-Gommern, Germany

Background: Treatment with biologics has led to a fundamental change in the therapy of rheumatoid arthritis (RA). However, 30% of patients treated with TNF blockers still do not sufficiently respond to therapy. Switching to a 2nd TNF blocker vs. second generation biologic such as rituximab is still a matter of debate, especially which option might be superior in that situation. The objective of this trial was to assess the efficacy of one course with 2 × 1g rituximab compared to an alternative TNF blocker in RA patients with one previous TNF blocker failure in a real life setting.

Methods: This was a non-interventional, retrospective cohort study with a mean observation period of 6.6 months (median 6.32, range 1.64–20.76). Of 196 patients (77% females; rituximab n=90) with active RA (DAS28 ≥ 3.2), 43.9% had previously received adalimumab and etanercept each, and 12.2% infliximab.

Results: Both cohorts were comparable regarding age (rituximab 56.6±11.1; TNF blocker 57.4±13.1 years), duration of disease (10.0±7.8 vs. 9.7±7.6 years), DAS28 (5.6±1.0 vs. 5.4±1.0) and concomitant DMARD therapy (77.8% vs. 77.4%) at initiation of 2nd treatment (baseline). The mean DAS28 reduction was significantly greater after 6.6 months treatment in the rituximab group as compared to the patients treated with a 2nd TNF blocker (-1.64 [95%-CI: −1.92; −1.36] vs. −1.19 [95%-CI: −1.42; −0.96], p=0.0133), see Figure 1 (left). This cohort difference was similar in the 156 patients seropositive for RF (−1.66 [95%-CI: −1.98; −1.34] vs. −1.17 [95%-CI: −1.43; −0.91], p=0.0176) and more pronounced in the 132 patients seropositive for CCP: a significant difference (p=0.0295) could already be observed after 12 weeks with further improvement until month 6.6 (−1.75 [95%-CI: −2.07; −1.43] vs. −1.06 [95%-CI: −1.34; −0.78], p=0.0016), see Figure 1 (right). The results from the 23 seronegative patients also favored rituximab but this difference was not significant. More rituximab than TNF blocker patients reached moderate/good EULAR response: 82.2% vs. 71.7%; with a significant difference in the CCP subgroup: 85.3% vs. 67.2% (p=0.0128).

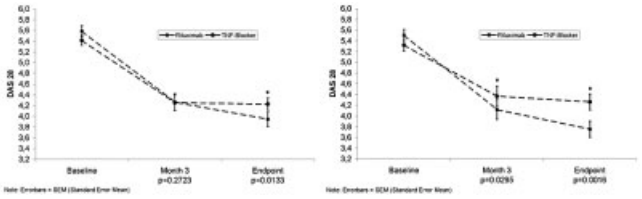

Figure 1. Course of the mean DAS28 (±SEM) in all patients (left) and CCP positive patients (right)

Conclusion: The results from this non-interventional, retrospective cohort study indicate that treatment with rituximab is superior to a 2nd TNF blocker therapy in RA patients after failure of the first TNF inhibitor in terms of clinically significant improvement as measured by the DAS28 score. An even stronger difference in clinical response was found in the patients seropositive for CCP. This observational data of a real life setting confirm the data of rituximab in TNF blocker non-responders as shown in the REFLEX study. In addition to previous publications we could show that CCP may be a useful predictive biomarker for response to rituximab in patients with TNF blocker treatment failure.

Risk of Malignancies in Patients with Rheumatoid Arthritis Treated with Biologic Therapy: Meta-Analysis of Controlled Trials. Maria A. Lopez-Olivo[4], Juan A. Martinez-Lopez[2], Jean H. Tayar[7], Jose Polo Cueto[5], Eduardo N. Pollono[3], M. Rosa Gonzales-Crespo[1], Stephanie Fulton[6] and Maria E. Suarez-Almazor[7]. [1]Hospital 12 de Octubre, [2]Spanish Society of Rheumatology, Spain, [3]Texas Tech University Health Science Center - Paul Foster School of Medicine, [4]The University of Texas M.D. Anderson Cancer Center, Houston, TX, [5]The University of Texas MD Anderson Cancer Center, [6]University of Texas, MD Anderson Cancer Center, Houston, TX, [7]UT M D Anderson Cancer Ctr, Houston, TX

Background: Biologic response modifiers (BRM) provide an important therapeutic alternative in patients with rheumatoid arthritis. Because these biologic agents interfere with the immune system, there are concerns regarding their safety and an increased risk of malignancies. The objective of this study was to assess the risk of malignancies in patients with rheumatoid arthritis enrolled in clinical trials of BRMs, in order to update the information reported in previous reviews of RCTs and determine if the newly approved BRMs have an increased risk for malignancies.

Methods: We searched for clinical trials on the use of abatacept, adalimumab, anakinra, certolizumab, etanercept, golimumab, infliximab,

rituximab, and/or tocilizumab for the treatment of rheumatoid arthritis, published through April 29, 2009. Sources included electronic databases (MEDLINE, EMBASE, and Web of Science). Review of 12,480 citations revealed 55 controlled trials. Two independent reviewers evaluated risk of bias in the methods of selected studies using the risk of bias instrument (Cochrane Collaboration) and extracted data. Information on reported number of malignancies, type and time of occurrence when available was collected.

Results: Fifty-three trials with 23,696 patients were included. Compared with placebo, patients in the TNF antagonists group were 1.38 times more likely to develop malignancy at one year, but this was not statistically significant (95% CI, 0.76, 2.48) with a 0.33% (95% CI: −0.16%, 0.82%) absolute risk difference between groups. The number needed to harm was 305 (95% CI: 122, ∞) for one additional malignancy within a treatment period of 12 mo. No statistically significant risk of developing a specific type of malignancy was found in the TNF antagonist-treated patients compared to placebo. Total number of solid malignancies (breast, lung, colon, prostate) were greater for patients treated in tocilizumab group compared to placebo (RR: 6.47, 95% CI: 0.34, 124.16) and skin cell carcinoma was increased when certolizumab was given in combination with methotrexate against placebo plus methotrexate (RR 3.56, 95% CI 0.18, 68.63), but these results were not statistically significant.

Conclusions: On the basis of the studies reviewed here, there is no evidence that BRMs for the treatment of the RA confide a greater risk for malignancies, but further long-term studies and continuing post-marketing surveillance are required.

408

Risk of Malignancy during Anti-TNF alfa Therapy in Patients with Rheumatoid Arthritis: Systematic Review and Meta-Analysis of Registries, Long-Term Extension Studies and Randomized Controlled Trials.

Pierre Le Blay[3], Gael Mouterde[4], Thomas Barnetche[1] and Bernard G. Combe[2]. [1]Bordeaux University Hospital, [2]Hopital Lapeyronie, Montpellier, France, [3]Hopital Lapeyronie, France, [4]Hopital Lapeyronie

Background: TNF antagonists have shown their efficacy in rheumatoid arthritis (RA) and are now widely used. Some data derived from randomized control trials (RCTs) suggest that anti-TNF might be associated with an increased risk of malignancy [1], but results from long term safety follow up and registries are controversial.

Objective: To assess the risk of malignancy in TNF antagonists treated-RA patients, by performing a systematic review and meta-analysis based on data from registries, long term extension studies, and RCTs of 2 newly licensed anti-TNF.

Method: A systematic review of literature was performed until January 2010. Bibliographic references were selected from Embase and Medline databases, and abstracts from both the EULAR and the ACR annual meetings.The Mantel-Haenszel method was used to provide a common odds-ratio (OR) estimate and 95% confidence interval (CI) in anti-TNF– versus disease modifying antirheumatic drug (DMARDs) treated patients for registries and for certolizumab and golimumab RCTs. Statistical heterogeneity was assessed on the basis of the Q test (χ^2), using a significance level of 0.05. OR and 95% CI were shown on forest plots. Standardized Incidence Ratio (SIR), versus the general population, were extracted for long term extension studies and registries.

Results: The literature search identified 641 articles and 110 abstracts of which respectively 25 and 2 were selected for analysis. Retrieved data allowed meta-analysis on 4 registries and 5 RCTs. Based on registries (40128 Patient-years (PY) in anti-TNF treatment group and 59862 PY under DMARD treatment in control group), the pooled OR for malignancy was 0.81 (95% CI 0.71–0.94), without significant heterogeneity.

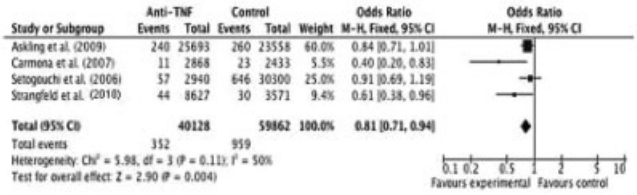

Figure 1. Meta-analysis of registries for risk of total malignancy.

In golimumab and certolizumab RCTs, the pooled OR for total malignancy and for non melanoma skin cancers were respectively 1.07 (95% CI 0.35–3.25) and 0.83 (95% CI 0.24–2.87), without heterogeneity.

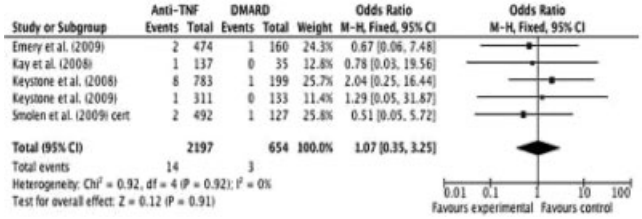

Figure 2. Meta-analysis for risk of total malignancy with certolizumab and golimumab.

Among 3 long term extension studies, no increase in the incidence of total malignancy was noted (SIRs ranging from 0.84 to 1.07). A similar observation was made in 4 registries (21225 PY), (SIRs ranging from 0.74 to 1.36, none being statistically significantly higher than 1).

Conclusion: This meta-analysis of registries did not find an increased risk of malignancy in anti TNF treated-RA patients. Data from long term extension studies and RCTs with new TNF antagonists confirmed these results.

Rituximab vs TNF-Inhibitor Cycling in Patients Who Previously Failed to TNF-Inhibitors: The MIRAR Study.

Juan-Jesús Gómez-Reino[1], Raimon Sanmartí[2], Ana-Belen Romero[3] and Laura Monclus[3]. [1]Hospital Clínico Universitario / Xeral de Galicia, Santiago de Compostela, [2]Hospital Clinic, Barcelona, [3]Roche

Purpose: Rituximab (RTX) is used to deplete B cells, and control disease activity in, mainly, anti-TNF failing RA patients. Another option is to switch to another anti-TNF, and it is not yet clear which of these two options is the more successful strategy. The objective of this study is to compare in a clinical setting the effectiveness of RTX treatment vs. an alternative anti-TNF in RA patients failing to an anti-TNF.

Methods: Multicentre, prospective, 3-year observational study of a cohort of patients with RA who received either RTX or an alternative anti-TNF, having previously inadequate response to at least 1 anti-TNF. Assessments included DAS28, EULAR response and HAQ at 9–12 months. At the time of this analysis, more evaluable patients were included since last published results[1]. All analysis were done with SAS 9.1.3. Appropriate tests were used for comparisons.

Results:

Table 1. Baseline patient characteristics

	Rituximab	TNF-inhibitor	P-value
Female	346 (81.41%)	958 (79.77%)	0.4646
Age (mean SD)	55.73 (12.47)	54.55 (13.46)	0.2583
>4 years since diagnosis of RA	292 (86.65%)	787 (78.23%)	0.0008
Extra-articular manifestations of RA	137 (44.05%)	255 (26.18%)	<0.0001
Prior number of TNF inhibitors failure			<0.0001
1	210 (60.69%)	762 (79.89%)	
≥2	136 (39.31%)	229 (20.11%)	
Previous use of ≥2 DMARDs	193 (94.15%)	860 (87.31%)	0.0053
Previous toxicity with DMARDs	78 (38.61%)	291 (29.82%)	0.0141

Significantly more patients in RTX had > 4 years since diagnosis, extra-articular manifestations, ≥ 2 DMARDs and ≥ 2 previous number of anti-TNF, toxicity with DMARDS (Table 1) and higher DAS28. At 9–12 months, change in DAS28 is significantly larger in RTX (-1.84) than alternative anti-TNF (-1.34) (P=0.0156; difference: 0.4999, 95% CI: 0.0954, 0.9043) (Figure 1). EULAR good-mod. response rate is better in RTX

(82.56%) than alternative anti-TNF (70.83%) (P= 0.04); Probability of good-moderate response is affected by baseline DASS28 (OR= 2.532, 95% CI: 1.837, 3.489). There were no differences in change of HAQ (P= 0.3141) nor in proportion of patients with HAQ > 0.22 (P= 0.1754).

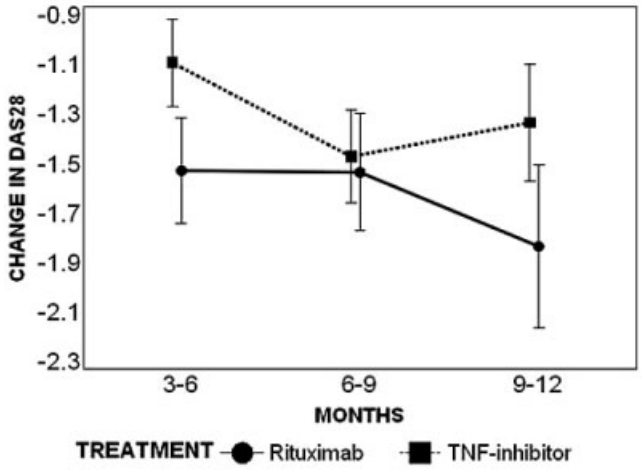

Figure 1. mean (95% confidence intervals) changes in DAS28

Conclusion: Data from the MIRAR Study confirms that switching to RTX provides an alternative therapeutic option to TNF cycling in patients with RA who have previously failed TNF inhibitor therapy. DAS28 reduction was significantly higher in the RTX group.

Rituximab vs. Anti-TNF after Failure of Anti-TNF: An Observational Study. Katerina Chatzidionysiou[2] and Ronald Van Vollenhoven[1]. [1]Karolinska University Hospital, Stockholm, Sweden, [2]Karolinska University Hospital, Stockholm

Background: The purpose of this study was to determine whether patients who had failed one or more anti-TNFs achieve better results when switching to another anti-TNF or when switching to rituximab.

Methods: The Stockholm registry ''STURE'' was used. Treatment results at 3 and 6 months were analysed by 1) biologic used; 2) whether as second, third or fourth biologic; 3) type of TNF switch; and 4) reason for discontinuation (lack of efficacy or intolerance).

Results: A total of 850 patients switched to an alternative biologic, 679 to a TNF antagonist and 171 to rituximab. There was a significant improvement in the DAS28 scores for both RTX and anti-TNF groups from baseline to 6 months. The mean (S.D.) reduction of DAS28 was 1.79 (1.35) for the RTX group and 1.37 (1.44) for the anti-TNF group (p=0.03). Specifically, mean ΔDAS28 was 1.15 (1.4) for infliximab and adalimumab taken together and 1.58 (1.46) for etanercept. A significant difference was observed between rituximab and anti-TNF monoclonal antibodies (p=0.002, 95% CI = 0.24; 1.06) but not between rituximab and etanercept (p=0.32, 95% CI = −0.21; 0.6).

In figure 1 the mean improvements in DAS28 can be seen according to the type of TNF switch. Having failed a TNF soluble receptor, RTX was significantly better than an anti-TNF monoclonal antibody (p=0.03). For patients who had failed a TNF monoclonal antibody RTX leads to numerically but not significantly greater reductions in DAS28 than an alternative anti-TNF antibody or etanercept.

When the reason for discontinuation of previous treatment was intolerance, rituximab achieved significantly greater reduction in DAS28 compared to anti-TNF, 2.05 (1.17) versus 1.52 (1.26) (p=0.04).

Conclusion: In this observational cohort, patients who had failed anti-TNF had slightly better overall results when treated with rituximab than with another anti-TNF, but both options provided clinical benefits. The superiority of rituximab was observed when compared to anti-TNF monoclonal antibodies but not to etanercept. Unexpectedly, the advantage of RTX was most clearly seen in patients who had failed anti-TNF due to intolerance.

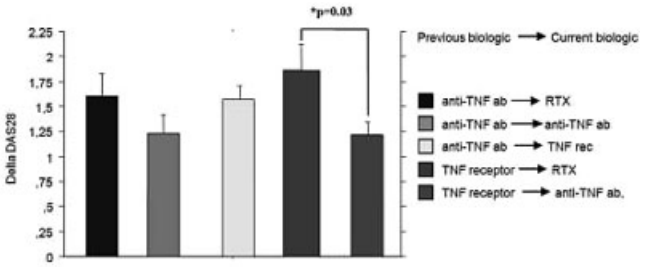

Figure 1. Change in DAS28 at 6 months for patients who switched from an anti-TNF monoclonal antibody (aTNFab) or a TNF soluble receptor-construct to rituximab or an alternative anti-TNF.

Disclosure: K. Chatzidionysiou: None; **R. Van Vollenhoven:** Roche, 2, 5.

Safety and Tolerability of Tocilizumab in Long-Term Extension Studies of Rheumatoid Arthritis. Mark C. Genovese[5], Anthony Sebba[7], Andrea Rubbert-Roth[6], Juan J. Scali[1], Moshe Zilberstein[3], Emma Vernon[4] and Ronald F. van Vollenhoven[2]. [1]Durand University Hospital, Buenos Aires, Argentina, [2]Karolinska University Hospital, Stockholm, Sweden, [3]Roche, Nutley, NJ, [4]Roche, Welwyn, UK, [5]Stanford University Medical Center, Palo Alto, Palo Alto, CA, [6]University of Cologne, Cologne, Germany, [7]University of South Florida, Palm Harbor, FL

Background: Tocilizumab (TCZ) is an effective RA therapy that targets interleukin-6-receptor (IL-6R) signal transduction. The objective of this analysis was to assess the longer-term safety of TCZ in RA patients using pooled data from clinical trials (OPTION, TOWARD, RADIATE, AMBITION, and LITHE) and ongoing long-term extension studies.

Methods: Pooled analysis of patients who received ≥1 TCZ dose in the core or extension studies (GROWTH95 and GROWTH96) from initial exposure through August 28, 2009.

Results: A total of 4009 patients received TCZ with a median (mean) treatment duration of 3.1 (2.7) years and a total observation time of 10,994 patient-years (PY). The AE rate was 321.1/100 PY (95% CI: 317.8, 324.5); infections were the most frequent AE (70.7/100 PY). The SAE rate was 14.6/100 PY (95% CI: 13.9, 15.4); infections were the most frequent SAE (4.5/100 PY; 95% CI: 4.1, 4.9). Rates of SAEs and serious infections were stable over time (Table). The rate of deaths was 0.4/100 PY (95% CI: 0.3, 0.6). The rate of malignancies was 0.8/100 PY, excluding nonmelanoma skin cancer (NMSC); the rate of NMSC was 0.3/100 PY. The overall rate of malignancies did not exceed reported background rates (SEER database), and overall rates, including NMSC, have remained stable with continued TCZ therapy (Table). GI perforations, including potential occurrence of sequelae from GI perforations (eg, abscess, strictures), occurred at a rate of 2.6/1000 PY (95% CI: 1.8, 3.8); 59% (17/29) of these patients had colonic diverticular perforations. Preliminary epidemiologic data revealed that although the GI perforation rate was higher than in the general population, it was similar to rates in the RA population. Rates/100 PY of myocardial infarction and stroke were 0.3 (95% CI: 0.2, 0.4) and 0.2 (95% CI: 0.1, 0.3), respectively, were stable over time (Table), and did not exceed expected rates in the RA population (myocardial infarction, 0.3–0.8/100 PY; stroke, 0.5–0.7/100 PY). Eight patients experienced anaphylactic reactions and withdrew from the study. The rate of AEs leading to withdrawal was 5.4/100 PY; the most common AEs leading to withdrawal were laboratory abnormalities (1.2/100PY, primarily transaminase elevations), infections/infestations (1.0/100PY), and neoplasms (benign, malignant, or unspecified, 0.7/100PY).

Table. Event Rate Per 100 PY (95% CI) Over 12-Month Periods

	0–12	13–24	25–36	37–48
AEs	416.6 (409.8, 423.4)	296.5 (290.4, 302.7)	271.7 (265.4, 278.0)	250.7 (243.0, 258.5)
SAEs	15.7 (14.4, 17.1)	13.7 (12.4, 15.1)	15.1 (13.6, 16.6)	13.6 (11.8, 15.5)
Serious infections	4.6 (3.9, 5.4)	3.9 (3.2, 4.6)	5.1 (4.3, 6.1)	4.6 (3.6, 5.8)
Malignancies[a]	0.9 (0.6, 1.3)	1.1 (0.8, 1.5)	1.3 (0.9, 1.8)	1.4 (0.9, 2.1)
MI	0.3 (0.1, 0.5)	0.2 (0.1, 0.4)	0.3 (0.1, 0.5)	0.5 (0.2, 1.0)
Stroke	0.3 (0.1, 0.5)	0.1 (0.0, 0.3)	0.2 (0.1, 0.4)	0

[a]Including NMSC.

Conclusions: Rates of SAEs, serious infections, malignancies, and CV events have remained stable with continued exposure to TCZ. These results suggest that the longer-term safety profile of TCZ is not different from that established in the phase 3 studies.

Safety of Combination Therapies in Early RA: A Systematic Comparison between Combination DMARDs and TNF Inihibitors with Methotrexate. Margaret H. Y. Ma[2], Andrew P. Cope[1] and David L. Scott[2]. [1]Surrey, United Kingdom, [2]Academic Department of Rheumatology, King's College London

Background: The use of combination regimes plays a central role in the contemporary treatment of early Rheumatoid Arthritis. As these therapies become increasingly intensive and aggressive, drug toxicity is now a crucial issue. The aim of this study was to systematically evaluate the frequency and type of adverse effects associated with combination disease-modifying anti-rheumatic drugs (DMARDs) and tumour necrosis factor inhibitors (TNFi) combined with methotrexate (MTX) when compared with MTX monotherapy.

Methods: A systematic literature search of Cochrane Library, EMBASE, Pubmed and Ovid Medline identified 15 relevant RCTs from 1960 to March 2010. The following outcome measures were assessed: patient withdrawal due to toxicity, total adverse events, serious adverse events (total and by individual systems), nausea, malignancy and deaths. Review Manager 5 was used for meta-analysis.

Results: The preliminary search identified 459 citations. Out of these, seven RCTs compared combination DMARD therapies with MTX monotherapy, seven RCTs compared TNFi/MTX with MTX monotherapy and one RCT included both treatment arms. Table 1 shows the baseline characteristics of the trials.

Table 1. Trial Characteristics.

Malignancy	TNFi/MTX	5 [13, 21-23, 26]	8	1015	0.8	0-4	10	1122	0.9	0-4	1.15 (0.46, 2.93)	2.53	ns
	Combo DMARDs	5 [13, 14, 16, 17, 19]	7	388	1.8	0-5	4	393	1.0	0-2	0.58 (0.18, 1.89)	1.08	ns

However, the remaining outcomes (total numbers of adverse events, the number of serious infections, malignancies and deaths) did not differ significantly between the combination treatment arms and MTX monotherapy arms. Events in individual systems were rare and did not show major differences between groups.

Conclusion: Our systematic review showed that combination therapies using synthetic or biological agents increased patient withdrawals due to toxicity when compared to monotherapy. There were more serious adverse events using biologics with methotrexate whereas nausea was an issue for combination synthetic DMARDs. However, there were no significant differences in total numbers of adverse events, serious infections, malignancies and deaths. Events reported in individual system were too rare to draw definitive conclusions. Based on the available evidence, intensive therapies in early rheumatoid arthritis appear to be justified.

Scleritis: A New Paradoxical Effect of Etanercept? A Series of 3 Cases and a Systematic Literature Review of Etanercept-Associated Inflammatory Eye Disease. Cécile Gaujoux-Viala[1], Cecilia Giampietro[2], Thomas Gaujoux[3], Hang-Korng Ea[4], Philippe Orcel[4] and Frédéric Lioté[4]. [1]Paris 6 – Pierre et Marie Curie University; Rheumatology, Pitié-Salpêtrière Hospital, Paris, France, [2]Paris 6 – Pierre et Marie Curie University; Rheumatology, Pitié-Salpêtrière Hospital, Paris, France 2University of L'Aquila, L'Aquila, Italy, [3]Paris 7 University, Medicine Faculty; AP-HP, Lariboisière Hospital, Ophtalmology Department, Paris, France, [4]Paris Diderot University, School of Medicine; Lariboisière Hospital, AP-HP, Rheumatology Department, Paris, France

Background: The widespread use of TNFα antagonists has led to the recognition of paradoxical adverse effects, defined as the onset or exacerbation of disorders that are usually improved by TNFα antagonists. Cutaneous psoriasis, Crohn disease and uveitis exacerbations have been extended reported. Scleritis, a serious and sight threatening ocular inflammatory disease, has recently been described like another possible paradoxical event of anti-TNF-α and particulary of etanercept.

Objectives: 1) to report 3 cases of severe bilateral scleritis caused by administration of etanercept for rheumatoid arthritis, and 2) to review the literature related to inflammatory eye diseases associated with the use of etanercept.

Methods: 1) Three cases of severe bilateral scleritis during etanercept therapy were analyzed. 2) A systematic review of the literature in PUBMED, EMBASE, Cochrane library and hand search was performed until May 2010 using terms as etanercept, Enbrel, scleritis, uveitis, orbital myositis and inflammatory eye disease.

Results: 1) Three patients with seropositive rheumatoid arthritis developped for the first time during their long-lasting disease (disease duration: 9, 20 and 21 years), scleritis or sclero-uveitis 7–28 months after the initiation of etanercept. In all patients the underlying disease had well responded to anti-TNF alpha therapy. Ocular inflammation underwent remission after discontinuation of etanercept and no other relapses were observed. Interestingly, 1 patient experienced a worsening of symptoms after rechallenge of treatment and drug discontinuation led to rapid resolution.

2) 34 cases of inflammatory eye diseases believed to be associated with the use of etanercept have been reported in the literature: 26 uveitis, 7 scleritis, 1 orbital myositis, concerning 14 RA, 8 juvenile idiopathic arthritis, 10 ankylosing spondylitis and 2 psoriatic spondylarthropathy. Mean age of patients was 44.1 $\pm$ 13.7 years and 84.6% were women. The mean rheumatic disease duration was 11.8 $\pm$ 9.6 years. Regarding the time-to-onset, the average time between the beginning of etanercept therapy and the onset of symptoms was 12.3 $\pm$ 9.1 months, with exposure times ranging between 1 and 36 months. Dechallenge was performed in 19 patients, leading to resolution of symptoms. Rechallenge was done in 6 cases.

Conclusion: Ocular inflammation is paradoxically a potential adverse event of etanercept even in previously uninvolved eyes. Patients being treated with TNFα soluble receptors should be closely monitored for the development of ocular signs and symptoms in order to detect flares secondary to etanercept therapy and necessitating discontinuation.

Serious Infections with Ocrelizumab in Rheumatoid Arthritis: Pooled Results from Double-Blind periods of the Ocrelizumab phase III RA program. P Emery[1], W Rigby[2], PP Tak[3], T Dörner[4], MC Genovese[6], G Ferracioli[7], E Martin-Mola[8], M Dougados[9], H Travers[10], E Fisheleva,[10] W Dummer[11]. [1]Univ of Leeds, Leeds, United Kingdom; [2]Dartmouth, Lebanon, NH; [3]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands; [4]Charité Univ Hospital, Berlin, Germany; [5]Oklahoma Univ Health Sci Ctr, Oklahoma City, OK; [6]Standford Univ, Palo Alto, CA; [7]Catholic Univ, Rome, Italy; [8]La Paz Univ Hospital, Madrid, Spain; [9]Hopital Cochin, Paris, France; [10]Roche, Welwyn Garden City, United Kingdom; [11]Genentech, South San Francisco, CA

Purpose: Ocrelizumab (OCR), a novel humanized monoclonal antibody that selectively targets CD20+ B cells, has been studied in 4 phase III randomized clinical trials in different patient (pt) populations with active rheumatoid arthritis (RA). Here, we report safety data from the double-blind, placebo (PBO)-controlled (DBPC) periods in phase III studies.

Methods: The OCR RA program includes 4 randomized, DBPC globally conducted trials assessing the safety and efficacy of OCR given as 2 infusions of 200 mg or 500 mg (400 mg × 1 in FEATURE) every 6 months in combination with methotrexate (MTX) or leflunomide (LEF). STAGE studied OCR in combination with MTX vs MTX alone in pts with an inadequate response (IR) to MTX. SCRIPT included pts with an IR to at least one TNF inhibitor and was conducted in combination with either MTX or LEF. FEATURE investigated a single infusion regimen (400 mg) in pts who failed MTX and/or biologic DMARDs. FILM included pts who were MTX-naïve. Pooled safety data was analyzed for the DBPC periods of the RA phase III trials (48 wks in STAGE and SCRIPT, 52 wks in FILM, and 24 wks in FEATURE). Frequencies and rates (events per 100 pt-yrs) of serious infection events (SIEs) were assessed by dose and region. Pts who received either 200 mg × 2 or 400 mg × 1 were grouped together in pooled analyses.

Results: SIE rates in each treatment group of each study are shown in **Table**. Increased SIE rates were predominantly seen with OCR 500 mg × 2. Following pooling of the 4 studies by treatment group, the weighted difference from PBO in the number of pts with at least one SIE was calculated to be 0.6 (95% CI: −1.3 to 2.4) for OCR 200 mg × 2 and 2.4 (95% CI: 0.3 to 4.5) for OCR 500 mg × 2. Thus, statistically significant increases in the number of pts experiencing an SIE were only seen in the 500 mg group. In a sub-analysis of SIE rates in one year trials, pooled by dose and region (Asia vs Other), OCR pts in Asia had relatively higher rates compared to rates seen in pts from non-Asian (Other) regions (**Table**), although the imbalance was also seen in non-Asian regions vs PBO. There were 9 opportunistic infections in 9 pts in OCR-treated pts comprised of 2 de novo pulmonary tuberculosis, 1 Pneumocystis jiroveci suspected, 1 hepatitis B, 1 Mycobacterium kansasii infection, 1 esophageal candidiasis, 1 Varicella pneumonia, 1 histoplasmosis, 1 fungal pneumonia and there was one 1 Mycobacterium abscessus reported on PBO. None of these events resulted in death. No cases of PML were observed. 2 fatal infections (both pneumonias) occurred in the OCR 500-mg group in STAGE.

Conclusions: The pooled SIE rates were increased for OCR 500, but not OCR 200 compared to the PBO group in the DBPC periods with the imbalance primarily driven by rates in Asia. A detailed evaluation of risk factors for SIEs is underway. The same infection-related safety signal seen in the OCR high-dose has not been observed with rituximab.

Subsequent Therapy of Patients with Biologic Response Modifiers after a Diagnosis of Coccidiomycosis Infection. Sara Taroumian[3], Jeffrey R. Lisse[5], Eric P. Gall[5], Rafael G. Grau[5], Neil M. Ampel[2], Susan E. Hoover[4], James Yanes[4] and Berchman Vaz[1]. [1]Tucson, AZ, [2]Southern Arizona VA Health Care System, Tucson, AZ, [3]The University of Arizona Department of Internal Medicine, Tucson, AZ, [4]The University of Arizona Section of Infectious Diseases, Tucson, AZ, [5]The University of Arizona Section of Rheumatology, Arizona Arthritis Center, Tucson, AZ

Background: Coccidioides (cocci) are dimorphic fungi endemic to California, Arizona, New Mexico, Texas, Mexico, and Central and South America (1). Annually, approximately 100,000 people in the endemic areas of the United States are diagnosed (dx) with primary cocci (2). Chronic and disseminated disease may occur in up to 5% of patients (3); immunocompromised patients are very high risk.

Methods: A chart review of all patients seen at least once in a university-based outpatient rheumatology clinic in Tucson, AZ between 2007–2009 identified 298 patients who received biologic response modifiers (BRM), including anti-TNF drugs (TNF). Twenty four patients developed cocci during treatment with BRM. The review emphasized the mode of dx, clinical manifestations, antifungal treatments, the duration of treatment, and the course of action taken after the dx was made.

Results: Twenty four patients developed cocci during treatment. Prior to cocci dx, 3/24 patients were taking only cytotoxic agents and 2/24 were on unclear immunosuppressive agents. The following table summarizes the medications at the time of dx in the remaining patients.

Medications at the Time of Cocci Diagnosis:

Biologic Response Modifier (BRM)	BRM alone	Cytotoxic agent (one or two in combo with BRM) (Methotrexate, Leflunomide, Azathioprine)
Infliximab (Inf)	9/24	3/24
Etanercept (Etr)	1/24	3/24
Adalimumab (Ada)	0/24	3/24

Mode of Cocci Diagnosis	Pos serologies only (EIA)	Pos serol plus CXR/CT chest findings w/o pulm symptoms	Dissemination to skin, joint or lungs with pulm symptoms
Number of Patients	4/24	13/24	6/24

After the dx was made, all TNFs and DMARDs were held in 13/24 patients. 5/24 continued TNFs and/or DMARDs w/o any change in their regimen and 4/24 continued/started DMARDs but anti-TNFs were held. Two remaining patients had an unclear course of treatment after their cocci dx. Of the 13 patients in whom all TNFs and DMARDs were held, 11/13 were

restarted on either a DMARD alone or in combination with a TNF; 2 were not restarted. 17/24 patients had non-disseminated cocci. 4/17 were treated with Fluconazole (Fluc) until their cocci serol turned negative. 2/17 were lost to follow up. These patients continued to receive anti-TNFs w/o any cocci reactivation. 6/24 patients had severe cocci with dissemination to skin or joints. 5/6 patients will continue Fluc as long as they need to be treated w/ an immunosuppressive agent. Of all the patients reviewed in this study, 4/24 were found to have some evidence of cocci reactivation.

Conclusions: Despite clinicians' hesitation in treating a patient with BRM after dx of cocci, restarting BRM appears to be safe in some patients with non-disseminated disease. Patients with severe or disseminated disease who need to be treated with BRM most likely need to also continue treatment with an antifungal agent.

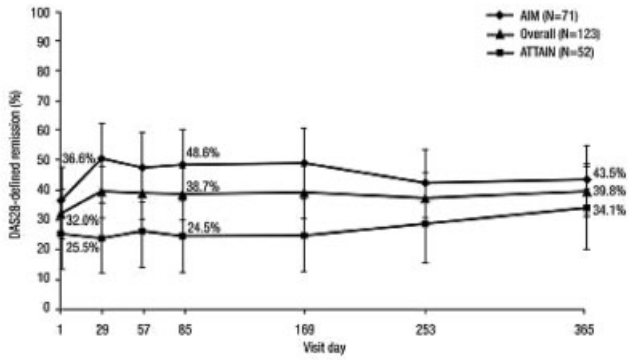
Switching Patients (pts) with Rheumatoid Arthritis (RA) from Intravenous (IV) to Subcutaneous (SC) Abatacept Is Well Tolerated and Sustains Previously Established Efficacy. Edward C. Keystone[9], Joel M. Kremer[6], Anthony S. Russell[7], Jane H. Box[1], Carlos Abud-Mendoza[5], Mario Alberto Garza Elizondo[4], Allison Luo[2], Richard Aranda[2], Ingrid Delaet[2], Rene Swanink[3], Sheila Gujrathi[2] and Michael E. Luggen[8]. [1]Box Arthritis and Rheumatology of the Carolinas, Charlotte, NC, [2]Bristol-Myers Squibb, Princeton, NJ, [3]Bristol-Myers Squibb, Braine-l'Alleud, Belgium, [4]Faculty of Medicine, Universidad Autónoma de Nuevo León, Monterrey, NL, Mexico, [5]Regional Unit of Rheumatology, Faculty of Medicine and Central Hospital, University of San Luis Potosí, San Luis Potosi, Mexico, [6]The Center for Rheumatology, Albany, NY, [7]University of Alberta, Edmonton, AB, Canada, [8]University of Cincinnati College of Medicine, Cincinnati, OH, [9]University of Toronto and Mount Sinai Hospital, Toronto, ON, Canada

Background: IV abatacept is effective and well tolerated in pts with RA[1,2]. For some pts, the flexibility and convenience of self-administered treatment is desirable. Here, we evaluate the safety, immunogenicity and maintenance of efficacy in pts who switched from long-term IV abatacept to SC abatacept formulation.

Methods: This was an open-label, single-arm trial. Consenting and eligible pts completing ~5 years of the AIM (Abatacept in Inadequate Responders to Methotrexate)[1] or ATTAIN (Abatacept Trial in Treatment of Anti-TNF INadequate Responders)[2] IV abatacept trials were enrolled and self-administered SC abatacept 125 mg/week via ready-to-use, prefilled syringes (no IV loading months, clinically indicated adjustments were allowed. Safety for the first 3 months administered). Initially, pts were maintained on the same stable doses of corticosteroids, DMARDs and analgesics received during the IV trials; after 3 after switching from IV abatacept was the primary endpoint, reported in all pts who received ≥1 dose of SC abatacept. Immunogenicity, reported up to Month 3, was assessed by ELISA and electrochemiluminesence (ECL). Proportions of pts achieving Low Disease Activity State (LDAS; DAS28 [CRP] ≤3.2) and DAS28-defined remission (DAS28 [CRP] <2.6) are reported over 1 year. Data are as-observed for patients with available data at the visit of interest.

Results: In total, 123 pts entered the study (AIM, n=71; ATTAIN, n=52); mean age was 54.3 years, mean DAS28 was 3.4 and mean tender and swollen joint counts were 8.9 and 4.8, respectively. At Month 3, 120 (97.6%) pts were ongoing; no pts discontinued due to lack of efficacy. By Month 3, adverse events (AEs) were reported in 49 (39.8%) pts overall. One pt (0.8%) discontinued due to an AE (musculoskeletal pain, unlikely related to treatment) and one pt (0.8%) experienced a serious AE (worsening RA, unrelated to treatment). Two (1.6%) pts had local injection site reactions (erythema, pain); both were mild in intensity. Overall, 8/122 (6.6%) pts had a positive abatacept-induced antibody response by ELISA; six of those eight had a positive response before enrollment. No pt had a positive response based on ECL. The proportions of pts (95% CI) achieving LDAS and remission was sustained after switching from IV to SC abatacept (N=123); LDAS: Day 1, 43.4% (34.6–52.2); Month 3, 54.6% (45.7–63.6); Year 1, 51.3% (42.1–60.5). Remission is shown in Figure 1.



Visit day	1	29	57	85	169	253	365
AIM, n	71	69	69	70	71	71	69
ATTAIN, n	51	50	49	49	48	45	44
Overall, n	122	119	118	119	119	116	113

Error bars represent 95% confidence intervals

Conclusions: These data demonstrate that switching pts from IV to SC abatacept is well tolerated, with few and mild local injection site reactions, and is associated with low immunogenicity. Furthermore, efficacy was sustained and not compromised following the switch.

The Effect on MTX Polyglutamate Concentration Profile after Changing from Oral to Subcutaneous Methotrexate in Rheumatoid Arthritis. Lisa K. Stamp[4], John L. O'Donnell[1], Peter Chapman[3], Mei Zhang[2], Jill James[3], Christopher Frampton[5] and Murray Barclay[5]. [1]Canterbury Health Laboratories, Christchurch, New Zealand, [2]Canterbury Health Laboratories, [3]Christchurch Hospital, [4]University of Otago, Christchurch, New Zealand, [5]University of Otago

Background: The pharmacokinetics of oral methotrexate (MTX) in RA have been described previously (1). Some patients may change from the oral to subcutaneous (SC) route of administration to try to reduce adverse effects or improve disease control. The aim of this study was to determine the effect of changing from oral to SC administration of MTX on the concentrations of red blood cell MTX polyglutamates (RBC $MTXGlu_n$).

Methods: Twenty-two patients on stable dose weekly oral MTX were changed to SC weekly MTX at the same dose. Trough RBC $MTXGlu_n$ concentrations were measured by HPLC in samples taken weekly until week 8, then fortnightly until week 16 and then 4-weekly until week 24. Median concentrations were fitted to a standard first-order exponential model with Graph Pad Prism 5.0.

Results: Of the 22 patients, 72.7% were female and mean age was 53.4 years (32–70). The mean duration of RA was 7.3 years (0.75 – 21). All patients were receiving 20mg MTX weekly followed by folic acid 5mg/week four days later. There were no dose changes during the study period.

RBC $MTXGlu_3$, $MTXGlu_4$, and $MTXGlu_5$ concentrations increased significantly from week 0 to week 24, by factors of 1.3, 1.9 and 2.6-fold respectively. However, there was no significant change in RBC $MTXGlu_1$ or $MTXGlu_2$ concentrations. There was a significant reduction in the proportion of RBC $MTXGlu_1$ and $MTXGlu_2$ and increase in the proportions of RBC $MTXGlu_3$, $MTXGlu_4$, $MTXGlu_5$ and $MTXGlu_{3-5}$ contributing to the total RBC MTXGlu from week 0 to week 24.

$MTXGlu_3$, $MTXGlu_4$, $MTXGlu_5$ and $MTXGlu_{3-5}$ concentrations fitted

the first-order exponential model well whilst $MTXGlu_1$ and $MTXGlu_2$ fitted poorly (Figure). The half-life of accumulation was 8.9 weeks for $MTXGlu_3$, 12.2 weeks for $MTXGlu_4$ and 9.9 weeks for $MTXGlu_5$ and 10.4 weeks for $MTXGlu_{3-5}$. The time to achieve 90% of steady state was 29.8 weeks for $MTXGlu_3$, 40.4 weeks for $MTXGlu_4$ and 33.2 weeks for $MTXGlu_5$ and 34.5 weeks for $MTXGlu_{3-5}$.

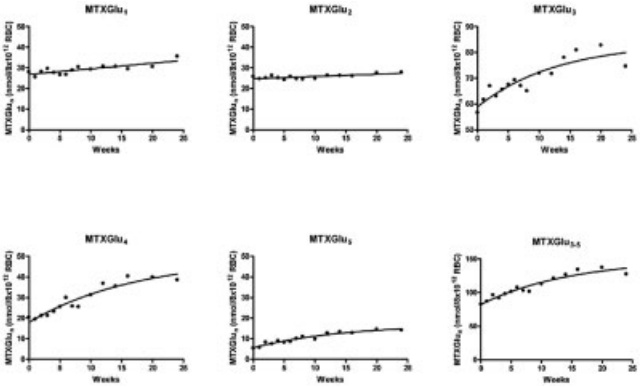

Figure 1. Median $MTXGlu_n$ concentrations and fitted curves over 24 weeks.

Conclusions: Changing from oral to SC MTX resulted in an alteration in the ratio of short and long chain MTX polyglutamates. It took at least 6 months for long chain MTX polyglutamates to reach 90% of steady state after changing to SC administration. However, the time to reach steady state was shorter than that observed in patients commencing oral MTX. Adequate time must be allowed to determine clinical response to a change in route of administration of MTX.

TNF Switch after Failure of One or More TNF Inhibitors—Results of an Observational Study. Katerina Chatzidionysiou[2] and Ronald Van Vollenhoven[1]. [1]Karolinska University Hospital, Stockholm, Sweden, [2]Karolinska University Hospital, Stockholm

Background: The optimal alternative treatment for those patients who fail an anti-TNF is not clearly described. The purpose of this study was to determine whether patients who had failed one or more anti-TNFs benefit from switching to another anti-TNF and whether the type of switch is significant.

Methods: The Stockholm registry ''STURE'' was used and treatment results at 3 and 6 months were analysed according to DAS28 reductions and EULAR responses by type of TNF switch, number of switches and reason for discontinuation (lack of efficacy or intolerance).

Results: 850 patients who had previously failed a TNF inhibitor switched to another biologic: 679 switched to an alternative TNF antagonist, 308 to etanercept, 294 to adalimumab and 77 to infliximab. By the end of 6 months statistically significant improvements in DAS28 were observed ($p<0.0001$ for etanercept and adalimumab and $p=0.006$ for infliximab). At 3 and 6 months significantly greater reductions in DAS28 were observed for etanercept compared to the anti-TNF monoclonal antibodies taken together (1.56 ± 1.34 vs. 1.14 ± 1.26, $p=0.005$ and 1.58 ± 1.46 vs. 1.15 ± 1.4, $p=0.01$, respectively). At 6 months the percentage of EULAR good/moderate/no responders was 16.6/38.7/44.7 for the anti-TNF monoclonal antibodies and 29.4/35.3/35.3 for etanercept ($p=0.009$). Table 1 summarizes the response to therapy according to the type of switch. The difference between etanercept and monoclonal antibodies was observed both for the second and the third switch. At 6 months the subgroup of patients who discontinued previous anti-TNF monoclonal antibody for reason of loss of efficacy achieved significantly better results when switched to etanercept than when switched to an alternative antibody (ΔDAS28 2.11 ± 1.5 vs. 1.09 ± 1.43, $p=0.008$).

Table 1. Response to therapy with an alternative TNF inhibitor (monoclonal antibody or soluble TNF receptor) according to DAS28 reductions and EULAR response during the first 6 months.

	TNF monoclonal ab ↓ TNF monoclonal ab	TNF monoclonal ab ↓ Etanercept	Etanercept ↓ TNF monoclonal ab
ΔDAS28 at 3 months	1.15 ± 1.51	1.56 ± 1.33	1.15 ± 1.12
ΔDAS28 at 6 months	1.24 ± 1.5	1.57 ± 1.45	1.22 ± 1.25
EULAR Good response	20.9%	29.4%	15.4%
EULAR Moderate response	29.8%	35.3%	41.9%
EULAR No response	49.3%	35.3%	42.7%

Conclusion: In this observational cohort patients having failed anti-TNF therapy do benefit from switching to other TNF inhibitors. Better results were observed when switching from a TNF monoclonal antibody to etanercept rather than to an alternative antibody, especially when the reason for failure of the first was loss of efficacy.

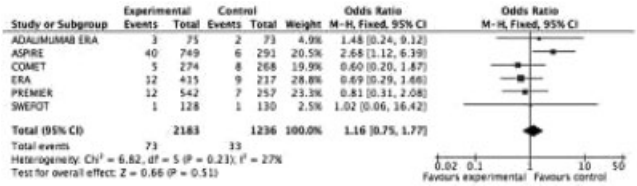
TNF Therapy and the Risk of Serious Infection and Malignancy in Patients with Early Rheumatoid Arthritis: A Meta-Analysis of Randomized Controlled Trials. Andrew E. Thompson[2], Janet E. Pope[1] and Scott W. Rieder[3]. [1]St Joseph Health Care London, London, ON, Canada, [2]University of Western Ontario, London, ON, Canada, [3]University of Western Ontario

Background: The efficacy of TNF-inhibition has been shown in numerous trials including patients with both early and established rheumatoid arthritis (RA). As a result, TNF-inhibition has significantly improved the signs and symptoms, function, radiographic progression and quality of life for patients with RA. The most important side effects of TNF-inhibition are the risks of serious infection and the potential for malignancy. Although product monographs include warnings & precautions about these side effects they do not provide an estimate of risk. Meta-analysis of published clinical trial data and registry data are common methodologies used to estimate this risk. However, the challenge with current meta-analytic data and on-going registry data is the inclusion of heterogeneous populations with varying degrees of co-morbidity. This heterogeneity makes it very difficult to understand and communicate risk for individual patients. It is important to know if early RA has the same risk of serious infection or malignancy compared with older patients with long-standing RA and multiple co-morbidities.

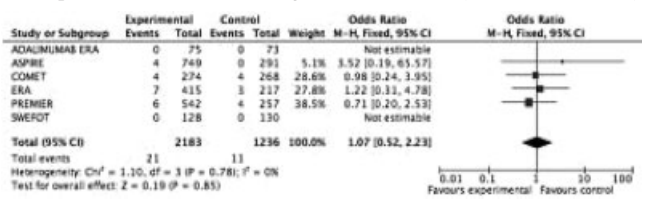
Objective: To conduct a meta-analysis of the rates of serious infection and malignancy in patients with early rheumatoid arthritis who have were started on anti-TNF therapy and were naïve to DMARD/Methotrexate therapy.

Methods: A systematic literature search was conducted through the summer of 2009. All studies included were randomized, double-blind, placebo-controlled of patients with early rheumatoid arthritis who were started on anti-TNF therapy without prior DMARD/Methotrexate use. Six trials met our inclusion criteria that included 2183 patients receiving biologic therapy and 1236 patients receiving control therapy. All data extracted was from published trials.

Results: A pooled odds ratio (Mantel-Haenszel methods with a continuity correction designed for sparse data) was calculated for serious infections (requiring hospitalization) and malignancies. The pooled odds ratio for serious infections was 1.16 (95% CI, 0.75–1.77).



The pooled odds ratio for malignancies was 1.07 (95% CI, 0.52–2.23).



There was no significant difference between the anti-TNF therapy and the control therapy in both serious infection rates and malignancy rates.

Conclusions: While other meta-analyses have shown an increased risk of serious infection and malignancy in patients taking anti-TNF therapy, our results show that there is not an increased risk when the patients have early disease and haven't previously failed DMARD/Methotrexate therapy.

Treatment with Infliximab Improves Clinical Response and Physical Function in Patients with Moderate or Severe Rheumatoid Arthritis Actively Switch from Etanercept or Adalimumab Therapy. Roy M. Fleischmann[8], John A. Goldman[2], Marjatta Leirisalo-Repo[4], Ellen I. Zanetakis[7], Hisham S. El-Kadi[1], Herbert L. Kellner[6], Rebecca Bolce[3], Jim Wang[5], Raphael Dehoratius[3] and Dennis Decktor[3]. [1]Arthritis and Osteoporosis Association, Freehold, NJ, [2]Atlanta Center for Clinical Research, [3]Centocor Ortho Biotech Services, LLC, [4]Helsinki University Central Hospital, Helsinki, Finland, [5]Johnson and Johnson Pharmaceutical Research and Development, LLC, [6]Medizinische Poliklinik/Munich University Hospital, Munchen, Germany, [7]Oklahoma Center for Arthritis Therapy, Tulsa, OK, [8]University of Texas SW Medical Center, Dallas, TX

Background: Anecdotal evidence suggests that RA pts with active disease, despite tx with SC TNFα inhibitors, respond to infliximab (IFX). The dosing flexibility described in the IFX prescribing information allows for the tx of continued active disease by adjusting dose for achievement of specific targeted clinical outcomes.

Purpose: To evaluate the safety & efficacy of IFX in RA pts with moderate or severe RA despite tx with etanercept (ETN) or adalimumab (ADA).

Methods: This is a Phase 4, multicenter, open-label, assessor-blinded, active switch study of IFX in pts with active RA who received MTX and had inadequate response (DAS28 score $\geq$ 3.6 and $\geq$ 6 swollen and $\geq$ 6 tender joints) to ETN or ADA. Pts were on stable dose of $\geq$ 7.5 mg/wk of MTX for $\geq$4 wks prior to screening. Pts receiving ETN were switched no less than 1 wk and no more than 2 wks after the last dose; pts receiving ADA were switched no less than 2 wks and no more than 4wks after the last dose. Pts received open-label 3 mg/kg IFX infusions at wks 0, 2, and 6. Pts who either achieved/maintained EULAR response at wks 14 or 22 remained on current IFX dose. IFX dose was increased by 2 mg/kg for pts who did not achieve/lost response. EULAR response was evaluated at wk 10 post induction (primary endpoint) and following incremental increases in IFX dose in pts not adequately responding to the initial IFX doses. Physical function was assessed using HAQ.

Results: Of the 203 pts enrolled, data for 197 were evaluable. 60.9% and 39.1% of pts were previously treated with ETN or ADA, respectively. Baseline demographics were reported previously.[1] EULAR response was achieved by 49.7% of pts at wk 10 (55.6%, per protocol analysis) and 51.8% at wk 26 (61%, per protocol analysis) with/without dose adjustment. Among pts responsive to 3mg/kg induction dose, 45% maintained response through wk 26. ACR 20, 50, and 70 responses were achieved in 28.4%, 12.2 %, and 1.5% of pts at wk 10, respectively. These responses improved to 35.5% (ACR20), 18.3% (ACR50), and 7.1% (ACR70) at wk 26. Mean CDAI and SDAI were 40.1 and 41.2, respectively, at baseline and significantly improved to 21.45 ($p< 0.001$) and 22.28 ($p<0.001$), respectively, at wk 26. 48.3% of pts previously treated with ETN and 57.1% of pts previously treated with ADA achieved a EULAR response at wk 26. Changes from baseline at wk 10 and 26 in DAS 28, HAQ, SJC, and TJC are described (Table). At least 1 AE and serious AE were reported in 70.4% and 4.9% of pts, respectively; 6.9% of pts experienced at least 1 infusion reaction (1.6% of infusions were associated with an infusion reaction).

Conclusion: RA pts actively switched from tx with ETN or ADA to IFX, without a washout period, demonstrated a statistically significant and clinically important improvement in EULAR response and physical function. IFX was generally well-tolerated with no new safety signals observed.

Table. Summary of mean (SD) change from baseline at wks 10 and 26

	Baseline	Change from baseline to wk 10	Change from baseline to wk 26
DAS28 (ESR)	6.193 (0.981)	−1.076 (1.146)*	−1.468 (1.437)*
DAS28 (CRP)	5.701 (0.896)	−1.088 (1.090)*	−1.436 (1.312)*
HAQ improvement	1.334 (0.577)	−0.173 (0.455)*	−0.223 (0.497)*
SJC	17.335 (10.537)	−6.960 (10.686)*	−8.283 (11.380)*
TJC	30.188 (16.893)	−10.460 (14.067)*	−13.197 (14.304)*

Varicella Zoster Virus (VZV) Infections Are Increased in Patients with Rheumatoid Arthritis (RA) Treated with Anti-TNF Therapy; Results from the British Society for Rheumatology Biologics Register (BSRBR). James Galloway[1], Alison Moseley[2], Lousie Mercer[2], Will Dixon[2], Bo Fu[2], Andrew Ustianowski[2], Kath Watson[2], Mark Lunt[2], BSRBR Control Centre Consortium[2], Kimme Hyrich[2], Deborah Symmons[2] and on Behalf of the British Society for Rheumatology Biologics Register[2]. [1]University of Manchester, Manchester, United Kingdom, [2]University of Manchester

Introduction: VZV infection is highly prevalent with 95% of adults showing seropositivity. The initial infection typically occurs in childhood causing chicken pox. Reactivation later in life results in herpes zoster (shingles). The immune defence against both chicken pox and herpes zoster is T-cell mediated. Anti-TNF therapy interacts with this pathway and hence theoretically predisposes to VZV associated disease. The aim of this study was to compare rates of herpes zoster in rheumatoid arthritis (RA) patients treated with anti-TNF agents or non-biologic disease modifying anti-rheumatic drugs (DMARDs); and to compare the rates for the individual anti-TNF agents.

Methods: The BSRBR was established in 2001 to evaluate the safety of anti-TNF therapies etanercept (ETN), infliximab (INF) and adalimumab (ADA) in patients with RA. The anti-TNF treated cohort was recruited alongside a comparator group with active disease (DAS28 >4.2) treated with DMARDs. Patients were recruited between 01/10/2001 and 30/06/2008 and followed up by consultant and patient questionnaires. For this analysis patients were followed until the first episode of herpes zoster infection, death or 31/12/2009, whichever came first. An infection was attributed to anti-TNF if diagnosed while the patient was actively receiving the drug (up to the date of the first missed dose). A Cox proportional hazards model was used to compare rates between cohorts and adjustment was made for differences in baseline characteristics including age, gender, disease severity, disease duration, baseline steroid exposure and co-morbidity using an inverse probability of treatment weighting propensity model.

Results: (see table)

Three hundred and twenty two herpes zoster infections occurred in the anti-TNF cohort: IR 7.8/1000 (pyrs) (95% CI 7.0, 8.7) and 46 in the DMARD cohort (IR 4.0/1000 pyrs (95% CI 3.0, 5.4) (Table). The adjusted hazard ratio for herpes zoster was 2.2 (95% CI 1.4, 3.6). A greater proportion of the cases in the anti-TNF cohort were severe (defined as herpes zoster being a primary reason for hospitalisation, requiring intravenous antivirals or being multidermatomal) 6% vs 0.02%. A similar pattern of risk was seen for each anti-TNF therapy with no statistical difference between etanercept and the monoclonal antibodies. In total, 12 cases of chicken pox infection were reported in the anti-TNF cohort and none in the DMARD cohort.

Conclusion: Anti-TNF therapy is associated with a significantly increased risk of VZV associated disease. This information would support the evaluation of VZV vaccination in an RA population.

Table. Baseline characteristics and incidence of VZV infections

	DMARD	All anti-TNF	ETN	INF	ADA
Subjects, n	3,666	11,864	4,136	3,472	4,256
Mean age, years (SD)	60 (12)	56 (12)	56 (12)	56 (12)	57 (12)
Female gender, (%)	2648 (72)	9038 (76)	3190 (77)	2624 (76)	3224 (76)
Disease Duration: years, median (IQR)	6 (1–15)	11 (6–19)	12 (6–19)	12 (6–19)	10 (5–18)
Baseline steroid use: n (%)	834 (23)	5243 (44)	1977 (48)	1609 (46)	1657 (39)

Altered microRNA Expression in the Murine Tri-Congenic B6.Sle123 Model. Barry Garchow[1], Yiu Tak Leung[3], Roberto Caricchio[2] and Marianthi Kiriakidou[1]. [1]Department of Medicine, University of Pennsylvania School of Medicine, Philadelphia, PA, [2]Temple Univ Med Office Bldg, Philadelphia, PA, [3]Thomas Jefferson University Hospital, Philadelphia, PA

Statement of Purpose: microRNAs (miRNAs) have emerged over the last decade as a conserved class of non-coding RNAs that regulate gene expression. Current evidence supports a key role for miRNAs in the development and function of the immune system and emerging evidence underscores the importance of this pathway in autoimmunity. However, the expression and function of miRNAs in SLE and the signaling pathways regulated by miRNAs in lupus remain largely unknown.

Research in our laboratory focuses on the function of miRNAs in the tri-congenic mouse model B6.Sle123. Autoimmune disease in B6.Sle123 is characterized by autoantibodies, lymphosplenomegaly and glomerulonephritis, strongly resembling human lupus. We studied miRNA expression in mouse lupus B and T cells over the course of twelve months; before manifestation of renal disease and as it progresses from mild proteinuria to fatal nephrotic syndrome.

Methods: Mice (B6.Sle123 and C57BL6/J) were sacrificed at 2, 6 and 12 months of age and their spleens harvested. Splenocytes from individual mice were FACS purified into CD19+, CD3+CD44lowCD62Lhigh and CD3+CD44lowCD62Lhigh cell populations. For quantitative real-time PCR, total RNA from purified cells was reverse-transcribed using microRNA specific stem-loop primers. RT products were amplified by real-time PCR. Fold expression differences were calculated using the ΔΔCt method. For Northern blotting, total RNA from purified cells was separated on 15% urea-polyacrylamide gels, blotted and UV crosslinked. microRNAs were visualized by autoradiography and quantitated using the GelQuant software. For Western blotting, total protein from purified cells were separated by PAGE and blotted on nitrocellulose membranes. Bands were visualized by chemiluminescence and quantitated with ImageJ software.

Data Summary: We asked if altered microRNA expression in B6.Sle123 B and T lymphocytes correlates severity of renal disease. Here we report that several microRNAs are differentially expressed in B and T lymphocytes from lupus mice and their expression correlates with the severity of lupus nephritis. All eight miRNAs that we showed as upregulated in B cells from mice with severe SLE nephritis (miR-21, 34a, 221, 222, 223, 155 and 142-5p) and have been also recently reported as upregulated in human lupus nephritis.

Conclusions: Our findings show that several microRNAs with known key roles in the development and function of lymphocytes are differentially expressed in B6.Sle123 derived B and T cells and their expression correlates with the severity of renal disease. Correlation of our results with recently published data of miRNA expression in PBMCs from patients with lupus nephritis indicates that B6.Sle123 is a suitable model to study the miRNA function in lupus. We are now focusing on identifying miRNA-dependent signaling pathways that are uniquely affected in this model, in which disease manifestations and disordered mechanisms overlap with those in human SLE. In our studies we employ novel in vivo experimental methods to knock down endogenous miRNAs in B and T cells in order to dissect these pathways.

Amelioration of Lupus Nephritis by a Macromolecular Prodrug of Dexamethasone in NZB/W F1 Mice. Fang Yuan[2], Richard K. Nelson[2], Xin-ming Liu[2], Karen A. Gould[2] and Dong Wang[1]. [1]Univ Nebraska Med Ctr, Omaha, NE, [2]University of Nebraska Medical Center

Purpose: Though developed with specific molecular targets, most lupus nephritis drugs do not have tissue specificity to renal inflammation sites, leading to limited efficacy and potentially severe systemic side effects. To address this problem, we propose to develop P-Dex, a macromolecular prodrug of dexamethasone (Dex) using N-(2-hydroxypropyl)methacrylamide (HPMA) copolymer, which would specifically target the kidneys of lupus nephritis subjects to improve efficacy and reduce systemic toxcities associated with Dex phosphate treatment.

Methods: Female NZB/W F1 lupus-prone mice (16-wk-old) were treated with Dex phosphate (1.32 mg/kg, daily i.p. injections for 8 wks) and P-Dex (250 mg/kg, monthly i.v. injections for 8 wks) with HPMA homopolymer (PHPMA) and saline as controls. The overall doses of P-Dex and Dex phosphate are equivalent in terms of Dex content. Albuminuria was measured weekly using Ablustix. Mean arterial pressure (MAP) was measured by the tail cuff method every 4 wks. Serum was isolated from blood collected from the saphenous vein every 4 wks. Mice were sacrificed 1 wk after cessation of treatment (wk 9). Kidneys were harvested for histological assessment of nephritis. Femurs were harvested for bone mineral density (BMD) analysis.

Results: P-Dex treatment of NZB/W F1 mice resulted in an attenuated onset of nephritis (as measured by durable albuminuria $\geq$ 2 or 100 mg/dL). At wk 9, the incidence of albuminuria was 0% in the P-Dex group, whereas the incidence of albuminuria was 100% in saline treated group, 70 % in PHPMA group and 46.7% in Dex phosphate group ($p<0.001$). A significant improvement of hypertension (MAP was reduced from 134 ± 16 mmHg to 110 ± 11 mmHg, $p < 0.01$) was only found in P-Dex treated group. Furthermore, the P-Dex treated group had a significantly higher femur BMD value than the Dex phosphate group ($p < 0.001$). No significant difference in BMD value was found among the P-Dex, saline and PHPMA groups.

Conclusion: P-Dex displayed highly efficient attenuation of lupus nephritis and improved renal function, compared to the treatment with equivalent dose Dex phosphate. It also significantly reduced the bone loss caused by long-term Dex phosphate treatment. Collectively, these data suggest that the macromolecular prodrug of dexamethasone could provide more effective amelioration of lupus nephritis with reduced systemic toxicity.

An Intrinsic B Cell Defect That Affects Toll-Like Receptor Signaling Supports Autoimmunity in New Zealand Black Chromosome 13 Congenic Mice. Christina Loh[2], Evelyn Pau[3], Nan-Hua Chang[1] and Joan E. Wither[2]. [1]University Health Network, [2]University of Toronto, Toronto, ON, Canada, [3]University of Toronto

Purpose: Introgression of a New Zealand Black (NZB) chromosome 13 interval onto the B6 background (denoted, c13) is sufficient to produce many of the hallmarks of lupus, including, high titre anti-chromatin antibody (Ab) production, abnormal B and T cell activation, and renal disease. In this study we sought to characterize the immune defects leading to these pathogenic abnormalities.

Methods: Bone marrow (BM) chimeras were generated by reconstituting lethally irradiated B6, B6.Thy1aIgHa, or B6.CD45.1 mice with B6, B6.Thy1aIgHa, B6.CD45.1, c13, c13.Ig, or various mixtures of BM cells.

Anti-hen egg lysozyme (HEL) immunoglobulin (Ig) and/or soluble HEL transgenes (Tg) were crossed onto the c13 mouse strain (denoted, c13.Ig and c13.Ig.sHEL) to assess B cell tolerance. Antibody production was measured by ELISA and splenic cellular profiles were examined by flow cytometry. For Toll-like receptor (TLR) stimulation, splenocytes from 10–14 week old B6, c13, B6.Ig, or c13.Ig mice were cultured in the presence of poly(I:C) (TLR3), imiquimod (TLR7), or ODN1826 (TLR9) and/or HEL for 72 hrs. Proliferation was measured by CFSE dilution.

Results: Serologic and cellular characterization of hematopoietic radiation chimeras and anti-HEL Ig transgenic mice revealed that the autoimmune phenotype in c13 mice could be transferred by BM cells. Assessment of mixed hematopoietic chimeric and c13.Ig mice indicated that autoreactive congenic B cells were required for disease initiation. Examination of c13.Ig.sHEL mice, a classic model of B cell anergy, revealed that B cell anergy was intact in congenic mice. However, there was enhanced selection and/or survival of endogenous B cells resulting in high titer anti-chromatin and -Sm/RNP antibody production in these mice. Given the preferential generation of anti-nuclear over anti-HEL antibodies, we examined whether nucleic-acid sensing TLR signaling was altered in these mice. Congenic B cells were hyper-responsive to the TLR3 ligand, polyinosine-polycytidylic acid (poly(I:C)), a double stranded RNA analogue, demonstrating enhanced proliferation, survival, and induction of intracellular TLR3 expression as compared to control B cells. Using mixed cell cultures, this response was found to be intrinsic to congenic B cells.

Conclusions: An intrinsic defect affecting self-reactive B cell selection and/or function that is associated with TLR3-hyper-responsiveness is required for initiation of autoimmunity in NZB chromosome 13 congenic mice.

Breach of B Cell Tolerance in New Zealand Black Chromosome 1 Congenic Mice. Nan-Hua Chang[1], Evelyn Pau[3], Christina Loh[3] and Joan E. Wither[2]. [1]Toronto Western Research Institute, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada, [3]University of Toronto

Purpose: The production of anti-nuclear antibodies in lupus indicates a breach of B cell tolerance, however the precise defects that lead to this breach are unknown. Our laboratory has produced C57BL/6 (B6) congenic mice with homozygous NZB chromosome 1 intervals and localized the genetic locus leading to autoantibody production in these mice to a 96–100 cM interval, which contains *Nba2*. In this study we have backcrossed anti-hen egg white lysozyme (HEL) Ig and soluble HEL transgenes (double Tg, dTg) onto the B6.NZBc1(96–100 cM) background to assess B cell anergy.

Methods: Serum IgM and IgG anti-HEL antibody production was measured by ELISA. Splenic B cell populations were characterized by flow cytometry. Upregulation of CD86 and B cell apoptosis was determined by flow cytometry following stimulation of splenocytes with anti-IgM $F(ab)'_2$ Ab or HEL for 18 hrs. To quantify phosphatidylinositol 3,4,5,-triphosphate production ($PI(3,4,5)P_3$), splenocytes were stimulated with anti-IgM $F(ab)'_2$ Ab for 5 min, fixed with 1% paraformaldehyde, stained intracellularly with an anti-$PI(3,4,5)P_3$ Ab. Calcium flux was measured by stimulating Indo-1-labeled immature anti-HEL Ig Tg B cells (generated by culturing bone marrow in IL-7 for 5 days) with anti-IgM $F(ab)'_2$ Ab.

Results: B6.NZBc1(96–100 cM) dTg B cells produced increased levels of IgM and IgG anti-HEL Abs indicating a breach of B cell anergy in these mice. IgM^a down-regulation and the proportion of T1, T2, follicular and marginal zone B cells were similar in B6 and B6.NZBc1(96–100 cM) dTg mice, however B6.NZBc1(96–100 cM) dTg mice had an increased proportion of IgM^a B cells expressing edited Ig-lambda light chains. Following stimulation with anti-IgM Ab or sHEL, B cells from B6.NZBc1(96–100cM) dTg mice demonstrated enhanced up-regulation of CD86 and decreased apoptosis, suggesting defective anergy induction. To gain further insight into the mechanism leading to this defect, upregulation of $PI(3,4,5)P_3$ was contrasted in B6 and B6.NZBc1(96–100 cM) dTg B cells following Ig receptor cross-linking. B6.NZBc1(96–100 cM) dTg B cells demonstrated enhanced generation of $PI(3,4,5)P_3$, indicating that altered B cell signaling leads to the B cell anergy defect. Consistent with this possibility, calcium mobilization was impaired in naïve immature anti-HEL Ig Tg B cells from B6.NZBc1(96–100cM) mice following Ig receptor cross-linking

Conclusion: Our findings demonstrate that genetic loci within the NZB chromosome 1 (96–100 cM) interval lead a breach of B cell anergy.

Dysfunction of Hematopoietic Stem Cells in Lupus Mice. Haitao Niu[2], Luokun Xie[3], Laurence Marguerite Morel[4], Betty Diamond[1] and Yong-rui Zou[3]. [1]Feinstein Institute for Medical Research, Manhasset, NY, [2]The Feinstein Institute for Medical Research, Manhasset, NY, [3]The Feinstein Institute for Medical Research, [4]University of Florida

Background: Systemic lupus erythematosus (SLE) is a multi-organ autoimmune disorder. Among the various clinical manifestations of SLE, leukopenia and lymphopenia represent the most prevalent initial abnormality, and are associated with higher disease activity. The specific cause of leukopenia and lymphopenia in SLE is unknown. Conceivably, the chronic inflammatory milieu may impair the maturation and survival of hematopoietic cells. Alternatively, hematopoietic stem cells (HSCs) of SLE patients may be functionally defective, thereby resulting in poor hematopoietic regeneration. We investigated whether HSC function is impaired in a mouse model of SLE, and whether the change in HSC function is a cell-intrinsic event or affected by the microenvironment of SLE.

Materials and Methods: We determined whether HSCs undergo functional changes in B6.Sle1.2.3 triple congenic (TC) mice. TC mice are C57/BL6 mice that carry three NZM2410-derived major lupus susceptibility loci and develop severe systemic autoimmunity and fatal nephritis. 7-month-old TC female mice with high levels of autoantibodies and proteinuria were selected for the studies. B6 female mice were used as controls. *First, we examined whether the pool size of HSCs was changed in TC mice.* We determined the HCS cellularity in the bone marrow (BM) by flow cytometry. Primitive hematopoietic cells were detected with antibodies for lineage negative (Lin^-: B220, CD3, CD4, CD8, CD11b, Gr1, TER119) and $c\text{-}Kit^+$ and $Sca\text{-}1^+$ (referred to as LSK cells). Long-term reconstituting HSCs (LT-HSCs) were further identified as $CD48^-$ $CD34^-CD150^+$ LSK cells. *Second, we examined whether the pathological microenvironment of lupus mice alters HSC quiescence* by measuring the cell-cycle status of HSCs based on their content of pyronin stained RNA and Hoechst stained DNA. *Third, we examined whether HSC localization was altered in lupus mice* by determining the HSC frequency in the periphery. *Lastly, we analyzed HSC function by transplantation assays.* To do so, 2×10^6 BM cells from TC or control C57/BL6 mice ($CD45.2^+$) were transferred into irradiated B6.SJL mice ($CD45.1^+$). Four months later, hematopoietic reconstitution was determined by the frequencies of donor derived ($CD45.2^+$) HSCs, lymphocytes and myeloid lineage cells.

Results: We found that LT-HSCs were 4-fold more abundant in the BM of TC mice than that in control mice. This expansion of the HSC compartment was accompanied by an increase in the number of cycling HSCs in the BM and mobilization of HSCs in the periphery in TC mice. More importantly, HSCs from TC mice transplanted into healthy recipients displayed altered HSC function, indicating a cell-intrinsic defect. Finally, we found that HSCs from TC mice showed a bias towards differentiation into the myeloid versus the lymphoid lineage.

Conclusion: Our data demonstrate that HSC function is altered in lupus mice through a cell-autonomous process. The dysfunction of HSCs in lupus mice may contribute to lymphopenia observed in SLE patients. These results highlight the importance of restoring HSC function for lupus therapy.

Engraftment of PBMC from SLEand ACL Donors into BALB-Rag2−/− IL2Rgc-KO Mice: A Promising Model for Studying SLE. Danieli Andrade[1], Milena Vukelic[2], Patricia B. Redecha[1], Xiaoping Qing[1], Giorgio Perino[3], Jane E. Salmon[2] and Gloria C. Koo[4]. [1]Hospital for Special Surgery, NY, NY, [2]Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgry, NY, NY, [4]Hospital for Speicail Surgery, New York, NY

Purpose: Our goal was to construct a SLE mouse model that resembles the human disease and has human cells which may be studied to define pathophysiology and targeted for treatments.

Methods: We infused peripheral blood mononuclear cells (PBMC) from SLE patients into the severe combined immuno-deficient mouse, BALB-Rag2 −/− IL2Rgc −/− mice (DKO), which lack T, B and NK cells. PBMC from 5 SLE patients (5 anti-dsDNA positive and 2 of these were ACL positive) and 4 normal donors (ND) at 3–5 ×106/mouse were infused IV and IP to non- irradiated 4–5 weeks old DKO mice, 2–5 DKO mice/donor. We evaluated the engraftment of human CD45+ cells and lymphocyte subsets.

We monitored the plasma human IgG concentration, anti-dsDNA antibody, anti-cardiolipin (CL) antibody, proteinuria, and performed histologic examination of the liver and kidney.

Results: We found 100% engraftment of human PBMC in 38 DKO mice studied. In both SLE-DKO and ND-DKO mice, we found 5–10% human CD45+ cells in the PBMC fraction 2 weeks post engraftment, and these cells expanded to 50–80% at 4–6 weeks. PBMC from both SLE-DKO and ND-DKO mice contained 70–90% human CD3+ cells. In SLE-DKO mice, as reported in SLE patients, there were fewer CD3+4+cells (5.1±1.9 %) and more CD3+8+ cells (81.6± 3.9 %), significantly different from that in ND-DKO mice, which had normal distribution of CD3+CD4+ (66.2 ±2.5 %) and CD3+8+ (16.5 ± 2.1%) cells in the PBMC (SLE-DKO vs. ND-DKO: P<1.3E-08 for CD4+, P< 2.1E-07 for CD8+ populations). CD19+ B cells were present mainly in the peritoneum and bone marrow, and CD11c cells were found in the spleen. Human CD45+ cells, assessed by FACS analyses, were also present in the lung, liver, and kidney. There was no significant difference in plasma human IgG levels between SLE-DKO and ND-DKO mice (32.3 ±13 and 26.4 ±7 ug/ml, respectively). Anti-dsDNA antibodies were found in SLE-DKO mice (3.97 ± 1.6 IU/ml) and lower in ND-DKO mice (2.2 ± 0.7 IU/ml, DKO=1 ± 0.02), but not significantly different between the 2 groups (P<0.25). Strikingly, levels of ACL antibody were higher in all SLE-DKO mice infused with cells from an ACL positive patient (SLE-DKO, 8.5 ±1.4 vs ND-DKO, 3.6 ± 0.2 GCL-U; P<0.019, un-engrafted DKO, 3.6 ± 0.8 GCL-U). SLE-DKO mice had evidence of nephritis. After 4–6 weeks of engraftment, they had proteinuria, (SLE-DKO: 93.5 ± 25 ug/mg; ND-DKO: 22 ± 3.3 ug/mg albumin/creatinine; P<0.01; un-engrafted DKO:17.8 ug/mg). Kidney sections showed human IgG deposits. In SLE- DKO mice engrafted with PBMC from an ACL-positive patient, we found micro-thrombi in the glomeruli of the kidney, and the liver showed fibrosis and necrosis. By 4–5 weeks after engraftment, 50% of the SLE-DKO mice died, whereas ND-DKO lived >7 weeks (SLE-DKO vs ND-DKO, P<0.04).

Conclusion: We have created a novel humanized SLE-DKO mouse that exhibits many characteristics of immunologic and clinical features of SLE. Importantly, we recapitulated clinical manifestations of APS in mice infused with PBMC from an ACL-positive patient. The SLE - DKO mouse promises to be an excellent model to study the pathophysiology of SLE and test human-specific therapies. Supported in part by NIH fund, R01 AR03889 and CNPQ 200591/2008-8.

Enhancement of IL-17 and Interferon-gamma Inflammatory Pathways in IRF9$^{-/-}$ MRL/*lpr* Mice with Disrupted Type I Interferon Signaling. Alvina D. Chu[2], Nicole H. Kattah[3], Michael T. Wong[3], Catherine Tadina[3] and Paul J. Utz[1]. [1]Stanford Univ Schl of Med, Stanford, CA, [2]Stanford University School of Medicine, Palo Alto, CA, [3]Stanford University School of Medicine

Purpose: Multiple inflammatory pathways have been implicated in the pathogenesis of systemic lupus erythematosus (SLE) including those involving type I interferons (IFNs), IFN-gamma, and IL-17. The development of an IFN gene signature, isotype-switched autoantibodies, and kidney disease in the pristane-induced BALB/c model of SLE has been correlated with the predominance of type I IFNs in diseased mice. The role of type I IFNs in the development of disease is less clear in the MRL/*lpr* mouse model of SLE, in which IFN-gamma has been demonstrated to play an important role. Using a newly-generated MRL/*lpr* strain lacking IRF9, a protein crucial for the transcription of type I IFN-regulated genes, we aimed to determine how disruption of type I IFN signaling alters the autoantibody profiles and inflammatory features of disease, including IFN-gamma and IL-17 production by lymphocyte subsets.

Methods: IRF9$^{-/-}$ BALB/c mice were backcrossed to the MRL/*lpr* background for 8 generations. Serum and urinary protein measurements were collected monthly from age-matched female IRF9$^{-/-}$ and IRF9$^{+/+}$ MRL/*lpr* littermates. At 18 weeks of age, sera were analyzed for isotype-specific autoantibodies directed against lupus autoantigens by ELISA. Cells isolated from the spleen and lymph nodes were analyzed for cytokine production including IL-17A and IFN-gamma by ELISPOT, intracellular cytokine staining by flow cytometry, and quantitative RT-PCR analysis.

Results: Despite a defect in type I IFN signaling, IgG autoantibodies targeted against Sm/RNP, RiboP, and whole histones were detected in IRF9$^{-/-}$ MRL/*lpr* mice, including those of the IgG2a subtype. An analysis of cytokine pathways revealed increased IL-17A and IFN-gamma production by splenocytes in the IRF9$^{-/-}$ samples compared to IRF9$^{+/+}$ samples by ELISPOT and quantitative RT-PCR. IRF9$^{-/-}$ samples demonstrated greater IFN-gamma production by flow cytometry, particularly in the CD4^{+} T-cell compartment.

Conclusions: Taken together, these results demonstrate that disruption of the type I IFN signaling pathway at IRF9 in MRL/*lpr* mice does not significantly alter IgG autoantibody profiles or class switching to the IgG2a subtype. Autoantibody production correlated with an enhancement of IL-17 and IFN-gamma, supporting a role for Th17 and Th1 interactions with autoreactive B cells in this model. These results are strikingly different from those of pristane-induced IRF9$^{-/-}$ BALB/c mice, highlighting the heterogeneity of genetic backgrounds and disease mechanisms in lupus-like disease. On a broader scale, these results hold implications for the development of new treatment strategies for human SLE, where modulation of type I IFNs in some patients may potentially result in the enhancement of other inflammatory pathways influencing disease.

Epistatic Interactions between Lupus Susceptibility Loci on New Zealand Black Chromosomes 1 and 13 Lead to Marked Expansion of Dendritic Cell Populations but Have Little Effect on Autoimmunity. Yui Ho Cheung[2], Evelyn Pau[2] and Joan E. Wither[1]. [1]University Health Network, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada

Purpose: In previous work we have shown that mice with introgressed homozygous NZB chromosome 1 (63.1 to 192.1 Mb; B6.NZBc1) or 13 intervals (48 to 113 Mb; B6.NZBc13) have high titer IgG anti-nuclear antibodies and develop glomerulonephritis. In this study we have produced bicongenic mice with both NZB intervals, to determine whether interactions between the two loci lead to exacerbation of the autoimmune phenotype.

Methods: Splenic cellular populations were examined by flow cytometry. Serum levels of autoantibodies were measured by ELISA and the presence of glomerulonephritis (GN) determined by light microscopy. Cytokine mRNA levels in freshly isolated splenocytes were examined using real time PCR. Splenic TLR responses were assessed by measurement of cytokine production following stimulation.

Results: B6.NZBc1c13 mice demonstrated marked expansion of the CD11c+ dendritic cell (DC) compartment (5 fold as compared to B6 mice and 2–3 fold as compared to single congenic mouse strains). Increases in both the plasmacytoid DC population (B220+CD11c+NK1.1-) and myeloid DC population (CD11b+CD11c+) contributed to this expansion. Despite these cellular changes, the levels of IgM and IgG autoantibodies, and severity of GN in bicongenic mice were similar to single congenic mice. However, bicongenic mice had significantly elevated levels of total IgA and IgA anti-chromatin, -ssDNA and -dsDNA antibodies when compared with single congenic mouse strains. Consistent with the increased IgA production, bicongenic mice had markedly increased levels of baff mRNA and the number of BAFF-producing myeloid DC in their spleens. mRNA levels of tnf were also increased in bicongenic mice. In contrast, the levels of Type I IFN and IFN-inducible genes were reduced in the spleens of 8 mo old bicongenic mice. To gain further insight into the immune mechanism leading to reduced production of Type I IFN in these mice, freshly isolated splenocytes from young and old mice were stimulated with various TLR ligands. At 8 wks of age, TLR-induced IFNα and TNFα secretion was similar in bicongenic and B6 mice. Despite the ~5 fold expansion of pDC in 8-mo-old mice, levels of IFN-α secretion were reduced in bicongenic mice, indicating a marked reduction in secretion of IFNα on a per cell basis, whereas TNFα production was relatively preserved. To further examine the regulation of cytokine production in bicongenic mice, DC were expanded by culturing bone marrow cells isolated from 8 wk old mice with FLT3L for 7 days and stimulated with various TLR ligands. DC from bicongenic mice demonstrated increased TNFα but not IFNα production following stimulation with TLR7 ligands.

Conclusions: Epistatic interactions between lupus susceptibility loci on NZB chromosomes 1 and 13 lead to marked expansion of DC populations with little impact on the autoimmune phenotype. DC from bicongenic mice appear to be shifted towards TNFα production which may lead to the impaired production of IFNα and reduced disease severity in older mice.

Hypercholesterolaemia and Autoimmunity Interact in a Mouse Model of Systemic Lupus Erythematosus To Enhance Both Atherosclerosis and Renal Inflammation, but by Distinct Mechanisms. Myles J. Lewis[2], Talat H. Malik[2], Liliane M. Fossati-Jimack[2], Daniele Carassiti[2], Terence H. Cook[2], Dorian O. Haskard[1] and Marina Botto[1]. [1]Imperial College, London, United Kingdom, [2]Imperial College

Background: Although SLE is known to accelerate atherosclerosis, the underlying mechanisms are not known. We explored the hypothesis that hypercholesterolaemia and autoimmunity interact in driving both arterial wall and renal pathology through immune-complex deposition.

Methods: Atherosclerosis prone low density-lipoprotein receptor deficient mice ($Ldlr^{-/-}$) were crossed with B6.129-*Sle16* congenic autoimmune mice, which develop high titres of lupus autoantibodies, and studied on low fat (LF) and high fat (HF) diets at 22 weeks of age.

Results: The *Sle16* locus significantly increased atherosclerosis in $Ldlr^{-/-}$ mice, as measured by *en face* aortic lesion area (LF $p<0.0001$; HF $p<0.002$) and by aortic root lesion analysis (LF $p<0.05$; HF $p<0.0001$). Unexpectedly, aortic root lesions in *Sle16*.$Ldlr^{-/-}$ mice had significantly less complement C3 than those in $Ldlr^{-/-}$ mice, but similar IgG deposition. The *Sle16* locus caused a reduction in serum C3, associated with renal immune-complex deposition. *Sle16*.$Ldlr^{-/-}$ mice showed augmented renal inflammation, with enhanced glomerular C3 deposition compared to B6.129-*Sle16* mice, but again no difference in glomerular IgG deposits.

Conclusions: The data suggest that hypercholesterolaemia enhances immune complex-mediated renal damage by amplifying complement activation, but do not support a role for arterial wall immune complex deposition and complement activation in accelerated atherosclerosis. On the contrary, systemic complement depletion by immune-complexes may contribute to atherogenesis by reducing the protective role of complement in disposal of apoptotic debris. The results predict that aggressive treatment of hyperlipidaemia in SLE may reduce lupus nephritis, as well as reduce accelerated atherosclerosis.

IL-17 Promotes Autoimmunity in Pristane-Induced Lupus. Elaine V. Lourenco, Chunlin Cai, Bevra H. Hahn and Antonio La Cava. UCLA

IL-17 promotes inflammatory responses in several autoimmune conditions. Although it has been shown that IL-17 can be found elevated in systemic lupus erythematosus (SLE) patients and in lupus mice, it has not yet been directly proven that this association underlies a promoting role of this cytokine in the development and/or progression of the disease. To test whether IL-17 can facilitate the development of SLE, we treated IL-17-deficient or wild-type mice with pristane, a hydrocarbon oil that induces a lupus-like disease characterized by the development of lupus-associated autoantibodies and glomerulonephritis. Wild type and IL-17-deficient mice were treated with pristane or saline, and serological and pathological evaluations were done at serial times points post treatment. It was found that pristane promoted hypergammaglobulinemia that was more prominent in wild type than in IL-17-deficient mice, and the difference became statistically significant by three months post-treatment ($p<0.04$) and was maintained thereafter ($p<0.001$). IL-17-deficient mice treated with pristane also developed lower serum levels of anti-single-stranded DNA and anti-chromatin antibodies in comparison with wild type mice treated with pristane, and the onset of glomerulonephritis of the kidney was as well delayed in the IL-17-deficient mice. These results suggest that the presence of IL-17 facilitates the development of murine lupus-like disease induced by pristane. The formal demonstration that IL-17 has a promoting role in the accelerated development of serological and pathologic manifestations of SLE may have implications in the targeting of this pro-inflammatory cytokine for therapeutic purposes in the disease.

IL-21 Promotes Autoimmune Features in Chronic Graft Versus Host Disease by Enhancing T Follicular Helper Development and B Cell Response. Vinh Nguyen[3], Irina G. Luzina[1], Qing Chen[1], Horea Rus[1] and Violeta Rus[2]. [1]Baltimore, MD, [2]Univ of Maryland Schl of Med, Baltimore, MD, [3]University of Maryland School of Medicine, Baltimore, MD

Studies in murine models of lupus have indicated increased production of IL-21 and attenuation of autoimmune features following IL-21 blockade. IL-21 exerts an autocrine effect on T follicular B helper cells (TFH) cells and also stimulates B cell proliferation, plasma cell (PC) differentiation and germinal center (GC) expansion. To determine whether IL-21 promotes systemic lupus through effects on TFH cells or B cells, we assessed the effect of IL-21/IL-21R signaling on B cells independent from the effect on CD4 T helper cells using IL-21R−/− or IL-21R+/+ mice as donor or hosts in the P-into-F1 and Bm12-into-B6 models of chronic Graft Versus Host Disease (cGVHD). cGVHD induced by injection of IL-21R−/− CD4 cells from B6 mice into B6D2F1 hosts was characterized by a decrease in the expansion of donor CD4, TFH and GC cells and decrease in levels of anti-ssDNA antibody (Ab). When cGVHD was induced by injecting Bm12 spleen cells into IL-21R−/− B6 mice, parameters of cGVHD including B cell activation assessed by MHC class II upregulation, GC B cell and PB/PC differentiation, IgG anti-dsDNA Ab production were significantly decreased compared to IL-21+/+ hosts. The decreased B cell activation and autoantibody titers in the IL-21R−/− hosts were unlikely to be the result of defective priming of donor T cells or activation of host dendritic cells as CD4+ T cells exhibited similar expression of CD44 and CD69 and proliferated more efficiently in IL-21R−/− hosts than in IL-21R+/+ hosts. Similarly, DC displayed similar expression of CD80, CD86. Consistent with the decrease in GC B cells, splenic GCs in IL-21R−/− hosts detected by immunohistochemistry staining on day 7, 14 and 28, were smaller, ill-formed and disrupted compared to those in IL-21R+/+ hosts. Long-term studies showed decreased severity of lupus-like renal disease in the IL-21R−/− hosts. These results suggest that IL-21 promotes autoimmune features in lupus by enhancing both the expansion of TFH cells and the differentiation of autoreactive B cells into autoAb producing cells.

Interferon Regulatory Factor-5 (IRF-5) Is Critical for the Development of Lupus in MRL/lpr Mice. Yoshifumi Tada[3], Seiji Kondo[4], Shigehisa Aoki[2], Syuichi Koarada[3], Hisako Inoue[3], Rie Suematsu[3], Akihide Ohta[1] and Kohei Nagasawa[3]. [1]Department of Clinical Nursing, Saga University, Saga, Japan, [2]Department of Pathology, Saga University, Saga, Japan, [3]Department of Rheumatology, Saga University, Saga, Japan, [4]National Hospital Organization Kyushu Medical Center, Fukuoka, Japan

Objective: Interferon Regulatory Factor-5 (IRF-5) is a transcription factor that mediates intracellular signals activated by engagement of the Toll-like receptors (TLRs). IRF-5 polymorphisms are associated with increased or decreased risk of systemic lupus erythematosus (SLE) in various human populations but the precise role of IRF-5 in SLE development is not understood. We examined the role of IRF-5 in the development of murine lupus.

Methods: We crossed gene-targeted IRF-5-deficient (IRF-5−/−) mice to MRL/Mpj-lpr/lpr (MRL/lpr) mice and examined the progeny for survival, glomerulonephritis, autoantibody (autoAb) levels, immune system cell populations, and dendritic cell (DC) functions.

Results: We show that IRF-5−/−MRL/lpr mice survive longer than control IRF-5+/+MRL/lpr mice and display only very mild glomerulonephritis. The glomerular deposition of IgG and C3, and the infiltration of CD4+T cells and macrophages into glomeruli was significantly decreased in IRF-5−/−MRL/lpr mice. Anti-nuclear antibodies, anti-dsDNA antibodies, anti-Sm antibodies, and anti-RNP antibodies were decreased in mouse serum, and numbers of activated CD4+ T cells were reduced in the spleen. Splenic DCs from IRF-5−/−MRL/lpr mice produced lower levels of inflammatory cytokines when treated in vitro with TLR7 or TLR9 ligands or immune complexes. Interferon-α production in response to CpG was also decreased.

Conclusion: Our results show that IRF-5 is a crucial driver of lupus development in mice, and indicate that IRF-5 may be an attractive new target for therapeutic intervention to control disease in SLE patients.

Interferonα Causes SLE by Expanding CD3$^+$ CD4$^-$ CD8$^-$ Double Negative T Cell (DN T Cell). Chieri Akiyama[1], Eriko Honda[1], Akira Hashiramoto[2], Dean W. Felsher[3] and Shunichi Shiozawa[2]. [1]Department of Biophysics, Graduate School of Health Science, Kobe University, Kobe, Hyogo, Japan, [2]Department of Biophysics, Graduate School of Health Science, Kobe University/Department of Medicine, Graduate School of Medicine, Kobe University/The Center for Rheumatic Disease, Kobe University Hospital, Kobe, Japan, [3]Stanford University, School of Medicine, Division of Oncology, Department of Medicine and Pathology, Stanford, CA

Objective: Interferon alpha (IFNα) has been suggested to cause systemic lupus erythematosus (SLE), however, the direct proof for this is lacking. We showed by solely increasing IFNα in doxycycline-inducible transgenic mice (IFNα Tg mice) that IFNα induces autoantibodies including serum anti-dsDNA antibody, serum immune complex (IC) and lupus-like tissue injuries (Uchimura C *et al*. Arthritis Rheum 56 (suppl.9):S200).

We now show that IFNα causes SLE by expanding CD3$^+$ CD4$^-$ CD8$^-$ double negative T cell (DN T cell) to induce lupus glomerulonephritis.

Methods: Mouse IFNα (mIFNα) cDNA, amplified by RT-PCR, was subcloned into pTet Splice vector under the control of TetOp promoter to generate TetOp-mIFNα. This was microinjected into fertilized eggs of C57BL/6 to generate TetOp-mIFNα Tg mice. The EμSR-tTA Tg mice of FVB/N background was mated with TetOp-mIFNα Tg mice to obtain double Tg mice (IFNα Tg mice). Serum IFNα was measured using Mu-IFN-α ELISA kit. Serum autoantibodies and IC were measured with ELISA, referring to pooled sera of MRL/*lpr* female adult mice (arbitrary units).Proteinuria were measured semiquantitatively using urine dipsticks. Frozen kidney sections were stained for C3 and IgG using immunofluorescent antibodies. To detect intracellular IFNα, splenocytes (1×10^6/ml) were stimulated with ionomycin and phorbol 12-myristate 13-acetate for 4 h in the presence of blefeldin A. Cells were then stained with anti-CD4 and anti-CD8 antibodies, followed by fixation, permeabilization with saponin and treatment with anti-IFNα antibody. The CD3$^+$ (5×10^6), CD4$^+$(5×10^6), CD8$^+$ (5×10^6), and DN(3×10^5) subsets derived from the IFNα Tg mice of 30 weeks after cessation of Dox were transferred twice into naïve recipients, and renal histopathology was studied 21 days after transfer.

Results: In IFNα Tg mice, pathological lesion consisted of IC-deposited glomerulonephritis, interstitial lung disease, liquefaction and positive lupus band test in the skin epidermis, onion skin lesion in the spleen and inflammatory infiltrates to salivary gland and bile duct. Activated effector CD4$^+$ and CD8$^+$ T cells producing IFNα were increased, in which IFNα^+CD8$^+$ T cell with effector phenotype, i.e., full-matured CTL, and in particular, activated CD3$^+$CD4$^-$CD8$^-$ double negative T cell (DN T cell) was increased. The DN T cells not only infiltrated to the glomerular lesions of IFNα Tg mice but also induced *de novo* glomerulonephritis when transferred into naïve recipients. Thus, IFNα is responsible for the core manifestation of SLE except for anti-Sm autoantibody.

Conclusion: IFNα causes SLE by expanding CD3$^+$ CD4$^-$ CD8$^-$ double negative T cell (DN T cell) to induce lupus glomerulonephritis.

IRF4-Deficient Lupus-Prone MRL/*lpr* Mice Lack Serum Ig/Auto-Abs and Th17 Cells but Develop Non-Immune Complex-Mediated Diffuse Proliferative Glomerulonephritis and Dermatitis/Ear Necrosis. Hideharu Sekine[4], Takeshi Machida[1], Eiji Suzuki[3], Efrain Martinez Avila[3], Phil Ruiz[5], Christopher M. Reilly[6] and Gary S. Gilkeson[2]. [1]Fukushima Medical University, Fukushima, Japan, [2]Med Univ of South Carolina, Charleston, SC, [3]Medical University of South Carolina, Charleston, SC, [4]Medical University of South Carolina/Fukushima Medical University, Charleston, SC, [5]University of Miami, Miami, FL, [6]Virginia Tech, VA

The transcription factor interferon regulatory factor 4 (IRF4) is a member of the IRF family of transcription regulators and required for Ig-production/maturation of B cells and development of Th17 cells. We found that the Irf4 gene is over-expressed in CD4$^+$ T cells in lupus-prone MRL/*lpr* mice compared to non-lupus mice. To investigate the role of IRF4 in the development of lupus, we analyzed disease expression in *Irf4*$^{-/-}$ MRL/*lpr* mice until time of sacrifice.

Sera and urine were collected biweekly from groups of *Irf4*$^{-/-}$ and wild-type MRL/*lpr* mice starting at 12 weeks. Serum Ig/anti-dsDNA Ab levels and urinary albumin excretion levels were measured by ELISA. Mice were sacrificed at 24 weeks of age and ear, back skin and kidneys were removed for pathological analysis. Splenic immune cell populations were analyzed by flow. To determine Th1/Th2/Th17 cell numbers, splenic CD4$^+$ T cells from 12 weeks old MRL/*lpr* mice were purified by magnetic selection, cultured with PMA/ionomycin, and IFN-γ, IL-4 or IL-17 production was detected by flow and ELISPOT assay.

Unlike wild-type MRL/*lpr* mice, all *Irf4*$^{-/-}$ MRL/*lpr* mice had undetectable levels of serum Ig and anti-dsDNA Abs and no albuminuria. *Irf4*$^{-/-}$ MRL/*lpr* mice had no glomerular immune complex (IC)/C3 deposits, epithelial cell reaction, crescent formation or renal vasculitis, however, they had significant dermatitis/ear necrosis and pathologic observable nephritis characterized by diffuse glomerular hypercellularity and mesangial matrix expansion consistent with diffuse proliferative glomerulonephritis. *Irf4*$^{-/-}$ MRL/*lpr* mice showed significantly increased numbers of splenic CD4$^+$ T cells ($66.7\pm6.6\times10^6$ vs $41.4\pm5.8\times10^6$; $p = 0.016$) while all other splenic immune cells were significantly decreased compared to wild-type controls. Notably, splenic CD19$^+$/IgM$^+$ B cells and CD8$^+$ T cells were significantly decreased/absent in *Irf4*$^{-/-}$ MRL/*lpr* mice compared to wild-type MRL/*lpr* mice. Bone marrow analysis revealed B cell development arrest before the stage of CD19$^+$/B220^{high}/CD43^{low} immature B cells in *Irf4*$^{-/-}$ MRL/*lpr* mice. Flow/ELISOPT assay showed absence of IL-17 producing cells in *Irf4*$^{-/-}$ MRL/*lpr* mice, however, they had significantly increased numbers of IFN-γ producing cells ($59.2\pm20.2\times10^6$ vs $6.6\pm1.5\times10^6$; $p = 0.027$) and IL-4 producing cells ($4.30\pm0.27\times10^6$ vs $0.39\pm0.08\times10^6$; $p < 0.0001$) compared to control MRL/*lpr* mice.

Our results indicate that IRF4 is required for the full expression of lupus like renal disease in MRL/*lpr* mice, most likely by maintenance/modulation of autoreactive B cells and specific T cell subsets. Importantly, development of proliferative glomerulonephritis and skin disease were still present in *Irf4*$^{-/-}$ MRL/*lpr* mice indicating that their pathogenesis, in these mice, is independent of autoAb/IC-mediated mechanisms or Th17 cells, and is most likely induced by Th1 and/or Th2 cells. Absence of IL-17 producing CD4$^+$ T cells and significantly increased numbers of IFN-γ or IL-4 producing CD4$^+$ T cells in the spleens of *Irf4*$^{-/-}$ MRL/*lpr* mice suggested a dual role of IRF4 for development of Th17 cells and inhibition of Th1 and Th2 cell development in MRL/*lpr* mice.

Long-Term Anti-CD20 Treatment Reduces Antibody-Secreting Ells in NZB/W Lupus Mouse. Wensheng Wang[2], Terasa Owen[2], Travis Ichikawa[2] and Jennifer H. Anolik[1]. [1]University of Rochester, Rochester, NY, [2]University of Rochester Medical Center, Rochester, NY

Objective: Although anti-CD20 antibody efficiently depletes most B cells, B-cell depletion (BCD) has shown variable efficacy in clinical trials as a therapy for systemic lupus erythematosus (SLE). To better understand the mechanisms of action of anti-CD20 and the effect on SLE, a lupus-prone mouse model was used to study the alteration in antibody-secreting cells after B cell depletion.

Methods: For short-term treatment, NZB/NZWF1 female mice (24–30 wks old) with durable proteinuria $>$ 2+ (100 mg/dl) were dosed weekly $\times$ 4 with anti-mCD20 antibody (IgG2a, a gift from Biogen Idec)(n=6) or control antibody IgG2a and sacrificed 1 wk after the last treatment. To study longer-term effects of BCD, 27 wk old NZB/NZWF1 female mice with high titer anti-dsDNA antibodies were dosed weekly with anti-mCD20 antibody or control IgG via retro-orbital injection. One group was treated weekly $\times$ 4 (n= 6) and sacrificed 8 wks later. Another was treated weekly $\times$ 12 (n= 6) and sacrificed 1 wk after the last treatment. Cells from spleen, bone marrow (BM) and kidney were collected and total IgG and dsDNA antibody secreting cells (ASC) were determined by ELIspot.

Results: Nephritis improved after anti-mCD20 treatment (neither 4 wks nor 12 wks treated mice were found to develop nephritis [3+ proteinuria]) compared to control (5/6 mice developed nephritis 4+). Although BCD was efficient (>90% B220+ cell depletion), there was no difference in the numbers of anti-dsDNA-secreting cells and total IgG-secreting cells in either spleen, BM or kidney after 4 treatments of anti-mCD20, over the short-term (evaluation 1 wk after the last treatment- see Table) or long-term (evaluation 8 wks after the last treatment, data not shown). Interestingly, in untreated mice the ratio of anti-dsDNA/total IgG-secreting cells in the kidney was significantly higher than in spleen and BM (p<10-4) suggesting that the kidney is a reservoir of either production or maintenance of autoreactive ASCs. In

striking contrast, long-term treatment with anti-mCD20 resulted in significant decreases in total IgG and anti-dsDNA-secreting cells in spleen. In addition, the average size of total IgG-secreting cell spots from kidney decreased significantly, suggesting a shift in the antibody producing capacity after anti-mCD20.

Short-term Treatment

	IgG			dsDNA		
	Ctrl	a-CD20	*t-test*	Ctrl	a-CD20	*t-test*
Spleen	115.6 ± 35.6	61.9 ± 17.5	0.12	3.4 ± 1.0	2.6 ± 0.58	0.3
BM	15.9 ± 4.2	21.2 ± 3.2	0.26	0.66 ± 0.17	0.46 ± 0.11	0.28
Kidney	68.3 ± 4.1	81.5 ± 21.0	0.11	30.3 ± 8.8	37.3 ± 8.3	0.18

Long-term Treatment

	IgG			dsDNA		
	Ctrl	a-CD20	*t-test*	Ctrl	a-CD20	*t-test*
Spleen	132.2 ± 23.0	4.21 ± 3.66	0.0011	2.03 ± 0.30	0.21 ± 0.15	0.00091
BM	33.27 ± 7.02	12.9 ± 4.54	0.032	0.80 ± 0.22	0.18 ± 0.06	0.018
Kidney	269.8 ± 64.93	85.86 ± 19.85	0.028	63.77 ± 17.77	3.58 ± 1.76	0.013

per 10E4 cells

Conclusion: Long-term anti-CD20 treatment significantly reduces ASCs in spleen and moderately reduces ASCs in bone marrow and kidney. Treatment also appears to alter antibody secretion in kidney. Therefore, longer term B cell depletion may have increased efficacy as a treatment for SLE.

Mitochondrial Dysfunction in T Cells Precede Disease Development in Lupus-Prone Mice. Tiffany Telarico[4], David R. Fernandez[4], Ann F. Hofbauer[2], Gary S. Gilkeson[1], Jim C. Oates[3] and Andras Perl[5]. [1]Med Univ of South Carolina, Charleston, SC, [2]Medical University of South Carolina, [3]MUSC, Charleston, SC, [4]SUNY, [5]Upstate Medical Univ, Syracuse, NY

Purpose: T lymphocytes from patients with systemic lupus erythematosus (SLE) exhibit increased nitric oxide (NO) production, elevation of the mitochondrial transmembrane potential ($\Delta\Psi m$) or mitochondrial hyperpolarization (MHP), and ATP depletion which predispose to pro-inflammatory death via necrosis. T lymphocytes express the endothelial isoform of NO synthase (eNOS). Here, we examined whether mitochondrial dysfunction precedes the onset of disease in murine models of SLE.

Methods: Mitochondrial function, calcium flux, and the production of nitric oxide (NO) and underlying changes in gene expression were investigated in MRL/lpr, MRL/lpr/iNOS−/−, MRL/lpr/eNOS−/−, MRL, C57BL/6-lpr, C57BL/6, NZB × NZW F1, Balb-c/NZW, NZM2328, and NZM2328/R27 female mice that were matched for age and studied in parallel. $\Delta\Psi m$ (DiOC6 and TMRM), mitochondrial mass (MTG and NAO), NO production (DAF-FM and DAR-4M), reactive oxygen species (DCF-DA), intracellular reduced glutathione (GSH by MCB fluorescence) and cytosolic ([Ca2+]c) and mitochondrial calcium ([Ca2+]m) were measured by flow cytometry. Expression of the voltage-dependent anion channel 1 (VDAC1) and transaldolase that regulate GSH and $\Delta\Psi m$ was investigated in splenocytes and CD4+ T cells by western blotting. As disease development, glomerulonephritis was monitored by proteinuria and histopathology. P values < 0.05 calculated by GraphPad Prism version 5.0 using paired or unpaired two-tailed t-test were considered significant.

Results: MHP, increased mitochondrial mass, [Ca2+]m and ROI production and reduced GSH were found in CD3+ T cells from disease-free MRL/lpr but not from MRL or from C57BL/6-lpr mice relative to C57BL/6 control mice at 3 months of age. Consistent with these changes, expression of the VDAC1 (up to 7 –fold increase, $p=0.0008$) and transaldolase (67% increase, $p=0.034$), genes that influence $\Delta\Psi m$, were elevated in MRL/lpr splenocytes and CD4+ T cells. NO production, $\Delta\Psi m$ and mitochondrial mass were all increased in 11-month-old (NZB × NZW) F1 mice after disease onset, but these parameters were not consistently elevated prior to disease development at 6 months of age. However, increased expression of VDAC1 was detected at 6 months of age and preceded the onset of SLE (3.5-fold increase; $p=0.006$). NO production (DAF-FM fluorescence), $\Delta\Psi m$ (TMRM fluorescence), mitochondrial mass (NAO), [Ca2+]c and [Ca2+]m stores were reduced in CD3+ T cells from C57BL/6/eNOS−/− mice relative to C57BL/6 controls. NO production (DAF-FM fluorescence $p=0.001$) and mitochondrial and [Ca2+]c stores were reduced in CD3+ T cells from MRL/lpr eNOS−/− mice (Fluo-3 fluorescence; $p=0.03$) relative to MRL/lpr controls.

Conclusion: Mitochondrial dysfunction, characterized by MHP and increased [Ca2+]m as well as overexpression of VDAC1 and transaldolase, precede disease development in lupus-prone mice. Increased [Ca2+]m of MRL/lpr mice may be dependent on the expression of eNOS.

Molecular Mechanisms of Lupus Dyslipidemia in Mice. Nilamadhab Mishra[1], Kailin Yan[3] and Qiang Cao[2]. [1]Wake Forest Univ Health Scienc, Winston-Salem, NC, [2]Wake Forest University Health Sciences, [3]Wake Forest University Unv Health Sciences

Introduction: Lupus dyslipidemia is characterized by increased total cholesterol, triglycerides, LDL, VLDL and decreased HDL. The molecular mechanisms of abnormal lipid profiles in lupus patients currently are not properly understood. In this study, we generated mice that has lupus dyslipidemia on chow diet and studied the pathways that are responsible for increased cholesterol and triglycerides in plasma.

Materials and Methods: $LDLr^{-/-}$ and $Fas^{-/-}$ (*lpr/lpr*) mice on the B6 background were purchased from the Jackson Laboratories (Bar Harbor, ME). These mice were interbred to produce mice homozygous for both LDLr−/− and *lpr* confirmed by PCR genotyping. $LDLr^{-/-}$(LDLr) and $LDLr^{-/-}lpr^{-/-}$ (LDLrLpr) mice were fed on chow diet. Thirteen female mice from each group were sacrificed at the age 24–28 weeks.

Results: LDLrLpr mice developed a lupus phenotype demonstrated by autoantibody production (ANA, anti-dsDNA, anti-sm, anti-cardiolipin antibodies), increased body weight, splenomegaly, hepatomegaly, and generalized lymphadenopathy compared to LDLr mice. LDLrLpr mice had a significantly increased proteinuria score (1.5 ± 0.2 vs. 1.1 ± 0.06; $p<0.02$) and renal histology score (1.8 ± 0.4 vs. 0.4 ± 0.1; $p<0.004$) compared to $LDLr^{-/-}$ mice. The lymphocyte population in the spleen measured by flow cytometry resulted in significantly increased CD4+Tcells (21% vs. 16%; $p<0.003$), double negative T cells (59% vs. 26%; $p<0.001$), and CD138+ plasma cells (12% vs. 0.4%; $p<0.001$) and decreased CD8+Tcells (6% vs. 14%; $p<0.001$) in LDLrLpr mice compared to LDLr mice similar to human lupus. Lipid analyses in LDLrLpr mice compared to LDLr mice on chow diet demonstrated significantly elevated total cholesterol (mg/dl) (347.0 ± 31.65 vs. 220.9 ± 8.235; $p<0.0008$), triglycerides (118.8 ± 18.51 vs. 42.85 ± 3.665; $p<0.0005$), VLDL (66.85 ± 17.54 vs. 3.385 ± 0.4875; $p<0.0014$) and LDL cholesterol (214.9 ± 22.22 vs. 148.1 ± 8.049; $p<0.0093$) without significant difference in HDL level. The increased level in triglycerides due to increased triglyceride secretion as measured by triton block experiment and decreased hepatic and lipoprotein lipase activity in LDLrLpr mice. The increased plasma cholesterol is due to increased cholesterol synthesis and decreased fatty oxidation in liver in LDLrlpr mice as measured by gene expression analysis.

Conclusion: Increased cholesterol synthesis, decreased fatty acid oxidation, increased triglyceride secretion and decreased lipase activity are the molecular mechanisms of dyslipidemia in lupus mice.

Nuclear Modifications during Apoptosis Are Required To Maintain Tolerance to Nuclear Antigens. Neelakshi R. Jog[1], Eline Luning-Prak[2] and Roberto Caricchio[1]. [1]Temple University, [2]University of Pennsylvania

Background: Our previous data show that in spontaneous models of lupus, the absence of caspase activated DNase (CAD)-generated nuclear modifications during apoptosis results in increased anti-nuclear antibody generation and severe nephritis. These data suggested that CAD generated apoptotic nuclei are a source of auto-antigens (autoAgs) that are involved in negative regulation of autoreactive B cell during development. In the present study we investigated the role of CAD in induction of tolerance in vivo. To this end we used 3H9 mice, an established model of anergy towards chromatin.

Methods: 3H9 mice carry a rearranged heavy chain reactive against dsDNA, and shows developmental arrest of autoreactive B cells. To determine whether absence of CAD, and therefore autoAgs, breaks tolerance in this anergic model, we generated CAD deficient 3H9 mice [3H9(−/−)]

Results: Contrary to 3H9+/+, 3H9−/− mice were able to break tolerance early in life and produce high titers of anti-dsDNA and anti-

chromatin antibodies. The antibodies made in 3H9−/− mice did not, however, differ in specificities as determined by immunofluorescent ANA. The autoreactive B cells in 3H9+/+ mice undergo stringent negative selection due to the presence of autoreactive heavy chain. Therefore we analyzed B cell development and maturation by flow cytometry. The developing B cells from bone marrow were divided into Hardy fractions D (L chain rearrangement), E (immature IgM+), and F (IgM+, recirculating B cells). Compared to wild type, both 3H9+/+ and 3H9−/− mice had increased numbers of fraction D cells, suggesting increased light chain rearrangements. In the periphery, both 3H9+/+ and 3H9−/− mice showed increased mature marginal zone B cells, and immature T2 transitional B cells, and increased lambda inclusion. These data show that absence of CAD does not alter the unique B cell development or maturation in 3H9 mice. The 3H9 heavy chain pairs with endogenous lamda1 light chain to generate anti-dsDNA antibody allowing to follow in vivo the fate of autoreactive B cells. In 3H9 mice lambda1+ cells are excluded from B cell follicles in secondary lymphoid organs and are not able to mature into autoantibody producing B cells. We therefore investigated the fate of lambda1 + cells in the absence of apoptotic nuclear modifications. We stained frozen spleen sections from 3H9+/+ and 3H9−/− mice with B220 to identify B cell follicles and lambda1 to identify the auto-reactive B cells. As expected, in 3H9+/+ mice the lambda1+ cells did not enter the B cell zone and accumulated at the T-B interface. In 3H9−/− mice, however, lambda1+ cells were not excluded from B cell follicles, and entered the B cell zone. These data show that in agreement with our hypothesis, auto-reactive B cells escape to the periphery in absence of CAD-dependent nuclear fragmentation.

Conclusions: Based on our data we conclude that in mice genetically predisposed to autoimmunity, the apoptotic nuclear modifications generated by CAD are necessary to maintain tolerance toward nuclear Ags.

PARP-1 Deficiency Leads to More Severe Glomerulonephritis and Increased Mortality in an Inducible Mouse Model of SLE. Maximilian F. Koenig[1], Serena M. Bagnasco[1], Janelle Montagne[1], Antony Rosen[2] and Thomas Grader-Beck[2]. [1]Johns Hopkins School of Medicine, [2]Johns Hopkins School of Medicine, Baltimore, MD

Purpose: PARP-1 regulates essential cellular functions, including cell death and DNA repair. Lower levels of PARP-1 activity have repeatedly been found in SLE patients. Functional PARP-1 deficiency may therefore play an important role in the pathophysiology of SLE. In this study we define the role of PARP-1 deficiency on the autoantibody response and end-organ disease phenotype in an inducible mouse model of SLE.

Methods: Lupus-like disease was induced in a chronic graft-versus-host disease (cGVHD) model of SLE by injecting B6 mice (wild-type or PARP-1−/−) with sex- and age-matched B6©-H2-Ab1bm12/KhEgJ (bm12) splenocytes. Proteinuria and serum autoantibody levels to ssDNA and histone H1 were measured serially over the course of the disease (14 weeks). At termination of the experiment, kidney sections were evaluated by hematoxylin/eosin staining as well as by immunofluorescence for IgG and C3 deposition in a blinded manner.

Results: Male B6 PARP-1−/− disease mice showed increased mortality compared to wild-type disease mice (4/6; 66% vs. 0/8; 0%; P= 0.015). This increase was gender-specific and not observed in female mice. PARP-1-deficient male mice developed higher levels of proteinuria associated with a nephrotic phenotype and wasting. Histological examination of renal tissue in PARP-1-deficient male mice showed abundance of hyaline, PAS-positive material within tubules as well as glomerular hyperplasia and marked sclerosis. These changes were not seen in wild-type and PARP-1−/− female mice. The burden of IgG deposition assessed by immunofluorescence intensity was comparable between wild-type and PARP-1 deficient mice. However, C3 deposition at the glomerular basement membrane (GBM) was more prevalent in PARP-1−/− male mice compared to wild-type male mice. This GBM deposition of C3 was closely correlated with the severity of proteinuria. Autoantibody levels of anti-ssDNA and anti-histone H1 over the course of the disease were similar in wild-type and PARP-1 deficient male disease mice.

Conclusion: PARP-1 deficiency is associated with more severe glomerulonephritis and increased mortality in an inducible cGVHD mouse model of SLE. This effect is specific for male mice and is not reflected by changes in the antibody response to commonly observed lupus autoantigens. The level of PARP-1 expression and activity in the target tissue may play an important role for disease phenotype and severity in SLE.

Recombinant Chaperonin 10 Suppresses Cutaneous Lupus and Lupus Nephritis in MRL-(Fas)lpr Mice. Onkar P. Kulkarni[3], Mi Ryu[3], Claudia Kantner[3], Miklos Sardy[2], Dean Naylor[1], Richard Brown[1], Daina Vanags[1] and Hans-Joachim Anders[3]. [1]CBio Ltd, Eight Mile Plains, Queensland, Australia, [2]Department of Dermatology and Allergology, University of Munich, Munich, Germany, [3]Medizinische Poliklinik-Innenstadt, University of Munich, Munich, Germany

Purpose: Systemic lupus erythematosus (SLE) is a systemic autoimmune disorder mostly affecting young females. The autoimmune disease manifestations are still treated with unspecific immunosuppressants such as steroids or cytotoxic drugs that cause serious toxicities. Since patients largely suffer from inflammatory tissue damage and not from autoimmunity per se, selective anti-inflammatory compounds may offer protection from tissue damage without causing immunosuppression.

Chaperonin 10 fulfills an essential role in mitochondrial protein folding and an extracellular role in immunomodulation suggesting potential therapeutic value for the treatment of inflammatory disorders1. Accordingly, in early phase II clinical studies in human patients the efficacy and safety of Cpn10 in treating signs and symptoms of rheumatoid arthritis2 and chronic plaque psoriasis (CPP)3 has been established. Here recombinant Cpn10 was examined for its' ability to additionally control the autoimmune manifestations of SLE.

Methods: Female MRLlpr/lpr mice with lupus-like autoimmunity were given either Cpn10 (100μg/mouse, 5mg/kg) or placebo (Tris-buffred saline) by intraperitoneal injection every alternate day from 10 to 22 weeks of age. Clinical signs were recorded over the study period, and mortality was recorded every week throughout the study. Plasma samples were collected prior to sacrifice after 11 weeks of treatment. Urine samples were collected in week 22 of age. Tissue samples for histology were immediately fixed in formalin prior to paraffin fixation.

Results: Cpn10 entirely prevented the lupus-like cutaneous lesions as compared to vehicle-treated MRLlpr/lpr mice as evident from macroscopy as well as from microscopical evaluation. Cpn10 also improved lupus nephritis as evident from serum creatinine levels, albuminuria, and the histomorpholocial scores of disease activity and chronicity ($p<0.05$). Autoimmune lung disease remained unaffected by Cpn10 treatment. However, Cpn10 prolonged overall survival of MRLlpr/lpr mice (90% survival vs. 65% for treated mice, $p<0.05$). The therapeutic potential of Cpn10 on skin and kidney disease was not associated with any significant effects on either T cell, dendritic cell or B cell counts in spleen, on plasma IFN-γ, TNF-α or IL-10 levels, plasma DNA autoantibody levels or on markers of lymphoproliferation.

Conclusion: Our study clearly demonstrates that Cpn10 prevents cutaneous lupus and suppresses lupus nephritis in MRLlpr/lpr mice without affecting the underlying autoimmune process or systemic inflammation. Hence, Cpn10 shows significant potential for the treatment of selective human SLE-related tissue pathologies, such as cutaneous lupus and lupus nephritis whilst possibly offering an improved safety profile by not blocking healthy immune responses. This work taken together with previously published data in human RA and CPP trials, provides evidence of Cpn10's utility beyond a single indication.

TGF-β-Induced CD4+Foxp3+ Cells Suppress Lupus-Like Syndrome through Induction of Formation of Tolerogenic DC. Xiaohui Zhou[4], Julie Wang[4], David A. Horwitz[2], Huimin Fan[3], Hejian Zou[1], Zhongmin Liu[3] and Song Guo Zheng[4]. [1]Fudan University Medical School, [2]LAC/USC Medical Center, Los Angeles, CA, [3]Tongji University Medical School, [4]University of Southern California

Background: Regulatory T cells (Tregs) play vital roles in maintaining immune homeostasis and self tolerance. Recent studies revealed that dendritic cells (DCs) might be main target of Tregs and also induce immune tolerance. We have previously reported that adoptive transfer of TGF-β-induced Tregs (iTregs) prevents the appearance of lupus syndrome induced by injection of

DBA/2 mouse splenocytes to (DBA/2 × C57BL/6) F1 mice, we here ask if interaction between iTregs and DCs contributes to disease control.

Materials and Methods: DBA/2 naïve CD4+ cells were stimulated with anti-CD3/CD28 beads and IL-2 ± TGF-β (control or iTregs) for 5 days. 5×106 control or iTregs with 80×106 DBA/2 splenocytes were adoptively transferred to F1 mice. ALK-5 inhibitor and anti-IL-10R Ab were i.p injected twice a week for four weeks in some groups. On day 11 after transfer of control or iTregs, CD11c+ cells were selected from splenocytes in F1 mice and injected (1×106) with 80×106 DBA/2 splenocytes to F1 mice. Surface and intracellular staining included CD80, CD86, CD11c, IA-b, Foxp3, CD25, H-2Kd, H-2Kb. IgG and anti-DNA in sera was analyzed with ELISA and mice survival was monitored.

Results: A single injection of 5×106 iTregs markedly prevented increased IgG production, decreased anti-dsDNA autoantibodies, suppressed proteinuria and prolonged survival of these mice. The treatment with anti-TGF-b or ALK5 inhibitor completely, with anti-IL10R partially blocked the suppressive capacity of iTreg following injection in vivo. Moreover, iTreg suppressed CD80 and CD86 expression by DCs in vitro and in vivo. Adoptive transfer of these DCs in F1 mice received iTregs but not control cells to GVHD model can significantly prevent the development of lupus symptoms. The protective effect of these DCs was dependent on TGF-b/TbR signal but not IL-10/IL-10R signal. Thus, the protective effect of iTreg is dependent on TGF-b and/or IL-10 and formation of tolerogenic DCs that have developed TGF-b- but not IL-10-dependent suppression on lupus.

Conclusion: iTregs may suppress lupus-like syndrome through induction of formation of tolerogenic DC with TGF-b dependence pathway. iTregs may have therapeutic potential in treating autoimmune diseases.

Widespread Upregulation of mEPCR in Kidney, Spleen and Liver of a Nephritic NZM B/W F1: Implications to Microvascular Disease. Sherry Xu[1] and Robert M. Clancy[2]. [1]NYU School of Medicine, [2]Tisch Hospital 4–407, New York, NY

Purpose: Membrane endothelial protein C receptor (mECPR), a cofactor for the anti-inflammatory activity and anti-coagulant activity of the Protein C pathway, is a prominent inducer of anti-apoptotic pathways in endothelial cells, and thus maintains vascular tone and normal blood flow in the microvasculature.

We previously found that mEPCR is highly expressed in the cortical peritubular capillaries of kidneys from patients with active lupus nephritis, as compared with normal human kidneys. This profound upregulation of mEPCR was observed even in areas absent tubulointerstitial damage; we therefore hypothesized that mEPCR may be an important anti-injury molecule in the cascade(s) leading to renal damage in Systemic Lupus Erythematosus.

Method: We used the autoimmune murine strain NZB/W F1 mice, and a nonautoimmune strain of mice with a podocyte-specific microRNA knockout of dicer (dicer k/o), which both display proteinuria. Healthy control mice were also utilized. Tissue was harvested from spleen, liver and kidney. Paraffin sections were stained using an anti-mEPCR antibody via avidin-biotin method. The isotope for mEPCR was used as a negative control. Intensity of immunostaining was scored from 0 to 3+, and staining was considered positive if >1+ and negative when 0 or trace (0.5+). The percent of tissue with positive staining for mEPCR was scored as focal or diffuse.

Results: At four months of age, anti-ds DNA and anti-ss DNA were evident in all NZB/W F1 mice. At early onset of proteinuria, the mEPCR immunostain of cortical peritubular capillaries (PTCs) was, in four cases, 2+ and diffuse, with an isotype control that stained appropriately negative. mEPCR was also negative in the cortical PTCs of 6 healthy control mice. Mice with dicer k/o develop proteinuria at 6 weeks; however, expression of mEPCR was negative in the cortical PTCs. In order to evaluate whether the changes in the microvasculature extend beyond the clinically targeted organ, paraffin sections of liver and spleen were evaluated for mEPCR. The liver of each NZB/W F1 mouse displayed, at the sinusoids, a 2+, diffuse profile of mEPCR expression. In addition, in the spleen of NZB/W F1 we observed a 3+ focal mEPCR staining at the vasculature which supports the white pulp. The expression of mEPCR was negative for liver and spleen in healthy mice and in nonautoimmune nephritic mice.

Conclusion: Consistent with the human studies, evaluation of the cortical peritubular capillaries from NZMB/W F1 mice, a classic murine model of lupus nephritis but not a murine model with nephritis secondary to a genetic podocytopathy, revealed an increase in mEPCR. These data are consistent with the notion that there is widespread activation of the microvasculature. The capacity of endothelial cells to utilize anticoagulation pathways is not restricted to the kidney, and expression of mEPCR in the microcirculation likely represents an attempt to limit microvascular inflammation in spleen, liver and kidney.

Anti C1q Antibodies in Patients with Systemic Lupus Erythematosus and Cutaneous Vasculitis: A Controlled Study. Shirish R. Sangle[1], Loh Yet Lin[2], Esther Sanchez[2], Davies Rachel[2] and David P. D'Cruz[2]. [1]St Thomas' Hospital, London, United Kingdom, [2]St Thomas' Hospital, United Kingdom

Objective: To evaluate the prevalence of anti-C1q antibodies (aC1q) in patients with systemic lupus erythematous (SLE) as a possible marker for cutaneous vasculitis (CV).

Material and Methods: We prospectively enrolled 46 patients with SLE who fulfilled ACR classification criteria. Twenty three patients had clinically documented CV while 23 had no previous evidence of CV. The BILAG disease activity score was documented and active CV rashes were photographed. aC1q were measured by using ELISA and a aC1q titre above 15 units/ml was considered as positive. Statistics was by chi square test. This study was approved by the St Thomas' Hospital Ethics committee and all patients gave written informed consent.

Result: The median age of patients in the CV group was 37 years (27–46) and that of the non –CV patients was 44 (29 –66) years. In the CV group, 9 were Caucasian, 6 Asian and 8 Afro Caribbean and in the non-CV group 13 Caucasian, 5 Afro Caribbean and 5 Asian in origin. In the CV group the median BILAG score for vasculitis manifestations was 3 (3–4). In the CV group 22 had positive ANA, 18 ds DNA, 10 ENA, 13 Ro (SSA) and 6 had La (SSB) antibodies. In the non –vasculitis group 22 had positive ANA, 16 ds DNA, 10 ENA, 12 Ro and 6 had La antibodies. The median complement (C3) levels in the CV were 0.88 (0.24 – 1.49) and C4 0.16 (0.03–1.17) as compared to 1.31 (0.33 – 1.65) and 0.17 (0.02–0.34) in the non-CV groups respectively.

Eighteen of 46 (8 in the CV) patients had positive antiphospholipid antibodies (aPL). Six patients in the CV group had renal involvement with none in the non-CV group. aC1q were positive in 14 of 23 (52%) in the CV group compared to 3 (13%) in the non-CV group ($p < 0.0023$). The median titre of aC1q in the CV group was 35 (5–400) u/ml compared to 6 (5–53) in the non-CV group. All patients with positive aC1q had positive ANA and ds DNA antibodies, 13 had ENA positive, 8 had Ro antibodies, 3 La antibodies, 4 each had RNP and RNP with Smith antibodies. In the CV group 13 patients had low C3, C4 levels of which 10 were aC1q positive and in the non-CV group 1 aC1q positive patient had low C3 and C4 levels. The median C3 and C4 levels in aC1q positive patients in the CV group were 0.55 (0.24–0.64) and 0.08 (0.03-0.017) as compared to 0.7 (0.33–0.91) and 0.17 (0.02–0.08) in the non-CV group respectively. Hypocomplementemia was significantly more prevalent in the CV group ($p < 0.046$). Six patients with positive aC1q were positive for aPL. Three of 6 patients with renal involvement were positive for aC1q in the CV group. aC1q were significantly more prevalent ($p<0.024$) in the CV without previous renal disease compared to the non-CV non-renal group of patients. There was a statistically significant positive correlation between patients with positive C1q anti ds DNA, ANA antibodies and low C3 C4 levels.

Conclusion: Anti C1q antibodies may be a marker of activity in cutaneous vasculitis in patients with systemic lupus erythematosus even in the absence of lupus nephritis.

Antimalarials May Attenuate the Risk of Metabolic Syndrome in SLE: Results from an International Imception Cohort Registry. M. H. X. Ting[2], R. P. Donn[3], M. Lunt[3], M. B. Urowitz[4], D. D. Gladman[1], D. Ibanez[1], C. Gordon[1], S. C. Bae[1], A. Clarke[1], S. Bernatsky[1], J. Hanly[1], D. Isenberg[1], A. Rahman[1], J. Sanchez-Guerrero[1], J. Romero-Diaz[1], P. R. Fortin[1], D. Wallace[1], E. Ginzler[1], A. Vasudevan[1], J. Merrill[1], G. S. Alarcon[1], B. Fessler[1], G. Sturfelt[1], O. Nived[1], K. Steinsson[1], M. Khamashta[1], M. Petri[1], S. Manzi[1], M. Dooley[1], R. Ramsey-Goldman[1], C. Aranow[1], R. Van Vollenhoven[1], M. Ramos[1], T. Stoll[1], K. Kalunian[1], A. Zoma[1], P. Maddison[1] and I. N. Bruce[3]. [1]Systemic Lupus International Collaborating Clinics, Toronto, ON, Canada, [2]The University of Manchester, Salford, Manchester, United Kingdom, [3]The University of Manchester, [4]Toronto Western Hospital, Toronto, ON, Canada

Background: The excess cardiovascular mortality in Systemic Lupus Erythematosus (SLE) is not completely accounted for by traditional risk factors. High waist circumference, high triglycerides, low HDL-cholesterol and impaired glucose homeostasis, the clustering of which constitutes the Metabolic Syndrome (MetS), may be implicated. Therapy related factors such as antimalarials and steroids, used widely in the management of SLE, may moderate these risks. We aimed to describe the baseline incidence of the MetS and its association with steroid and antimalarial use in an international prospective SLE cohort.

Method: Data was obtained from the SLE International Collaborating Clinics-Registry for Atherosclerosis (SLICC-RAS) cohort, collated from 30 centres worldwide. Information on 596 subjects, diagnosed with SLE within 1 year (baseline), was available. The International Diabetes Federation criteria was used to define the MetS, which included the presence of a high waist circumference plus two or more of elevated triglycerides or on specific therapy; reduced HDL-cholesterol or on specific therapy; raised blood pressure(BP) and raised fasting plasma glucose or known Type II diabetes mellitus.

Results: Of the 596 patients studied, 94 (15.8%) had MetS at their baseline visit. There was a significant difference in prevalence of MetS according to therapy with the highest prevalence being in the group taking steroids alone ($P < 0.014$) (Table). Similarly, the incidence of high triglycerides and glucose intolerance was also highest in the group on steroids alone ($P<0.00003$ and $P=0.010$ respectively). Compared to the steroid monotherapy group, the group on a combination of steroids and antimalarials were significantly less likely to fulfil the criteria for MetS ($P=0.002$), high BP ($P=0.005$) and high triglycerides ($P<0.0002$).

	Steroids alone (n = 160)	Antimalarials alone (n = 130)	Steroids and antimalarials (n = 253)	Neither steroids or antimalarials (n = 53)	P
Metabolic Syndrome	38 (23.8%)	18 (13.9%)	31 (12.3%)	7 (13.2%)	0.014
High waist circumference	69 (43.1%)	62 (47.7%)	106 (41.9%)	20 (27.7%)	0.639
High triglycerides or on specific therapy	77 (48.1%)	30 (23.1%)	75 (29.6%)	15 (28.3%)	0.00003
Low HDL-cholesterol or on specific therapy	32 (20%)	28 (21.5%)	54 (21.3%)	11 (20.8%)	0.985
High blood pressure	67 (41.9%)	35 (27.1%)	72 (28.5%)	17 (32.1%)	0.253
Raised fasting plasma glucose or Type 2 diabetes	40 (25%)	14 (10.8%)	55 (21.7%)	7 (13.2%)	0.010

Conclusion: In this early SLE cohort, steroid monotherapy was associated with the highest prevalence of MetS. The prevalence of MetS, increased blood pressure, increased triglycerides and glucose intolerance were all significantly lower with concomitant use of antimalarials. In addition to their anti-inflammatory effects, antimalarials likely have direct effects on vascular function and lipid metabolism that improves the overall metabolic and cardiovascular risk status of SLE patients.

Arthritis in an Ethnically Diverse Systemic Lupus Erythematosus Population. Guada Respicio[1], Clare Cleveland[1], Kim Taylor[1] and Lindsey A. Criswell[2]. [1]Rosalind Russell Medical Research Center for Arthritis, University of California, San Francisco, San Francisco, CA, [2]UCSF-Box 0500, San Francisco, CA

Purpose: Arthritis is one of the most common manifestations of SLE with reported prevalence ranging from 70–95%. Previous research documents ethnic differences in risk and outcome, however ethnic differences in arthritis in SLE have not been well characterized. Further, clinical, laboratory and other correlates of arthritis in SLE have not been fully investigated. We studied the frequency of arthritis among a large and ethnically diverse lupus cohort, as well as factors associated with the presence of this specific disease manifestation.

Methods: SLE patients were recruited from various sources, including specialty clinics and practices, community sources and nationwide outreach. The presence of arthritis as well as other ACR classification criteria was documented by review of medical records. Information about ethnic background was based on self report information as well as genotyping results for a set of ancestry informative markers (AIMs, n = 384). Chi square testing was used to identify ethnic differences in presence of arthritis. Other factors associated with arthritis were examined using multivariate logistic regression. Correlation analysis was used to identify patterns of association between arthritis and other disease manifestations with results displayed visually as heat maps.

Results: 2129 SLE patients were studied, including 1201 (56%) Caucasians, 297 (14%) Hispanics, 259 (12%) Asian/Pacific Islanders, and 248 (12%) African Americans (AA). 91% of patients were female, the average age at SLE diagnosis was 33 years, and the average disease duration at study entry was 9 years. Analyses demonstrated statistically significant ethnic differences in arthritis ($p = 0.003$), with the highest prevalence of arthritis documented for AA patients (75%) and lowest prevalence among Asian patients (59%). Among AA patients, analysis of AIM data did not demonstrate a significant association between the percent African ancestry and risk of arthritis. Results of multivariate logistic regression analyses as well as heat maps representing the degree of correlation between arthritis and other clinical manifestations revealed differential clustering of disease features across ethnic groups. Table 1 summarizes clinical features significantly associated with arthritis based on multivariate analyses of individual ethnic groups. Independent variables in these models included disease duration, sex, and the other ACR classification criteria.

Table 1. Multivariate analyses of ACR Clinical Criteria Associated with Lupus Arthritis

Ethnic Group	Significant clinical criteria (OR, p value)
Caucasians	Malar rash (1.39, 0.021) Serositis (1.70, 0.001)
African-Americans	Discoid rash (0.355, 0.019) Oral ulcers (2.72, 0.042) Renal (0.681, 0.024)
Hispanics	Discoid rash (0.231, 0.003) Renal (0.711, 0.023)
Asians/Pacific Islanders	None significant

Conclusions: These results demonstrate ethnic differences in risk of arthritis among SLE patients, with Asian patients having relatively lower risks of arthritis and AA patients having the highest risk of arthritis. Additional research will be required to further define the basis for these ethnic differences in disease expression.

Disclosure: G. Respicio: None; **C. Cleveland:** None; **K. Taylor:** None; **L. A. Criswell:** None.

Association of Low-Dose Pulsed Intravenous Cyclophosphamide Therapy and Amenorrhea in 62 Patients with Systemic Lupus Erythematosus: A Case-Control Study. Sayumi Baba[1], Yasuhiro Katsumata[4], Yasushi Kawaguchi[2], Kae Takagi[1], Takahisa Gono[1], Yuko Okamoto[1], Yuko Ota[1], Masako Hara[1] and Hisashi Yamanaka[3]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Tokyo Women's Medical University, Tokyo, Japan, [3]Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan, [4]Tokyo Women's Medical University

Purpose: Amenorrhea is a serious adverse effect associated with cyclophosphamide (CY). Although low-dose intravenous CY (IVCY) regimen has been proposed to reduce its various adverse effects in the treatment for major organ involvements in systemic lupus erythematosus (SLE), the beneficial effect of low-dose IVCY on amenorrhea has not been fully elucidated. We aimed to clarify the incidence of amenorrhea following low-dose IVCY and the association between amenorrhea and clinical parameters.

Methods: We performed a case-control study on women younger than 45 years who were treated with low-dose IVCY (500 mg/body/pulse) plus steroid or steroid alone (0.8–1.0 mg/kg/day of predonisolone) for active SLE in our university hospital from 2000 through 2009. Patients with pre-existing amenorrhea and patients who dropped out from our follow-up were also excluded. We conducted a questionnaire survey about secondary amenorrhea and reviewed

medical records from cases and controls. Amenorrhea was defined as lack of menses for at least 3 months. Sustained amenorrhea was defined as lack of menses for at least 12 months without resumption during the study period.

Results: Twenty-nine and 33 patients who were treated with low-dose IVCY (IVCY group) and steroid alone (steroid group) returned the questionnaire, respectively. The median cumulative dose of CY in the IVCY group was 1000 mg. All the patients in both groups were successfully treated and discharged. Amenorrhea developed more frequently in patients in the IVCY group than the steroid group (59% vs. 14%; $p = 0.02$; OR 3.5; 95% CI 1.3–11.0). The incidence of sustained amenorrhea was not statistically different between the groups (14% vs. 3%; $p = 0.18$). 'Age over 40 years at initiation of treatment' was the strongest risk factor for developing amenorrhea by the univariate analysis: Patients over 40 years of age had higher incidence of amenorrhea than younger patients ($p = 0.005$; OR 9.0; 95% CI 1.7–46.5) when both groups were analyzed as a whole. IVCY was also associated with amenorrhea ($p = 0.02$; OR 3.5; 95% CI 1.3–11.0). Sustained amenorrhea developed in 4 patients in the IVCY group and 1 patient in the steroid group and all these patients were in their forties. In contrast, menses resumed in all the patients younger than 40 years old irreverent to the treatment. The multivariate logistic regression demonstrated that 'age over 40 years at initiation of treatment' was significantly associated with amenorrhea ($p = 0.004$; OR 10.2; 95% CI 2.1–78.5). IVCY was weakly associated with amenorrhea without statistical significance ($p = 0.07$; OR 2.9; 95% CI 0.9–9.7).

Conclusions: Our data suggested that the strongest risk factor for developing amenorrhea in SLE patients treated with high-dose steroids with or without low-dose IVCY is 'age over 40 years at initiation of treatment.' In addition, even low-dose IVCY might also increase the risk for developing amenorrhea. Patients younger than 40 years old had minimum risk for sustained amenorrhea irreverent to treatment regimen. Higher risk of IVCY for sustained amenorrhea should be seriously pre-considered in patients over 40 years of age.

A large mutlicentre multinational inception cohort was established to study risk factors for atherosclerosis (AS) in SLE. This study describes vascular events during 10 years of follow-up and their attribution to AS.

Methods: Patients enter the cohort within 15 months of SLE diagnosis (≥4 ACR criteria). Clinical and laboratory features of SLE and comorbidities are gathered in a standardized protocol at yearly intervals. Vascular events are described and attributed on a specialized form. Events recorded include myocardial infarction (MI), angina, congestive heart failure (CHF), intermittent claudication (PVD), stroke, transient ischemic attack (TIA). Diagnosis of an event was confirmed using standard clinical criteria, relevant laboratory data and imaging where appropriate. Attribution to AS was made on the basis of lupus disease being inactive at the time of the event, and/or the presence of typical AS changes on imaging or pathology and/or evidence of AS elsewhere. Factors associated with AVE were analysed using descriptive statistics, t-tests and χ^2.

Results: Since 2000, 1593 patients have been entered into the cohort (89%F, age at SLE 35y, mean followup of 3.7 years). Thus far there have been 134 vascular events in 96 patients. These include: MI (16), angina (17), CHF (32), PVD (10), TIA (21) stroke (33), pacemaker insertion (5). 70 of the events were attributed to active lupus and 20 to other causes and 4 were unknown. 40 events in 26 patients were attributed to AS including: MI (8), angina (14), CHF (6), PVD (6), TIA (3), pacemaker (2), stroke (1).

Ten patients in the AS group had more than one event. Lupus duration at AS event was 2.7 ± 2.4 years. Compared to patients followed for 3 years without vascular events (n=770), at enrolment, patients with AS events were more frequently male (42% vs. 11% $p < 0.0001$) were older at diagnosis (54 ± 13 vs. 34 ± 13, $p<0.0001$), more frequently had hypertension (65% vs. 32% $p=0.0003$), and were more often obese (52% vs 30% $p=0.02$). While hypercholesterolemia, diabetes, smoking and family history of CAD were more common among those with AS events than those without, the difference was not statistically significant. There was no difference in proportion of Caucasian versus other ethnicities in the two groups.

Conclusion: Over the follow-up of an inception cohort with SLE there were 134 vascular events but only 40 were attributable to AS. Patients with AS events were more likely to be male, older age at diagnosis, more frequently obese and more often had hypertension.

Attention Deficit and Hyperactivity Disorder Scores Are Elevated and Associated with Disease Activity and Fatigue in Patients with Systemic Lupus Erythematosus. Ricardo J. Garcia, Lisa Francis, Maha Dawood, Irene Ramos, Stephen Faraone and Andras Perl. SUNY

Purpose: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune inflammatory disease characterized by predisposition to pro-inflammatory T cell death by necrosis due to mitochondrial dysfunction, oxidative stress, and depletion of intracellular glutathione. The potential benefit of reversing glutathione depletion is being investigated in a double-blind placebo-controlled treatment trial of N-acetylcysteine in patients with stable disease (ClinicalTrials.gov Identifier: NCT00775476). Since disease activity in SLE may result in neuropsychiatric manifestations and N-acetylcysteine has been found to improve memory in animal models (Basic Clin Pharmacol Toxicol. 105:98–104, 2009), we investigated whether disease activity in patients with SLE is associated Attention Deficit Hyperactivity Disorder (ADHD) which may serve as a neuropsychiatric marker and target of treatment.

Patients and Methods: The validated ADHD Self-Report Scale (ASRS) Symptom Checklist (Psychol Med 35:245-56, 2005; Ann Clin Psychiatry 18:145–148, 2006) was used to evaluate 22 SLE patients at baseline. As a control for biochemical and immunological studies, a healthy donor matched for ethnicity, gender, and age of the SLE patient within 10 years was bled on the same morning and also asked to complete the ASRS checklist. In the SLE group, 20 of 22 patients were Caucasian, one was African American, and one was Asian. In the control group, 21 of the 22 donors were Caucasian and one was Asian. Mean age was 42.27 years (standard deviation, SD= 12.85, range= 21–64) in the SLE group. Mean age was 44.23 years (SD=10.86, range=23–62) in the control group. All patients were female. SLE disease activity was assessed by using the British Isles Lupus Assessment Group (BILAG) and Systemic Lupus Erythematosus Disease Activity Index (SLEDAI). Fatigue was estimated using the Fatigue Assessment Scale (J Psychosom Res 54:345–352, 2003).

Results: The mean ± SD of part A, part B and total ASRS scores were 10.56 ± 5.75, 9.82 ± 6.01 and 20.36 ± 10.32, respectively, in the control

population. Using two-tailed t-test, the mean ± SD of part A, part B and total ASRS scores were increased at 17.23 ± 7.77 (p = 0.0001), 14.36 ± 5.89 (p = 0.004) and 31.59 ± 12.69 in the SLE group (p = 0.0004). Using Pearson's correlation, fatigue scores correlated with part A (r = 0.76, p<0.0001), part B (r = 0.44, p=0.04) and total ASRS scores (r=0.68, p=0.0005). SLEDAI correlated with part A (r = 0.50; p=0.02) and total ASRS scores (r=0.48, p=0.02). There was no correlation between BILAG and ASRS scores.

Conclusion: Elevated ASRS scores indicate the presence of previously unrecognized and clinically significant symptoms of ADHD in patients with SLE relative to healthy controls matched for age, gender, and ethnic background. ADHD symptoms may be a source of cognitive impairment in SLE, which could lead to functional disability. Longitudinal studies are needed to determine if ADHD symptoms predict the subsequent onset of severe neuropsychiatric disorders that frequently follow the onset of idiopathic ADHD in children (Am J Psychiatry 167:409 417, 2010).

Autoantibody Response to Adjuvant and Non-Adjuvant H1N1 Vaccination in SLE. Murray B. Urowitz, Anoja Anton, Domonique Ibañez and Dafna D. Gladman. Toronto Western Hospital, Toronto, ON, Canada, Toronto Western Hospital, Toronto, ON, Canada

It has been reported that influenza vaccination increases autoantibody production and/or disease activity in a significant proportion of patients with SLE. A further concern would be whether adjuvant containing vaccinations might further enhance autoantibody production in these patients. During the recent H1N1 epidemic we investigated whether the use of adjuvant and nonadjuvant containing H1N1 vaccine induced increased authoantibody production in patients with SLE.

Methods: Patients with SLE who received H1N1 vaccination (with or without adjuvant) and had a battery of 9 autoantibodies tested before and 1 and 3 months after vaccination were included. Antibodies tested included rheumatoid factor (nephelometry), antinuclear antibody (immunofluorescence), anti-DNA (Farr), anti-RNP, anti-SM, anti-Ro, anti-La, anti-Scl70 and anti-Jo1 (ELISA). Patients were evaluated according to the standard protocol including items necessary to calculate SLEDAI-2K and SDI. Descriptive statistics and McNemar test were performed to evaluate change in antibodies positivity. These were repeated in the adjuvant and the non adjuvant groups separately.

Results: 103 patients (94F, 9M), with mean age at vaccination of 43.9 (±15.2) years, disease duration 14.2 (±11.0) years. Mean SLEDAI-2K was 4.38 (±4.28), SDI of 1.26 (±1.52). 64% were taking steroids and 62% on immunosuppressives. 51 patients received adjuvant and 52 nonadjuvant vaccines. Antibody testing was performed a mean of 1.9 months prior to the vaccination. First post-vaccination sample was taken a mean of one month and the second sample was taken a mean of 3.5 months after vaccination. The percent of patients with changes in antibodies following vaccination was not statistically significant for most antibodies. In rheumatoid factor 80% remained unchanged while 15% who were negative became positive while 5% who were positive became negative (p=0.07). This was more pronounced in the non adjuvant group then in the adjuvant group where 88% remained unchanged, 12% converted for positive and none converted to negative compared to 71% remaining unchanged, 18% converting to positive and 12% converting to negative (p=0.03 and p=0.53 respectively). In Anti-Ro 83% remained unchanged while 3% converted to positive and 14% converted to negative(p=0.03) but no difference was significant when looking at the vaccine type. No other antibodies changes significantly in either group. After adjusting for the number of tests performed none of the associations was significant.

Conclusion: H1N1 vaccination (both adjuvant and non adjuvant) did not increase the levels of autoantibodies in patients with SLE.

Belimumab, a BLyS-Specific Inhibitor, Reduced Corticosteroid Use in Patients with Active SLE: Results from the Phase 3 BLISS-52 and -76 Studies. R. F. van Vollenhoven[9], A. Gallacher[3], S. Navarra[11], E. M. Ginzler[8], M. A. Dooley[10], R. Cervera[4], E. K. Li[2], R. A. Levy[5], R. Gúzman[7], Z. J. Zhong[6], S. Cooper[6], L. Pineda[6], D. Hough[6], D. J. Wallace[1] and for the BLISS-52 and -76 Study Groups. [1]Cedars-Sinai/UCLA, Los Angeles, CA, [2]Chinese University of Hong Kong, Hong Kong, China, [3]Hospital Británico de Buenos Aires, Argentina, [4]Hospital Clinic, Barcelona, Spain, [5]Hospital Universitário Pedro Ernesto, Rio de Janeiro, Brazil, [6]Human Genome Sciences, Inc, Rockville, MD, [7]SaludCoop, Bogotá, Colombia, [8]SUNY Downstate Medical Center, Brooklyn, NY, [9]The Karolinska Institute, Stockholm, Sweden, [10]University of North Carolina at Chapel Hill, Chapel Hill, NC, [11]University of Santo Tomas Hospital, Manila, Philippines

Purpose: To assess the corticosteroid-sparing activity of belimumab in patients on corticosteroids at baseline with seropositive SLE over 52 and 76 wk of treatment.

Methods: 1684 seropositive (ANA ≥1:80 and/or anti-dsDNA ≥30 IU/mL) SLE patients with SELENA-SLEDAI ≥6 were enrolled in the phase 3, 52-wk (BLISS-52; NCT00424476) and 76-wk (BLISS-76; NCT00410384) international trials and randomized to IV belimumab 1 or 10 mg/kg, or placebo, plus standard-of-care (SOC) therapy, on d 0, 14, and 28, and then q28d, for 48 or 72 wk. The use of corticosteroids and corticosteroid taper was according to clinical need; use beyond prespecified limits resulted in patient designation as a treatment failure.

Results: 1453 patients (86.3%) were taking corticosteroids at baseline. Mean baseline characteristics were similar across treatment groups: SLE disease duration 6.4 y; daily prednisone equivalent dose 12.5 ± 8.1 mg; 976 patients (67.2%) with prednisone ≥7.5 mg/d; 64.1% with antimalarials, 50.0% with immunosuppressants, 25.7% with nonsteroidal anti-inflammatory drugs. For the pooled dataset, of 976 patients taking prednisone >7.5 mg/d, SLE response index rates were 50.3% and 53.7% with belimumab 1 and 10 mg/kg, respectively (p<0.05 for both), vs 40.6% with placebo. Of patients taking prednisone >7.5 mg/d at baseline, 20.1% and 17.9% with belimumab 1 and 10 mg/kg, respectively (p<0.05 for both), vs 12.3% with placebo were able to reduce prednisone use by ≥25% from baseline to ≤7.5 mg/d during wk 40–52. Of 376 BLISS-76 patients taking prednisone >7.5 mg/d at baseline, 26.9% (p=0.07) and 24.2% (p=0.27) with belimumab 1 and 10 mg/kg, respectively, vs 17.5% with placebo were able to reduce prednisone use by ≥25% from baseline to ≤7.5 mg/d during wk 64–76. Mean steroid reductions in the pooled data set of patients with baseline prednisone >7.5 mg/d, were 4.0 mg/d (p=0.40) and 4.6 mg/d (p=0.15) with belimumab 1 and 10 mg/kg, respectively, vs 3.5 mg/d with placebo at wk 52. In the pooled dataset, of 708 patients (42.0%) taking prednisone ≤7.5 mg/d at baseline, 13.8% (p=0.28) and 10.9% (p=0.044) with belimumab 1 and 10 mg/kg, respectively, vs 18.0% with placebo required an increase in prednisone to >7.5 mg/d at wk 52. Of 443 BLISS-76 patients taking prednisone ≤7.5 mg/d at baseline, 13.5% (p=0.33) and 11.8% (p=0.17) with belimumab 1 and 10 mg/kg, respectively, vs 18.1% with placebo required an increase in prednisone to >7.5 mg/d during wk 64–76.

[a]% patients with average prednisone dose decrease to ≤7.5 mg/d from >7.5 mg/d at baseline (dropout = failure); [b]% patients with average prednisone dose increase to >7.5 mg/d from ≤7.5 mg/d at baseline (last observation carried forward); *p < 0.05
SE, standard error.

Conclusion: In patients with seropositive SLE on corticosteroids, belimumab significantly reduced SLE disease activity at wk 52 and permitted significantly more meaningful corticosteroid dosage reductions than placebo. These analyses suggest that treatment with belimumab may have corticosteroid-sparing activity.

Belimumab, a BLyS-Specific Inhibitor, Reduced Disease Activity, Flares, and Prednisone Use in Patients with Seropositive SLE: Combined Efficacy Results from the Phase 3 BLISS-52 and -76 Studies. M. A. Petri[5], R. A. Levy[3], J. T. Merrill[7], S. Navarra[10], R. Cervera[2], R. F. van Vollenhoven[8], S. Manzi[11], D. Gladman[9], A. Gallacher[1], L. Pineda[4], Z. J. Zhong[4], D. Hough[4], W. Freimuth[4], R. A. Furie[6] and for the BLISS-52 and -76 Study Groups. [1]Hospital Británico de Buenos Aires, Argentina, [2]Hospital Clinic, Barcelona, Spain, [3]Hospital Universitário Pedro Ernesto, Rio de Janeiro, Brazil, [4]Human Genome Sciences, Inc, Rockville, MD, [5]Johns Hopkins University School of Medicine, Timonium, MD, [6]North Shore LIJ Health System, Lake Success, NY, [7]Oklahoma Medical Research Foundation, Oklahoma City, OK, [8]The Karolinska Institute, Stockholm, Sweden, [9]Toronto Western Hospital, Toronto, ON, Canada, [10]University of Santo Tomas Hospital, Manila, Philippines, [11]West Penn Allegheny Health System, Pittsburgh, PA

Purpose: To assess the efficacy of belimumab in patients with seropositive SLE over 52 wk of treatment by pooling the data from 2 large phase 3 clinical trials.

Methods: 1684 seropositive (ANA ≥1:80 and/or anti-dsDNA ≥30 IU/mL) SLE patients with SELENA-SLEDAI (SS) ≥6 on stable standard-of-care therapy for ≥30 d were enrolled in 2 phase 3, double-blind, placebo-controlled international trials of belimumab 1 or 10 mg/kg or placebo, plus standard-of-care (NCT00424476/NCT00410384). Patients were dosed on d 0, 14, and 28, and then q28d, for 48 or 72 wk. Efficacy analyses included SS, BILAG, and SS Flare Index (SFI). The primary endpoint in both trials was wk-52 SLE Responder Index (SRI): improvement in SS (≥4-pt decrease), no new BILAG A and no more than 1 B flare, and no worsening (<0.3-point increase) in Physician's Global Assessment (PGA) vs baseline at wk 52.

Results: Mean baseline characteristics were similar across treatment groups: age 37.8 y; female 94.1%; race: Caucasian 47.4%, Asian 21.1%, indigenous American 22.7%, African-American 8.8%; SLE disease duration 6.4 y; SS 9.7; BILAG 1A/2B 61%; anti-dsDNA+ 69.4%; low C4 56.1%; proteinuria (>0.5 g/24h) 20.1%; antimalarials 65.3%; prednisone ≥7.5 mg/d 58.0%; immunosuppressants 48.7%. SRI response rates were 46.2% (p=0.006) with belimumab 1 mg/kg and 50.6% (p<0.0001) with 10 mg/kg vs 38.8% with placebo (table). Significant improvement was seen with belimumab 10 mg/kg vs placebo for: SRI at wk 52; SS ≥4-point reduction; mean % reduction in PGA at wk 24; reduction in prednisone use; and new BILAG 1A/2B flares. Statistically significant improvement compared with placebo was seen in at least 1 belimumab treatment group for time to response, mean duration of response, time to first flare (all and severe) by SFI, and new BILAG 1A/2B organ domain scores.

Conclusion: Belimumab significantly reduced SLE disease activity and SLE flare rates; delayed time to first SLE flare; and reduced prednisone use in patients with seropositive SLE.

BILAG-Measured Improvement in Moderately and Severely Affected Body Systems in Patients with Systemic Lupus Erythematosus (SLE) by Epratuzumab: Results from EMBLEM™, a Phase IIb Study. Kenneth C. Kalunian[5], Daniel J. Wallace[1], Michelle A. Petri[2], Frederic A. Houssiau[6], Marilyn C. Pike[3], Brian Kilgallen[4], Lexy Kelley[4] and Caroline P. Gordon[7]. [1]West Hollywood, CA, [2]Timonium, MD, [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [4]UCB, Smyrna, GA, [5]UCSD School of Medicine, La Jolla, CA, [6]Universite Catholique Louvain, Brussels, Belgium, [7]University of Birmingham, Birmingham, United Kingdom

Background: The efficacy of 2 epratuzumab doses was demonstrated in a 12-week, multi-center, randomized, double-blind, placebo-controlled, Phase IIb study in SLE (NCT00624351). Statistically or clinically significant efficacy was seen with epratuzumab 600 mg every week for 4 weeks and 1200 mg every other week (EOW) for 2 weeks, respectively, with responder rates twice those of placebo. The aim of this analysis was to assess improvement in BILAG 2004 index according to body systems in the epratuzumab 600 mg weekly and epratuzumab 1200 mg EOW dose groups (cumulative dose = 2400 mg).

Methods: A combined index of disease activity was used to assess efficacy (defined as BILAG improvement: reduction in all body systems of baseline BILAG A to B/C/D and BILAG B to C/D; no BILAG worsening in other organ systems; no deterioration in SLEDAI or physician's global disease activity assessment). Independent central readers determined BILAG grades for all 9 systems. Results for the BILAG improvement component of the combined index in body systems for which a sufficient number of patients per treatment group (≥5) had baseline disease activity to assess response are reported: musculoskeletal, mucocutaneous, cardiorespiratory, neuropsychiatric, constitutional and renal.

Results: Similar numbers of patients had BILAG A/B at baseline in all treatment arms in each system, apart from cardiorespiratory (where the placebo arm contained more patients) (Table). By Week 12, more patients in the epratuzumab 600 mg weekly group, compared with placebo, had an improvement from BILAG A/B to BILAG D in the 6 body systems, indicating no active disease. A higher percentage of patients receiving epratuzumab 1200 mg EOW, compared with placebo, had an improvement in baseline BILAG A/B scores to BILAG C or D in musculoskeletal, mucocutaneous, neuropsychiatric, and renal systems. Improvements were particularly prominent in the cardiorespiratory and neuropsychiatric systems. In the cardiorespiratory system, all 7 patients in the epratuzumab 600 mg weekly group had improved to a BILAG D at Week 12. Similarly, in the neuropsychiatric system, 5 out of 6 patients in the epratuzumab 600 mg weekly group improved from BILAG B at baseline to BILAG D at Week 12.

Table. Change in BILAG grade among subjects with flares at baseline

Body system	Treatment group	BILAG grade at baseline A/B (Severe/moderate disease) n	BILAG grade (shift) at Week 12 A/B (Severe/moderate disease) n (%)	C (Stable disease) n (%)	D (Inactive disease) n (%)
Musculoskeletal	Placebo	31	18 (58)	7 (23)	6 (19)
	Emab 600 mg weekly	35	13 (37)	12 (34)	10 (29)
	Emab 1200 mg EOW	34	13 (38)	10 (29)	11 (32)
Mucocutaneous	Placebo	31	18 (58)	9 (29)	4 (13)
	Emab 600 mg weekly	32	19 (59)	4 (13)	9 (28)
	Emab 1200 mg EOW	32	15 (47)	10 (31)	7 (22)
Cardiorespiratory	Placebo	17	10 (59)	2 (12)	5 (29)
	Emab 600 mg weekly	7	0 (0)	0 (0)	7 (100)
	Emab 1200 mg EOW	9	8 (89)	0 (0)	1 (11)
Neuropsychiatric	Placebo	11	6 (55)	3 (27)	2 (18)
	Emab 600 mg weekly	6	1 (17)	0 (0)	5 (83)
	Emab 1200 mg EOW	8	3 (38)	0 (0)	5 (63)
Constitutional	Placebo	9	1 (11)	1 (11)	7 (78)
	Emab 600 mg weekly	7	0 (0)	0 (0)	7 (100)
	Emab 1200 mg EOW	10	2 (20)	2 (20)	6 (60)
Renal	Placebo	5	3 (60)	2 (40)	0 (0)
	Emab 600 mg weekly	6	3 (50)	1 (17)	2 (33)
	Emab 1200 mg EOW	6	3 (50)	3 (50)	0 (0)

Emab, Epratuzumab.
Placebo, N = 38.
Emab 600 mg weekly, N = 37.
Emab 1200 mg EOW, N = 37.

Conclusions: Treatment with epratuzumab 600 mg weekly during a 12-week cycle provided greater BILAG improvement over placebo in disease activity in all affected body systems. Within specific body systems, most patients had symptom reduction or absence of active disease after treatment. Efficacy was particularly prominent in cardiorespiratory and neuropsychiatric systems in which symptom improvements are often difficult to achieve. Within specific body systems, the majority had symptom reduction or absence of active disease after treatment. This analysis supports the finding that epratuzumab may be an effective treatment for SLE.

Biologics Use in SLE in 7 Centers—Data from the International Registry for Biologics in SLE (IRBIS). Ronald Van Vollenhoven[4], Søren Jacobsen[9], Daniel J. Wallace[1], John G. Hanly[8], Michelle A. Petri[2], David A. Isenberg[10], Ann E. Clarke[7], Julia F. Simard[3], Christian A. Pineau[6], Sasha R. Bernatsky[5] and for the SLICC Group. [1]West Hollywood, CA, [2]Timonium, MD, [3]Clinical Epidemiology Unit, Stockholm, Sweden, [4]Karolinska University Hospital, Stockholm, Sweden, [5]McGill UHC/RVH, Montreal, QC, Canada, [6]McGill Univ Health Center, Montreal, QC, Canada, [7]Montreal General Hospital, Montreal, QC, Canada, [8]Queen Elizabeth II Health Services Center, Halifax, NS, Canada, [9]Rigshospitalet-4242, Copenhagen, Denmark, [10]UCL Div of Medicine, London, United Kingdom

Background: No biologic agents are approved for use in SLE, but off-label use is possible in various settings. In order to obtain information regarding biologics use in SLE, members of the SLICC group recently initiated the International Registry for Biologics in SLE (IRBIS).

Methods: SLICC/IRBIS investigators were asked to provide retrospective data on all patients treated with a biologic for SLE at their center. Standardized case report forms (CRFs) were used to collect demographic, disease-specific, and treatment data at the time of biologic initiation and at yearly follow-up. A retrospective data collection is currently in progress, and data from the first 7 reporting centers were analyzed.

Results: 165 patients were treated off-label with a biologic agent, in all cases rituximab (RTX). Additional groups of patients were treated in open-label extensions of RCTs with belimumab (n=16) and epratuzumab (n=21) – these patients were not further analyzed here. Age (mean±SD) was 39.4±12.3 and 92% were female. 57% were Caucasian, and smaller proportions Southeast Asian, Asian/Indian subcontinent, African-American, Latino, or other (each <10%). Disease duration when the biologic was initiated was 11.2 ± 8.1 years. SLEDAI at biologic start was 10.5 ± 6.7, SLICC-damage index 1.45 ± 1.71, and glucocorticoid (GC) dosage (prednisone equivalent) 15.0 ± 13.8 mg. Two different dosing regimes for RTX were used: 375 mg/m2 × 4 (37%) and 1000 mg ×2 (63%). Concomitant cyclophosphamide (CYX) was used in 54% of patients. The major organ manifestations leading to biologic treatment were lupus nephritis (LN) in 46% of patients, skin disease in 20%, hematological in 10%, musculoskeletal in 9%, CNS in 8%, and other in 14% (some patients having more than one). Both disease-control and steroid-sparing were given as reasons for choosing a biologic. At 1-year follow-up (n=92) additional immunosuppressives (ISs) had been started in 13 patients. Both SLEDAI and GC dose had decreased (SLEDAI to 5.9±5.3; GC to 9.0±10.9 mg, p<0.0005 for both comparisons, and excluding patients on new IS). SLEDAI at baseline was higher in LN patients than in non-LN but similar at follow-up. The higher-dose RTX regime was employed more often in LN; baseline SLEDAI for these patients was higher, and the decrease greater, than for the lower-dose regimen. A similar pattern was seen for changes in SLEDAI when RTX was used with as compared to without concurrent CYX.

Conclusions: Off-label biologics use in this multi-center international cohort was limited to rituximab; additional groups of patients on other biologics are followed in open-label extensions of clinical trials. Biologics in SLE are used for LN as well as for a range of other SLE manifestations. Both disease control and a steroid-sparing effect are targeted. At 1-year follow-up, lupus activity and concomitant glucocorticoid dosage had decreased, and this could not be attributed to other IS treatment.

The complete retrospective dataset from all participating centers, and the initiation of the prospective IRBIS registry, will provide much-needed data on the use of and results achieved with biologics in SLE.

Carotid Plaque Area Correlates Better Than Intima Media Thickness with Cardiovascular Risk Factors and Clinical Ischemic Heart Disease in Lupus Patients. Lihi Eder, Murray B. Urowitz, Dominique Ibanez and Dafna D. Gladman. Toronto Western Hospital, Toronto, ON, Canada

Aim: Patients with Systemic Lupus Erythematosus (SLE) have a significantly increased risk of accelerated atherosclerosis and cardiovascular disease (CVD). The extent of sub-clinical atherosclerosis can be assessed by an ultrasound (US) measurement of carotid intima-media thickness (c-IMT) and carotid plaque area (c-PA). In the general population, c-PA correlates with ischemic events better than c-IMT. The aim of this study was to investigate whether c-PA can serve as a preferred surrogate measure for sub-clinical atherosclerosis in SLE.

Methods: The study patients were recruited from a large single centre prospective cohort of SLE patients. Demographic, clinical and laboratory information was stored in a computerized database. The database was searched for subjects with a history of a documented ischemic heart event, including angina pectoris or myocardial infarction. Consecutive SLE patients without a history of CVD were recruited as controls. High resolution images were acquired with an optimized US system for carotid imaging. Each plaque was scanned in a longitudinal view until maximum area of the plaque was in the plane of view. The plaque area was measured by tracing the perimeter with a cursor. Total plaque area was recorded as the sum of all plaques in the right and left carotid arteries. Mean c-IMT was measured using a computerized software, in the left and right common carotid arteries. Correlation between c-PA and c-IMT were evaluated. Both measures were compared in patients with and without a history of CVD. To facilitate direct comparisons, c-IMT and c-PA were transformed into z scores. Logistic regressions were used to evaluate the Odds Ratio(OR) and 95% Confidence Interval (95% CI) of c-IMT and c-PA in their association with CVD, hypertension, cholesterol, high density lipoprotein (HDL) and low density lipoprotein (LDL).

Results: 72 SLE patients participated in the study, of whom 19 had a history of ischemic heart event. Carotid IMT correlated only moderately with c-PA (r=0.46, p<0.001). Both c-IMT and c-PA were significantly higher in the group with ischemic heart event (712.7 ± 106.7 vs. 606.4 ± 96.0 mm, p<0.001 for c-IMT and 0.447 ± 0.577 vs. 0.048 ± 0.100 p=0.008 cm^2 for c-PA). After transforming c-IMT and c-PA into z scores, c-PA showed a stronger association with clinical ischemic event (OR 10.8 95% CI 2.5–46.9, p=0.001) than c-IMT (OR 2.8, 95% CI 1.5–5.2, p=0.001). Elevated c-PA was significantly associated with high LDL levels (OR 7.6, p=0.04) and with low HDL level (OR 4.78 p=0.02) however, no association was seen with hypertension or total cholesterol level. Carotid IMT did not correlate with any of the traditional cardiovascular risk factors. None of the measures correlated with SLE disease duration.

Conclusions: In SLE patients, c-IMT correlates moderately with c-PA suggesting that they measure different phenotypes of atherosclerosis. Carotid Plaque area correlated better than c-IMT with cardiovascular risk factors and ischemic heart events suggesting that it may serve as a better tool for investigation of atherosclerosis in SLE.

Circulating Pro-Angiogenic Cells Are Reduced in Patients with SLE Independent of the Presence of Coronary Artery Calcification. Joshua Baker[1], Lifeng Zhang[2], Sotonye Imadojemu[2], Alexis Sharpe[2], Sarita Patil[2], Jonni Moore[2], Emile R. Mohler III[2] and Joan Marie Von Feldt[3]. [1]University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, [3]University of Pennsylvania-Philadelphia, Veterans Affairs Medical Center, Philadelphia, PA

Purpose: Circulating pro-angiogenic cells (PACs), often termed endothelial progenitor cells, are reduced in number in patients with SLE. A reduced number of PACs has been strongly associated with the presence of atherosclerosis and predicts cardiovascular events in other populations. We sought to determine if reduced PAC numbers in patients with SLE is dependent on the presence of advanced coronary artery calcification (CAC).

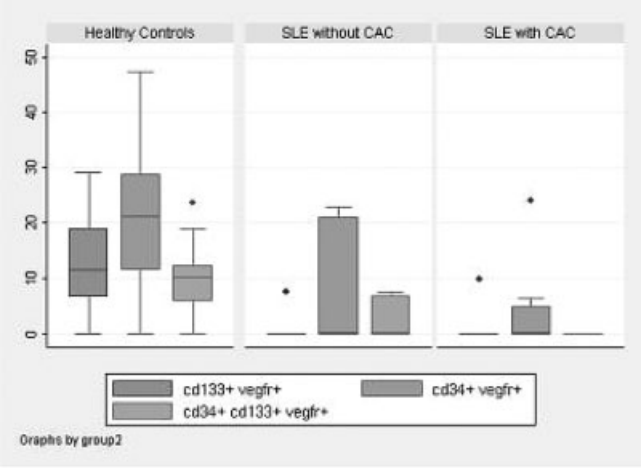
Methods: Patients were included if they met 4 criteria for the diagnosis of

SLE and had previous coronary calcium scores which placed them in either the >75th percentile or <25th percentile for their age. Exclusion criteria included a history of advanced renal disease, cardiovascular events, or current use of >10 mg of prednisone. 17 SLE patients and 13 healthy controls (HC) were included in the study. White blood cells from 30mL peripheral blood were stained for PAC and progenitor cell (PC) markers including CD34, CD133, and VEGFR and analyzed by flow cytometry as previously described (1). SLE patients had repeated coronary imaging with CT as well as carotid ultrasound to determine carotid intima-media thickness. Non-normal data were analyzed with non-parametric tests of significance.

Results: There was no difference in age betweeen HC and SLE. SLE patients were more likely to be hypertensive, and SLE patients with CAC were more likely to be hypertensive, smokers, and have longer disease duration than SLE patients without CAC. Patients with SLE had a significant decrease in PAC numbers when compared to HC. CD133+/CD34+/VEGFR+ cells were deficient in SLE patients (Median, IQR) 10.2 (5.8, 12.3) v. 0 (0, 0) (p<.0001). Compared to HC, SLE patients without evidence of CAC also had significantly lower numbers of PACs (Median, IQR) 10.2 (5.8, 12.3) v. 0 (0, 6.7) (p=0.02)). Total numbers of PCs (CD133+/CD34+) were not significantly decreased in patients with SLE ((Mean + SEM) 1007 + 154 v. 824 + 170 (p=0.2)). No significant difference was seen in PAC number between SLE patients without CAC and those with advanced CAC ((Median, IQR) 0 (0, 6.7) v. 0 (0, 0) (p=0.1). Increased carotid intima-media thickness did not correlate with CAC or decreased numbers of PACs in SLE patients.

Group	Healthy Controls	SLE patients without CAC	SLE patients with advanced CAC
CD133+, VEGFR+	11.5 (6.7, 18.9)	0 (0, 0) (p = 0.005)	0 (0, 0) (*p = 0.6)
CD34+, VEGFR+	21.2 (11.5,28.8)	0 (0, 20.9) (p = 0.05)	0 (0, 4.9) (*p = 0.9)
CD34+, CD133+, VEGFR+	10.2 (5.8, 12.3)	0 (0, 6.7) (p = 0.02)	0 (0, 0) (*p = 0.1)

* p value for comparison between SLE groups



Conclusions: Our study is the first to show that reduced numbers of PACs in SLE patients may be observed even in the absence of coronary calcification. Depletion of total circulating PCs does not appear to fully explain this difference.

Effect of Belimumab, a B-Lymphocyte Stimulator–Specific Inhibitor, on Functional Antibodies to Pneumococcal, Tetanus, and Influenza Vaccines.

W. W. Chatham[6], D. J. Wallace[1], W. Stohl[11], K. Latinis[8], S. Manzi[10], J. McCune[9], D. Tegzová[3], J. McKay[5], H. E. Avila-Armengol[4], T. O. Utset[7], Z. J. Zhong[2], D. Hough[2], W. Freimuth[2], T. S. Migone[2] and for the BLISS-76 Study Group. [1]Cedars-Sinai/UCLA, Los Angeles, CA, [2]Human Genome Sciences, Inc, Rockville, MD, [3]Institute of Rheumatology and Rheumatological Clinic, Prague, Czech Republic, [4]Instituto Jalisciense de Investigacion Clinica, Guadalajara, Mexico, [5]Oklahoma Center for Arthritis Therapy & Research, Tulsa, OK, [6]UAB Arthritis Clinical Intervention Program, Birmingham, AL, [7]University of Chicago, IL, [8]University of Kansas Medical Center, Kansas City, KS, [9]University of Michigan Health System, Ann Arbor, MI, [10]University of Pittsburgh School of Medicine, PA, [11]USC Keck School of Medicine, Los Angeles, CA

Purpose: To evaluate the effect of belimumab plus standard of care (SOC) on antibodies against pneumonia, tetanus, and influenza in SLE patients with history of vaccination against these pathogens prior to study entry.

Methods: The phase 3, multicenter, randomized, double-blind, placebo-controlled, 76-wk BLISS-76 study evaluated the efficacy and safety of belimumab 1 or 10 mg/kg (IV infusion over 1 h on d 0, 14, and 28, and every 28 d thereafter through 72 wk) plus SOC vs placebo plus SOC in patients with seropositive SLE (ANA ≥1:80 and/or anti-dsDNA ≥30 IU/mL; NCT00410384). History of receiving pneumococcal, tetanus, and influenza vaccines was obtained at screening. Patients receiving a pneumococcal (n=73) or tetanus (n=81) vaccine within 5 y prior to d 0, or an influenza vaccine (n=146) within 1 y prior to d 0, were tested for vaccine antibody levels on d 0 and at wk 52. Immunoglobulin-G antibodies were measured for each vaccine (multi-analyte immune detection for pneumonia, enzyme-linked immunosorbent assay for tetanus, and hemagglutination inhibition test for influenza). Endpoints used to determine the impact of belimumab on vaccine responses included % change in antibody levels from baseline to wk 52 in patients with pre-existing antibodies, and proportion of patients with protective antibodies at baseline who maintained protective levels at wk 52.

Results: Consistent with the preservation of the memory B-cell compartment (CD20+/27+ B cells), belimumab did not cause a statistically significant decrease in pre-existing antibodies to pneumococcal and tetanus vaccines; most patients were able to maintain protective titers to these vaccines, and changes were similar across treatment groups (table). Pre-existing antibody responses to seasonal influenza vaccines were generally not affected by treatment with belimumab, although a statistical, but not clinically relevant, difference (<1-fold median change in titers) between treatment groups was observed for some antigens; the percentages of patients that maintained protective specific titers at the end of 52 wk were similar in the belimumab and placebo treatment groups.

SE, standard error.

Conclusion: In this study, treatment with belimumab did not significantly affect the ability of SLE patients to maintain a protective immune response to prior immunizations.

Effect of Systemic Lupus Erythematosus (SLE) on Pregnancy Outcome: An Analysis of 268 Pregnancies. Chi Chiu Mok and Ling Yin Ho. Tuen Mun Hospital

Objectives: To compare the maternal and fetal outcomes of pregnancies before and after the onset of SLE.

Methods: Female patients who fulfilled the ACR criteria for SLE and were ever pregnant were interviewed for the details of the maternal and fetal outcomes regarding their pregnancies. Comparison of the outcomes of pregnancies that occurred before and after the onset of SLE was made.

Results: 113 SLE patients with a history of pregnancy were studied. There were a total of 268 pregnancies: 216 pregnancies occurred before onset of SLE; 47 pregnancies occurred after SLE onset; and in 5 pregnancies, SLE was first diagnosed during conception. The maternal age was 28.7±5.6 and 26.4±5.0 years, respectively, in pregnancies that occurred after and before the onset of SLE. Induced abortion was significantly more common in pregnancies occurring after than before the onset of SLE (35% vs 18.1%; p=0.01). Spontaneous abortion also occurred at a higher frequency in pregnancies that occurred after SLE onset, but the difference was not statistically significant (12% vs 8.3%). Among 216 pregnancies that occurred before SLE onset, 158 (73%) ended up with live births and there was one (0.5%) intrauterine fetal death. The mean fetal birth weight was 2.98±0.51 kg. For pregnancies that occurred after SLE onset, only 55.3% ended up with liver births. The fetal birth weight was significantly lower than that in pregnancies that occurred before SLE onset (2.74±0.46 vs 2.98±0.51 kg; p=0.03). Low fetal birth weight (<2.5kg) was more common in pregnancies that occurred after SLE onset than those occurring before onset of SLE (14% vs 7%; p=0.19). The mean gestational age of fetus was also significantly lower in pregnancies that occurred after SLE diagnosis (36.1±2.7 vs 37.9±2.8 weeks; p=0.02). Preterm delivery was significantly more common in pregnancies after SLE onset (36% vs 7%; p<0.001). There were more maternal complications (eg. preeclampsia, proteinuria and lupus flares; 30.8% vs 3.8%; p<0.001) and fetal complications (eg. neonatal lupus, heart problems, infections, anemia; 3.8% vs 2.5%; p=0.75) in pregnancies that occurred after SLE diagnosis than before onset of SLE.

Conclusion: SLE increases the frequency of maternal complications and adversely affects fetal outcomes in terms of fetal loss, prematurity and low birth weight.

Effects of Disease Activity and Use of Antimalarials on the Risk of Coronary-Artery Calcifications in SLE Patients. Juanita Romero-Díaz[3], Florencia Vargas-Worackova[1], Eric Kimura-Hayama[2], Carlos Aguilar-Salinas[3] and Jorge Sanchez-Guerrero[4]. [1]Instituto Nacional ce Ciencias Medicas y Nutricion Salvador Zubiran, [2]Instituto Nacional de Cardiologia Ignacio Chavez, [3]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, [4]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico

Traditional cardiovascular risk-factors do not fully explain premature atherosclerosis in SLE. We aimed to identify lupus-related factors associated with coronary-artery calcifications in an inception cohort for the study of atherosclerosis.

Methods: We included 139 patients (93% females) with SLE of recent-onset at enrollment, w/o preexisting coronary heart disease. At enrollment, a standardized medical evaluation was done assessing lupus characteristics, medications, cardiovascular risk-factors, and laboratory tests (lipid profile, homocystein, hsCRP, autoantibodies). Patients were seen every 3–6 months, and assessed for disease activity and medications. Every year, information was updated and a blood sample drawn.

At 5.5 ± 2.9 years of follow-up, all the 139 patients and 100 healthy subjects, matched for age and sex, were screened for coronary-artery calcifications using a 64-slice Multidetector Computed Tomography.

A nested analysis of lipids and inflammatory molecules was conducted among all lupus patients with calcifications and a random sample without calcifications (ratio 1:4), matched for age, sex and disease duration. Measurements were done in samples drawn at enrollment, mid follow-up, and at screening: total cholesterol, cHDL, cLDL, triglycerides, Lp(a) lipoprotein, and Apo B; CD40 ligand, IL-6, IP-10, MCP-1, sICAM-1, vCAM-1 (ELISA). Also, fasting levels of homocystein, and hsCRP were determined at enrollment and at screening.

Results: At enrollment, mean (SD) age of lupus patients was 27.2 (9.1) years, lupus duration 5.4 (3.8) months, and SLEDAI-2K score 6.9 (5.8). At screening for calcification, mean age of patients and controls was similar (31.8 ± 8.8 vs. 32.2 ± 9.8 years), as most cardiovascular risk-factors; however lupus patients had more often hypertension, higher levels of homocystein and hsCRP, wider waist, and females were more often post-menopausal, P<0.05.

Coronary-calcifications were detected in 10 patients (7.2%) and 1 control (OR 7.7, 95% CI 1.05–336.3, P = 0.02). Calcium scores in 9 patients ranged between >0–20, and in the remaining patient 402; in the positive control it was 239. Calcifications in lupus patients were detected since age 21–30 years and from 3 years of diagnosis.

In comparison to patients w/o calcifications, patients with calcifications were older, females more often postmenopausal, had higher Apo-B levels, IgG aPL antibodies, and the Framingham risk-scores were higher (p<0.05). Disease activity along the course of lupus was higher (SLEDAI-2K AUC 20.3±8.3 vs. 13.7±8.3, P=0.02), and the period of moderate/severe activity longer (SLEDAI-2K score ≥7, 20.0±18.3 vs. 8.0±12.5 months, P=0.006). Cumulative doses of prednisone and cyclophosphamide were higher (P<0.05), but use of antimalarials lower (20% vs 65%, P=0.006). Longitudinal analyses of lipids, cytokines and chemokines did not show differences. Logistic regression analysis showed an independent association of age, Apo-B, lupus activity (P=0.004), and use of antimalarials (P=0.008) with calcifications.

Conclusions: Lupus activity is an independent risk factor for coronary-artery calcifications, a risk that might be reduced using antimalarials.

Elevated Levels of Plasma Micro-Particles (PMPs) in Systemic Lupus Erythematosus (SLE) Are Associated with Higher Risk of Thrombosis. Aisha Lateef[3], Laurence S. Magder[4], Jayesh Jani[2], Thomas S. Kickler[2] and Michelle A. Petri[1]. [1]Timonium, MD, [2]Johns Hopkins University, [3]National University Health System, Singapore, Singapore, [4]University of Maryland Medical School

Objective: PMPs are sub-micron, membrane-bound vesicles, released during cell activation, apoptosis and exposure to shear stress. They are pro-thrombotic, expressing high levels of phosphatidylserine and tissue factor on outer membranes. PMPs modulate nitric oxide and prostacyclin production from endothelial cells, as well as monocyte chemotaxis and adherence to the endothelium.

Elevated levels of PMPs have been associated with pro-thrombotic disorders, including acute coronary syndromes, stroke, diabetes, hypertension, and hypertriglyceridemia. In addition, elevated PMP levels have been associated with inflammatory diseases such as SLE and cancer-associated thrombosis.

D-dimers are fibrin degradation products, reflecting activation of thrombosis and fibrinolysis. Elevated levels have been shown to predict risk of thrombosis in patients with atrial fibrillation on anticoagulation.

We evaluated the association of thrombotic events with PMP and d-dimer levels in a cohort of patients with SLE.

Methods We measured PMP and d-dimer levels in 894 SLE patients in a prospective cohort. The relationship between PMP and d-dimer levels and thrombotic events was evaluated using survival analysis.

Results: Of the 894 patients, 234 had at least one thrombotic event at some time in their life. The first event was DVT (108 patients), Stroke (70 patients), MI (23 patients), Other venous (19 patients), and Other arterial thrombosis (14 patients). Elevated levels of PMP (>5nM) were associated with higher risk of thrombotic events (RR=1.4, p=.05). We subdivided the group with elevated levels of PMP into different strata and the increased risk remained in all groups (Table). The risk was even higher if these patients were positive for lupus anti-coagulant or anticardiolipin antibodies (RR=1.5, p=.007). Elevated levels of d-dimer (>0.88 mg/L) were not predictive of higher risk of thrombosis in SLE.

Conclusion: We found that elevated PMP was associated with thrombosis in SLE. Elevated PMPs can affect the vasculature in many ways, leading to heightened inflammatory and thrombotic effects. They can induce adhesion molecules on endothelial cells, resulting in increased inflammation of atherosclerotic plaque. At the same time, their pro-thrombotic potential may favor thrombosis and clot formation.

We are now evaluating the effects of therapeutic intervention on PMP levels.

Evaluation of Cardiac Function and Myocardial Damage in Women with Systemic Lupus Erythematosus (SLE) by Cardiac MRI. Mala S. Kaul[2], Han Kim[2], E. William St Clair[2] and Megan E. B. Clowse[1]. [1]Duke Univ Med, Durham, NC, [2]Duke University, Durham, NC

Background: Cardiac magnetic resonance imaging (cMRI) can provide great detail about cardiac structure and function in a single session without harmful radiation. Very small areas of myocardial scar tissue can be identified using delayed gadolinium enhancement (DE) techniques. Additionally, impairments in coronary flow reserve may be measured by velocity-flow imaging, which identifies microvascular dysfunction. A recent study using cMRI found perfusion defects in 44% of asymptomatic SLE patients undergoing stress testing as well as areas of DE indicative of myocardial damage in 37% of patients.[1] Our objective was to take advantage of the sensitivity of cMRI to further evaluate the state of the myocardium in asymptomatic patients with SLE.

Methods: Consecutive patients meeting ACR Classification Criteria for SLE without history of cardiovascular disease or antiphospholipid syndrome were recruited from our university lupus clinic between January 2010 and May 2010. All patients underwent a comprehensive cMRI including adenosine stress perfusion imaging, and pre- and post- test electrocardiograms. Data collected included a chest pain history using the Rose chest pain questionnaire, SLEDAI scores, cardiovascular risk factors, disease duration and antiphospholipid antibody status.

Results: All 15 patients included in the study were women, with a mean age of 45 years (range 31–61 years); 60% were African American and the remainder were Caucasian. 27% patients had hyperlipidemia, and 47% had hypertension. 60% of patients were either obese (BMI >30) or overweight (BMI >25). The mean duration of SLE was 12 years (range 3 to 30 years) and average SLEDAI score was 3.5 (range 0 to 12). A previous history of chest pain was reported in 40% of patients. Only one patient tested positive for serum antiphospholipid antibodies.

No patient had evidence of prior myocardial infarction by ECG (Q-waves). By cMRI, left ventricular ejection fraction was normal. No patient had evidence of ischemia. The coronary flow reserve, a marker of coronary microvascular dysfunction, was normal in all patients. Delayed gadolinium enhancement of the myocardium, which is indicative of prior myocardial damage was identified in 3 (20%) of the patients. Additionally, 4 (27%) patients had evidence of delayed gadolinium enhancement of the papillary muscles and 1 patient had mild aortic regurgitation. An incidental thymoma was discovered in 1 patient. None of the subjects had pericardial effusion or thickening, or other valvular abnormalities.

Conclusion: In contrast to a previous study, asymptomatic patients with SLE were shown to have well preserved myocardial function, relatively normal cardiac structure, and no evidence of ischemia. Coronary flow reserve was not severely impaired. Small areas of myocardial and papillary muscle damage, however, were found in a minority of patients in our study, confirming that these abnormalities may be found in SLE despite a paucity of symptoms or other evidence of cardiovascular disease.

Fulvestrant (Faslodex) an Estrogen Selective Receptor Down Regulator in the Therapy of Female SLE Patients, One to Two Year Following Faslodex Study Termination Revealed Mild Reactivation of the Serologic Parameters and Disease Activity. Nabih I. Abdou[1], Virginia Rider[3] and Cindy A. Greenwell[2]. [1]Center for Rheumatic Disease Allergy & Immunology, Kansas City, MO, [2]Center for Rheumatic Disease Allery & Immunology, Kansas City, MO, [3]University of Pittsburg, Pittsburg, KS

Background: Estrogen plays a role in upregulation of intracellular signals by binding to estrogen receptors. In SLE, the disease predominantly affects females. Faslodex (fulvestrant) competes for receptor binding in vitro and inhibits estrogen action in immune cells. This study investigated the role of the estrogen receptor blocker (Faslodex) given in a double blind protocol, monthly in vivo for one year with clinical and serological parameters. The bone density was measured pre-study and at the end of study. There was an observational visit one to two years after the completion of study.

Objective: We would like to examine the clinical status and immunologic parameters of female SLE patients at the end of the one-year study compared to the one-to-two year follow-up observation period after study completion.

Methods: Sixteen female SLE patients with moderate disease activity (SLEDAI 7.87+/− 3.7) were entered into the one-year double-blind placebo controlled Faslodex study. Eight patients received Faslodex IM monthly and eight received placebo IM monthly. Parameters checked pre-study and monthly as well as 3 months post study were SLEDAI, ANA, C3, C4, CH^{50}, urinalysis, anti-dsDNA, liver enzymes, creatinine, serum estrogen and Faslodex levels, and the bone density was done pre-study and at end-of-study. Two of these sixteen were lost to follow-up. At one to two years post study, 12 patients had SLEDAI, ANA, anti-dsDNA, C3 and C4 or CH^{50}, UA, liver enzymes, and creatinine measured.

Results: During the one-year study there was a significant drop in SLEDAI in the Faslodex group. SLEDAI pre-study of 8.25 dropped to 3.75 one to two years post Faslodex ($p < 0.02$). Antids-DNA in the same group dropped from 9.25 to 5.75 IU/ml ($p < 0.01$). The drop of anti-dsDNA persisted for one to two years after the study. There were no significant changes in any other parameter, including the estrogen levels and bone density.

Conclusion: Blocking estrogen receptors in vivo by an estrogen selective receptor down-regulator could be considered as a new therapeutic approach for moderately active female SLE. No untoward effects were seen in the patients studied by blocking the estrogen receptor without changes in estrogen levels or drop in the bone density. Only the anti-dsDNA was significantly decreased, but the complement leverls, ANA, and other measured parameters did not change. Faslodex is safe and could be a good alternative for the treatment of moderately active female SLE patients. We would like to extend this study for a longer duration and larger doses of Faslodex.

Disclosure: N. I. Abdou: None; **V. Rider:** None; **C. A. Greenwell:** None.

Hydroxychloroquine Can Interfere with Flow Cytometric Analysis of Blood Cells from Patients Taking This Medication. Louise Fraser[1], Graham H. Mitchell[1], Shirish Sangle[2], Lee Meng Choong[2], Richard Ellis[1], Jo Spencer[1] and David P. D'Cruz[3]. [1]Department of Immunobiology, King's College London, [2]Lupus Research Unit, St Thomas' Hospital, [3]St Thomas Hospital, London, United Kingdom

Background: Immunological investigation of blood cells from patients with systemic lupus erythematosus (SLE) often involves flow cytometry. Quinoline ring-containing compounds are known to fluoresce. Therefore we asked whether the drug hydroxychloroquine (HCQ) might fluoresce and whether this might interfere with flow cytometric analysis of blood cells from patients taking this drug.

Methods: Blood cells from 13 patients with SLE were studied. They were all female, age range 19 to 71 years (average 45 years) with range of disease duration between 3 and 30 years (average 14 years). 9 patients were taking HCQ, and 5 taking steroids. In addition 3 disease controls and 10 healthy controls were studied. Peripheral blood lymphocytes were analysed by flow

cytometry, either with no stain or with a standard assay for expression of kappa and lambda light chains by B cells, which uses FITC, PE and APC channels. Data were analysed with Flowjo software. All the patients studied fulfilled the ACR classification criteria. The study was approved by the St Thomas Hospital Ethics committee and all subjects gave written informed consent.

Results: Blood cells from patients taking HCQ showed fluorescence on FITC, PE and APC channels when no fluorochrome conjugated antibodies were added to the assays. This was apparent when cells were sampled from any of the gates placed based on forward scatter and side scatter including the lymphocyte gate, and identified approximately 20% of cells as distinct populations (Figure).

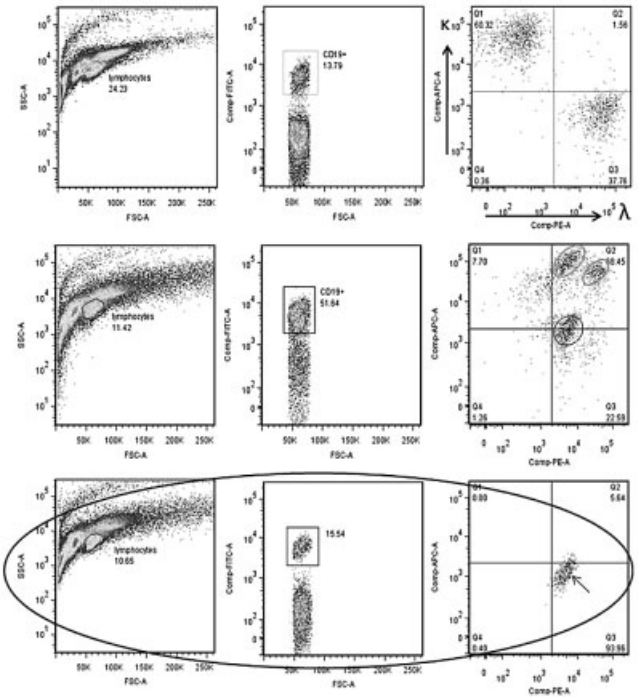

Figure. A. Analysis of healthy control blood. Lymphocytes (first column) were selected for expression of CD19 (second column) and the ratio of kappa: lambda light chain expression observed (third column).
B. When the process was repeated with blood from a SLE patient taking HCQ, the number of cells in the apparent CD19 gate increased. The profile of kappa and lambda expression was skewed (circles).
C. When cells from patients taking HCQ underwent the same procedure fluorescence in the FITC (second column), APC and PE channels was observed.

Blood cells from all individuals studied were assayed for kappa and lambda light chain expression on CD19 B cells by flow cytometry. The assays were standardized using blood from healthy control individuals and the percentage of B cells expressing each light chain determined accordingly. We observed that the fluorescence caused a shift so that cells appeared artifactually in the top right hand quadrant of the flow cytometric analysis of bloods from patients taking HCQ.

Conclusion: HCQ appears to have a broad spectrum of fluorescent excitation and emission which can interfere with flow cytometric analysis of blood cells from patients taking this medication. It is important when analyzing bloods from patients taking this drug that each sample is standardized according to its own isotype matched fluorescent control antibody.

Immunogenicity of the Quadrivalent Recombinant HPV Vaccine in Female Systemic Lupus Erythematosus Patients Aged 9 to 26 Years. Arzu Soybilgic[2], Karen Onel[1], Tammy O. Utset[1], Kenneth A. Alexander[1] and Linda Wagner-Weiner[1]. [1]Univ of Chicago, Chicago, IL, [2]University of Illinois at Chicago, Chicago, IL

Background: Women with SLE have higher rates of persistent HPV infections than healthy women. HPV vaccine is safe and effective in healthy females aged 9–26 years. There are no data on the immunogenicity of HPV vaccine in females with SLE.

Objectives: To evaluate immunogenicity of recombinant quadrivalent HPV vaccine in female SLE patients aged 9–26 years.

Methods: Prospective, open-label, pre-post intervention study. All patients met ACR Criteria for SLE. Exclusion criteria: disease exacerbation within past 30 days resulting in ≥6 points increase in SLEDAI, increase in corticosteroid dose, initiation of new immunosuppressive medication or hospitalization; rituximab in the past 6 months; current cyclophosphamide treatment; previous HPV vaccination; pregnancy. HPV vaccine was given at months 0, 2, 6. Patients were monitored by physical examination, SLEDAI, lupus laboratories at months 0, 2, 4, 6 and 7. Each patient's SLEDAIs and laboratory profile in the year prior to vaccine administration were used as controls for that patient. Antiphospholipid, anti-ENA, HPV antibodies were measured at months 0 and 7. Primary outcome measures were change in SLEDAI and mean geometric HPV antibody titers. The secondary outcome measure was induction of autoantibodies.

Results: 26 patients, ages 12 to 26 years, were enrolled. 24 and 19 patients received two and three doses of HPV vaccine, respectively. Seven patients dropped out of the study: 2 pregnancies, 1 non-compliant, 2 moved out-of-state, 2 secondary to increased arthralgias. 19 patients completed the study.

Type-specific immunoassays with type-specific standards were used to assess immunogenicity to each vaccine HPV type. These assays measured antibodies against neutralizing epitopes for each HPV type. The immunogenicity analyses were conducted in a per-protocol immunogenicity (PPI) patient population. This population consisted of individuals who were seronegative to the relevant HPV type(s) at enrollment, received all three vaccinations, and did not deviate from the study protocol in ways that could interfere with the effects of the vaccine.

Immunogenicity was measured by (1)the percentage of individuals who were seropositive for antibodies against the relevant vaccine HPV type, and (2) the Geometric Mean Titer (GMT) (reported as Mmu/ml). GMTs were measured at month-7 because across all populations in previous clinical trials anti-HPV antibody titers peaked at month-7. HPV Antibody was determined by test kits, and cutoff values for seropositivity were titers at or above 20, 16, 20 and 24 mMU/mL for HPV 6, 11, 16 and 18 respectively.

Of the 19 patients who completed the study,16 had samples available at month-7 for analysis. Seropositivity rates after three doses of the vaccine were 90.9%, 100%, 100%, and 92.3%, and GMT were 641.4, 587.1, 28.44, 422.0 mMu/ml for HPV 6,11,16 and 18 respectively. One patient who received rituximab after the first vaccine dose had no antibody response at month 7.

Conclusion: The recombinant quadrivalent HPV vaccine was immunogenic in females aged 9–26. Only one patient who received rituximab after the first vaccine dose had no antibody response. Limitation of our study was the relatively small sample size.

Immunoglobulin Levels as Potential Predictors of Response to B-Cell Depletion (BCD). Sara C. Croca[1] and David A. Isenberg[2]. [1]Hospital de Santa Maria, Department of Medicine 1, Lisbon, Portugal, [2]UCL Div of Medicine, Room 331, 3rd Floor, London, United Kingdom

Objectives: The use of BCD achieved by a combination of intra-venous methylprednisolone, cyclophosphamide and the anti-CD20 monoclonal antibody Rituximab has been reported to be an effective treatment for refractory systemic lupus erythemathosus (SLE) flares. The duration of the period of BCD is linked to the length of clinical improvement/ remission. Low C3 levels at the time of BCD predict a faster relapse but other predictors of the period of BCD are yet to be established. In this study we looked at the serum immunoglobulin levels (sIg) over time in order to assess whether they could provide an effective predictor of response to treatment.

Methods: Between July 2001 and December 2009, 78 lupus patients were treated with BCD at the University College Hospital London (UCLH). Patients were assessed at baseline and at 3 and 6 months after treatment with regards to the sIg levels (IgA, IgG, IgM). We selected patients with a minimum 12-month follow-up with consistent measurements of sIg over time (n= 44). The outcomes were defined as depletion status at 6 months (depleted: absolute CD 19 (CD19abs)≤ 0.005 ×109; non-depleted/ repopulated: CDabs> 0.005×109) and retreatment within 12 months of the first BCD treatment.

Results: Following the first BCD cycle, 86.4% (n= 38) were successfully depleted. However, six months after treatment, only 40.9% (n= 18) remained depleted. Depleted patients at 6 months had significantly lower baseline IgA

(p= 0.0003) and IgG levels (p< 0.001) with no differences with regards to the IgM levels. In addition, when comparing baseline and 6 months measurements, patients that remained depleted had a 40% reduction in the IgA levels whereas non-depleted patients had only a 10% reduction and this was statistically significant (p< 0.00001). No differences were found with respect to IgG and IgM reduction rates. A third of the patients (n= 14) were retreated within 12 months of BCD. Retreated patients showed significantly higher levels of IgA throughout follow-up (p= 0.002). No differences were found in terms of IgG and IgM between retreated and non-retreated patients.

Conclusions: We report that sIg levels, particularly IgA, may predict both duration of depletion following treatment with BCD and need to retreat. Recent data (DiLillo et al) suggest that the absence of a long term fall in antibody titres following BCD may be associated with the presence of long-lived plasma cells. Given the fact that serum IgA derives mainly from bone marrow plasma cells, the relation between higher levels of IgA could represent higher numbers of long-lived plasma cells that in turn could account, at least to some extend, for a poorer response to BCD. Further investigation of the potential role of long-lived plasma cells in the maintenance of an auto-immune memory after BCD is needed to confirm this hypothesis.

Disclosure: S. C. Croca: None; **D. A. Isenberg:** None.

Influenza Humoral Immune Responses in Patients with Systemic Lupus Erythematosus. Evan Glenn Vista[3], Sherry Crowe[2], Linda Thompson[2], Gillian Air[4] and Judith A. James[1]. [1]Oklahoma Med Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]University of Oklahoma Health Science Center

Background: Annual seasonal flu vaccination has been the standard of care among the general population. Controversy still exists as to whether flu vaccination is effective among systemic lupus erythematosus (SLE) patients, who are identified by the United States Centers for Disease Control as a high risk group as part of the immunocompromised population. Select clinical and demographic factors may influence the response to influenza infection and vaccination among SLE patients. Flu vaccine is given at a particular period of the year in the clinical setting; however, nearly all previous studies have been limited in sample size, racial composition and focused on patients with relatively quiescent disease. This study assessed a large cadre of ethnically diverse SLE patients to identify clinical, demographic and therapeutic features associated with poor influenza vaccination responses.

Methods: A total of 201 SLE patients who fulfilled the American College of Rheumatology (ACR) criteria provided informed consent. Influenza antibody titers were tested at up to five-fold dilutions. A very low and a very high titer were defined as an endpoint titer of 1:200 and 1:10,000 respectively. Patient demographics and clinical profiles, including current medications, were collected. Antinuclear antibodies (ANA), anti-dsDNA, anti-Ro, anti-La, anti-Sm, anti-RNP, anti-Ribo P, anti-cardiolipin IgG were measured. Test for proportions and modified Wald method were used to compute for the 95% confidence interval of each influenza humoral immune endpoint titer.

Results: The sample population was comprised of 92 African Americans (45%), 98 Caucasians (48%) and 17 belongs to other or mixed races (7%). The median age of all subjects from this study is 43.5 years (range 17 to 87) and 87% are females. The mean influenza antibody endpoint titers were computed at 1:2146 (SD 2.48, CI 1802 to 2492), 17 subjects (8.5%, CI 0.05 to 0.13) were very low and 15 subjects (7.5%, CI 0.45 to 0.12) were very high. The majority (78 subjects) had an endpoint titer of 1:1000 (38.8%, CI 0.32 to 0.46). Endpoint titers for the others are as follows: 27 subjects (13.4%, CI 0.09 to 0.19) with 1:300 and 64 subjects (31.8%, 0.26 to 0.39) with 1:3000. Comparing the very low and very high endpoint titers, no significant differences in terms of sex, age and race were seen. In terms of their ACR criteria, patients with very high endpoint titers have higher incidence of discoid rash (30% vs 10%), photosensitivity (70% vs 50%) and serositis (60% vs 30%), while patients with very low endpoint titers fulfilled more immunologic criteria (80% vs 20%). Among the autoantibodies, no difference were seen in the ANA titers and the presence of anti-nRNP was significantly higher for those with very low endpoint titers (7/17 vs 1/15, OR 9.9 p <0.04). More patients with very low endpoint titers have concomitant prednisone medication than those with very high endpoint titers (12/17 vs 4/15, OR 6.6 p< 0.03).

Conclusions: Humoral immune responses to influenza were seen among patients with SLE. The variability of flu antibody titers could be influenced by factors that include current medications with steroids and select autoantibody production such as anti-RNP.

Low-Dose Combination of Mycophenolate Mofetil and Tacrolimus for Refractory Lupus Nephritis: An Open-Labeled Trial. Chi Chiu Mok, Chi Hung To, Pak To Chan, Ka Lung Yu and Ling Yin Ho. Tuen Mun Hospital

Objectives: To evaluate the efficacy of low-dose combination of mycophenolate mofetil (MMF) and tacrolimus (Tac) for refractory lupus nephritis

Patients and Methods: Patients with refractory lupus nephritis were recruited. Inclusion criteria: (1) Active nephritis documented by renal biopsy within 24 months of entry; (2) Failure to respond to ≥ 2 immunosuppressive regimens which consist of high-dose corticosteroid combined with one other agent (eg. cyclophosphamide [CYC], azathioprine [AZA], MMF, cyclosporin A [CSA], Tac) together with ACE inhibitors ± angiotensin receptor blockers (ARB). Each regimen should be used for ≥6 months at the maximally tolerated dosage of the drugs; (3) Serum creatinine (Scr) ≤200umol/L. Exclusion criteria: (1) Previous intolerance to either MMF/Tac; (2) Scr >200umol/L; (3) Informed consent unavailable. Treatment failure to previous regimens was defined as any one of the following: (1) Failure of proteinuria to improve to <3g/day or urine protein-to-creatinine (uP/Cr) ratio to <3.0; or <50% of pre-treatment / baseline values; (2) Deteriorating Scr by ≥20% or loss in creatinine clearance (CrCl) by ≥30% compared to baseline not accounted by causes other than active nephritis; (3) Persistent active urinary sediments (RBC, active cellular casts ≥5/HPF). While prednisolone (≤10mg/day) and ACE inhibitors/ARB were continued, other immunosuppressive agents were discontinued and replaced by the current regimen, which consisted of MMF (1g/day) and Tac (4mg/day) in two divided doses. Patients were followed prospectively at least 2-monthly for the primary end-point (clinical response) at 12 months and adverse events.

Results: Up to May 2010, 11 patients were recruited. The mean age of these patients was 35.7±10 years and the mean SLE duration was 106±47 months at study entry. The distribution of the histological classes of lupus nephritis was as follows: ISN/RPS class IVG or III (36%), pure V (27%), V+III (36%). Previous treatment regimens received by these patients were: high-dose prednisolone (N=11), CYC (pulse/oral) (N=4), AZA (N=11), MMF (N=8), CSA (N=2) and Tac (N=7). All patients had been receiving the maximally tolerated doses of ACE inhibitor±ARB. The mean Scr, CrCl, uP/Cr, 24-hour proteinuria and serum albumin was 80.5±29umol/L, 85.3±32ml/min (8 patients [73%] had CrCl of <90ml/min), 2.85±1.4, 2.67±1.0g and 31.3±4.8g/L, respectively. Seven (64%) patients had active urinary sediments and 9(82%) patients had active lupus serology. Eight patients had completed 12 months' follow-up. Significant improvement in proteinuria and urinary sediments was observed in 7 (88%) patients and improvement started to occur at month 4–6. At month 12, a proteinuria of <1g/day and stabilization of CrCl was achieved in these patients. One patient was refractory to this regimen and withdrawn from the study. Treatment was well tolerated. The following adverse events were reported: minor infections (N=3), diarrhea (N=1), anorexia (N=1) and leg cramps (N=1).

Conclusions: Low-dose combination of MMF and Tac is a viable option for treating refractory lupus nephritis. A proper comparative trial with the novel biological agents is warranted.

Lupus Disease Severity Is Not a Risk for Cervical Intraepithelial Neoplasia in SLE. J. Patricia Dhar[3], Lucie Gregoire[3], Wayne Lancaster[3], Azadeh Stark[1], Ann Schwartz[3], Daniel Schultz[2], Lynnette Essenmacher[3], Joel Ager[3], Lisa Chiodo[3], Mujitaba Husain[3] and Robert J. Sokol[3]. [1]Geisinger Health Systems, Danville, PA, [2]Hernry Ford Health Systems, Detroit, MI, [3]Wayne State University, Detroit, MI

Purpose: Women with systemic lupus erythematosus (SLE) are at increased risk for cervical intraepithelial neoplasia (CIN), possibly related to immunodysregulation. We hypothesized that women with SLE who developed CIN would be younger, have more severe disease and have received more immunosuppressive treatment.

Methods: In a case-control design, clinical characteristics of SLE women with CIN (cases) were compared to two groups of SLE women without CIN (controls). Diagnoses of cervical intraepithelial neoplasia (CIN) were confirmed from formalin fixed blocks of cervical tissue from 113 women with

SLE. Clinical data were obtained by chart review. Logistic regression was used to evaluate for any significant differences in clinical variables between the cases and the controls. Two sets of controls were used for comparison with a ~2:1 match for each control group to the cases group. For the first set, only the year of entry into our Lupus Clinic was controlled for ("unmatched" group, n=206); a second non-overlapping control group was matched for age, race, and year of entry into the clinic ("matched" group, n=212). The second matched control group was used to control for the three matching factors to allow smaller, but important effects of other factors, such as lupus severity, to emerge.

Results: For the cases, these predominantly African American (75.2%) women with SLE had a mean age at cervical biopsy of 38.5 years, with low grade CIN (CIN I/II) the most prevalent (80.5%) histology. Logistic regression showed that the cases differed from the both matched and unmatched controls only by being only one to two years younger (32.1 yrs. vs. 33.1 yrs. and 34.1 yrs., respectively) at lupus diagnosis. We did not combine the control groups because they were statistically significantly different from each other. Using the control group matched for age and race, logistic regression analysis showed no significant differences between cases and controls for any of the clinical variables. In particular, there were no significant differences for factors related to SLE (disease severity, use of immunosuppressive drugs, use of corticosteroids alone), chronic metabolic diseases (hypertension, diabetes), and HPV risk factors (marital status, smoking, gravidity, parity). Power analyses for both the unmatched and matched comparisons were similar for both lupus severity and immunosuppressive medications. At these sample sizes, with a two sided test, an alpha=.05 and 80% power, the difference in population proportions detectable was approximately 0.17, which is between a small and moderate difference. None of the described differences approached this magnitude of effect.

Conclusions: The key finding of this study is that SLE patients who develop CIN are not clinically different from SLE patients who do not develop CIN. In particular, worsened disease severity and immunosuppressive treatment do not appear to be susceptibility factors for CIN in SLE. All female SLE patients should be monitored closely for CIN, with at least annual PAP smears.

Lupus Nephritis: Decrease in Proteinuria and Sustained Stabilization of Disease Activity in Patients under Prolonged Immunoadsorption (IAS). Georg H. Stummvoll[2], Peter Biesenbach[1], Sabine Schmaldienst[1], Josef Smolen[3] and Kurt Derfler[1]. [1]Dept. of Nephrology, Medical University of Vienna, Austria, [2]Dept. of Rheumatology, Medical University of Vienna, Vienna, Austria, [3]Dept. of Rheumatology, Medical University of Vienna, Austria

Introduction: SLE is characterized by pathogenic autoantibodies and immune complexes which can effectively be removed by extracorporeal procedures such as IAS. After up to one year of IAS, we had previously observed a reduction of proteinuria, disease activity and pre-treatment autoantibody levels in highly active SLE with renal involvement. Antibody removal, however, does not block the formation of new autoantibodies. Thus, a high percentage of these patients underwent prolonged IAS (>1 yr for up to 10yrs) and are the focus of this report. We evaluated patients under prolonged IAS for sustainability or further improvement of the primary response to IAS (proteinuria, disease activity, anti-dsDNA-Abs) and for the number of flares, infections, adverse events and tumors.

Patients and Methods: IAS therapy was started in highly active SLE patients with lupus nephritis (proteinuria 7.1±4.8 g/day, SIS 15±6, SLEDAI 20±8, anti-dsDNA 394±712 IU/ml) if i.v. CYC was contraindicated or ineffectual. 13 patients responding to initial IAS therapy were included into the prolonged IAS program, showing moderate disease activity at the start of the extension period (proteinuria 2.0±2.4, SIS 4±2, SLEDAI 3±2, anti-dsDNA 47±36 IU/ml). We defined the end of observation (EoO) upon either completion of 10 yrs of IAS therapy or by 1.1.2009.

During IAS, oral immunosuppression and ACE/ATII-inhibitors were kept constant, steroids were tapered as clinically feasible. IAS was performed with high affinity columns and the effective removal of serum Ig was monitored. Severe infections were defined as requiring i.v. therapy or hospitalization, flares according to the SELENA protocol.

Results: Under prolonged IAS (mean observation period of 6.7±3.5 years), proteinuria further decreased from 2.0±2.4 g/d to 0.9±1.7g/d ($p<0.05$) at the EoO and Creatinine clearence increased to normal ranges in all patients. Disease activity and anti-dsDNA levels could be stabilized at low levels (SIS3±3, SLEDAI 3±4, anti-dsDNA 26±24 IU/ml at EoO).

Complete remission (proteinuria <0.5g/d, SIS/SLEDAI ≤4, pre-treatment dsDNA <25 IU/ml) was achieved in 9 (69%) patients. One patient flared and was discontinued. Ten (77%) patients are still under IAS therapy at the EoO. In 2 patients, IAS was stopped because of a sustained response. Severe infections (0.1±0.3 per patient year) and severe flares (0.1±0.2 per patient year) were uncommon. There were no anaphylactic or orthostatic adverse events or tumors.

Conclusion: Prolonged IAS leads to stabilization of disease activity in moderately active SLE patients and can induce sustained remission in previously refractory SLE while showing an acceptable safety profile.

Peripheral Vascular Disease in Systemic Lupus Patients. Rayford June[3], Robert C. Gilkeson[1], Shweta Bhatt[4] and Lisabeth Scalzi[2]. [1]Case Western Reserve University, [2]Penn State Univ Hershey Medical, Hershey, PA, [3]Penn State Univ Hershey Medical, [4]University of Rochester

Background: Systemic lupus erythematosus (SLE) is an independent risk for cardiovascular disease (CVD). Ankle brachial index (ABI), a simple measure of peripheral vascular disease (PVD), is known to be associated with CVD. We hypothesized that ABI would be lower in SLE subjects versus controls. In addition, we determined whether SLE-related, traditional, and/or non-traditional CVD risk factors help predict those SLE patients with PVD.

Methods: In a cross-sectional analysis of 134 SLE subjects and 77 age, sex, and racially-matched controls, SLE-related covariates and cardiovascular risk factors were measured. None of the participants had any history of known CVD. Measures of subclinical CVD were assessed including ABI, coronary artery calcification (CAC), and carotid intimal medial thickness (IMT). Covariates were compared between SLE and controls using chi-square testing for ordinal measures and a Student's t-test for continuous variables. In SLE patients, comparisons of the covariates were made between those patients in the lowest tertile (ABI ≤ 1.0) versus all others. A final logistic regression model was performed investigating correlations including all significant ($p \leq 0.10$) risk factors in the univariate analyses.

Results: When controlled for age, ABI was significantly lower between SLE and control subjects 1.05 vs. 1.09 ($p=0.003$). Significant covariates ($p \leq 0.05$) in the univariate analyses, examining those SLE patients in the lowest tertile versus those with higher ABI, included race (with Black SLE patients being more likely to have an ABI ≤ 1.0), a positive smoking history, and present or previous diagnosis of hypertension (HTN). In the final model, controlling for HTN, race, and homocysteine, only a smoking history ($p=0.02$) was significantly associated with having an ABI in the lowest tertile. There were no significant associations of CAC or carotid IMT with the lowest ABI tertile.

Conclusion: PVD, as measured by ABI, is more common in SLE patients as compared to non-SLE patients. Smoking is independently associated with PVD in SLE patients. SLE patients should be counseled of the increased risk of tobacco use and cardiovascular risk associated with their disease. Similar to other inflammatory diseases, an ABI of 1.0 (rather than 0.9 in the general population) is a more appropriate lower limit of normal when screening for PVD in SLE.

PiHDL and High Plasma Leptin Levels Are Predictors of Longitudinal Progression of Subclincal Atherosclerosis in SLE. Maureen A. McMahon[5], Jennifer M. Grossman[7], Lori Sahakian[5], Brian Skaggs[5], John D. FitzGerald[6], Christina Charles-Schoeman[3], Alan H. Gorn[4], Michael H. Weisman[2], Daniel J. Wallace[1] and Bevra H. Hahn[8]. [1]West Hollywood, CA, [2]Cedars-Sinai Medical Center, Los Angeles, CA, [3]UCLA, Santa Monica, CA, [4]UCLA Medical Center, Los Angeles, CA, [5]UCLA School of Medicine, Los Angeles, CA, [6]UCLA School of Medicine Rehabilitation, Los Angeles, CA, [7]University of California Los Angeles, Sherman Oaks, CA, [8]University of California Los Angeles School of Medicine, Los Angeles, CA

Purpose: Women with SLE have an unexplained increase in atherosclerosis (ATH). We previously reported that 45% of SLE women vs. 5% of controls have pro-inflammatory HDL (piHDL), and that piHDL confers a 16-fold increased risk for the concurrent presence of carotid artery plaque. It is unknown, however, whether piHDL predicts future progression of atherosclerosis. Here we hypothesize that baseline presence of piHDL is associated with longitudinal accumulation of subclinical atherosclerosis.

Methods: Female SLE and healthy age-and gender- matched subjects not taking statins were studied. B-mode and Doppler scanning of carotid arteries was performed at baseline and at 24–36 months. Antioxidant function of HDL was measured as the change in fluorescence intensity caused by oxidation of DCFH by LDL in the presence or absence of test HDL. Fluorescence in the absence of HDL was normalized to 1.0. Values greater than 1.0 after the addition of HDL indicated piHDL. Plasma leptin was measured using ELISA (Biovendor).

Results: Follow-up carotid ultrasounds were completed on 185 SLE women and 84 controls. Overall, 21% (39) of SLE patients had accumulation of new plaques (defined as any new or accumulating plaque) vs. 15% (13) of controls. Among the 39 SLE patients in our cohort with plaque progression, 33 (85%) had piHDL, compared to 39% of SLE patients with no new plaques ($p<0.0001$). Follow-up intima media thickness (IMT) was also higher in patients with piHDL at baseline than in those without; 0.62 ± 0.14 vs. 0.52 ± 0.07 ($p<0.0001$). In addition, plasma leptin levels were also higher in SLE patients with plaque (28.3 ± 23.0 vs. 22.9 ± 26.8, $p=0.01$). After multivariate analysis, the only significant factors predictive of plaque progression in SLE were the baseline presence of piHDL, with an OR of 14.2 (95% C.I. 2.2 – 161.3, $p<0.001$), the baseline presence of plaque, OR 14.9, (95% C.I. 1.8 – 238.9, $p=0.02$), elevated leptin levels in the highest quartile (>34 ng/mL), OR 5.1, (95% C.I. 1.7 – 18.2, $p=0.03$) and increasing age, OR of 1.1; (95% C.I. 1.03 – 1.22, $p=0.004$).

Conclusions: piHDL and plasma leptin are strong predictors for the future progression of subclinical atherosclerosis in women with SLE.

Positivity for Anti-RNP Antibody Is a Risk Factor for Adverse Effects by Trimethoprim-Sulphamethoxazole, a Prophylaxis Agent of *P. jiroveci* Pneumonia, in Patients with Collagen-Vasular Diseases. Reika Maezawa[1], Kazuhiro Kurasawa[2], Satoko Arai[2], Takayoshi Owada[2] and Takeshi Fukuda[2]. [1]Clinical Immunology, Dokkyo Medical University, Mibu, Tochigi, Japan, [2]Dokkyo Medical University, Mibu, Tochigi, Japan

Purpose: *Pneumocystis jiroveci* pneumonia (PCP) is a serious complication in patients with immunosuppressive therapy for collagen-vascular diseases (CVD). For prophylaxis of PCP, Trimethoprim-sulphamethoxazole (TMP-STX) is widely used. TMP-STX prevents the development of PCP, but often caused adverse effects (AEs) such as leucopenia, fever, and rash. However, risk factors for AEs by TMP-STX in CVD patients are unknown and also clinical features of AEs remain to be clarified. The aim of this study is to identify risk factors for AEs of TMP-STX, and to clarify clinical features of the AEs in CVD patients with immunosuppressive therapy.

Methods: We reviewed medical records of consecutive 541 patients who received TMP-STX as prophylaxis for PCP from 2003 to 2009 in our department. Subjects were 312 patients with CVD including 82 SLE, 60 myositis, 55 vasculitis, 26 SSc and 12 MCTD, and 229 patients with pulmonary diseases including 116 interstitial pneumonia and 56 lung cancer. These patients received corticosteroid (more than 30mg/day predonisolone) with/without immunosuppressants.

Results: AEs by TMP-STX were observed in 30 out of 541 patients (5.5%). Incidence of the AEs in CVD was 7.1%, significantly higher than that in pulmonary diseases (3.5%). In CVD, patients with SLE, MCTD and adult Still's disease frequently developed the AEs (11%, 33% and 13%, respectively), compared to those with myositis and vasculitis(4% and 5%). Particularly, incidence of the AEs in patients with anti-RNP antibody were significantly higher than those without the antibody (a-RNP(+) vs. (-); 21% vs 7%). High incidence of the AEs in RNP positive patients was observed in SLE. In addition, incidence of the AEs in CVD patients without anti-RNP antibody was similar to that in pulmonary diseases. Incidence of the AEs were similar between patients with and without antibodies such as anti-DNA, anti-SS-A, and anti-Sm antibodies.

Clinical features of the AEs in patients with CVD were different from those with pulmonary diseases. Fever was most frequent symptom in AEs in patients with CVDs, while no fever was observed as AEs in those with pulmonary diseases.

Conclusion: SLE and MCTD, and positively for anti-RNP antibody are risks factor for adverse effects by trimethoprim-sulphamethoxazole in collagen-vascular disease patients

Disclosure: R. Maezawa: None; **K. Kurasawa:** None; **S. Arai:** None; **T. Owada:** None; **T. Fukuda:** None.

473

Potential Risk Factors for Lupus Nephritis. Mehrnaz Hojjati[3], Semi Ayub[4], Qi Wang[5], Timothy W. Behrens[2], Emily Gillespie[5] and Michelle A. Petri[1]. [1]Timonium, MD, [2]Genentech Inc, South San Francisco, CA, [3]Univ of Minnesota, Minneapolis, MN, [4]Univ of Minnesota, Little Canada, MN, [5]Univ of Minnesota

Introduction: Kidney involvement is a major clinical problem in systemic lupus erythematosus (SLE). Consideration of possible predictive factors for development of lupus nephritis (LN) may help to identify high-risk patients. The purpose of this study was to assess whether certain demographic, clinical and immunological variables can predict the occurrence of lupus nephritis (LN).

Methods: We studied 679 SLE patients enrolled from the Hopkins Lupus Cohort via the Autoimmune Biomarkers Collaborative Network. Patients were classified into 2 groups: (1) LN, defined as patients who had either a) renal biopsy, World Health Organization class II-V and/or b) met ACR criteria for LN (persistent proteinuria ≥3 or cellular casts attributable to SLE) and/or c) Lupus Activity Index renal subscore ≥1. (2) Non-LN (SLE patients with no history of LN and maintaining renal subscore=0, urine protein=0, urine RBC≤5 per high power field and serum creatinine ≤1.1mg/dl over the enrollment period. The variables assessed at the beginning of the study were from 2 domains, the demographic/clinical domain and the laboratory/immunologic domain. Chi-square tests were used to examine the association between LN and each variable, and we used t-tests to compare mean age and disease duration between LN and non-LN. Logistic regression was used for prediction of LN from knowledge of the person's demographic, clinical, laboratory and immunologic information at study entry. Stepwise multivariate regression was used to select the best set of predictors after adjusting for SLE disease duration.

Results: Of the 679 patients studied, there were 348 LN patients and 222 non-LN. The LN patients were significantly younger (mean age 40.82, SD=12) compared to non-LN patients (mean age 45.6, SD=12.7; $p<0.0001$). Mean SLE disease duration was 132 (SD=104) months in the LN group compared to 112.1 (SD=87) months in the non-LN group ($p=0.014$). Photosensitivity was negatively associated with LN (51.01% in LN group vs 61.3% in non-LN, $p=0.02$). Variables were included in the stepwise logistic regression model as significant predictors for LN are shown in Table 1.

Table 1. Variables included in stepwise multiple regression model for LN.

Variable	Adjusted odds ratio	p-value
Obesity	1.62	0.04
Hypertension	2.54	0.0001
High cholesterol	1.7	0.02
Male gender	3.3	0.003
Caucasian ethnicity	0.42	0.0001
Hispanic and Asian ethnicity	1.5	0.08
Age	0.95	<0.0001
Low C4	2.3	0.0009
dsDNA antibody	1.6	0.05
Anemia	2.45	<0.0001
Thrombocytopenia	1.9	0.02

Interestingly, when we included only demographic and clinical variables in the logistic regression model, smoking was negatively associated with LN (adjusted OR=0.65, $p=0.04$); however, disease duration (adjusted OR=1.003, $p=0.005$) and diabetes (adjusted OR=1.7, $p=0.02$) were positively associated with LN. Anti RNP (adjusted OR=2.1, $p=0.004$) and low C3 (adjusted OR=2.04, $p=0.0009$) were also positively associated with LN when we included only lab/immunologic parameters in the logistic regression model.

Conclusion: Our results suggest that certain demographic, clinical and laboratory/immunologic factors may be predictive of LN, including obesity, high cholesterol, diabetes, and disease duration.

Predictors of Rate of Progression in Organ Damage in SLE. Sneha Purvey[2], Laurence S. Magder[3], Hong Fang[2] and Michelle A. Petri[1]. [1]Timonium, MD, [2]Johns Hopkins University School of Medicine, [3]University of Maryland School of Medicine

Purpose: The SLICC/ACR Damage Index (SDI) has become the accepted measure of permanent organ damage in SLE over time. Multiple cross-sectional and a few prospective studies have examined predictors or associates of damage. The damage may be due to lupus, its treatment or co morbid factors. We identified these in the largest on-going prospective study in SLE.

Methods: 2063 SLE patients (92.44% female, 56.27% Caucasian, 37% African-American, mean age 48.1years) were included. The SLICC/ACR Damage Index was calculated from diagnosis onwards in a prospective cohort. The analysis is based on the SDI at the last visit of the patients in the cohort using a linear regression model. Based on a scatter plot, the assumption of a linear relationship between the mean SDI and SLE duration appeared reasonable.

Results: The table shows the mean SDI at diagnosis and the mean rate of SDI progression in subgroups defined by predictors of interest.

Proteinuria	Never	0.68	Ref gp	0.10	Ref gp
	Ever	1.23	.005	0.12	.11
Corticosteroid Use	Never	0.37	Ref gp	0.08	Ref gp
	Ever	0.96	.007	0.10	.472
Immunosuppressive Use	Never	0.75	Ref gp	0.09	Ref gp
	Ever	1.28	.009	0.11	.23
Hydroxychloroquine Use	Never	1.43	Ref gp	0.12	Ref gp
	Ever	0.68	.0004	0.10	.25

Conclusion: Surprisingly, some variables associated with damage at diagnosis (age, corticosteroid use, immunosuppressive use, less use of hydroxychloroquine) were not associated with damage progression. The most important demographic predictor of progression was income, not gender or ethnicity, in contrast to other studies. The most important serologic test of progression was the lupus anticoagulant, not anti-dsDNA or other antiphospholipid antibodies. Patients already damaged at diagnosis had a higher rate of progression. Disease activity clearly increased the rate of progression, as expected. These data clearly point to the need for effective prophylactic therapy for the lupus anticoagulant, and the need for tight control of disease activity.

Pregnancy Outcomes among African American Patients with Systemic Lupus Erythematosus (SLE) Compared to Controls. April Barnado[1], Lee Wheless[4], Anna K. Meyer[4], Gary S. Gilkeson[2] and Diane L. Kamen[3]. [1]Duke University Medical Center, Durham, NC, [2]Med Univ of South Carolina, Charleston, SC, [3]Medical University of South Carolina, Charleston, SC, [4]Medical University of South Carolina

Purpose: SLE impacts women of childbearing age and the diagnosis is associated with adverse pregnancy outcomes. However, the question of whether there is a difference in outcome risk before and after diagnosis of SLE has not been well studied. Using data from a longitudinal study of Gullah African Americans, we compared pregnancy outcomes before and after SLE diagnosis to controls to test the hypothesis that there is a predisease state which negatively affects pregnancy outcomes.

Methods: Cases and controls reporting at least one pregnancy were drawn from a longitudinal observational cohort started in 2002. Controls were all Gullah African American females either related or unrelated to cases. We collected demographic, socioeconomic, and pregnancy data. Stillbirth was defined as pregnancy loss at or after 22 weeks and spontaneous abortion (SABs) as loss before 22 weeks. Low birth weight was defined as < 5 pounds, 8 ounces and preterm live birth as delivery before 37 weeks. Categorical variables were examined by chi-square tests. Differences in the means of continuous variables were tested using Student's t-test. We modeled pregnancy outcome associations with case status using multiple logistic regression to calculate odds ratios (OR) and 95% confidence intervals (CI). Two-sided p-values ≤ 0.05 were considered significant.

Results: Cases (n = 188) were younger (46 ± 12 vs 52 ± 13 years, $p<0.01$), less likely to have some form of insurance (83.4% vs 87.9%, $p=0.21$), and had similar years of education (13.2 vs. 13.1) compared to controls (n=205). Cases had fewer pregnancies (2.6 vs 3.2, $p < 0.01$) and fewer live births (2.3 vs. 2.8, $p < 0.01$) than controls. Overall, compared to controls, cases were more likely to have adverse outcomes including preeclampsia (OR 2.15, 95% CI 1.27–3.25), preterm live birth (OR 2.63, 95% CI 1.56 – 4.44), low birth weight (OR 2.30, 95% CI 1.35–3.90), SABs (OR 2.08, 95% CI 1.39–3.10), and stillbirths (OR 4.52, 95% CI 1.38–15.80), even after adjustment for age, education, insurance and pregnancy number. We found that the odds of adverse pregnancy outcomes increased after the diagnosis of SLE and, consistent with our hypothesis, that the risk was also higher prior to disease onset in women who later developed SLE compared to controls. (Table 1).

Table 1. Odds ratios and 95% confidence intervals for adverse pregnancy outcomes occurring before and after SLE diagnosis compared to controls in an African American population. All estimates are adjusted for age, education, insurance and number of the pregnancy.

	Stillbirth	Spontaneous abortion	Elective abortion	Preterm live birth	Low birth weight	Preeclampsia
Controls (660 pregnancies)	1.00 (reference)	1.00 (reference)	1.00 (reference)	1.00 (reference)	1.00 (reference)	1.00 (reference)
Cases before diagnosis (272 pregnancies)	4.01 (1.25–12.82)*	1.78 (1.16–2.72)*	1.36 (0.62–3.00)	2.26 (1.30–3.92)*	2.00 (1.14–3.50)*	1.99 (1.14–3.46)*
Cases after diagnosis (76 pregnancies)	4.31 (1.18–15.81)*	3.03 (1.91–4.82)*	1.88 (0.78–4.54)	3.26 (1.73–6.11)*	2.80 (1.47–5.34)*	2.45 (1.27–4.69)*

* = p-value <0.05.

Conclusions: Among a large cohort of African American women, we found significantly higher numbers of adverse pregnancy outcomes in cases, both before and after diagnosis of SLE, compared to controls. Our findings are consistent with a predisease state that predisposes to adverse pregnancy outcomes. Studies are underway to determine factors contributing to the predisease risk and to the increased risk following diagnosis of SLE.

Background: Metabolic Syndrome (MetSyn) is likely to be a significant predisposing factor to atherosclerotic vascular disease (ASVD) in Systemic Lupus Erythematosus (SLE). The purpose of this study is to determine the prevalence and persistence over two years of MetSyn in a multicentre, international inception cohort of patients with SLE.

Methods: An international inception cohort registry has enrolled 1593 recently diagnosed patients with SLE from 30 centres in 11 countries. All patients are assessed according to a standard protocol including clinical and laboratory variables, and SLEDAI-2K and SDI are calculated at enrollment and annual follow-up visits. The International Diabetes Federation definition for MetSyn was used and included the following criteria: increased waist circumference (≥ 94 cm for men, ≥ 80 cm for women) plus any two of raised triglycerides or specific treatment for this lipid abnormality and/or reduced HDL cholesterol or specific treatment for this lipid abnormality and/or raised blood pressure and/or increased fasting plasma glucose or previously diagnosed type II diabetes. A minimum of 2 of the latter 4 must be known for the definition to be valid.

Results: Of the inception cohort of SLE patients (89F, 48% Caucasian, age at diagnosis 35), 13.6% had MetSyn at baseline (Table 1).

Table 1. Presence of MetSyn criteria in inception cohort of 1593 patients.

	Present or Abnormal	Normal
Metabolic Syndrome	195 (13.6%)	1238
Waist Circumference	649 (47.6%)	715
BMI	265 (17.4%)	1259
Either Waist or BMI	700 (45.4%)	841
TG	374 (28.7%)	928
HDL	227 (31.4%)	495
BP	721 (45.9%)	851
BS	225 (16.9%)	1105

Although the prevalence of MetSyn is approximately 12% at any given time, the cumulative prevalence increases progressively to 25% by year 8. Most of the increased prevalence occurred within the first 3 years.

In total, 644 patients had at least two years of follow-up data available

The incidence of MetSyn over two years was 11.0% and in the subgroup of 88 with MetSyn at enrolment persistence of MetSyn was 17.0% (Table 2).

Table 2. Presence, incidence and persistence of MetSyn in 644 patients with two years of follow up.

Met Syn At enrol	Met Syn at Yr 1	Met Syn at Yr 2	# Patients	
556 without MetSyn at enrolment				
absent	absent	absent	495	Incidence 61/556 (11.0%)
absent	absent	present	23	
absent	present	absent	26	
absent	present	present	12	
88 with MetSyn at enrolment				
present	absent	absent	42	Persistence 15/88 = 17.0%
present	absent	present	12	
present	present	absent	19	
present	present	present	15	

Conclusion: MetSyn is present in 13.6% of newly diagnosed patients with SLE and persists in 17% of these patients over two years. Future work will determine the relationship between MetSyn prevalence and persistence with inflammatory disease activity and inflammation biomarkers as well as the effect of steroid exposure and lupus phenotype on the development and persistence of MetSyn.

Risk of Renal Flares and Decline in Renal Function in Patients with Active Lupus Nephritis Treated with Mycophenolate Mofetil (MMF). Chi Chiu Mok[2], King Yee Ying[1], Cheuk Wan Yim[3] and Woon Leung Ng[3]. [1]Princess Margaret Hospital, [2]Tuen Mun Hospital, [3]United Christian Hospital

Purpose: To study the risk of renal flares and renal function deterioration in patients with active lupus nephritis treated initially with combined prednisolone and MMF.

Method: Data were extracted from an open randomized controlled trial of the efficacy of MMF vs tacrolimus for induction treatment of lupus nephritis. All patients recruited into the MMF arm were treated with prednisolone (0.6mg/kg/day for 6 weeks and tapered) and MMF (2–3g/day) for 6 months. Patients with good clinical response were shifted to azathioprine (AZA) (2mg/kg/day) and continued on low dose prednisolone (<10mg/day) for maintenance. Renal function and clinical outcome at last visit was assessed. Factors associated with decline of renal function were analyzed by Cox regression.

Results: Data from 56 patients who had completed the induction phase of the controlled trial were analyzed. The mean age was 36.0±12.8 years and SLE duration was 55.3±63 months. The histological classes of lupus nephritis (RPS/ISN) were IVG (32%), IVS (9%), III (21%) and V/V+III/IV (38%). The activity and chronicity scores were 7.4±3.6 and 2.8±1.6, respectively. 24(43%) patients were hypertensive and 27(48%) were nephrotic at presentation. The mean daily MMF dosage administered was 2.20±0.44g (2g in 75% and ≥2.5g in 25%). At 6 months, 33(59%) patients achieved good clinical response (urine P/Cr <1.0, improvement in lupus serology and urinary sediments, with no deterioration of creatinine clearance [CrCl] by ≥10%) and 13(23%) patients achieved good partial response (same criteria but urine P/Cr <2.0). These patients received AZA (86.4±23mg/day) for maintenance therapy. At last visit (median follow-up 36 months), 20 renal flares occurred in 17 patients (13 nephritic and 7 proteinuric). The cumulative risk of renal flare was 7.3% at 12 months and 31% at 36 months. Six (11%) patients had loss of CrCl by ≥30% at last visit, 5 of whom developed stage 4/5 chronic kidney disease (CrCl ≤30ml/min). The cumulative risk of loss of CrCl by ≥30% was 5.4% at 12 months and 7.5% at 36 months. Cox regression revealed that nephrotic syndrome, hypertension, CrCl <90ml/min

at baseline, failure to achieve good response at 6 months and the occurrence of renal flares were unfavorable factors for renal function loss.

Conclusions: Combined prednisolone and MMF is effective for the initial treatment of active lupus nephritis. However, patients with nephrotic syndrome, impaired renal function and hypertension at onset are associated with a higher risk of renal damage.

Safety and Efficacy of a Pandemic 2009 Influenza A (H1N1) Monovalent, Unadjuvanted Vaccine in Systemic Lupus Erythematosus Patients. Alexis Mathian[3], Herve Devilliers[2], Anne Krivine[1], Nathalie Costedoat-Chalumeau[3], Julien Haroche[3], Du Boutin-Le Thi Huong[3], Bertrand Wechsler[3], Baptiste Hervier[3], Makoto Miyara[3], Nathalie Morel[3], Jean-Charles Piette[3], Brigitte Autran[3], Flore Rozenberg[1] and Zahir Amoura[3]. [1]Hôpital Cochin, [2]Hôpital Dijon, [3]Hôpital Pitié Salpêtrière

Objective: to assess the safety and efficacy of pandemic 2009 influenza A (H1N1) vaccination in patients with Systemic Lupus Erythematosus (SLE), and to evaluate factors influencing the immune response.

Methods: A hundred and eleven SLE patients were vaccinated with a pandemic 2009 influenza A (H1N1), monovalent, inactivated, unadjuvanted, split-virus vaccine in December 2009-January 2010 and received a second dose of vaccination three weeks after. Sera were obtained before each injection and three weeks after the last injection. Adverse events and SLE activity were recorded at each visit. The haemagglutination inhibition test was used to measure antibody titers. The antibody response was evaluated in three ways: the proportion of subjects with antibody titers $\geq$ 1:40 (seroprotection), the proportion of subjects with either a prevaccination HI titer $<$ 1:10 and a post-vaccination titer $\geq$ 40 or a prevaccination titer $\geq$ 10 and an increase in the titer by a factor of four or more (seroconversion) and the factor increase in the geometric mean antibody titers (GMTs) after vaccination (Geometric Mean Ratio (GMR)).

Results: According to international guidelines used to evaluate influenza vaccines, immunogenicity criteria were met, but not for all criteria, at day 21: seroprotection rate was 66.7% (95% CI 57.9–75.4) (below the required level of 70%), seroconversion rates was 60.4% (95% CI 51.3–69.5) (above the required level of 40%) and GMR was 8.5 (95% CI 3.2– 12.0) (above the required level of 2.5). The second vaccine administration did result in additional increased in humoral response. Indeed, immunogenicity criteria were fully met at day 42: seroprotection rate was 80.0% (95% CI 72.5–87.5) ($p = 0.0002$ versus day 21), seroconversion rate was 71.8% (95% CI 63.4–80.2) ($p = 0.003$ versus day 21) and GMR was 10.3 (95% CI 2.9–14.2) ($p < 0.0001$ versus day 21). None of SLE patients developed symptoms suggestive of influenza infection. Vaccine was well tolerated and did not increase disease activity. At day 21 and day 42, in the multivariate analysis, failure to obtain seroconversion was statistically associated with the use of an immunosuppressive treatment and lymphocytes count $<$ 1000/mm3. Failure to obtain seroprotection was statistically associated with the same parameters and a total serum IgM level $<$1 g/l at day 21. As expected, GMR values were significantly lower in SLE patients treated with an immunosuppressive drug. Vaccine was fully effective after one injection in patients with lymphocyte $>$ 1000/mm3 and not treated with immunosuppressive drugs.

Conclusions: pandemic 2009 influenza A (H1N1) unadjuvanted vaccination is safe and effective in SLE patients. Our study shows that SLE patients with normal lymphocyte count and not treated with immunosuppressive have a normal vaccine response.

Serum Osteoprotegrin (OPG) in Systemic Lupus Erythematosus. Adnan N. Kiani[2], Pal Aukrust[3], Thor Ueland[3], Laurence S. Magder[4], Hollan Ivana[3] and Michelle A. Petri[1]. [1]Timonium, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Oslo University Hospital, [4]University of Maryland

Purpose: Osteoprotegerin (OPG), is a member of the tumor necrosis factor (TNF) receptor family. It has recently been demonstrated that OPG is produced by a variety of tissues, including the cardiovascular system (heart, arteries, veins), lung, kidney, and immune tissues, as well as bone. OPG–RANKL signaling pathway is strongly related to vascular calcification. We determined the association of this biomarker with subclinical atherosclerosis in SLE at baseline and two years later.

Methods: 166 SLE patients (91% female, 64% Caucasian, 31% African-American, 5% others, mean age 45 yrs) had both measurement of subclinical atherosclerosis (coronary artery calcium CAC, carotid intima-media thickness (IMT) and OPG measurements.

Results: OPG was highly correlated with age ($p<.0001$) which is highly correlated with CAC and carotid IMT. However, once we adjusted for age, the relationship with atherosclerosis was diminished. We subdivided OPG levels into low, medium and high tertiles.

Table 1. Shows the association between OPG and the presence of coronary artery calcium

	Baseline Coronary Artery Calcium		New Coronary Artery Calcium at follow-up[1]	
	Odds Ratio	P-value	Odds Ratio	P-value
OPG level				
Low	1.0 (Ref Group)		1.0 (Ref Group)	
Medium	2.3 (1.0, 5.2)	.043	0.5 (0.4, 6.3)	.60
High	1.3 (0.6, 3.1)	.49	4.1 (0.7, 23.1)	.11

[1] Among those who did not have coronary artery calcium at baseline.

Table 2. Shows the association between OPG and the mean carotid IMT.

	Baseline IMT		Change in IMT	
OPG	Difference in Mean IMT	P-value	Difference in Mean change in IMT	P-value
OPG level				
Low	0.0 (Ref Group)		0.0 (Ref Group)	
Medium	0.02 (−0.01, 0.06)	.26	0.01 (−0.02, 0.06)	.49
High	0.02 (−0.01, 0.06)	.23	0.01 (−0.03, 0.05)	.61

The mean IMT among those with medium OPG was 0.02 points higher than for those with low OPG. This difference was not significant ($p=.26$).

Conclusion: OPG has been associated with atherosclerosis in the general population. In our 166 SLE patients OPG was strongly associated with age. Once we adjusted for age, there was no association of OPG with subclinical atherosclerosis nor with change in atherosclerosis two years later.

Steroid Free Remission in Systemic Lupus Erythematosus. Akiko Suda[3], Haruko Ideguchi[1], Shigeru Ohno[1], Mitsuhiro Takeno[2], Shohei Nagaoka[4] and Yoshiaki Ishigatsubo[5]. [1]Center for Rheumatic Disease, Yokohama City University Medical Center, [2]Department of Internal Medicine and Clinical Immunology, Yokohama City University Graduate School of Medicine, [3]Department of Rheumatology, Yokohama Minami Kyosai Hospital, Yokohama, Japan, [4]Department of Rheumatology, Yokohama Minami Kyosai Hospital, [5]Yokohama City Grad Sch of Med, Yokohama, Japan

Objectives: Although survival prognosis of SLE has been greatly improved by treatment with corticosteroids and immunosuppressants in some patients with SLE, some of the patients are suffering from adverse effects of long term corticosteroid therapy. Steroid free remission is an idealistic goal in management of SLE patients. We here examined the frequency of steroid free remission and analyzed clinical factors which are involved in achieving steroid-free remission in patients with SLE.

Methods: We retrospectively reviewed clinical charts of 288 patients (all Japanese, male 21, female 267, age 46.5 + 0.87 y.o., disease duration 15.0 + 0.58 years) who met 1997 ACR SLE Classification Criteria and received medical care in our hospitals. Therapeutic plans including steroid tapering in individual patients were determined by the attending physicians. The patients were divided into three groups based on steroid usage; concurrent user, never user, and steroid free remission that was defined as a 3-month consecutive period of no disease activity without corticosteroid. Clinical features and backgrounds were compared among the three groups.

Results: We found that 279 patients (96.9%) had received steroid at any time during the clinical course, whereas 9 (3.1%) patients had never received steroid (never users). Fifty two patients (18.0%) achieved steroid free remission. Of them, 45 patients (15.6%) maintained remission without steroid

(steroid free remission). Total 234 patients (81.3%) including 7 patients (2.4%) who experienced disease flare after cessation of corticosteroid were receiving corticosteroids at the study (concurrent users). Patients in steroid free remission were all female. They were older, and had longer disease duration than patients in concurrent user group. Renal involvement was less frequent (steroid free remission: 31.6% vs concurrent users: 50.9%, $P<0.05$), and negative anti-DNA angtiboydy was more frequent (26.3% vs 14.5%, $P<0.05$). Immunosupressants were more frequently used in concurrent users than patients in steroid free remission ($P<0.05$). The percentage of patients followed by practicing physician (S.O) were more frequently observed in steroid free patients (41.9% vs 16.3%, $p<0.01$). There was no difference in other factors including initial dose of steroid, initial disease activity, neurological disease and hematological disorders between the two groups.

Table. Factors associated with steroid free remission

	total (n = 288)	concurrent users (n = 234)	steroid free remission (n = 45)	p
age at study entry (y.o.)	46.5 ± 0.7	45.5 ± 0.9	51.2 ± 5.5	<0.05
disease duration at study entry (y.o.)	15.0 ± 0.6	14.4 ± 0.6	19.9 ± 1.6	<0.01
renal involvement (%)	48.8	50.9	26.7	<0.01
negative anti-DNA antibody (%)	82.3	85.5	64.4	<0.01
Immunosupressants use (%)	37.5	41.9	22.2	0.01
practicing physician (S.O.) (%)	23.1	16.3	41.9	<0.01

Conclusions: The present study shows that female, older age and absence of renal involvement, anti-DNA antibody and practicing physician (S.O) were associated with steroid free remission.

The Novel Pandemic Influenza A (H1N1) 2009 Vaccine: Low Rate of Seroconversion after Vaccination in Systemic Lupus Erythematosus.

Eduardo F. Borba[4], Carla G. S. Saad[5], Ana Luisa G. Calich[5], Sandra G. Pasoto[5], Vilma S. T. Viana[5], Maria do Carmo S. T. Timenetsky[2], Alexander R. Precioso[3] and Eloisa Bonfa[1]. [1]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [2]Instituto Adolpho Lutz, Brazil, [3]Instituto Butantan, Brazil, [4]Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [5]Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo, Brazil

Purpose: To evaluate efficacy and safety of a single vaccination with a novel split virion, inactivated, non-adjuvanted pandemic H1N1 influenza vaccine (A/California/7/2009/Instituto Butantan/Sanofi Pasteur S.A.) in systemic lupus erythematosus (SLE) patients.

Methods: 173 SLE patients (ACR criteria) of a single tertiary center and 159 healthy age-matched subjects were immunized with H1N1 influenza vaccine. Exclusion criteria were: fever, egg allergy, and autoimmune neurological diseases. At entry SLE patients and controls received a single dose of influenza vaccine containing A/California/7/2009 H1N1 strain. Patients and controls were evaluated at baseline (immunization day) and 21 days post-vaccination. Disease safety was monitored by SLEDAI. Antibody titers were evaluated by hemagglutination inhibition (HAI) assay. Seroconversion to vaccination was defined by either an antibody titer of 1:10 or less before and of at least 1:40 after or at least 1:10 before and at least four-fold increase in antibody titer 21 days after single vaccination. Vaccine adverse effects were also analyzed.

Results: Before vaccination, 8 (4.6%) patients and 20 (11.1%) controls ($p=0.01$) had a HAI titer of ≥1:40 and 21 days after vaccination 115 (66.4%) patients and 136 (85.5%) controls ($p=0.0001$) had a HAI titer of ≥1:40. Seroconversion rate for H1N1 was significantly lower in SLE patients compared to controls [108 (62.4%) vs. 123 (77.35%), $p=0.0041$]. Vaccine-related side-effects were only mild and transient with a similar frequency in both groups ($p>0.05$).The comparison of the 108 seroconverters patients with 65 nonresponders revealed a similar mean age, female predominance, mean disease duration, mean number of SLE criteria and mean SLEDAI score ($p>0.05$). In contrast, nonresponders were more often under mycophenolate mofetil than seroconverters (27.7 vs. 12.9%, $p=0.02$) with a tendency of higher frequency of immunomodulators (78.5 vs. 64.8%, $p=0.062$) and prednisone (64.6 vs. 50%, $p=0.082$) therapies. Regarding lupus safety at the time of immunization the mean SLEDAI was 3.5 ± 4.2 (0–24) and only 12 patients had an increased in SLEDAI scores (6.9%) whereas 133 remained stable (76.8%) and 28 had decreased (16.2%). Forty patients (23.1%) had SLEDAI ≥ 6 at baseline and none, except one, had an increase in SLEDAI.

Conclusions: The pandemic vaccine is safe in SLE patients regardless of disease activity but seroconversion is lower than in healthy subjects, particularly in patients under MMF therapy. Further studies are necessary to determine if a second dose will increase the seroconversion rate.ClinicalTrials.gov Identifier: NCT01151644

The Presence of Renal Platelet Microthrombosis in Patients with Lupus Nephritis Correlates with the Degree of Macrophagic Infiltration.

Elena Gonzalo[4], María Paz Martinez-Vidal[2], Begoña Santiago[4], Natalia Redondo[4], Estibaliz Loza[1], José Luis Pablos[3] and María Galindo[3]. [1]Fundación Española de Reumatología, Sociedad Española de Reumatología, Madrid, Spain, [2]Servicio de Reumatología, Hospital 12 de Octubre, Madrid, Madrid, Spain, [3]Unidad de Investigación y Servicio de Reumatología, Hospital 12 de Octubre, Madrid, Madrid, Spain, [4]Unidad de Investigación, Hospital 12 de Octubre, Madrid, Madrid, Spain

Introduction: Intravascular CD61+ platelet microthrombi are found in the kidney of patients with lupus nephritis independently of the presence of antiphospholipid antibodies. Our objective was to analyze the correlation between CD61+ intravascular platelet microthrombi and intra or extraglomerular CD68+ macrophagic infiltration degree as a marker of active inflammation.

Methods: Seventy-two kidney biopsies from systemic lupus erythematosus (SLE) patients were immunohistochemically stained with CD68 (macrophage) and CD61 (platelet glycoprotein-IIIa). Intra or extraglomerular macrophagic infiltration was quantified using the image-processing program Image J. CD61+ microthrombi were identified as percentage of stained cells. Clinical data were retrospectively collected at the time of kidney biopsies, and during the follow-up for a mean time of 7.5 years after biopsies and were correlated to the immunohistochemical findings. The associations between categorical variables were tested using the chi-square or Fisher's exact test, where appropriate. The odds ratios with the corresponding 95% CIs were calculated. For continuous variables, the comparisons were carried out using the t-test for two independent samples. P-values <0.05 were considered significant.

Results: most of SLE kidneys showed glomerular (94%) and extraglomerular (87%) macrophagic infiltration. Both glomerular and extraglomerular CD68+ macrophagic infiltration were higher in patients with proliferative (WHO subtypes III and IV) nephritis ($p=0.001$). The CD68+ glomerular infiltration degree was increased in samples with CD61+ platelet aggregates ($p=0.03$), whereas CD68+ extraglomerular infiltration was higher in samples with histological thrombotic microangiopathy ($p=0,02$) and focal cortical atrophy ($p=0.02$). The CD68+ glomerular infiltration grade was also higher in patients with positive a-dsDNA ($p=0.009$), hypocomplementemia ($p=0.01$), microhematuria ($p=0.02$), the presence of cellular casts in urine sediment ($p=0.03$), and was significantly associated with SLE activity index (SLEDAI) at the time of kidney biopsy ($p=0.02$). Preliminary results have shown a potential correlation between CD68+ macrophagic infiltration and higher levels of complement factor C4d expression ($p=0.04$). Patients with kidney failure at biopsy presented higher mean extraglomerular macrophagic infiltration ($p=0.03$). However, the presence of CD61+ platelet aggregates and density of CD68+ macrophagic infiltration were not associated with response to treatment, renal function evolution or nephritis relapse rate.

Conclusions: In lupus proliferative nephritis, intra and extraglomerular macrophagic infiltration degree correlates with acute impairment of kidney function. Presence of acute microthrombi provides a good correlation with cellular infiltration grade. However, none of these parameters is a good

prognostic marker of the renal function evolution or response to treatment. Further studies are needed to better define correlation between the presence of renal thrombosis and inflammatory cells infiltration and activation of complement system in patients with lupus nephritis.

The Relationship between N Terminal Pro Brain Natriuretic Peptide (NT-proBNP) and Atherosclerosis in SLE Patients. Diana Goldenberg[2], Emily Miller[2], Naveed Sattar[3], Paul Welsh[4], Mary Roman[5] and Jane E. Salmon[1]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]University of Glasgow, Glasgow, United Kingdom, [4]University of Glasgow, [5]Weill Cornell Medical College, New York, NY

Background: NT-proBNP is a biomarker of cardiovascular health in the general population that is independently associated with heart failure, coronary artery disease, stroke and death. It has been suggested that serum NT-proBNP levels are higher in SLE patients than controls, but its relationship with markers of atherosclerosis is still unclear. Because traditional cardiac risk factors do not adequately identify the SLE patients with increased risk for premature atherosclerosis, there is a need for a biomarker to improve risk stratification. The aim of this study was to investigate the relationship between NT-proBNP and atherosclerosis in SLE patients.

Methods: One hundred and twenty four patients meeting American College of Rheumatology diagnostic criteria for SLE who were participating in a longitudinal study of cardiovascular disease at the Hospital for Special Surgery were studied. Patients underwent clinical and laboratory assessment, echocardiography and carotid artery ultrasonography to detect plaque. Patients were defined as having atherosclerosis based on whether they had plaque (focal protrusion >50% of the thickness of the surrounding wall) on carotid ultrasonography. Echocardiography was performed and left ventricular ejection fraction, degree of mitral regurgitation and left atrial diameter were measured. SLEDAI was used to calculate SLE disease activity. Serum NT-proBNP levels were measured using a clinically validated electrochemiluminescence method (Roche Elecsys 2010). Group differences in NT-proBNP were compared using t-tests and independent correlates of NT-BNP and plaque were determined by multivariate regression analysis.

Results: The mean age of the124 SLE patients was 43.4 ± 13.7 years and 95.2% of the patients were female. Atherosclerotic plaque was present in 38.2 %. The mean SLEDAI score was 3.7± 4.8; range 0–22. Only 2.6% of the patients had diabetes and 12.7% were current smokers. Mean serum NT-proBNP was 346.1±1251 pg/ml (median 82.5 pg/ml, range 5–12905 pg/ml). As a reference, the baseline median NT-proBNP level measured using a similar electrochemiluminescence method in women in the general population was 66 pg/mL. Log transformed NT-proBNP was associated with higher left atrial diameter, lower body mass index and lower ejection fraction. SLE patients with atherosclerosis had higher NT-proBNP levels than SLE patients without atherosclerosis (615.4 pg/ml ± 286.5 vs 151.7 pg/ml ± 27.4; P = 0.044. However, in our regression models neither serum log NT-proBNP, gender, BMI nor SLEDAI predicted plaque. Age and lower ejection fraction were the only independent correlates of plaque.

Conclusions: In our analysis of 124 SLE patients with and without atherosclerosis, serum NT-proBNP levels correlated with plaque presence on carotid ultrasonography. As anticipated, it is likely that age and markers of cardiac function are in part mediating this relationship in our patient population. Prospective studies are now needed to determine the utility of NT-proBNP as a biomarker for predicting atherosclerosis in SLE patients.

Underuse of Hydroxychloroquine among Patients with Systemic Lupus Erythematosus. Aimee O. Hersh[2], Daniel J. Shapiro[3], Edward H. Yelin[4] and Gabriela Schmajuk[1]. [1]Stanford University, Palo Alto, CA, [2]UCSF, San Francisco, CA, [3]UCSF, [4]University of California, San Francisco, CA

Purpose: Recent literature supports the routine use of hydroxychloroquine (HCQ) in the management of systemic lupus erythematosus (SLE), with evidence for reduced disease activity, lower rates of renal progression, better lipid profiles, and improved survival. The extent to which patients with SLE receive HCQ nationwide is unknown. The purpose of this study was to determine the frequency and factors associated with HCQ prescribing in a nationally representative sample of patients with SLE.

Methods: We examined HCQ use among ambulatory visits for patients with SLE (ICD-9-CM code 710.0) using the National Ambulatory and National Hospital Ambulatory Medical Care Surveys. These surveys record information about treatments provided among a nationally representative sample of patient visits to ambulatory settings. The primary outcome was HCQ use; this was defined as either new or continued HCQ prescription associated with each incident visit. Continued medications include those previously prescribed by other physicians (i.e. HCQ by a rheumatologist when the incident visit is to a primary care physician). Independent variables included patient demographics (age, gender, race/ethnicity), insurance status (private versus public), steroid use (as a marker of disease activity), physician specialty (rheumatologist versus other), and geographic region. Multivariable logistic regression was performed to identify factors independently associated with receipt of HCQ.

Results: Between 1998–2007, there was an average of 975,000 ambulatory visits for SLE per year. Hydroxychloroquine was prescribed for 32% (95% CI 24.1–40) of patients with SLE seen during these visits. Ninety percent of patients were female, 24% were non-white, mean age was 49 years, 54% had private insurance, and 39% received corticosteroids. In bivariate analyses, there were no differences in HCQ use based on patient age, race, gender, insurance status, steroid use or geographic region. HCQ prescribing was higher among visits to rheumatologists versus other physicians (51 vs. 17%, p= 0.0001). In a multivariable analysis, after adjusting for potential confounders, the only factor independently associated with HCQ use was a visit to a rheumatologist (OR 4.57, 95% CI 1.80–11.56).

Conclusion: Hydroxycholoroquine use was suboptimal in this national sample of SLE patients. Given recent evidence about the beneficial effects of HCQ on survival in SLE, interventions are needed to increase HCQ use, particularly among those patients seen by non-rheumatologists.

Vitamin D Deficiency in Systemic Lupus Erythematosus (SLE) Is Not Associated with Coronary Artery Calcium (CAC) or Carotid Plaque. Adnan N. Kiani[2], Laurence S. Magder[3] and Michelle A. Petri[1]. [1]Timonium, MD, [2]Johns Hopkins University, School of Medicine, Baltimore, [3]University of Maryland

Purpose: Vitamin D deficiency is common in SLE. In the general population, vitamin D deficiency is associated with cardiovascular disease, diabetes mellitus and certain cancers. However, a recent study of vitamin D in African-Americans found that increased vitamin D levels were associated with more carotid and aortic plaque (1). We asked whether there was any similar relationship in SLE.

Methods: 167 SLE patients (93% female, 63% Caucasian, 32% African-American, mean age 45 yrs) had both measurement of subclinical atherosclerosis (coronary artery calcium, carotid intima-media thickness IMT (IMT), carotid plaque) and vitamin D.

Results: Vitamin D values ranged from 4 to 79 (mean 22.3, median 21). Among African-American Vitamin D values ranged from 4 to 55 (mean 15, median 11). Table1 shows the percentage with levels of CAC, by vitamin D status.

Vitamin D status	Coronary Artery Calcium Score		
All Patients	0	0.1 to 100	>100
Low (n = 133)	74 (56%)	45 (34%)	14 (11%)
Normal (n = 34)	22 (65%)	11 (32%)	1 (3%)
African-American			
Low (n = 47)	21 (45%)	21 (45%)	5 (11%)
Normal (n = 5)	4 (80%)	1 (20%)	0 (0%)

Of those with low Vitamin D, a higher proportion had a coronary calcium score >100 (11%), compared to among those with normal Vitamin D (1%). Among African-American patients this proportion was 11% and 0 respectively. However, these trends were not statistically significant (p=.17 and 1.0).

Table 2. Shows the mean coronary artery calcium score and carotid IMT, by vitamin D status.

Variable All Patients	Mean (SD) among those with low vitamin D	Mean (SD) among those with high vitamin D	P-value
Log-CAC score	1.17 (1.96)	1.04 (1.72)	.72
Carotid IMT	0.58 (.11)	0.57 (0.09)	.78
African-American			
Log-CAC score	1.38 (1.99)	0.87 (1.96)	.59
Carotid IMT	0.61 (.13)	0.61 (0.12)	.95

Table 3. Shows the association between vitamin D levels and presence of carotid plaque at baseline, for all patients and African-Americans.

	Vitamin D Level	Carotid Plaque Present	Carotid Plaque Absent	P-value
All Patients	Low (n = 130)	25 (19%)	105 (81%)	0.63
	Normal (n = 34)	5 (15%)	29 (85%)	
African-American	Low (n = 44)	11 (25%)	33 (75%)	0.57
	Normal (n = 5)	0 (0%)	5 (100%)	

Table 4. Mean Vitamin D (as a quantitative variable), in all patients and among African-American defined by presence or absence of high coronary artery calcium score, or carotid plaque.

All patients	Mean Vitamin D (SD)	P-value
Coronary Artery Calcium Score		
None (n = 96)	23.4 (13.8)	.26
.1–99 (n = 56)	21.6 (12.7)	
100+ (n = 15)	17.7 (9.6)	
Carotid Plaque		
Absent (30)	22.8 (13.0)	.41
Present (134)	20.6 (14.4)	
African-American Coronary Artery Calcium Score		
None (n = 25)	16.7 (12.7)	.51
.1–99 (n = 22)	13.7 (7.9)	
100+ (n = 5)	12.0 (7.8)	
Carotid Plaque		
Absent (38)	15.8 (11.6)	.31
Present (11)	12.1 (5.6)	

Conclusion: Vitamin D was not associated with any measure of subclinical atherosclerosis in SLE. In contrast to the study in African-Americans (1. J Clin Endocrinol Metab 95: 1076, 2010), higher vitamin D was not associated with MORE carotid plaque. In fact, in SLE, there was a suggestion that those with low vitamin D were more likely to have a coronary artery calcium score greater than 100 (11% vs. 1% and 11% vs. 0 among African-American).

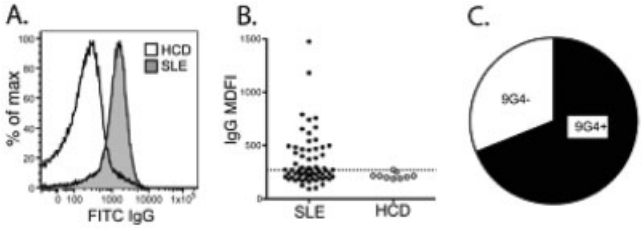
9G4 Autoantibodies Dominate the Anti-Apoptotic Cell Autoimmune Response in SLE. Scott A. Jenks[1], Elise Palmer[2], Elides Marin[2] and Ignacio Sanz[1]. [1]Univ of Rochester, Rochester, NY, [2]Univ of Rochester

Purpose: To understand the prevalence and characteristics of anti-apoptotic cell autoantibodies (APCA). These aspects of the autoimmune response in SLE remain poorly understood despite strong experimental evidence showing that impaired clearance of apoptotic cells in SLE provides an abundant source of immunogenic disease-related autoantigens and is likely to play a central role in disease pathogenesis. A flow cytometric assay for the quantification of serum APCA antibodies was applied to a cohort of SLE patients to ascertain the total amount of APCA. Given the high specificity of 9G4 autoantibodies for SLE and their association with disease activity we also determined the contribution of 9G4 autoantibodies to APCA reactivity. In this study we identify a high prevalence of IgG APCA that is heavily contributed to by 9G4+ antibodies.

Methods: Serum from 68 SLE patients with a spectrum of disease activity and 9 healthy volunteers, was used to assess 9G4+, IgG and IgM antibody binding to apoptotic Jurkat cells and to viable lymphocytes using multi-parameter flow cytometry (Fig A). Camptothecin was used to induce apoptosis in a CD45/B220-negative Jurkat cell line (J45.01). Viable lymphocytes were obtained from healthy control peripheral blood and identified as naïve B cells (CD19+IgD+CD27-). Positive binding to either naïve B cells or apoptotic cells was determined as an median fluorescence intensity ≥2 standard deviations of the mean median fluorescence intensity of healthy controls.

Results: After normalization of serum samples for total IgG quantity, 60% of patients displayed elevated levels of APCA. IgG APCA binding was prevalent as 53% of positive samples showed only IgG binding and 26% IgG and IgM (Fig B) whereas IgM only binding was 19%. APCA levels correlated with disease activity as measured by SLEDAI (p=0.014). 9G4 autoantibodies contributed substantially to APCA activity, 67% of APCA positive samples demonstrated strong 9G4 binding (Fig C). Moreover, initial depletion experiments indicate that up to 75% of all IgG APCA activity in SLE serum is contributed by 9G4+ antibodies. When the specificity of 9G4 binding was examined, the majority (55%) of the samples bound both naïve lymphocytes B and apoptotic cells, however, 35% bound only apoptotic cells and 10% bound just naïve B cells.



Conclusions: Our results demonstrate that APCA antibodies are common in SLE and their abundance correlates with disease activity. Moreover, our results indicate that the SLE-specific 9G4 antibody fraction represents the majority of APCA. These observations provide the basis for ongoing studies of the identity of apoptotic cell antigens responsible for the expansion of an SLE-specific autoreactivity. This work also illustrates the value of measuring APCA reactivity in future studies of B cell tolerance and suggests that these measurements may contribute to clinical studies and management of SLE.

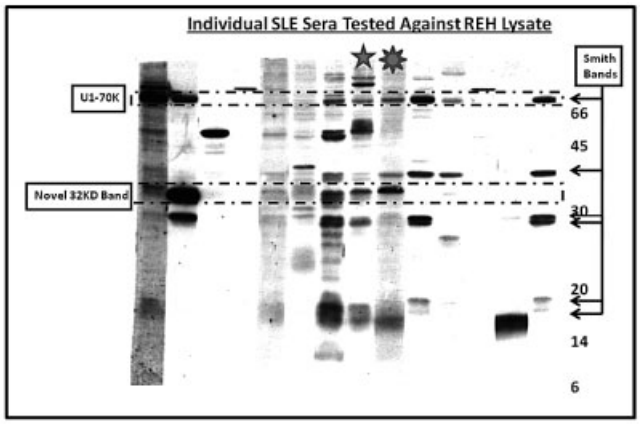
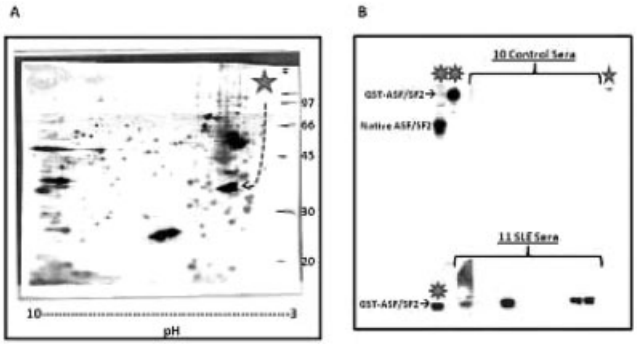
ASF/SF2, a Protein Involved in Multiple RNA and microRNA Processing Pathways, Is a Novel Autoantigen in SLE. Amit Golding[6], Ehtisham Akhter[4], Tonie Hines[3], Felipe Andrade[4], Ranjan Sen[5], Livia Casciola-Rosen[2], Antony Rosen[7] and Michelle A. Petri[1]. [1]Timonium, MD, [2]John Hopkins University, Baltimore, MD, [3]John Hopkins University, [4]Johns Hopkins University School of Medicine, Baltimore, MD, [5]NIA/National Institues of Health, [6]NIAID/National Institutes of Health, Bethesda, MD, [7]The Johns Hopkins University, Baltimore, MD

Purpose: In an attempt to discover novel lupus autoantigens, we sought to use lymphocytes as a source of antigen. Lymphocytes are likely to be a physiologic source of antigen due to the high frequency of lymphocyte cell death and their proximity to antigen receptors.

Methods: For our source of antigen, we used NP40-whole cell lysates of cultured REH cells. REH, is a non-EBV transformed, human ALL line with a combination of features of immature T and B cells. In our initial screen, SLE sera were used in standard Western Blots from 1D SDS-PAGE of REH lysates and a number of sera showed reactivity with a band of molecular weight range 32–34 kD (Figure 1).



This protein appeared to be unique from known lupus autoantigens such as anti-Smith bands and anti-Ku70/RNP. Subsequently, a large quantity of REH lysate was prepared in the appropriate buffer and resolved by 2D gel electrophoresis followed by transfer to membrane, scanning of the Ponceau stained blot and Western Blotting with one of the sera showing strong reactivity with the 32 kD band (Figure 2A).



A repeat 2D gel of REH lysate was coomassie-stained to visualize the proteins and, based on the alignment previously seen between the Western Blot and the 2D Ponceau Stain, the appropriate protein "dots" were sent for peptide sequencing by Mass spectrometry.

Results: The top non-keratin "hit" was SFRS1, also known as ASF/SF2, with 23% sequence coverage. In order to confirm that the SLE sera were in fact identifying ASF/SF2 as a novel autoantigen, the recombinant GST-fusion protein (MW 55kD) was purchased from ABNOVA and tested by immunoblotting using control and SLE patients' sera. We found that 12/57 (21%) of SLE patients' sera reacted with purified ASF/SF2 as compared to 0/25 of control normal sera. A representative blot is shown in [Figure 2B]. Studies to define antibody titers and correlation with disease activity are underway.

Conclusions/Discussion: ASF/SF2 is a member of the SR family of proteins that are involved in RNA splicing and are regulated by serine phosphorylation by SRPK1. More recently, ASF/SF2 has also been shown to be involved in processing microRNAs separate from its role in RNA splicing. Intriguingly, ASF/SF2, has also been implicated as a proto-oncogene in a number of malignancies. It will be interesting to look for anti-ASF/SF2 antibodies in individuals with certain malignancies and to attempt to correlate these with autoimmune manifestations versus protective immunity. We will also look for anti-ASF/SF2 antibodies in other rheumatologic conditions and investigate the role of phosphorylation and other protein modifications in the creation of autoantibodies.

Association of adam33 Polymorphisms with Systemic Lupus Erythematosus. Seung-Cheol Shim, Mi-Kyoung Lim and Dong-Hyuk Sheen. Eulji University, Daejeon, Korea, Republic of

Background: A Disintegrin and Metalloprotease 33 (ADAM33) is a member of a family of genes that encode membrane-anchored proteins with a disintegrin and a metalloprotease domain, and is located on chromosome 20p13. Recently, the polymorphisms in Adam33 have been found to be associated with asthma. Among the rheumatic diseases, systemic lupus erythematosus (SLE) is a prototypic Th2-mediated autoimmune disease like allergic disorders.

Purpose: To assess whether genetic functional variants of ADAM33 are associated with susceptibility to SLE or development of specific phenotypes in patients with SLE.

Methods: We have identified 48 SNPs, and nine SNPs were selected with regard to the LD pattern. Genotyping for g.10918G>C, g.12433T>C and g.13506C>G in the ADAM33 gene was conducted with PCR–RFLP methods, and genotyping for g.-330C>T, g.517 A>G, g.8227 G>A, g.9511 G>T, g.12462 C>T, g.12988 C>A polymorphisms was performed by single-base extension (SBE), using the ABI Prism® SNaPshot™ Multiplex kit (Applied Biosystems). We conducted an association study for ADAM33 polymorphisms in 190 SLE patients, 469 healthy controls, and 390 rheumatoid arthritis (RA) patients as a disease control. Haplotype analyses of related variants were performed as well.

Results: Significant associations of ADAM33 polymorphisms with susceptibility to SLE were found at g.8227 G>A, g.12988 C>A, and g.13506 C>G (P value were all below 0.001). Polymorphisms at g.8227 G>A was associated with the ANA titers among SLE patients (P = 0.012). In addition, we analysed the haplotype, and found a positive association of susceptibility to SLE with the major haplotype CGCG (P = 3.5E-11). There was no association between ADAM33 polymorphisms and RA as expected.

Conclusion: ADAM33 polymorphisms were strongly associated with susceptibility to SLE and the development of specific clinical manifestations.

Binding of Apoptotic Fetal Cardiocytes by Anti-Ro/La Antibodies Stimulates uPA/uPAR-Dependent Activation of TGFbeta and Potentiates Fibrosis. Paraskevi Briassouli[2], Daniel Rifkin[1], Jill P. Buyon[1] and Robert M. Clancy[1]. [1]New York University School of Medicine, [2]New York Univesity Medical Center, New York, NY

Purpose: Organ injury induced by antibodies characteristic of Sjogren Syndrome and Systemic Lupus Erythematosus, while varied in the adult and fetus, may share in common a link between apoptosis and ultimate fibrosis. In congenital heart block (CHB), binding of maternal anti-Ro/La antibodies to apoptotic cardiocytes impairs their removal by healthy cardiocytes and increases uPA/uPAR-dependent plasmin activation. Immunological staining of CHB hearts reveals AV node TGFb staining and TGFb activation promotes fibroblast transdifferentiation, a scarring phenotype. Since the uPA/uPAR system plays a role in TGFb activation, this study evaluated whether anti-Ro/La binding to apoptotic cardiocytes via plasmin activation stimulates TGFb and promotes a profibrosing phenotype.

Methods and Results: Initial analysis showed increased TGFb in supernatants from co-cultures of healthy cards and apoptotic cards incubated with IgG fractions from mothers whose sera contain anti-Ro/La antibodies and who had a child with CHB (apo-CHB-IgG) compared to co-cultures of healthy cards and apoptotic cards incubated with control IgG (apo-nl-IgG). Using a luciferase bioassay of active TGFb, supernatants from co-cultures of healthy cards and apo-CHB-IgG cards exhibited increased levels of active TGFb compared to those cocultured with apo-nl-IgG cards (511pg/ml CHB-IgG RLU vs 217 nl-IgG RLU; p=0.007; n=7). Abrogation of RLU via anti-TGFb antibody or TGFb inhibitor (SB431542) confirmed TGFb activation was solely due to TGFb. Significantly increased uPA levels (903 pg/ml vs 508 pg/ml; p =0.01; n=5) and uPA activity (0.8 units vs 0.04 units; p=0.005; n=3) were demonstrated in supernatants generated from coculture of healthy cards and apo CHB-IgG cards compared to healthy cards and apo nl-IgG, respectively. To determine whether uPA activity was responsible for TGFb activation, coculture experiments were conducted in which the apo-CHB-IgG cards were treated with anti-uPAR or anti-uPA antibodies or the plasmin inhibitor aprotinin prior to coculturing with healthy cards. In all instances treatments attenuated TGFb activation and uPA activity. To evaluate the profibrotic role of the observed TGFb activation, supernatants from either apo -CHB-IgG or apo-nl-IgG cocultures with healthy cards were applied to serum deprived cardiac fibroblasts. Only supernatants derived from cocultures of healthy cards and apo -CHB-IgG cardiocytes promoted transdifferentiation as evidenced by increased SMAc staining, an effect that was decreased when fibroblasts were treated with supernatants where cocultures were pretreated with uPAR antibodies. Supporting the hypothesis that increased uPA activity is causally related to the pathogenesis of CHB, cord

blood samples from 12 of 18 children with CHB exhibited increased uPA activity and uPAR cleavage compared to 4 of 14 non CHB children exposed to maternal anti-Ro antibodies.

Conclusions: These data suggest that binding of anti-Ro/La antibodies to apoptotic cardiocytes by virtue of increased uPAR-dependent uPA activity trigger TGFb activation thus initiating and amplifying a cascade of events that promote myofibroblast transdifferentiation and scar.

Binding Target for C-Reactive Protein Is Released from Secondary Necrotic Cells. Christina Janko[1], Christine Schorn[1], Luis Munoz[1], Manfred Rauh[3], Kirsten Lauber[2], Georg Schett[1] and Martin Herrmann[1]. [1]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Department of Internal Medicine I, University of Tuebingen, Tuebingen, Germany, [3]Department of Paediatrics and Adolescent Medicine, University of Erlangen-Nuremberg, Erlangen, Germany

Background: The C-reactive Protein (CRP) is an acute-phase protein whose serum concentration massively increases in response to tissue injury or inflammation. Beside opsonizing of bacteria CRP is known to bind calcium dependent to altered mammalian membranes (e.g. occurring in cell death) via phosphocholine, the polar headgroup of phosphatidylcholine and its derivates. CRP also opsonizes intracellular components leaking from necrotic cells.

This study was performed to analyse whether CRP differentially binds to primary and secondary necrotic cells. Primary necrosis is defined as immediate cell death appearing after severe cell death stimuli, whereas secondary necrosis follows after an apoptotic stadium.

Methods: We prepared Fitc-labelled CRP to determine the binding of CRP to primary and secondary necrotic cells by flow cytometry and confocal microscopy. The release of a CRP target from dying cells was detected in the supernatant by inhibition assays. The released CRP antagonist was identified by enzymatic cleavage and by mass spectrometry.

Results: The binding of CRP to primary necrotic cells was significantly stronger compared to secondary necrotic ones. We detected a CRP antagonistic activity in supernatants of secondary necrotic cells, which was identified as glycerophosphocholine (GlyceroPC). Actually, CRP binding to necrotic cells was blocked by synthetic GlyceroPC. The release of the CRP antagonist was significantly reduced by inhibitors of Phospholipase A2 and Caspases.

Conclusion(s): Secondary necrotic cells show a weaker binding of CRP resulting from the release of the CRP target during late apoptosis. That may have implications for opsonisation with CRP of dying and dead cells and for CRP-mediated effects in clearance. Secondary necrotic cells, for example in SLE patients, may release high amounts of the CRP antagonist with the following consequences (1) missing CRP binding targets on the dead cells and (2) neutralizing of circulating CRP, both possibly contributing to clearance failure.

C1q and Complement Proteins Induce a Non-Caspase-Dependent, Non–Necrotic, Cell Death, That Protects from Autoimmunity. Mizhir Atallah, Amir Grau and Dror Mevorach. Hadassah-Hebrew University

Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease of unknown etiology characterized by the presence of pathogenic high-titer autoantibodies to a diverse group of autoantigens. Eearly complement proteins are important in protecting humans against the development of SLE and the protective role of C1q and complement in SLE is mainly related to their role in clearance of dying cells. Since there are few other mechanism available for apoptotic cell clearance we were questioning whether C1q has unknown additional role that may lead to increased necrotic debris found in patients with SLE. Using spontaneous human neutrophil apoptosis in the presence of complement deficient sera we show that by 12h incubation with C1q-deficient serum there were 61.28% ± 14.51% viable cells compared with 46.1% ± 14.88% in autologous serum. Furthermore, there were more than three-fold higher rate of necrotic cells ($p<0.001$) when cells were incubated in autologous serum in comparison with C1q-deficient serum. We further characterized complement induced cell death by electron microscopy and caspase inhibitors to concluded that complement induced apoptotic, non-necrotic, non-caspase-dependent neutrophil death.

We further injected dying cells in the presence and absence of C1q and were able to show that in the absence of C1q, a lupus-like disease was developed whereas in the presence of C1q lupus-like disease was much milder (0.001) as judged by the development of immunoglobulins, autoantibodies, and kidney disease. Taken together, we conclude that C1q induced a non caspase-dependent cell death that is protected from necrosis and avoids autoimmunity. This is a novel role for C1q that was thus far suggested to have a role only in clearance of apoptotic cells. This observation and may add a new explanation for the presence of elevated necrotic debris in SLE patients.

Characterisation of Ex Vivo Leukocyte Rolling and Adhesion Responses in SLE. Eric F. Morand[1], Qiang Cheng[2], Alberta Hoi[2] and Michael J. Hickey[2]. [1]Monash University, Melbourne, Australia, [2]Monash University

Purpose: Systemic lupus erythematosus (SLE) is characterised by the presence of autoimmunity and inflammatory injury mediated by effector leukocytes recruited from the circulation. Mechanisms of increased leukocyte recruitment into affected tissues may include increased endothelial expression of chemokines and endothelial adhesion molecules, or disease-related alterations in leukocyte adhesive behaviour. The latter has not previously been investigated.

Aim: To determine whether SLE is associated with intrinsic alterations in blood leukocyte adhesive responses.

Methods: Rolling and adhesion interactions were quantified under flow conditions using fresh unstimulated whole peripheral blood (PB) leukocytes. PB was obtained from MRL/lpr lupus-prone mice and MRL+/+ control mice, and from healthy subjects (n=33) and patients with SLE (>4 ACR criteria) (n=57). Adhesive substrates used were platelet monolayers and/or recombinant VCAM-1.

Results: Compared to control mice, PB leukocytes from MRL/lpr mice exhibited markedly and significantly increased rolling and adhesion interactions on platelet monolayers. After adjustment for increased PB leukocyte counts in MRL/lpr mice, increases in leukocyte rolling and adhesion remained significant, at time points prior to the onset of clinical disease. This suggested an intrinsic alteration in leukocyte behaviour in a model of SLE. Therefore, we next studied this phenomenon in humans. Unstimulated PB leukocytes from SLE patients demonstrated significant increases in neutrophil rolling on platelet monolayers compared to healthy subject PB. Neutrophil rolling was P-selectin- and PSGL1-dependent. However, after correction for the increased PB neutrophil counts associated with steroid therapy in SLE patients, differences between SLE and healthy PB were non-significant. To investigate mononuclear cell interactions, recombinant VCAM-1 was used as an adhesive substrate. Lymphocytes formed the dominant PB leukocyte subset adherent to VCAM-1 in both SLE and control blood, and these interactions were alpha-4 integrin-dependent. After correction for SLE-related lymphopenia, no increase in PB lymphocyte adhesion interactions was present in SLE. However, a significantly increased proportion of SLE patient lymphocytes adherent to VCAM-1 underwent spreading, a motility response which precedes lymphocyte emigration. Significantly higher spreading responses were seen both in patients with active SLE (SLEDAI>4) and inactive SLE.

Conclusions: We describe a novel method for investigation of leukocyte recruitment events ex vivo in SLE. Increased PB leukocyte rolling and adhesion interactions were observed in MRL/lpr mice, prior to the onset of clinical disease. In contrast, neutrophil interactions with P selectin and lymphocyte interactions with VCAM-1 were normal in human SLE, but lymphocyte spreading responses on VCAM-1 were significantly increased in SLE PB. Further exploration of blood lymphocyte intrinsic migratory behaviour in SLE is justified, and may represent a novel therapeutic target.

Inhibition of Cytosolic Nucleic Acid Receptor Pathways Using the Small Molecule IKKε/TBK1 Kinase Inhibitor MPI-0485520. Burt Richards, Ju-Fen Zhu, Nathan Seager, Monica Cronin, Harry Austin, Thomas Douce, Daniel Cimbora, Ryan Holcomb, Daniel Wettstein and Paul Bartel. Myrexis, Inc., Salt Lake City, UT

Response to infection by bacterial and viral pathogens includes recognition of foreign nucleic acids. Several cytosolic nucleic acid receptors have been characterized, including the dsRNA receptors MDA5 and RIG-I and the dsDNA receptor DAI. Activation of cytosolic nucleic acid receptors leads to production of type I interferons and proinflammatory proteins through phosphorylation of IRF3 transcription factor by the IKK-related kinase TBK1.

We have developed a small molecule kinase inhibitor, MPI-0485520, that potently and selectively inhibits the IKK-related kinases IKKϵ and TBK1. MPI-0485520 also exhibits high oral bioavailability, favorable ADME/PK properties, and efficacy in a pharmacodynamic mouse model. To examine cytosolic nucleic acid receptor signaling through IKKϵ and TBK1, we activated receptors by introduction of dsRNA and dsDNA mimetics into the cytosol of mouse RAW264.7 and human THP-1 monocytic cell lines. Cells were subsequently dosed with MPI-0485520 and mRNA and protein levels of proinflammatory cytokines (IFNα/β, IP-10, IFIT1, MX1, RANTES, and IL-6) were monitored using qRT-PCR and ELISA. Both RAW264.7 and THP-1 cells exhibit robust induction of specific proinflammatory cytokines after cytosolic introduction of the RIG-I and MDA5 agonists, using low and high molecular weight poly(I:C), respectively. This induction was potently inhibited with MPI-0485520 for several of the induced cytokines. Treatment of mouse RAW264.7 cells with the dsDNA receptor agonist poly(dA:dT) also resulted in potent induction of proinflammatory cytokines that was inhibited by MPI-0485520 in a dose-dependent manner. THP-1 cells were not responsive to poly(dA:dT) suggesting that a dsDNA receptor is not present or is poorly induced in this cell line.

In addition to foreign nucleic acids, recent studies have demonstrated that accumulation of endogenous nucleic acids, due to improper disposal of retroelements, can generate a type I interferon response. Patients with mutations in TREX1, RNASEH2A/B/C, or SAMHD1 have a genetic predisposition to autoimmune diseases, including systemic lupus erythematosus, Sjögren's syndrome, and Aicardi-Goutieres syndrome (AGS). Trex1-knockout mouse studies support a model in which accumulated retroelements induce a cytosolic nucleic acid receptor that leads to type I interferon production via an IRF3-dependent pathway. We have demonstrated that production of type I interferons following activation of cytosolic nucleic acid receptors is potently blocked by MPI-0485520. These studies suggest that MPI-0485520 and other IKKϵ/TBK1 inhibitors may be efficacious in the treatment of forms of lupus, AGS, and Sjögren's syndrome caused by cytosolic nucleic acid receptor activation.

Inhibition of Interferon-Alpha by Sialylated IgG in Response to TLR7 and TLR9 Activation Is Mediated by a Soluble Factor Produced by Monocytes. Alice E. Wiedeman[2], Deanna M. Santer[2], Fabian Käsermann[1], Sylvia Miescher[1] and Keith B. Elkon[2]. [1]CSL Behring, [2]University of Washington

Objective: IgG in the form of intravenous immunoglobulin (IVIg) has been used as an anti-inflammatory agent in multiple autoimmune diseases. Recent studies reported that it is the small fraction of sialylated IgG (SA+) in human IVIg preparations that attenuates arthritis or immune thrombocytopenia. However, these studies were performed across species (human IgG injected into mouse models of disease). Our goal was to study the importance of the sialylated subset of IVIg in the inhibition of the inflammatory responses of *human* cells stimulated with TLR7 and 9 agonists that induce type 1 IFN.

Methods: Human IVIg preparations were enriched (SA+, 7- to 10-fold) or depleted (SA-, 2- to 5-fold) of the sialylated subset by lectin affinity chromatography. PBMC were isolated from whole blood of healthy individuals, cultured overnight in the presence of TLR7 (Loxoribine, CL097) or TLR9 (CpG) agonists with or without SA+ or SA- IgG at two doses (0.5 and 5 mg/mL). Antibodies to DC-SIGN, Fc receptors, as well as isotype controls (1ug/mL) were also used. In certain experiments, monocytes, B cells or NK cells were depleted or isolated from PBMC using magnetic beads. Some cultures were treated with TNF-α, IL-10, IL-6, and IL-8 or with antibodies to these same cytokines. Supernatants were collected 20 hours post-treatment and analyzed by ELISA for IFN-α, TNF-α, IL-10, IL-8, and IL-6.

Results: In response to the TLR agonists tested, SA+ IgG inhibited IFN-α production significantly more than SA- IgG ($p<0.05$), and the inhibition by SA+ IgG increased with higher doses ($p<0.05$). Blocking DC-SIGN or FcRs did not abrogate the inhibition by SA+ IgG. Inhibition of IFN-α by SA+ IgG was decreased by the depletion of CD14+ monocytes, but not depletion of CD19+ B cells or CD56+ NK/NKT cells. Supernatants from isolated monocyte cultures treated with SA+ IgG could transfer inhibition to fresh cultures of TLR agonist-stimulated PBMC or isolated pDC. Surprisingly, levels of TNF-α, IL-10, IL-6, and IL-8 were not inhibited by SA+ or SA- IgG, and in fact the production of TNF-α was modestly enhanced in cultures treated with SA+ compared to SA- IgG ($p<0.05$). Neutralization of TNF-α or IL-10 did not abrogate IFN-α inhibition by SA+ IgG.

Conclusions: SA+ IgG is more potent at inhibiting IFN-α production in response to TLR agonist stimulation compared to SA- IgG. Results suggest that SA+ mediated inhibition is not mediated through an Fc gamma receptor nor the human homolog of SIGN-R1, DC-SIGN. Soluble factor(s) produced by CD14+ monocytes mediate this inhibition by acting directly on pDC. Cytokine blocking studies indicate that cytokines TNF-α and IL-10, that are produced by monocytes and known to inhibit IFN-α, are not responsible. The greater potency of SA+ IgG has therapeutic implications for SLE because our results suggest that a lower dose of IVIG enriched for the active, sialylated subset may dampen IFN-α responses to TLR stimuli. Also, identification of the SA+ binding receptor and soluble factor(s) released from monocytes in response to SA+ IgG could reveal new targets for immune modulation of type 1 IFN in SLE.

IRF5 SLE-Risk Haplotype Is Strongly Enriched in Anti-Ro Positive Mothers of Neonatal Lupus Patients with Diverse Diagnoses. Timothy B. Niewold[2], Silvia N. Kariuki[2], Beverly S. Franek[2], Jill P. Buyon[1] and Robert M. Clancy[1]. [1]Division of Rheumatology, New York University School of Medicine, [2]Section of Rheumatology and Gwen Knapp Center for Lupus and Immunology Research, University of Chicago

Objective: In patients with systemic lupus erythematosus (SLE), IRF5 genotype is associated with anti-Ro autoantibodies. It is not clear whether this association with autoantibody profile is specific to SLE disease status. To examine this question, we assessed IRF5 genotypes in a large cohort of individuals who all had high titer anti-Ro autoantibodies and carried a variety of diagnoses including healthy/asymptomatic, Sjogren's syndrome (SS), and SLE.

Methods: We studied 85 European-ancestry individuals recruited to the Research Registry for Neonatal Lupus who all had high titer anti-Ro autoantibodies and a child with neonatal lupus. The diagnoses of these subjects were as follows: 15 healthy/asymptomatic, 10 SLE, 19 SLE/SS, 20 SS, and 21 undifferentiated autoimmune disease (UAS). IRF5 SNPs were genotyped using Taqman primer-probe sets to define previously reported European-derived SLE risk and protective haplotypes.

Results: The IRF5 SLE-risk haplotype defined by the rs10488631 C allele was enriched in subjects of all diagnoses except SS when compared to large published data sets of European-American controls [OR=2.30 (1.50–3.32), $p=8.4\times10^{-5}$]. Each of the asymptomatic, SLE, SLE/SS, and UAS mothers showed a very similar increase in rs10488631 allele frequency when examined individually (ORs range from 2.00 to 3.15, no significant differences between the asymptomatic, SLE, SLE/SS and UAS groups). The rs10488631 C allele frequency in the subjects diagnosed with SS was essentially the same as controls (OR=1.05). Interestingly, the rs3807306 C allele was significantly increased in the SS patients as compared to subjects from the other 4 diagnostic categories [OR=2.34 (1.14–4.79), p=0.026].

Conclusions: There was a significant increase in the frequency of the IRF5 SLE-risk haplotype in subjects with anti-Ro antibodies with varying diagnoses which was of comparable magnitude to the anti-Ro/IRF5 association observed in SLE (OR>2). Interestingly, the SS cohort was distinct from the other neonatal lupus mothers with respect to IRF5 genotype, and a different SNP was associated with SS status. These data suggest that the genetic association of IRF5 with autoimmunity is strongly influenced by serologic profile, and that the anti-Ro association with IRF5 genotype extends beyond the SLE disease state to some degree.

IRF8 Allele Associated with Susceptibility to Multiple Sclerosis Is Associated with Serum Interferon Alpha and Serologic Profile in Systemic Lupus Erythematosus. Beverly S. Franek[2], Silvia N. Kariuki[2], Jasmine Arrington[2], Rachel A. Mikolaitis[3], Meenakshi Jolly[3], Tammy O. Utset[2], Dimitrios T. Boumpas[1], George Goulielmos[1] and Timothy B. Niewold[2]. [1]Internal Medicine and Rheumatology, Clinical Immunology and Allergy, University of Crete Medical School, Heraklion, Greece, [2]Section of Rheumatology and Gwen Knapp Center for Lupus and Immunology Research, University of Chicago, [3]Section of Rheumatology, Rush University Medical Center

Objective: Alleles of IRF8 have been associated with susceptibility to both systemic lupus erythematosus (SLE) and multiple sclerosis (MS). While interferon alpha (IFN-α) is thought to be causal in SLE, recombinant human IFN-α is used as a therapy in MS. We investigated whether the IRF8 alleles associated with these two diseases were associated with differences in serum IFN-α or serologic profile in a multi-ancestral cohort of SLE patients.

Methods: The rs12444486 and rs17445836 single nucleotide polymorphisms (SNPs) in IRF8 (associated with SLE and MS respectively) were genotyped with Taqman primer-probe sets in 244 African-American and 137 European ancestry SLE patients. All patients had serum IFN-α and serology data available, and had been previously genotyped at SLE-risk SNPs in the IRF5 and IRF7 loci. Data from each ancestral background was analyzed separately initially, and combined in meta-analysis when associations were not significantly heterogeneous between ancestral backgrounds. Principal component analysis was used to control for proportional ancestry at the individual level.

Results: The MS-associated rs17445836 G allele was associated with the presence of anti-dsDNA autoantibodies in SLE patients of both ancestral backgrounds [meta-analysis OR=2.01 (1.09–3.68), p=0.024]. The same allele was also associated with increased serum IFN-α activity in both ancestral backgrounds (meta-analysis p=0.017). There was no evidence for statistical interaction between rs17445836 G and SNPs in IRF5 and IRF7 which have been previously associated with anti-dsDNA in SLE patients. No significant associations were observed between the SLE-associated rs12444486 SNP and serum IFN-α or serologic profile.

Conclusions: The rs17445836 G allele associated with susceptibility to MS was associated with anti-dsDNA antibodies and serum IFN-α in SLE patients of both African-American and European ancestry. This is interesting, given the therapeutic effect of IFN-α in MS patients, and the pathogenic effect of this same cytokine in SLE. Further exploration of the impact of the IRF8 locus upon in vivo IFN-α levels could provide insight into both diseases.

Leptin Promotes T Cell Autoimmunity through Modulation of the PKB/Akt/mTOR Pathway in Systemic Lupus Erythematosus (SLE) Patients. Elaine V. Lourenco, Bevra H. Hahn, Noriko Iikuni, Sarah J. Kim, Maida Wong, Ram P. Singh, Jennifer Grossman and Antonio La Cava. UCLA

Leptin is a pro-inflammatory (adipo)cytokine that promotes the onset and progression of organ-specific autoimmunity by facilitating pro-inflammatory immune responses. We investigated the possibility that leptin could modulate autoimmune T cell reactivity in systemic lupus erythematosus (SLE) patients, and found that the elevation of leptin in plasma from SLE patients (n=164) - as compared to matched controls (n=124)($p<0.0001$) - facilitated the proliferation and release of pro-inflammatory cytokines in peripheral autoreactive SLE $CD4^+$ T cells. These effects were abrogated if leptin was blocked by antibodies anti-leptin, anti-leptin receptor, or leptin receptor chimera. Interestingly, the effects of leptin were different on the $CD4^+CD25^-FoxP3^-$ effector T cells (T_{Eff}) and $CD4^+CD25^+FoxP3^+$ regulatory T cells (T_{Reg}). In particular, leptin promoted the proliferation and release of pro-inflammatory cytokines in T_{Eff} and it constrained the activity of T_{Reg}, with a net result of unabated autoreactive T_{Eff} responses. These effects associated with leptin-induced differential activation of the protein kinase B (PKB)/Akt/mTOR signaling pathway in autoreactive T_{Eff} versus T_{Reg}, and this action could be reversed by pharmacologic intervention. These findings identify a new mechanism through which leptin can concomitantly promote T cell autoreactivity and inhibit immune suppression in SLE, suggesting the possibility of targeted leptin-based intervention for the control of unbalanced T cell autoimmune reactivity in the disease.

Low C4A Gene Copy Number in Systemic Lupus Erythematosus. Kaline M. C. Pereira[4], Atila G. A. Faria[4], Eloisa S. Moreira[1], Viviane C. Santos[3], Marcelle Grecco[3], Neusa P. Silva[3] and Luis Eduardo C. Andrade[2]. [1]Hospital Sirio Libanes, Brazil, [2]Universidade Federal de São Paulo, Sao Paulo, Brazil, [3]Universidade Federal de Sao Paulo - UNIFESP, Brazil, [4]Universidade Federal de Sao Paulo - UNIFESP, Sao Paulo, SP, Brazil

Introduction: C4 is an important component of Complement system and plays an essential role in the activation cascades of the classical Complement pathway. Complete deficiency of C4 is among the strongest genetic risk factors for systemic lupus erythematosus (SLE). There are two C4 circulating isoforms (C4A and C4B) encoded by C4A and C4B genes, respectively, that differ by only five nucleotides. C4A protein is involved in immune complex and apoptotic debris clearance while C4B protein is relevant in the defense against microbes. C4A and C4B genes are located at a gene cassette within the MHC class III region and depict gene copy-number variation (CNV). The number of C4A copies may be related to susceptibility to SLE.

Objective: To investigate the C4A and C4B gene CNV in patients with SLE.

Methods: One hundred SLE patients (meeting SLE ACR criteria) were sequentially retrieved from the rheumatology outpatient clinic and 100 healthy individuals (HI) without evidence of autoimmune diseases were retrieved among blood bank donors. Peripheral blood leukocyte DNA was amplified by quantitative real-time PCR (qPCR) technique using sequence specific TaqMan® probes with minor groove binding (MGB) non-fluorescent quencher. Gene copy number (GCN) was determined by the delta-delta cycle threshold (DDCT) method. Samples with known C4A and C4B GCN were kindly provided by Dr. Szilagyi (Hungary).

Results: Gene copy number (GCN) varied from 2 to 8 for total C4 and from 0 to 5 for C4A and C4B. Patients with SLE had lower total C4 (C4A + C4B) and C4A GCN than HI. GCN for total C4 was lower in SLE patients (3.7 ± 1.2; 95% CI=3.5 – 3.9) in comparison with HI (4.3 ± 1.3; 95% CI= 4.0 – 4.5; p=0.003). This difference was due to C4A GCN variation that was lower in SLE (1.9 ± 1.0; 95% CI= 1.7 – 2.1) than in HI (2.3 ± 1.1; 95% CI=2.1 – 2.6; p=0.015). In contrast there was no difference in C4B GCN in both groups [(SLE = 1.8 ± 0.8; 95% CI= 1.6 – 1.9) and (HI = 1.9 ± 1.1; 95% CI=1.7 – 2.1) p=0.320]. The frequency of patients with only two C4 copies (C4A and/or C4B) was significantly higher in SLE (16%) than in HI (5%; p=0.028). The same was observed for subjects with only one C4A copy (SLE = 30%; controls = 16%; p=0.020). The frequency of patients with low C4 GCN (less than 4 copies) was significantly higher in SLE than in HI (40% versus 25%; p=0.022). The same was observed for low C4A gene dosage (less than 2 copies) (SLE = 35%; HI = 17%; p=0.009).

Conclusion: Patients with SLE presented lower C4A GCN as compared to control healthy individuals. This finding suggests that the ensuing relative deficiency in circulating C4A protein in individuals with low C4A GCN is one relevant risk factor for susceptibility to the development of systemic lupus erythematosus.

Lupus Immune Complex Gene Expression Arrays Reveal Divergent Pro- and Anti-Inflammatory Pathways Induced Depending on the Presence of Plasmacytoid Dendritic Cells and C1q. Deanna M. Santer and Keith B. Elkon. University of Washington, Seattle, WA

Background: Patients with Systemic Lupus Erythematosus (SLE) have an 'IFN-signature' that correlates with disease severity. RNA-containing immune complexes (ICs) stimulate IFN-alpha (IFN-a) production by plasmacytoid dendritic cells (pDCs) through activation of TLR7. We recently demonstrated that normal human serum contains potent inhibitors of IFN-a including IgG and the classical complement protein C1q. We showed that C1q inhibition of IFN-a required monocytes to indirectly inhibit pDCs, but thus far we only knew that the inhibition was soluble factor *independent*. The

purpose of this study was 2-fold: 1) To determine what genes are induced by C1q-containing ICs that could explain the mechanism by which C1q regulates IFN-a induction, and 2) To identify what other pathways, in addition to type I IFNs, are induced by SLE ICs.

Methods: SLE ICs were formed with diluted SLE serum (1:2000) or purified IgG and necrotic cell extract. ICs were added to normal donor peripheral blood mononuclear cells (PBMCs) or purified monocytes (>97% pure) in the absence (IC) or presence of C1q (C1q-IC) for 6 hours (microarray) or 40 hours (ELISA and flow cytometry). Controls included unstimulated and C1q alone treated cells. IFN-a and other pro-inflammatory cytokines were quantified by ELISA in culture supernatants and the expression of the activation markers CD86 and CD40 were determined by flow cytometry. Gene expression was quantified using Illumina Ref 8 beadchips and the results were confirmed by qRT-PCR with a total of 4 donors. ICs and necrotic extracts contained <0.06EU/ml endotoxin contamination.

Results: We found that SLE ICs altered the expression of 105 genes greater than 2-fold for PBMCs and only 7 genes for purified monocytes. Surprisingly, none of the ICs tested, whether formed with purified IgG or diluted serum, induced a typical pro-inflammatory response (e.g. TNF-a and IL-6) by PBMCs or monocytes. Rather, 40 of the top 50 genes induced in PBMCs were known type I IFN stimulated genes (ISGs). These ISGs were not induced in our monocyte microarrays. Upon addition of C1q to ICs, we observed a striking downmodulation of the expression of the 40 ISGs. In agreement with our findings that C1q is anti-inflammatory, we found that C1q-ICs specifically induced inhibitors of the NFkB, MAPK and Syk signaling pathways >1.5 fold compared to ICs alone. SLE ICs also upregulated the activation markers CD86 and CD40 on CD14+ monocytes within PBMC cultures, but upon depletion of pDCs or when using purified monocytes, ICs were significantly less stimulatory ($P<0.01$) despite the fact that C1q strongly promoted binding to, and endocytosis of ICs, by monocytes.

Conclusions: (1) In the absence of pDCs, SLE ICs are remarkably inefficient at stimulating PBMCs or isolated monocytes. (2) The presence of C1q in SLE ICs significantly downregulates the expression of 40 ISGs in both PBMCs and monocytes. (3) The presence of C1q in SLE ICs also alters the expression of genes that may impact inflammation through modulation of the NFkB, MAPK and Syk signaling pathways.

The clustering of multiple autoimmune disorders (ADs) in families is well known. Nevertheless, evidence of specific shared variants is sparse, and consequently the genetic mechanisms that may explain the patterns of disease aggregation remain unclear. This study is aimed at assessing which variants are common and different between SLE and other ADs. As such, we compared the variants reported as associated in genome-wide association studies (GWAS) of ADs to those identified in our large-scale analysis of SLE. We compiled a list with 381 non-MHC variants identified as significant in 49 GWAS of 16 ADs, available at the GWAS catalog (www.genome.gov/gwastudies). We combined the genotypic and imputed data from three published Caucasian cohorts (total of 1500 cases and 5706 controls)(Seligman et al, 2001; Remmers et al, 2007; Graham et al, 2008; Harley et al, 2008) and performed a joint- and a meta-analysis. When available, we used data from a previously described independent replication cohort of 2085 SLE cases and 2854 controls (Harley et al, 2008). All analyses were adjusted for admixture. Of the 213 SNPs that met quality control criteria, 44 survived a multiple comparisons adjustment with $P<0.05$ in the joint-analysis. Interestingly, the loci most shared between GWAS of ADs include IL23R, TNFAIP3, PTPN22, IL12B, IL12RA and PFKFB3-PRKCQ. Based on the number of genome-wide significant loci, we observe that SLE shares the most loci with Crohn's disease (TNFAIP3, ATG5, and 7p12.2), followed by both rheumatoid arthritis (TNFAIP3, BLK) and psoriasis (TNFAIP3, TNIP1), reflecting the number of published GWAS and associated SNPs available from the GWAS catalog. Several autoimmune variants were herein confirmed to be associated with SLE. These include SNPs in the TNFAIP3 (rs2230926, P=1.39×10–20; rs5029939, P=1.51×10–14; rs6920220, P=5.34×10-06), BLK (rs2736340, P=3.59×10-07; rs2618476, P=1.10×10-07), IL10 (rs3024505, P=6.45×10-05; rs3024493, P=4.38×10-05), and TYK2 (rs2304256, P=2.44×10-08) regions. Novel SLE loci include the VTCN1 (rs12046117, P=2.02×10-06), CD40 (rs1569723 P=1.26×10-03), IRGM (rs11747270, P=1.12×10-03) and IL12A (rs4680534, P=1.78×10-03) regions. This study expands the number of candidate loci associated with SLE and further dissects the extent of genetic overlap between SLE and other ADs.

MicroRNA miR-146a, Type I Interferon, and Race in Systemic Lupus Erythematosus. Paul R. Dominguez[1], Minoru Satoh[2], Angela R. Ceribelli[1], Eric S. Sobel[2], Yi Li[2], Westley H. Reeves[2] and Edward K. L. Chan[2]. [1]Department of Oral Biology, University of Florida, Gainesville, FL, [2]University of Florida, Gainesville, FL

Background: A few microRNAs (miRNA) have known gene expression regulatory roles in innate immunity. miR-146, a NFκB regulated transcript, is activated during lipopolysaccharide stimulation of monocytes and is critical in endotoxin tolerance to prevent cellular overstimulation when in excess of the TLR4 ligand. Interestingly, miR-146a has been reported to be upregulated in PBMCs and synovial tissue in rheumatoid arthritis patients but reported downregulated in PBMCs of SLE patients. The aim of the study is to determine whether the repressed expression of miR-146a reported in Chinese SLE can be observed in our US SLE cohort with more diversity in ethnic background.

Methods: Blood samples were collected from 124 SLE patients (European Americans (EA) 48 F, 10 M; African Americans (AA) 41 F, 2 M; Latin Americans (LA) 11 F, 6 M; others 6 F)) fulfilling ACR criteria and this included 35 patients with 2 or more collections from multiple visits to our autoimmune center. Total RNA, isolated from leukocytes, was analyzed by Taqman qPCR. miRNA copy number was determined using a standard curve. Expression of Type I interferon (IFN) signature genes (ISGs) and other cytokine/chemokine including TNFα, CCL2, CCL19, and CxCL10 was determined by ΔΔCT method. IFN score was calculated from ISGs (Mx1, OAS1, and Ly6e). Results were correlated with clinical data and analyzed by Wilcoxon/Kruskal-Wallis Test.

Results: Comparing CCL2, ISGs, and IFN score levels by race, AA had significantly higher levels compared to EA (p=0.016) and LA (p0.004), but LA had significantly lower levels than EA (p=0.038). miR-146a appeared to be higher in EA than AA or LA but did not reach significance. Reduced miR-146a expression was also observed in SLE patients with nephritis but did not reach significance. Correlation of miR-146a level with other clinical parameters including arthritis, pleritius, pericarditis, lymphopenia etc. did not show statistical significance. When 35 returning patients divided based on changes in miR-146a level comparing the first and the last visit, 11 had increased in miR-146a vs. 17 reduced. In the miR-146a reduced group (p=0.001), Mx1 (p=0.03), Ly6e (p=0.04), OAS1 (p=0.02), IFN score (p=0.02) reduced significantly whereas no significance were found for TNFα, CCL2, and CXCL10. The miR-146a increased group (p=0.0003) was more heterogeneous and none of the markers had statistically significant difference.

Conclusions: Comparison in race demonstrates with statistical significance that LA has the lowest level of IFN while AA has the highest. The data show potentially two groups: a miR-146a responsive group where miR-146a maybe regulating IFN production and a miR-146a resistant group where IFN production appears independent of miR-146a. For SLE patients with decreas-

ing levels of miR-146a in subsequent visit correlating with decreasing IFN score, this may represent the transition from active to remission state. In more active SLE, miR-146a levels most likely represent a balance in continuous IFN stimulation and innate controls as represented by patients with both high IFN score and miR-146a levels.

Multiple Independent Major Histocompatibility Complex Associations with Nephritis and Autoantibody Production in Systemic Lupus Erythematosus. Sharon A. Chung[7], Kimberly E. Taylor[7], Suzanne L. May[fo], Patricia P. Ramsay[9], Hong L. Quach[9], Julie A. Lane[2], Joanne Nititham[8], Janelle A. Noble[2], Diana L. Quach[9], Jennifer A. Kelly[3], Kathy L. Moser[4], Timothy W. Behrens[3], Michael F. Seldin[11], John B. Harley[r], Patrick M. Gaffney[4], Lisa F. Barcellos[9] and Lindsey A. Criswell[6]. [1]Children's Hospital Cincinnati Medical Center, Cincinnati, OH, [2]Children's Hospital Oakland Research Institute, Oakland, CA, [3]Genentech, Inc., South San Francisco, CA, [4]Oklahoma Medical Research Foundation, Oklahoma City, OK, [5]Oklahoma Medical Research Foundation, Oklahoma City, OK, [6]Rosalind Russell Medical Research Center for Arthritis, University of California, San Francisco, San Francisco, CA, [7]Rosalind Russell Medical Research Center for Arthritis, University of California, San Francisco, [8]Rosalind Russell Medical Research Center for Arthritis, University of California, San Francisco, CA, [9]University of California, Berkeley, CA, [10]University of California, Berkely, CA, [11]University of California, Davis, CA

Background: The most significant genetic associations with systemic lupus erythematosus (SLE) have been with the major histocompatibility complex (MHC), a gene dense region on chr6p21 spanning >5Mb. Prior attempts to identify MHC associations independent of *HLA-DRB1* (the most consistently associated MHC locus) were limited, in part, by the region's extensive linkage disequilibrium. In addition, MHC associations with SLE manifestations such as nephritis and autoantibody production have not been fully explored. Therefore, we performed high-density single nucleotide polymorphism (SNP) genotyping to identify MHC associations with lupus nephritis, anti-dsDNA, and anti-Ro/La (SSA/SSB) autoantibody production among SLE patients.

Methods: Using the Illumina Combined MHC panel, we genotyped 1,610 SLE cases of European descent for 2,360 MHC SNPs. SLE cases were also genotyped for *HLA-DRB1* and 384 ancestry informative markers. Lupus nephritis and autoantibody status was obtained from medical record review. We identified associations with *HLA-DRB1* alleles using a relative predispositional effects (RPE) method. Forward selection with conditional logistic regression (CLR) based on haplotypes was used to identify SNPs associated with particular SLE manifestations that were independent of each other and *HLA-DRB1*.

Results: After applying stringent quality control criteria (including removal of SLE cases with <90% northern European ancestry), we analyzed 1,974 SNPs in 1,125 SLE cases. Thirty-two percent (32%) had lupus nephritis, 50% had anti-dsDNA autoantibodies, and 27% had anti-Ro/La (SSA/SSB) autoantibodies. RPE analysis showed that different *HLA-DRB1* alleles were associated with lupus nephritis as compared to anti-Ro/La (SSA/SSB) autoantibody production (**1501* and **1302* for nephritis vs. **0301*, **0401*, **0404*, **1301*, and **0101* for anti-Ro/La). No *HLA-DRB1* alleles were significantly associated with anti-dsDNA autoantibody production (global χ^2 $p>0.05$). CLR analysis identified associations independent of *HLA-DRB1* in the *HLA-DOB*, *HLA-A/HCG9*, and *LEMD2* regions with lupus nephritis (OR for the most associated haplotype [OR_{hs}] 3.04, haplotype-specific p [p_{hs}]=3.1E-04). *HLA-DRB1*-independent associations were observed in the *HLA-DPA1/HLA-DOA*, *C6orf205*, and *OR2H2* regions with anti-Ro/La (SSA/SSB) autoantibody production (OR_{hs} 3.23, p_{hs}=1.6E-08). SNPs in or near *TAP2*, *C6orf10*, and *TRIM40/TRIM15* were associated with anti-dsDNA autoantibody production (OR_{hs} 2.82, p_{hs}=1.5E-08).

Conclusions: We have identified several significant MHC associations with lupus nephritis and autoantibody production that are independent of *HLA-DRB1*. Of interest, different genes/genetic regions were associated with these specific SLE manifestations. These results indicate that MHC genetic variation contributes significantly to disease heterogeneity in SLE.

NK Cells Regulate the IFN-α Production by Plasmacytoid Dendritic Cells Via Soluble Factors and Cell-Cell Contact. Niklas Hagberg[2], Olof Berggren[2], Gunnar V. Alm[1], Maija-Leena Eloranta[2] and Lars Rönnblom[2]. [1]Department of Biomedical Sciences and Veterinary Public Health, Swedish University of Agricultural Sciences, Uppsala, Sweden, [2]Department of Medical Sciences, Uppsala University, Uppsala, Sweden

Background: Overactivation of the type I IFN system has been demonstrated in patients with SLE and several other autoimmune diseases. We previously showed that the IFN-α production by pDCs stimulated with RNA-containing immune complex (RNA-IC) was regulated by NK cells and monocytes. NK cells enhanced the IFN-α production, while monocytes inhibited the NK cell stimulation of pDCs. The suppressive effect of monocytes was largely due to ROS, PGE2 and TNF-α, while the mechanisms for NK cell enhancement were hitherto unknown.

Objective: This study was performed to investigate the mechanisms whereby NK cells promote the IFN-α production by RNA-IC-stimulated pDCs. Furthermore, NK cells from SLE patients were also investigated for their capacity to enhance the IFN-α production.

Methods: pDCs and NK cells were isolated from PBMCs of healthy blood donors or SLE patients and stimulated with RNA-IC consisting of purified U1 snRNP and IgG from an SLE patient. Concentrations of IFN-α and 16 other cytokines in cell culture supernatants from pDCs, NK cells or cocultivations of pDCs and NK cells were determined using single or multiplex immunoassays.

Results: Soluble factors which could enhance the IFN-α production from RNA-IC stimulated pDCs were produced after FcγRIII-ligation or IL-12/IL-18 stimulation of NK cells. MIP-1α(CCL3), MIP-1β(CCL4), RANTES (CCL5), IFN-γ and TNF-α were found in the cell culture supernatants from FcγR-stimulated NK cells and MIP-1β was identified as partially responsible for the NK cell-mediated increase in IFN-α production. In addition, cell-cell contact via LFA-1 also contributed to the NK cell enhancement of IFN-α production by pDCs. When NK cells and pDCs were co-cultivated, the production of several other cytokines implicated in the pathogenesis of SLE, e.g. IL-6, IFN-γ and TNF-α, were also increased. NK cells from SLE patients and healthy blood donors were compared for their ability to promote the RNA-IC induced IFN-α production by pDCs. SLE NK cells were less stimulatory compared to NK cells from healthy blood donors when co-cultivated with pDCs and RNA-IC (p=0,004). However, addition of IL-12/IL-18 made the SLE NK cells as efficient as NK cells from healthy blood donors in enhancing the IFN-α production by pDCs.

Conclusions: This study describes novel mechanisms involved in the cross-talk between NK cells and pDCs which regulates the production of IFN-α. Both soluble factors such as MIP-1β and cell-cell-contact between NK cells and pDCs via LFA-1 were found to promote the IFN-α production. In addition, the regulatory function that NK cells exert on pDCs is altered in SLE patients. These results are of importance for understanding molecular mechanisms behind the increased IFN-α production in several autoimmune diseases and also indicate new potential therapeutic targets.

Novel Fc gamma Receptor 3B Gene (FCGR3B) Allele Variants and Polymorphism Distribution in Brazilian Systemic Lupus Erythematosus Patients and Blood Bank Donors. Viviane C. Santos[2], Marcelle Grecco[2], Kaline M. C. Pereira[2], Luis E. C. Andrade[2] and Neusa P. Silva[1]. [1]Universidade Federal de São Paulo, São Paulo, Brazil, [2]Universidade Federal de São Paulo, Brazil

Background: Immunecomplex (IC) deposition is a characteristic feature of systemic lupus erythematosus (SLE) and several pieces of evidence point towards an inefficient IC clearance in SLE. Fc gamma receptors (FcγR) are involved in the uptake and degradation of ICs by a variety of cells. FcγRIIa, FcγRIIb, FcγRIIIa and FcγRIIIb are polymorphic in humans and some alleles have been associated with SLE susceptibility. The FcγRIIIb gene (FCGR3B) presents three alleles, HNA-1a, HNA-1b and HNA-1c, characterized by specific nucleotides at six different positions in the 3rd exon.

Objectives: to determine FCGR3B polymorphic distribution and describe novel allelic variants present in SLE patients and blood bank donors, in Sao Paulo, Brazil.

Patient and Methods: peripheral blood was obtained from 260 consec-

utive SLE patients, attending the outpatient clinic of the Rheumatology Division at Universidade Federal de Sao Paulo, and from 246 ethnic-matched blood bank donors in Sao Paulo, Brazil. All individuals signed the informed consent approved by the Institutional Ethics Board. DNA was extracted by salting out and a 243bp sequence containing the polymorphic region of interest of the 3rd exon of FCGR3B was amplified by PCR. All samples were sequenced and processed in capillary gel electrophoresis (ABI 3130xl).

Results: Among SLE patients we found 52 homozygous for HNA-1a, and 208 heterozygous (188 HNA-1a/HNA-1b and 20 HNA-1a/HNA-1c). Among blood donors, HNA-1a homozygosis was found in 56, and heterozygosis in 190 (170 HNA-1a/HNA-1b and 20 HNA-1a/HNA-1c). Novel allelic variants (one HNA-1a and three HNA-1b) were also found. Point mutations, previously described in nucleotides not related to allelic discrimination (G230T, A249G, and G330T) were observed in both SLE (57) and blood bank donors (60). In addition we also identified 22 new point mutations in 76 SLE patients and 66 blood bank donors. There was no statistical difference between groups regarding genotype or phenotype distribution. Interestingly, homozygous individuals for the HNA-1b allele were not found in the population under study.

Conclusion: There was no association of FCGR3B gene polymorphism and SLE. Our results indicate that FCGR3B is a highly polymorphic gene possibly due to the existence of either somatic recombination or hyper mutation within this gene segment.

Numerical and Functional Deficiencies of Natural Killer T Cells in Systemic Lupus Erythematosus: Their Dysfunction Related to Up-Regulation of *Cbl-b*. Young-Nan Cho[2], Sung-Ji Lee[3], Seong-Rye Seo[3], Seung-Jung Kee[1], Tae-Jong Kim[3], Shin-Seok Lee[3] and Yong-Wook Park[2]. [1]Department of Laboratory Medicine, Chonnam National University Medical School and Hospita, [2]Department of Rheumatology, Chonnam National University Medical School and Hospital, Gwangju, Republic of Korea, [3]Department of Rheumatology, Chonnam National University Medical School and Hospital

Purpose: This study was designed to examine the frequency of natural killer T (NKT) cells and the response to α-galactosylceramide (α-GalCer) in systemic lupus erythematosus (SLE) and to investigate the clinical relevance of NKT cell levels.

Methods: Patients with SLE (n = 128) and age- and sex-matched healthy controls (n = 92) were enrolled in the study. NKT cell and CD1d levels were measured by flow cytometry. Gene expression was determined by reverse transcription-polymerase chain reaction, and cytokine secretion by multiple cytokine assay. Peripheral blood mononuclear cells (PBMCs) were cultured in vitro with α-GalCer. Proliferation indices of NKT cells were estimated by flow cytometry.

Results: Percentages and absolute numbers of NKT cells were significantly lower in the peripheral blood of SLE patients than in that of healthy controls, whereas CD1d levels in PBMCs were comparable between these two groups. Notably, this NKT cell deficiency was found to be correlated with SLE Disease Activity Index. NKT cell proliferation was found to be impaired in SLE patients, and cytokine production by NKT cells in response to α-GalCer was diminished. This poor responsiveness to α-GalCer was found to be due to a NKT cell dysfunction rather than to an abnormality in CD1d-expressing cells. Furthermore, this dysfunction was found to be related to the up-regulation of Cbl-b.

Conclusions: Our data show that NKT cell levels and functions are defective in SLE patients. Furthermore, these deficiencies were found to reflect disease activity. It would appear that these NKT cell abnormalities could contribute to immune system dysregulation in SLE.

Paucity of PD-L1 Expression on Monocytes during Active Systemic Lupus Erythematosus Is Regulated by IL-10, TNF-α and TGF-β. Anne M. Stevens[3], Jing-Ni Ou[1] and Alice Wiedeman[2]. [1]Center for Immunity and Immunotherapies, Seattle Children's Research Institute, Seattle, WA, [2]Department of Immunology, University of Washington, Seattle, WA, [3]Pediatrics, U. of Washington, Seattle, WA

Purpose: Programmed death ligand 1 (PD-L1) plays an important role in controlling autoreactive and follicular T helper lymphocytes, thus preventing autoimmune disease. Induced by inflammatory cytokines, PD-L1 is reportedly elevated on monocytes from patients with infections and rheumatoid arthritis, but is poorly expressed on Mo from SLE patients with active disease. Our goal was to define the mechanism for PD-L1 dysregulation in pediatric patients with SLE, and to clinically characterize those patients with loss of PD-L1.

Methods: Serial samples were obtained from 23 pediatric controls and patients with SLE (20 samples during active disease, SELENA-SLEDAI score >4, and 37 during remission). PD-L1 expression on $CD11c^+$ $CD14^{high}$ monocytes was assayed in cultured peripheral blood cells by flow cytometry. Cytokines in culture supernatants were assayed by multiplex ELISA. Area under the curve (AUC) measurements of non-parametric receiver operating characteristic (ROC) curves were used to compare the ability of PD-L1 expression to distinguish between subject groups.

Results: PD-L1 expression on healthy control monocytes was 2.7-fold higher than patients with active disease (mean induction $\pm$SD 27.8$\pm$20.4, 95% confidence interval (CI) 20.4–35.3 versus 10.5$\pm$11.4, 95% CI= 5.2–15.8, $p<0.005$). SLE patients in remission expressed normal levels of PD-L1 on monocytes (mean 24.2$\pm$16.5, 95% CI= 16.5–31.8, $p<0.0005$ versus active SLE). PD-L1 surface expression was induced on a mean of 80% of healthy Mo, whereas fewer Mo from patients with active SLE expressed PD-L1 (mean 52%, $p=0.00003$). ROC curves demonstrated how well PD-L1 expression distinguished between active and inactive disease (AUC 0.75) and between active SLE and healthy controls (AUC 0.79). Patients with renal SLEDAI criteria had a two-fold increase in PD-L1 expression on Mo compared to those without renal disease ($p=0.01$), but no correlation was detected with other clinical characteristics. PD-L1 expression on active SLE Mo could be restored by normal T cells or by supernatant from healthy cells producing IL-10 and/or TNF-α. Both IL-10 and TNF-α secretion correlated with PD-L1 expression, and either cytokine could restore PD-L1 expression on SLE Mo. Conversely, SLE cells over-produced TGF-β, and PD-L1 expression on healthy Mo was suppressed by TGF-β.

Conclusions: During an inflammatory response patients with SLE may be lacking a key step to limit autoreactive lymphocyte activity: the local, cytokine-mediated induction of PD-L1 expression on antigen presenting cells. Moreover, therapeutic agents that inhibit TNF-α may induce autoantibodies in part by preventing PD-L1 induction, thereby impeding an important mechanism of T and B lymphocyte regulation. Infection and other autoimmune diseases may potentially be distinguished from active SLE on the basis of monocyte PD-L1 expression.

RFX1 Regulates CD70 and CD11a Expression by Recruiting the Histone Methyltransferase SUV39H1 in Lupus T Cells. Ming Zhao, Xiaoyan Wu, Fei Gao, Qing Zhang, Heng Yin and Qianjin Lu. Second Xiangya Hospital, Central South University, Changsha, China

Background: Methylation of histone H3 lysine 9 (H3K9) represses gene expression. H3K9 is hypomethylated in $CD4^+$ T cells from systemic lupus erythematosus (SLE) patients, resulting in de-repression of genes involved in promoting auto-immune responses. However, the mechanism leading to H3K9 hypomethylation is unclear. The transcription factor RFX1 normally recruits DNMT1 and HDAC1 in $CD4^+$ T cells but is down-regulated in SLE $CD4^+$ T cells, reducing DNA methylation and histone acetylation and leading to the overexpression of the auto-immune related genes CD70 and CD11a. In this study we measured the methylation of H3K9 at the CD70 and CD11a loci in SLE $CD4^+$ T cells and investigated the involvement of RFX1 in H3K9 hypomethylation.

Methods: Peripheral blood monocytes (PBMCs) from 20 patients with SLE and 20 healthy controls were isolated by Ficoll-Hypaque density gradient centrifugation. $CD4^+$ T cells were isolated by positive selection using CD4 beads (Miltenyi, Bergisch Gladbach, Germany; purity was generally higher than 95%), and cultured in human T cell culture medium (Lonza, Walkersville, MD, USA). H3K9 tri-methylation levels at the CD70 and CD11a promoters were detected by chromatin immunoprecipitation (ChIP) and realtime PCR. SUV39H1 expression level was assessed by Western blot. Interactions of RFX1 with SUV39H1 and G9a were examined

by immunoprecipitation (IP). RFX1 expression and shRNA constructs were transfected into $CD4^+$ T cells using Human T cell Nucleofector kits (Lonza, Walkersville, MD, USA).

Results: Compared with healthy controls, the tri-methylation levels of H3K9 at the CD70 and CD11a promoters were lower in SLE $CD4^+$ T cells ($p < 0.05$). The protein level of the histone methyltransferase SUV39H1 was not different between SLE patients and healthy controls ($p > 0.05$). However, SUV39H1 was found to bind to the promoters of CD70 and CD11a. RFX1 immunoprecipitated with SUV39H1, but not G9a, in $CD4^+$ T cells and lupus $CD4^+$ T cells transfected with RFX1 exhibited an increase of H3K9 tri-methylation levels and decreased expression of CD70 and CD11a. In contrast, knocking down RFX1 expression by using RNAi down-regulated H3K9 tri-methylation levels at the CD70 and CD11a loci and activated their transcription in normal $CD4^+$ T cells.

Conclusions: RFX1 recruits SUV39H1 to the promoters of the autoimmune related genes CD70 and CD11a in $CD4^+$ T cells, and down-regulation RFX1 contributes to H3K9 hypomethylation leading to CD70 and CD11a overexpression in SLE $CD4^+$ T cells.

The HLA Haplotype DQA1+, DQB1+, DR4- Identifies Lupus Patients in Whom Anti-dsDNA Titers Correlate with Disease Activity. Mikhail Olferiev[1], Kyriakos A. Kirou[1], Dorthe Lundsgaard[4], Klaus S. Frederiksen[3], Jan Fleckner[2] and Mary K. Crow[1]. [1]Hospital for Special Surgery, New York, NY, [2]Novo Nordisk, [3]Novo Nordisk, Denmark, [4]Novo Nordisk, Copenhagen, Denmark

Objective: Anti-dsDNA titers are used by rheumatologists to assist in disease activity assessment of SLE patients. However, anti-dsDNA titers do not always correlate with disease activity. In this study we explored whether SLE patients with anti-dsDNA titers that parallel disease activity [based on SELENA SLEDAI (SS) score] differ in their PBMC transcriptional profile compared to other SLE patients.

Methods: Longitudinal PBMC and plasma samples were obtained over an average 6 visits (2–12) from 23 SLE patients and 5 healthy donors (HD). The duration of study follow-up for individual patients varied from 197 to 812 days. Plasma levels of autoantibodies were evaluated using the Multi-Analyte Profiling (MAP) technology (Rules-Based Medicine, Austin, TX). PBMC transcriptional profiles for each visit were established using Human Genome U133 Plus 2.0 Arrays.

Results: Microarray data analysis revealed 566 differentially expressed transcripts comparing HD samples versus samples of SLE patients during mild/moderate or severe SELENA SLEDAI flares, or those without a flare (ANOVA FC<2.0, $p<0.05$). From 44 tested autoantibodies 14 were significantly upregulated in SLE patients (T TEST and fold change (FC) = $p<0.05$ and >1.5). Eight autoantibodies, including anti-dsDNA, correlated weakly with disease activity based on SS. Nine patients showed high levels of anti-dsDNA autoantibody. Comparative analysis of transcripts between anti-dsDNA positive and negative patients identified 136 differentially regulated transcripts (FC>1.5 and $p<0.05$). Comparative analysis of those transcripts and autoantibody titer showed that anti-dsDNA autoantibodies correlated with multiple interferon signature genes and granulocyte markers (LTF, CEACAM6, MPO, and MMP9). Five SLE patients (22%) showed a strong correlation of anti-dsDNA titer and SS score ($R=0.9$; $p<0.001$). Comparative analysis of transcripts in those individuals compared with the other lupus patients identified 38 transcripts (FC>1.5; $p<0.05$). Of interest, the anti-dsDNA patients were all positive for HLA alleles DQA1, DQB1 and negative for DR4, in contrast to variable alleles for the rest of the patients (Fisher's test $p<0.01$).

Conclusion: SLE patients showing strong correlation of anti-dsDNA titers and disease activity have a distinct MHC class II haplotype. This observation, if confirmed, may help to identify SLE patients in whom anti-dsDNA titers are helpful in management of disease. This genetic background may favor skewing of the autoimmune response toward certain dsDNA epitopes that are particularly pathogenic.

The Integrity of Double Strand Break Repair in Pediatric Systemic Lupus Erythematosus Cells. Robert C. Davies[2], Kelly Pettijohn[2], Francesca Fike[2], Jiexi Wang[2], Shareef A. Nahas[2], Richard A. Gatti[3] and Deborah K. McCurdy[1]. [1]Mattel Children's UCLA-Rheumatology, Los Angeles, CA, [2]UCLA-Pathology and Laboratory Medicine, [3]UCLA-Pathology and Laboratory Medicine; Human Genetics

Introduction: Our laboratory previously demonstrated a delay in single strand break (SSB) processing in cells from pediatric patients with systemic lupus erythematosus (SLE). Because SSBs are often converted to double strand breaks (DSBs) at the replication fork and some DSB repair proteins are immnunogenic in SLE, i.e., DNA ligase IV, Ku 70/80, DNAPKcs, and XRCC4, we assessed the integrity of DSB recognition, signaling, and repair mechanisms in B-lymphoblastoid cell lines (LCLs) derived from pediatric and adolescent patients with SLE. This study assesses the integrity of DSB recognition, signaling, and repair mechanisms in LCLs derived from 16 pediatric and adolescent patients with SLE (pSLE).

Methods: Lymphoblastoid cells lines (LCLs) were established from the whole blood of 16 pSLE patients. Eight assays were used to assess four major pathways of repair of DSBs in pSLE LCLs. The assays included: (i) γ-H2AX and (ii) 53BP1 IR-induced nuclear foci (IRIF); (iii) immunoblot analysis of the kinetics of IR-induced phosphorylation of Structural Maintenance of Chromosomes 1 (SMC1); (iv) a DNA ligation assay to evaluate the NHEJ (v) neutral comet assay (vi) monoubiquitination of FANCD2 (vii) flow cytometry to assess the S-phase checkpoint; and (viii) colony survival assay as a measure of general radiosensitivity.

Results: Three of eight assays showed abnormal patterns of response to IR-induced DNA damage in some patients: 1) pSMC1 kinetics were intermediate in four patients, suggests defective repair, 2) the neutral comet assay was abnormal in half of the cells, showing delayed DSB repair, 3) colony survival assay showed radiosensitivity in half of the cell lines tested. We also observed reduced DNAPKcs, Ku70 and Ku80 proteins in one pSLE patient.

Conclusion: Our data suggest that DSB repair is compromised in pSLE LCLs as shown in the broad-based DSB repair assays (neutral comet assay, colony survival assay). This contrasts with results from our functional assays (γ-H2AX, 53BP1, NHEJ, FANCD2 monoubiquitination, S-phase checkpoint), which all appear normal. Although the majority of SLE cell lines exhibited DSB repair defects, the etiology of this remains unclear.

The Lupus Africa to US Gradient Revisited—Genetic Versus Environmental Factors in Lupus. Gary S. Gilkeson[1], Diane L. Kamen[4], Natasha M. Ruth[3], Anna Meyer[2] and Darrius Maggi[5]. [1]Med Univ of South Carolina, Charleston, SC, [2]MUSC, [3]MUSC, Charleston, SC, [4]MUSC PO Box 250637, Charleston, SC, [5]West Africa Fistula Foundation

Background: The Africa to US Lupus Gradient is a widely held belief that lupus is rare in west Africa while common in African Americans. This belief is based on limited assessments in Africa. If true, this gradient would provide novel insight into the genetic versus environmental causation of lupus. Assessing true lupus prevalence in west Africa is impossible at present, we therefore sought to assess prevalence of "autoimmunity", i.e. positive autoantibodies, in lupus unaffecteds.

Methods: Two unique cohorts were utilized for this study: the Gullah population in South Carolina and comparator patients of the West Africa Fistula Foundation in Sierra Leone. Sierra Leone is the ancestral home of the Gullah. All individuals were screened by history and exam to exclude lupus and SLE in a family member. The cohorts are all female and matched for age. Serum was obtained and autoantibody prevalence, viral seropositivity and vitamin D levels tested to assess autoimmunity prevalence and potential environmental factors implicated in lupus. ANA was done by Hep2 IFA, ACL by ELISA, anti-DNA by Crithidia and ENA by Ochterlony. Viral seroconversion was tested by standard ELISAs.

Results: A trend towards decreased ANA positivity that was not significant in the Sierra Leoneans was found (Table). A marked increase in APL positivity was found in the Sierra Leoneans, with no difference in antibodies against dsDNA, Sm, or RNP. Sierra Leoneans had significant increased seropositivity for EBV, CMV, HSV1 and HSV2. In addition there was a significant difference in serum 25OH vit D with a mean of 11ng/ml in the Gullah and 36ng/ml in the Sierra Leoneans. There was a trend towards lower

vitamin D levels in the Sierra Leoneans who were ANA+ >1/120 (mean 32 for ANA+ and 37 for ANA-). There were only three Sierra Leoneans that were seronegative for CMV/EBV and they were ANA-.

	SLEIGH Female Unrelated Controls (N = 122)	Sierra Leone Females (N = 70)	Age Adjusted p-value
ANA Positivity ≥1:40	35.2%	28.5%	NS
ANA Positivity ≥1:120	19.7%	15.7%	NS
ANA Titer >1:1000	3.3%	4.2%	NS
Cardiolipin IgG >20	4.9%	37.1%	<0.01
Cardiolipin IgM >20	0.0%	10.0%	<0.01
dsDNA or Sm positive	0.0%	0.0%	NS
RNP positive	0.8%	0.0%	NS
Ro (SSA) or La (SSB) positive	0.0%	2.8%	NS

Conclusions: Overall, there is a trend towards higher ANA reactivity in the Gullah, while ACL positivity is markedly higher in the Africans, possibly related to infections. Thus, autoimmunity is not significantly less common in Africans; differences in the prevalence of clinical lupus remain to be determined. There is a significant difference in environmental factors implicated in lupus including viral seropositivity and vitamin D levels. Further studies are needed to assess the lupus gradient hypothesis and the potential role of environmental factors in disease development.

The Variant of MHC Class I Polypeptide-Related Sequence (*MICA*) Is a Genetic Risk Factor for SLE Independent of *HLA-DRB1* and Modulates the Behavior of NK Cell *Via* NKG2D Receptor. Kohsuke Yoshida[1], Koichiro Komai[2], Kazuko Shiozawa[7], Aya Mashida[2], Takahiko Horiuchi[6], Yuki Tanaka[4], Masato Nose[5], Akira Hashiramoto[3] and Shunichi Shiozawa[3]. [1]Dept. of Biophysics, Kobe Univ. Graduate School of Health Sciences, Kobe, Hyogo, Japan, [2]Dept. of Biophysics, Kobe Univ. Graduate School of Health Sciences, Kobe, Japan, [3]Dept. of Biophysics, Kobe Univ. Graduate School of Health Sciences/Department of Medicine, Kobe University Graduate School of Medicine/The Center for Rheumatic Diseases, Kobe University Hosp., Kobe, Japan, [4]Dept. of Clinical Immunology, Rheumatology, and Infectious Diseases, Kyushu Univ., Fukuoka, Japan, [5]Dept. of Pathogenomics, Ehime Univ. Graduate School of Medicine, Ehime, Japan, [6]Div. of Genome Analysis, Medicine Institute of Bioregulation, Kyushu Univ., Fukuoka, Japan, [7]Rheumatic Diseases Center, Konan-Kakogawa Hosp., Kakogawa, Japan

Purpose: MIC (MHC class I polypeptide-related sequence) molecules interacts with NKG2D (natural-killer group 2, member D) and stimulates NK cells to release cytokines such as IFNγ and to exert cytotoxicity against its cellular targets. The expression of MICA is normally restricted to the intestinal and thymic epithelium, but is often aberrantly expressed on rheumatoid synovial cells or peripheral blood $CD14^+$ monocytes in patients with SLE. The *MICA* gene is located within the human leukocyte antigen (HLA) locus, and its exon5 coding transmembrane (TM) region contains a polymorphic microsatellite, which is classified according to the number of alanine-encoding GCT repeats as A4, A5, A5.1, A6 and A9. A single nucleotide polymorphism (SNP) at codon 129 in exon 3 of the *MICA* gene, Val129Met (rs1051792), has been shown to modulate the affinity of MICA to the NKG2D receptor. We previously showed that MICA 129Met and A9 alleles are genetically associated with the Japanese patients with SLE (Arthritis Rheum. 58: suppl (9). S815, 2008), but the genetic linkage between *MICA* 129, TM polymorphism and *HLA-DRB1* in patients with SLE and the effect of MICA polymorphism on the function of NK cell remain unclear. Here, we show that *MICA* 129Met/A9 is a genetic risk factor for Japanese patients with SLE independent of *HLA-DRB1* and modulates the behavior of NK cell *via* NKG2D receptor.

Methods: Japanese patients with SLE (n = 677) or controls (n = 350) were genotyped for *MICA* Val129Met (rs1051792), TM polymorphism and *HLA-DRB1*. The recombinant MICA-GST fusion proteins 129Val/A5 or 129Met/A9, which combine polymorphisms at 129Val and TMA5 or 129Met and TMA9, respectively, were tested on NK cell line NK92MI for the expression of NKG2D receptor, NK cell-mediated cytotoxicity against K562 target cells and IFNγ production.

Results: The *MICA* 129Met/A9 allele was significantly increased in the patients with SLE as compared with control: 178/647 (27.5%) vs. 56/321 (17.4%) ($P < 0.001$; OR = 1.6). Importantly, the frequency of *MICA* 129Met/A9 allele was also significantly increased in the patients with SLE: 24/100 (24.0%) vs. 31/234 (13.2%) ($P = 0.01$; OR = 2.2) as in the case with the population negative for the *HLA-DRB1 *1501* previously indicated as the risk allele for SLE in the Japanese population. When the disease-associated MICA 129Met/A9 protein was incubated with NK92MI cells, it significantly suppressed both the expression of cell surface NKG2D on NK92MI cells and the NK cell-mediated cytotoxicity against K562 cells more strongly than those with the most prevalent non-disease-associated MICA 129Val/A5 ($P < 0.05$ and $P < 0.01$, respectively). These findings are consistent with previous findings showing that NK cell cytotoxicity is significantly decreased in SLE. Interestingly, we also observed that the 129Met/A9 protein enhanced the release of IFNγ from NK92MI cells as compared with 129Val/A5 protein ($P < 0.01$), possibly because *MICA* 129Met variant has been shown to be higher affinity to the NKG2D receptor than the 129Val variant.

Conclusion: The MICA polymorphism is genetically associated with SLE independent of *HLA-DRB1**1501, and MICA appears to contribute to the pathogenesis of SLE by modulating NK cell function.

Acute Anterior Uveitis in Ankylosing Spondylitis: Clinical Characteristics and Impact of Biologic Therapy. Nai Lee Lui[1], Finbar (Barry) D. O'Shea[3], Hua Shen[2], Richard J. Cook[2] and Robert D. Inman[4]. [1]Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, [2]Department of Statistics and Actuarial Science, University of Waterloo, Canada, [3]St James's Hospital, Dublin, Ireland, [4]Toronto Western Hospital, Toronto, ON, Canada

Objective: To describe the characteristics of acute anterior uveitis (AAU), impact of biologic therapy on the incidence of AAU and to indentify predictors of AAU flare in an ankylosing spondylitis (AS) prospective longitudinal cohort.

Methods: We conducted a retrospective study of all AS patients developing AAU in a longitudinal AS cohort. All patients met the modified New York criteria for AS. Demographics and clinical characteristics (age of AS and AAU onset, HLA-B27 status) were recorded. Recurrence rates and impact of anti-TNF therapy were evaluated. Logistic regression analysis was used to determine predictors of AAU flare.

Results: Among the 464 AS patients, 132 patients with history of AAU were evaluated (28.4%). The mean age at onset of AAU is 31.7 years, higher than the age of AS onset (22.5) and diagnosis of AS (30.2) respectively. 10.2% (N=9) of patients developed AAU prior to the onset of AS symptoms, with a mean of 2.9 ± 2.4 years; while 77.3% (N=68) developed AAU after a mean of 11.5 ± 6.4 years following the onset of AS symptoms. There was no difference in the occurrence of AAU in male or female patients (p=0.19). 88.6% (N=109) of patients with AAU were associated with the HLA-B27 gene (OR 2.39, p=0.01). AS patients with history of AAU had more frequent enthesitis (p=0.024) but did not appear to require more anti-TNF therapy compared to AS patients without AAU (54.9% versus 45.1%; p=0.47). Following the commencement of anti-TNF, the AAU flare rate was 3.69 flares per 100 patient-yr compared to 15.72 flares per 100 patient-yr in AS patients who were treated with non-steroidal anti-inflammatory drugs (NSAIDs). There was no differential association with any particular biologic agent in 12 patients who developed AAU while on anti-TNF therapy. There was no correlation of indicators of higher AS disease activity (ESR, CRP, BASDAI or BASFI scores) at the time of AAU flares.

Conclusion: HLA-B27 is a strong predictor of AAU in AS patients. Higher incidence of enthesitis in AAU patients may suggest a potential similarity in the underlying pathogenic process between the two sites. Biologic therapy reduced the incidence of AAU. The incidence of AAU flare while on anti-TNF therapy is low and did not correlate with AS disease activity.

Ankylosing Spondylitis: High Frequency of Varicocele Associated with Teratozoospermia. Lucia A. Nukumizu[5], Carla G. S. Saad[5], Breno P. de Almeida[5], Jozélio F. Carvalho[5], Marcello Cocuzza[2], Celio R. Goncalves[5], Osmar Saito[1], Eloisa Bonfa[3] and Clovis A. A. Silva[4]. [1]Department of Radiology - Faculdade de Medicina da Universidade de São Paulo, Brazil, [2]Department of Urology - Faculdade de Medicina da Universidade de São Paulo, Brazil, [3]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [4]Pediatric Reumatology Unit, Faculdade de Medicina da Universidade de São Paulo, Brazil, [5]Rheumatology Division - Faculdade de Medicina da Universidade de São Paulo, Brazil

Purpose: To assess testicular function in male ankylosing spondylitis (AS) patients and controls.

Methods: 20 consecutive post-pubertal AS patients (modified New York criteria) were prospectively assessed for demographic data, urologic examination, testicular Döppler ultrasound (US), standardized semen analysis according to World Health Organization (WHO) guidelines and Kruger strict criteria, and anti-sperm antibodies. Selection criteria never under biological agents were included; sulfasalazine and methotrexate wash-out period of at least 3 months and no restriction to the use of non-steroidal anti-inflammatory drugs and/or low dose prednisone (≤ 10mg/day). The evaluation of AS included: clinical features, laboratory exams, treatment and scores (BASDAI, BASFI, BASMI and BASRIt). The control group consisted of 24 male healthy subjects.

Results: The median of current age was similar in AS and controls (31.5(23–44) vs. 34(17–53)yrs, p=0.353). The frequencies of left or bilateral varicoceles by clinical examination and by US were significantly higher in AS patients compared to controls (30% vs. 4%, p=0.035; 40% vs. 8%, p=0.027). Likewise, the median of vein diameters of pampiniform plexus in left testicles were significantly higher in AS patients *versus* controls (0.25(0.16–0.49) vs. 0.2(0.2–0.37)cm, p=0.009). Of note, the median of normal sperm forms by Kruger strict criteria was significantly lower in AS patients *versus* controls [3.25(0–14.5) vs. 6.75(0–18), p=0.035) and the frequency of teratozoospermia (abnormal sperm morphology) was significantly higher (55% vs. 8% p=0.0001). Reinforcing these findings, the median of normal sperm morphology by WHO guidelines was significantly lower in AS patients with ultrasonographic varicoceles compared to patients without varicoceles [13.5(2–27) vs. 22(10–32.5)%, p=0.049]. In addition, the median of normal sperm morphology by WHO guidelines and by Kruger strict criteria were alike in AS patients *versus* controls without ultrasonographic varicoceles (p>0.05). No differences were observed in penis median length and circumference in AS patients and controls, and testicular (left and right) by way of US in both groups (p>0.05). The median and frequencies of other parameters of sperm analysis and anti-sperm antibodies were comparable (p>0.05) in AS patients and controls. The demographic data, clinical findings and laboratory exams were also similar in AS patients with ultrasonographic varicoceles compared to patients without varicoceles (p>0.05), likewise tem median of BASDAI (4.21(1.66–6) vs. 3.95(1.04–8.68), p=0.899), BASFI (4.06(1.4–7.79) vs. 3.77(0–8.41), p=0.819), BASMI (4.5(0–7) vs. 6(0–8), p=0.486) and BASRIt (9(6–16) vs. 10(5–16), p=0.463).

Conclusions: This is the first demonstration that AS patients have a high frequency of varicoceles associated with isolated teratozoospermia. Further studies are necessary to determine if oxidative stress may underlie this testicular dysfunction in AS, since high levels of reactive oxygen species were reported to have a harmful effect in sperm quality of men with varicocele.

Application of Composite Disease Activity Scores in Psoriatic Arthritis to the PRESTA Dataset. Oliver M. FitzGerald[3], Philip Helliwell[5], Aizad Mumtaz[4], Laure Coates[5], Ronald Pedersen[2] and Charles T. Molta[1]. [1]Pfizer, Inc., Paoli, PA, [2]Pfizer, Inc., Collegeville, PA, [3]University College Dublin, Ranelagh Dublin, Ireland, [4]University College Dublin, Dublin, Ireland, [5]University of Leeds, Leeds, United Kingdom

Objectives: A number of rheumatoid arthritis composite disease activity indices have been used in clinical trials in psoriatic arthritis (PsA). Two composite disease activity measures have recently been proposed for PsA, but further validation is required. The purpose of this study is to compare the performance of the Composite Psoriatic Disease Activity Index (CPDAI) and the Disease Activity Index for Psoriatic Arthritis (DAPSA) in the PRESTA dataset, a large (N=752) randomised, double-blind, two-period study which evaluated the safety and efficacy of 2 doses of etanercept in the first study period on skin and joint disease in psoriasis subjects with active PsA.

Methods: Using the data obtained from the PRESTA study, the components of the CPDAI (4 domains, including joints [66 swollen/68 tender joint counts; HAQ]; skin [PASI; DLQI]; dactylitis [each digit rated 0 to 3]; and enthesitis [number of tendons showing enthesitis, 0–4, based on Achilles tendons and plantar fasciae bilaterally] and the DAPSA (patient global; pain assessment; 66/68 swollen and tender joint counts; and C-reactive protein [CRP]) were extracted. The performance of the scores at baseline and follow-up (weeks 12 and 24) was compared and also between the 2 treatment schedules (etanercept 50 mg QW v 50 mg BIW). Spearman correlations and both univariate and stepwise regression analyses were also used.

Results: Both CPDAI and DAPSA could distinguish response to treatment comparing baseline and 12- or 24-week values (<0.0001). CPDAI, and not DAPSA, could distinguish response in the 2 treatment groups at 12 weeks (p=0.0492) but not at 24 weeks. All domains contributed to the data variability of the CPDAI, with dactylitis (r=0.64) and enthesitis (r=0.60) the most significant. Joint scores (SJC: r=0.8; TJC: r=0.91) contributed most to the variability in DAPSA. For change in CPDAI from baseline, stepwise regression revealed that change in enthesitis, DAS28, HAQ, dactylitis and DLQI were most significantly associated. For change in DAPSA, change in all of the 5 components were significantly associated.

Conclusions: Both CPDAI and DAPSA are effective in determining treatment response in patients treated with etanercept for active psoriasis and psoriatic arthritis. Joint responses were equally reflected by both composite scores but CPDAI, which better reflects other domains such as skin, enthesitis and dactylitis, is the only composite score which can distinguish global treatment response between the 2 etanercept doses.

515

Association of BMI and Psoriatic Arthritis Disease Activity. Elena Eberle[2], Eric Knight[2], Donald A. Raddatz[2], Susan Messing[5], George Reed[4], Jeffrey D. Greenberg[1] and Joel M. Kremer[3]. [1]Millburn, NJ, [2]Bassett Healthcare, Cooperstown, NY, [3]The Center for Rheumatology, Albany, NY, [4]University of Massachusetts, Worchester, MA, [5]University of Rochester, Rochester, NY

Background: Obesity may induce a low-grade chronic inflammatory state. Adipocytes are involved in the recruitment and activation of macrophages, which produce TNF-alpha, IL-6, and IL-12. Studies have also shown an association between body mass index (BMI) and gouty arthritis and osteoarthritis of the hand joints. Psoriatic arthritis (PsA) patients have a significantly higher mean BMI and prevalence of obesity compared to population-based means. Therefore, we hypothesized that there may be an association between BMI and PsA disease activity.

Methods: We selected patients with PsA from the CORRONA database for a cross-sectional study. BMI was presented as a categorical and continuous variable. Patients were categorized into quartiles by weight including "Normal Weight" (BMI>=18.5, <25), "Overweight" (BMI>=25, <30), "Obese" (BMI>=30, <40), and "Morbidly Obese" (BMI>=40). Our primary outcomes were 28 tender joint count (TJC) and 28 swollen joint count (SJC). The secondary outcomes were physician global assessment of disease activity (PGDA), physician global assessment of skin involvement (PGSI), mHAQ, ESR, and CRP. We used Poisson regression models to investigate associations as relative risks between BMI categories and tender and swollen joint counts. Generalized estimating equations, employing a robust sandwich estimator for the variance of the beta weights, were used to assess the associations expressed as beta weights for secondary outcomes of interest.

Results: 1980 patients with PsA were identified from the CORRONA registry. 781 participants had ESR values and 593 individuals had CRP values. The majority of the patients had between 1 and 5 tender joints (80%) and between 1 and 5 swollen joints (82%). ESR in the obese quartile was 6 mm/h higher than the normal weight quartile and almost 10 mm/h higher in the morbidly obese quartile.

Table 1. Association between weight quartiles and tender joint count (TJC) and swollen joint count (SJC). Data are presented as relative risk (RR) per 1 joint increase with 95% confidence interval (CI). Normal Weight quartile (n = 344) serves as the reference group.

Primary Outcomes	Overweight (n = 636)	Obese (n = 702)	Morbidly Obese (n = 298)
TJC	1.00 (CI 0.81–1.24)	1.35 (CI 1.10–1.65)	1.53 (CI 1.22–1.93)
SJC	1.01 (CI 0.82–1.26)	1.30 (CI 1.06–1.60)	1.59 (CI 1.26–2.00)

Table 2. Association between weight quartiles and physician global assessment of disease activity (PGDA), physician global assessment of skin involvement (PGSI), mHAQ, ESR, and CRP. Normal Weight quartile (n = 344) serves as the reference group.*

Secondary Outcomes	Overweight (n = 636)	Obese (n = 702)	Morbidly Obese (n = 298)
PGDA	2.1339 (SE 1.2690) *p = 0.09*	4.2249 (SE 1.2570) *p = 0.0008*	5.9451 (SE 1.5377) *p = 0.0001*
PGSI	0.1544 (SE 0.0632) *p = 0.0147*	0.3077 (SE 0.0638) *p < 0.0001*	0.3103 (SE 0.0778) *p < 0.0001*
mHAQ	0.0218 (SE 0.0235) *p = 0.35*	0.1230 (SE 0.0244) *p < 0.0001*	0.2020 (SE 0.0327) *p < 0.0001*
ESR	0.2730 (SE 1.6003) *p = 0.86*	6.0946 (SE 1.7701) *p = 0.0006*	9.6867 (SE 2.1573) *p < 0.0001*
CRP	0.8044 (SE 1.0156) *p = 0.42*	0.7853 (SE 0.7853) *p = 0.39*	2.1585 (SE 1.5958) *p = 0.17*

* The beta weight expresses the rate of change in the outcome for the column BMI quartile vs. the Normal Weight quartile.

Conclusion: BMI>=30 was strongly associated with a higher disease activity in patients with PsA. This association may be the result of the induction of inflammation by adipose tissue as we found a positive relationship between ESR and obesity. There is presently limited recognition of this relationship amongst clinicians. Expanded investigations of the biologic factors associated with obesity and disease activity are needed in patients with Psoriatic arthritis.

Can We Discontinue Anti-TNF Therapy in Patients with Ankylosing Spondylitis and Remission? A Systematic Literature Review. Miguel A. Abad[3], Ana M. Ortiz[2], Estibaliz Loza[1], Juan A. Martinez Lopez[1], Maria P. Rosario[1] and Loreto Carmona[1]. [1]Fundación Española de Reumatología, Madrid, Spain, [2]Hospital Universitario de la Princesa, Madrid, Spain, Spain, [3]Rheumatology Unit, Hospital Virgen del Puerto, Plasencia, Spain, Spain

Background: The introduction of anti-TNF agents has changed the management of patients with Ankylosing spondylitis (AS). At present there is no doubt about the efficacy of anti-TNF agents: Infliximab (IFX), etanercept (ETN) and Adalimumab (ADA) in controlling symptoms of AS. However, it is unclear which should be the attitude once patients have achieved remission.

Objectives: To analyze the effect of discontinuing anti-TNF therapy in AS patients who achieved complete remission, and to assess whether the readministration would be effective and safe in case of relapse.

Methods: We conducted a systematic literature search for studies published up tol January 2009 on the efficacy of IFX, ETN and ADA in AS in Medline, Embase and the Cochrane Central databases. Selection criteria were: a)Type of study: clinical trials with any quality level (according to Jadad scale), b)Participants: patients with AS; c)Intervention: IFX, ETN or ADA d) Outcome: clinical relapse (according to ASAS criteria), time to relapse, effectiveness and safety after readministration of anti-TNFs. Two reviewers screened the titles and abstracts of the retrieved articles for selection criteria independently and collected the data by using ad hoc standard forms. One of them also graded the quality of the selected studies using a modification of the Oxford Centre for Evidence-based Medicine Levels of Evidence in its May 2001 update. A hand search was completed by reviewing the references of the included studies.

Results: We identified a total of 406 titles, of which 390 were excluded after reading the title and abstract. The final number of selected studies for a detailed review was 16. Finally 9 were excluded and 6 included (1 was a randomized controlled trial, 1 an open trial and the other 4 were follow-up studies) 2 evaluated ETN, 4 IFX. We did not found studies regarding ADA.

After the discontinuation of IFX in AS patients who achieved remission, almost 100% relapsed. The mean time to relapse was 17.5 weeks ± 7.9 weeks (range 7–45). Patients who were in partial remission and those with normal C-reactive protein levels at the time point of withdrawal had longer times to relapse. Retreatment with IFX was safe and the clinical improvement was similar to that before the treatment was stopped.

All of AS patients on ETN relapsed after treatment cessation. The median time to recurrence after discontinuation was 6.2 weeks ± 3 weeks, with relapse at 3 months 75% and 100% 9 months. Retreatment with ETN was efficacious and safe after readministration over 1 year in patients with active AS.

Conclusion: The discontinuation of IFX leads to a relapse in almost all of AS patients who achieved remission within weeks or few months (level of evidence 1b, grade of recommendation A). The reinfusion of IFX in AS patients is safe, and the clinical improvement is comparable to the observed before the discontinuation (level of evidence 4, grade of recommendation C).

The discontinuation of ETN leads to a relapse in almost all of AS patients who achieved remission within weeks or few months (level of evidence 1b, grade of recommendation A). The reintroduction of ETN achieved similar clinical response to that observed previously (evidence level 4, recommendation grade C).

Clinical and Demographic Characterization of a Colombian Cohort of Patients with Diagnosis of Spondylarthritis. Wilson A. Bautista[1], John Londoño[3], Marlon Porras[3] and Rafael R. Valle[2]. [1]Military Hospital, Division of Rheumatology, Bogota, Colombia, [2]Military Hospital, Division of Rheumatology, Bogota, Colombia, [3]Military Hospital, Division of Rheumatology, Bogota, Colombia

Purpose: The Spondyloarthropaties are a heterogeneous group of diseases characterized by axial as well as peripheral enthesitis and arthritis. Their presentation and clinical course is influenced by ethnicity, age at onset and sex; and share certain clinical features and laboratory findings, according to the population group. Given genetic susceptibility, environmental and socio cultural characteristics in our region, the clinical manifestations are different. Our objective is to describe clinical and demographic characteristics of a cohort of patients with spondyloarthropaties in our country.

Method: Data was collected from a database of Rheumatology Service; which includes the clinical and paraclinical information related to the disease. The patients were evaluated following the ASAS recommendations. Patient demographics, disease duration, family and personal history, clinical pattern (axial, peripherical), and HLA status were recorded. Questionnaires were administered for functional status (Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Bath Ankylosing Spondylitis Functional Index (BASFI). All analyses were performed using SPSS software.

Results: 282 patients with spondyloarthropaties were identified. 69.6% were men with a mean age of 35.9 years. The main characteristics are as follows: 99 (35.1%) with Ankylosing Spondylitis, 111 (39.4%) with Undifferentiated Spondyloarthritis, 51 (18.1%) with Reactive Arthritis, 10 (3.5%) with Psoriatic Arthritis and 1 (0.4%) with Inflammatory Bowel Disease associated to Spondyloarthritis. 9 patients (3.2%) did not have a specific diagnostic. In 244 (86.5%) patients who had HLA report, 146 (51.8%) were negative and 98 (34.8%) positive. 77 patients were B15 positive.

According to the form of disease onset, 92 patients (32%) had axial involvement, 98 (34.8%) had peripheral and 79 (28%) mixed onset. When we analyzed the data according to initial symptoms, we found that arthritis was the initial manifestation in 80 (28.4%) patients, enthesopathy in 17 (6%), back pain in 98 (34.8%), uveitis in 4 (1.4%) and buttock pain in 2 (0.7%) patients. In 70 patients (24.8%) several initial symptoms were presented to the onset of the disease. Inflammatory back pain was present in 215 (76.2%) patients. The average age of onset of symptoms was 28 with a minimum of 11 and maximum of 71. In addition, we found a history of infection in 30.1% of patients mainly acute diarrheal disease. Only 6.1% of the patients had known family history of spondiloarthritis. Also we evaluate the functional status and level of activity of the disease, using the BASFI and BASDAI questionnaires at the time of examination. The main BASDAI score was 5.53 and main BASFI score was 5.26.

Conclusion: The clinical and demographic presentation of Spondylarthri-

tis in our region compared to other pupulation groups is different. The subgroup of undifferentiated form is the more frequent clinical presentation and the history of infection is remarkable. Enrollment continues to increase the cohort and characterize the population.

Comparison of ASAS Partial Remission and Low ASDAS as Indicators of Remission-Like States in Ankylosing Spondylitis. Desiree van der Heijde[4], Joachim Sieper[3], Steve Brown[2], Frederic Lavie[1] and Aileen Pangan[2]. [1]Abbott Laboratories, Rungis, France, [2]Abbott Laboratories, Abbott Park, IL, [3]Charité Universitätsmedizin Berlin, Berlin, Germany, [4]Leiden University Medical Center, Leiden, The Netherlands

Introduction: Definition of remission in patients with Ankylosing Spondylitis (AS) has previously been based on the ASAS partial remission (ASAS PR) criteria. More recently, the AS Disease Activity Score (ASDAS) was developed and cut-offs validated, including low ASDAS (<1.3) as indicator of a remission-like state.

Objective: To compare the performance of ASAS PR and low ASDAS in identifying patients in remission in the 5-year ATLAS (Adalimumab Trial Evaluating Long-Term Efficacy and Safety for AS) clinical trial and to determine potential causes of observed differences in response rates.

Methods: Patients were randomized to receive adalimumab (ADA) 40 mg every other week (wk) or placebo (PBO) during a 24-wk double-blind period, followed by an open-label extension of up to 236 wks (total of 5 years). Efficacy and safety were assessed throughout the study. We evaluated the proportion of patients achieving ASAS PR, low ASDAS, ASDAS clinically important improvement (CII, decrease of at least 1.10 from baseline) and ASDAS major improvement (MI, decrease of at least 2.00 from baseline) at weeks 12 and 24 using a non-responder imputation analysis; and at weeks 52, 104 and 260 using observed analysis. Because ASDAS is calculated using the same components as the ASAS PR except for BASFI, plus the addition of CRP and peripheral pain/swelling (BASDAI Question 3), we also determined if baseline BASFI and mSASSS scores contributed to the observed differences in ASAS PR and low ASDAS response rates.

Results: ATLAS enrolled 315 patients (208 ADA, 107 PBO). Only patients in the ADA arm could have received 5 years of ADA therapy. At week 12 there were more subjects in the ADA arm compared with PBO who achieved ASAS PR (20.7% vs. 3.7%, $P<0.001$), low ASDAS (36.5% vs. 2.8%, $P<0.001$), CII (61.5% vs 17.8%, $P<0.0001$) and MI (39.9% vs. 3.7%, $P<0.0001$). At 1, 2, and 5 years of ADA exposure, the response rates (%) were higher for the 3 ASDAS-based response criteria compared with ASAS PR: (N, low ASDAS, CII, MI, ASAS PR) – 1 year (N=282, 42%, 69%, 47%, 33%); 2 years (N=261, 53%, 77%, 53%, 38%); 5 years (N=124, 61%, 87%, 65%, 51%). Higher baseline BASFI and mSASSS were noted for subjects who achieved low ASDAS but not ASAS PR, compared with those who achieved both low ASDAS and ASAS PR (Table 1). Even higher baseline BASFI and mSASSS were noted for those who did not fulfill either criteria. BASFI was the most frequently observed ASAS component to have not met the required value of <20 in the sub-group "low ASDAS +/ASAS PR -."

Duration of Adalimumab Exposure	*low ASDAS*	*ASAS PR*	*Mean (SD) Baseline BASFI*	*Mean (SD) Baseline mSASSS*
1 Year				
Any ADA (N = 79)	+	+	42.85 (19.93)	12.75 (14.52)
Any ADA (N = 39)	+	−	51.84 (20.78)	20.55 (20.04)
Any ADA (N = 149)	−	−	61.53 (20.88)	25.67 (21.68)
Any ADA (N = 15)	−	+	48.52 (19.20)	15.64 (19.74)
2 Years				
Any ADA (N = 90)	+	+	44.03 (19.09)	12.25 (14.16)
Any ADA (N = 47)	+	−	55.79 (20.80)	24.76 (22.11)
Any ADA (N = 114)	−	−	61.06 (21.70)	25.77 (22.54)
Any ADA (N = 10)	−	+	62.49 (20.56)	17.50 (15.58)
5 Years				
Any ADA (N = 55)	+	+	42.23 (17.55)	12.77 (14.49)
Any ADA (N = 20)	+	−	54.27 (25.61)	25.19 (23.77)
Any ADA (N = 41)	−	−	62.44 (18.80)	27.60 (24.33)
Any ADA (N = 8)	−	+	62.35 (16.23)	24.29 (18.33)

Conclusion: Low ASDAS detects more subjects in a remission-like state and allows for better differentiation between active treatment (ADA) and placebo than ASAS PR. This is likely due to the inclusion of BASFI in ASAS PR criteria, which may not reflect response to effective therapies if irreversible damage and functional disability are present.

Complex Assessment of Subclinical Vascular Disease Associated with Ankylosing Spondylitis. Nóra Bodnár[3], György Kerekes[2], Zoltan Szekanecz[1], Ildiko Seres[4], György Paragh[4], Pál Soltész[2], Gabriella Szücs[3] and Sándor Szántó[3]. [1]University of Debrecen Med Ctr, Debrecen, Hungary, [2]University of Debrecen Medical and Health Sciences Center, Department of Medicine, [3]University of Debrecen Medical and Health Sciences Center, Department of Rheumatology, [4]University of Debrecen Medical and Health Sciences Center, First Department of Medicine

Background: There have been recent studies indicating that ankylosing spondylitis (AS), as well as rheumatoid arthritis, may be associated with accelerated atherosclerosis and vascular disease.

Objectives: Here we assessed endothelial dysfunction, carotid atherosclerosis and aortic stiffness in AS in context with several clinical and laboratory parameters.

Methods: Forty-three AS patients and 40 matched healthy controls were studied. We assessed common carotid intima-media thickness (ccIMT), flow-mediated vasodilation (FMD) and pulse-wave velocity (PWV) in association with age, disease duration, smoking habits, body mass index, patient's assessment of pain and disease activity, BASDAI, BASFI, metric parameters, ESR, CRP and HLA-B27 status.

Results: We found impaired FMD (6.85±2.98 versus 8.30±3.96 %; p=0.005), increased ccIMT (0.65±0.15 versus 0.54±0.15 mm; p=0.01) and higher PWV (8.64± 2.44 versus 8.00±1.46 m/s; p=0.03) in AS patients compared to controls. ccIMT negatively correlated with FMD (r=−0.563; p=0.0001) and positively correlated with PWV (r=0.374; p=0.018). In addition, both ccIMT and PWV correlated with disease duration (r=0.559; p=0.013 and r=0.520; p=0.022, respectively), BASFI (r=0.691; p=0.003 and r=0.654; p=0.006, respectively), decreased lumbar spine mobility (r=−0.656; p=0.006 and r=−0.604; p=0.013, respectively) and chest expansion (r=−0.502; p=0.047 and r=−0.613; p=0.012, respectively) and increased wall-occiput distance (r=0.509; p=0.044 and r=0.614; p=0.011, respectively).

Conclusion: In this well-characterized AS population, impaired FMD, increased ccIMT and PWV indicate abnormal endothelial function, increased atherosclerosis and aortic stiffness, respectively. The early determination of FMD, ccIMT and PWV may be useful to assess and treat AS patients with high cardiovascular risk.

Correlates of Physical Function in Axial Spondylarthropathy: Fear of Movement as an Independent Contributor. Thijs Swinnen[3], Johan Vlaeyen[4], Wim Dankaerts[1], Rene Westhovens[5] and Kurt de Vlam[2]. [1]Department of Rehabilitation Sciences, Catholic University of Leuven, Leuven, Belgium, [2]Department of Rheumatology, University Hospitals Leuven, Sint Martens Leerne, Belgium, [3]Department of Rheumatology, University Hospitals Leuven, Department of Rehabilitation Sciences, Catholic University of Leuven, Leuven, Belgium, [4]Research Group on Health Psychology, Catholic University of Leuven, Department of Clinical Psychological Science, Maastricht University, Leuven, Belgium, [5]University Hospitals Leuven, Department of Rehabilitation Sciences, Catholic University of Leuven, Leuven, Belgium

Purpose: To establish the independent contribution of the psychological attribute "fear of movement and (re)injury" in explaining physical function in a large cohort of patients with axial Spondylarthropathy (aSpA).

Methods: We collected measures of anthropometrics (Body Mass Index), gender, disease duration, the use of medication (Biologicals and NSAIDs), physical function (Bath Ankylosing Spondylitis Functional Index), stiffness

(averaged items 5 and 6 of the Bath Ankylosing Spondylitis Disease Activity Index), pain (Numerical Rating Scale), spinal mobility (Bath Ankylosing Spondylitis Metrology Index) and fear of movement and (re)injury (Tampa Scale for Kinesiophobia[1]) in 126 patients with aSpA. We used a stepwise multiple linear regression modeling approach with physical function as the dependent variable. Because the assessment of fear of movement in aSpA is new, we checked for the Tampa Scale for Kinesiophobia's normal distribution and internal consistency with the Shapiro-Wilk and Cronbach's Alpha tests respectively. The level of significance was set at.05 for all analyses.

Results: Spinal mobility (mean=3.3;stβ=.409;p=.000), pain (mean=3.6;stβ=.347;p=.000), stiffness (mean=3.8;stβ=.277;p=.000), fear of movement and (re)injury (mean=25.6;stβ=.175;p=.000), the use of biologicals (no=0/yes=1:61/65;stβ=.118;p=.011) and gender (male=0/female=1:80/46;stβ=.103;p=.032) contributed significantly to physical function (mean=3.9). Disease duration (13.3years;p=.517), anthropometrics (mean=26.3;p=.273) and the use of NSAIDs (no=0/yes=1:52/74;p=.632) were not entered during the stepwise analysis. Pain partially mediated the effect of fear of movement on physical function as evidenced by simple mediation (Sobel test;p=.000) and after controlling for all other modeled variables in our mediation model (bootstrapping procedure;95% confidence interval=.0103-.0503). Our potent model on correlates of physical function explained as much as 76% of the variance (adjusted R^2) without violating any assumption of regression modeling. The Tampa Scale for Kinesiophobia scores were normally distributed (p=.348) and showed a good internal consistency (α=.81).

Conclusion: Fear of movement and (re)injury is an important contributor to physical function beyond traditional disease-specific outcome measures in patients with aSpA. The Tampa Scale for Kinesiophobia appears to be an appropriate instrument to assess fearful beliefs related to movement and (re)injury. Further exploration in this area is both justified and needed.

DC-STAMP (Dendritic Cell-Specific Transmembrane protein), a Potential Biomarker To Predict the Risk of Psoriasis Patients in Developing Psoriatic Arthritis. Yahui Grace Chiu[1], Sutha Shanmugarajah[3], Ben Panepento[1], Lihi Eder[2], Vinod Chandran[2], Dafna Gladman[2], Sharon Moorehead[1], Rick Barrett[1] and Christopher T. Ritchlin[1]. [1]AIR Unit, University of Rochester, Rochester, NY, [2]UHN-Toronto Western Hospital, Toronto, ON, Canada, [3]UHN-Toronto Western Hospital, Toronoto, ON, Canada

Purpose: 20% of psoriasis (Ps) patients (pts) develop psoriatic arthritis (PsA) within 10 years of Ps onset. Identification of an arthritis biomarker in Ps pts would facilitate early intervention and possibly delay and/or prevent onset of PsA. Previously, we reported an increased frequency of circulating osteoclast precursors (OCP) in one third of Ps pts without arthritis. We hypothesized that DC-STAMP (Dendritic Cell-Specific Transmembrane protein), a transmembrane protein that is required for the fusion of monocytes during osteoclast (OC) formation, may serve as an arthritis susceptibility biomarker in Ps.

Methods: We previously identified 4 major DC-STAMP expression patterns in human PBMC with an anti-DC-STAMP antibody by flow cytometry. Most healthy controls have low OCP and show DC-STAMP pattern I, whereas PsA pts demonstrate elevated OCP and are more likely to manifest DC-STAMP pattern IV. We analyzed DC-STAMP expression patterns by flow cytometry and OCP frequency in cultured monocytes in a longitudinal cohort of 24 Ps pts. They were assessed by rheumatologists based on standard criteria and did not have PsA. They have been followed for 3 years on average.

Results: Table 1 summarizes the baseline clinical features, DC-STAMP patterns and frequency of OC in 24 pts. Two, 6, 10, 6 Ps pts manifested DC-STAMP pattern I, II, III, and IV, respectively (column (a) & (b)). The OCP frequency (mean±standard deviation) is shown in column (c). Within 3 years, 2 pts developed PsA by the CASPAR criteria (column (f)). Their demographics and clinical variables are depicted in Table 2.

Table 1.

(a) DC-STAMP Pattern	(b) # of subjects	(c) OCP frequency (per 10^6 monocytes)	(d) Average of age	(e) PASI score	(f) # of pts develop PsA
I	2	47 ± 25	62	4.6	0
II	6	279 ± 365	57	2.9	0
III	10	380 ± 398	49	8.2	1
IV	6	1063 ± 954	36	4.1	1

Table 2.

Subject	Gender	Age	DC-STAMP pattern	OC frequency (per 10^6 monocytes)	PASI score 3 years ago	PASI score after arthritis onset	Years from Ps to PsA
#1	Female	58	III	580	3.5	3.1	5.7
#2	Female	48	IV	1185	6.6	12.2	4.7

Conclusions: Data from this longitudinal cohort registry suggest that DC-STAMP is a potential marker to predict development of PsA in Ps pts. Two pts who developed PsA have DC-STAMP pattern III and pattern IV, the most common patterns seen in PsA pts. Additional studies are required to further define the potential of DC-STAMP as an arthritis susceptibility biomarker.

Development and Validation of a Questionnaire for Evaluation of Spondyloarthritis Related Manifestations in the First Degree Relatives of Patients with Ankylosing Spondylitis. Roozbeh Sharif[4], John D. Reveille[6], Michael H. Weisman[1], Michael M. Ward[2], Laura A. Diekman[4], Mamatha Hanumanthaiah[5] and Shervin Assassi[3]. [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]NIH, NIAMS, IRP, Bethesda, MD, [3]Univ of Texas Health Science, Houston, TX, [4]Univ of Texas Health Science Center Houston, Houston, TX, [5]Univ of Texas Health Science Center Houston, [6]Univ Texas Health Sci Ctr, Houston, TX

Background: Previous studies have shown increased frequency of spondyloarthritis (SpA) related phenotypes in the first-degree relatives (FDR) of patients with Ankylosing Spondylitis (AS). However, large scale familial aggregation studies have been hampered by difficulties in screening and diagnosis confirmation. Our goal was to develop and validate a self-administered tool to evaluate the presence of SpA manifestations in the FDRs of AS patients.

Methods: A multidisciplinary team of rheumatologists, ophthalmologists, epidemiologists, and patient focus groups were involved in the design of the questionnaire. The low back pain questions were developed in close collaboration with the CDC/NHANES 2009 group and modified for utilization as a self-administered instrument. In the validation step, family members of AS patients completed the questionnaire and were subsequently examined by a rheumatologist at the study sites. A pelvic X-ray was obtained if inflammatory back pain (IBP) symptoms were present. We compared the questionnaire (method 1) to the physician evaluation (method 2) for each SpA manifestation and for the IBP criteria by Rudwaleit. IBP was defined as presence of at least 2/4 IBP criteria in conjunction with chronic lower back pain ($>$ 3 months) and age at symptom onset $\leq$ 50 years. The agreement and equivalency between the questionnaire and study site assessments were examined by Kappa statistics and Nam's equivalency test.

Results: Ninety one FDRs of AS patients with mean age of 50.7 (±16.6) years were enrolled, consisting of 36 parents, 28 siblings, and 27 children. Overall, 56% of study subjects were female and 87% were Caucasians. We confirmed IBP in 27, AS in 10, Achilles' tendonitis in 25, peripheral arthropathies due to SpA in 7, uveitis in 6, psoriasis in 4, reactive arthritis (ReA) in 2 study subjects. No case of inflammatory bowel disease was reported. As shown in Table, the agreement rates ranged from 76.9% to 98.9% between two modes of acquisition. The assessment for inflammatory back pain, Achilles' tendonitis, uveitis, psoriasis and reactive arthritis showed good to very good agreement between the questionnaire and site visit results. Furthermore, the questionnaire had adequate sensitivity and specificity for all SpA manifestations except for peripheral arthritis secondary to SpA. Particularly, the sensitivity and specificity of the instrument for capturing IBP according to Rudwaleit criteria was 81.8% and 88.4%, respectively. More

importantly, IBP per questionnaire had a sensitivity of 80% and specificity of 77% for AS as confirmed at the site visit.

Conclusion: These findings suggest that the developed questionnaire captures the SpA manifestations including AS with adequate diagnostic accuracy. This raises the possibility of utilization of this instrument for screening the FDR's of AS patients for SpA manifestations.

	Agreement	Expected agreement	Kappa	Nam's test of equivalence	Sensitivity	Specificity
Inflammatory back pain	86.81%	61.07%	0.6613	0.085	81.8%	88.4%
Achilles' tendonitis/ Plantar Fasciitis	85.71%	60.64%	0.6370	0.021	72%	90.9%
Peripheral Arthritis 2nd to SpA	93.26%	87.40%	0.4649	0.016	42.9%	97.6%
Uveitis	97.80%	87.68%	0.8216	0.001	83.3%	98.8%
Psoriasis	97.80%	89.59%	0.7889	0.007	100%	97.7%
Reactive Arthritis	98.90%	94.56%	0.7946	0.002	100%	98.9%
Low back pain screen question	79.12%	50.31%	0.5798	0.314		
Morning stiffness more than 30 Minutes	89.01%	59.09%	0.7314	0.073

Differences in Body Mass Index among Individuals with Psoriatic Arthritis, Psoriasis, Rheumatoid Arthritis, and the General Population. Vidula M. Bhole[1], Hyon K. Choi[5], Lindsay C. Burns[1], Cristián Vera Kellet[2], Diane V. Lacaille[1], Dafna D. Gladman[3] and Jan P. Dutz[4]. [1]Arthritis Research Centre of Canada, Vancouver, BC, Canada, [2]Department of Dermatology, Pontificia Universidad Católica de Chile, Santiago, [3]Toronto Western Hospital, Toronto, ON, Canada, [4]Univ of BC, Vancouver, BC, Canada, [5]Univ of British Columbia, Vancouver, BC, Canada

Purpose: To compare the adiposity among individuals with psoriatic arthritis (PsA), psoriasis (Ps), rheumatoid arthritis (RA), and general population (N), as well as identify correlates of adiposity among individuals with Ps and PsA.

Method: We included: 1) 448 dermatologist-diagnosed Ps patients and 2) 644 rheumatologist-diagnosed PsA patients from the International Psoriasis and Arthritis Research Team (IPART) database; 3) 350 RA patients who participated in a longitudinal study of RA care; and 4) the general population from Canadian Community Health Survey 3.1. All PsA cases met the Classification of Psoriatic Arthritis (CASPAR) criteria. We compared the body mass index (BMI) among the four groups (PsA, Ps, RA, N) using analysis of variance (ANOVA) and performed all pairwise comparisons using Tukey's test. We performed age-and-sex adjusted linear regression analyses using BMI as a continuous outcome, as well as logistic regression analyses using obesity ($\geq$30 kg/m^2) as a dichotomous outcome. We conducted multivariate analyses limited to Ps and PsA groups to determine the independent correlates of increased adiposity in these patients.

Results: The mean BMI (kg/m^2) for individuals with PsA, Ps, RA, and the general population were 29.6, 27.9, 27.3, and 26.1, respectively.

Table 1. Demographics and Body Mass Index (BMI) of the Study Population

	PsA	Ps	RA	N
N	644	448	350	115787
Age	50	47	65	50
Sex, female	41%	42%	68%	53%
BMI, mean (SD)	29.6 (7.3)	27.9 (5.7)	27.3 (6.0)	26.1 (5.0)

The differences in BMI were significant for all the categories (ANOVA p <0.0001, Tukey test p<0.05) except those between Ps and RA. Adjustments for age and sex using linear and logistic regressions did not change the results materially (all p values <0.0001). In the multivariate linear regression analysis limited to Ps and PsA groups, after adjustments for age, sex, smoking, Ps duration, Psoriasis Area Severity Index (PASI) score, DMARDs, glucocorticoids and biologics; BMI of PsA remained higher than that of Ps by 1.54 kg/m^2 (95% CI: 0.63–2.56). In similar multivariate logistic regression analyses, the odds ratio of obesity increased by 50% in those with PsA compared to those with Ps (95% CI: 1.09 – 2.05). Age, smoking, PASI score, glucocorticoid use, and female gender were significantly associated with a higher BMI or increased odds of obesity in patients with Ps or PsA.

Conclusion: BMI is higher in PsA (skin and joint disease) than that in Ps (skin disease), RA (joint disease) or the normal population. Furthermore, our results suggest that the BMI difference between PsA and Ps is independent of other risk factors of obesity. Other significant correlates of increased BMI or obesity among individuals Ps or PsA were age, smoking, PASI score, glucocorticoid use, and female gender.

Disease Activity Assessment by ASDAS Doesn't Predict Sacroiliac Inflammation with MRI in Axial SpA. Sibel Z. Aydin[2], Alex Bennett[1], Paul Emery[2], Dennis McGonagle[2] and Helena Marzo-Ortega[2]. [1]Defence Medical Rehabilitation Centre, Headley Court, Epsom, Surrey, [2]Section of Musculoskeletal Diseases, The Leeds Institute of Molecular Medicine. University of Leeds, UK

Objective: The ASDAS (Ankylosing spondylitis disease activity score) is a newly developed composite index to measure disease activity in AS. It incorporates items of back pain, morning stiffness, patient global assessment of disease activity, pain/swelling of the peripheral joints and the CRP using a weighted formula. In the present study we aimed to test the construct validity of ASDAS comparing it with active inflammation of the sacroiliac joints (SIJs) as shown by MRI.

Methods: Twenty-three patients (n=23) with axial SpA according to the ASAS criteria were included. All patients were questioned for the parameters included in ASDAS and had an MRI scan of the SIJs. ASDAS values were categorized according to the different cut-off levels recently presented at OMERACT 10 and compared to the MRI findings according to the guidance of ASAS proposals. Further scoring to identify patients with severe MRI sacroiliitis (grade 3 according to the Leeds MRI SIJ Scoring System) and total MRI scores (sum of scores at all quadrants with a maximum score of 24) were also available.

Results: All patients had active disease according to ASDAS (scores >1.3).

Table 1. Distribution of ASDAS according MRI findings

Disease activity according to ASDAS	ASDAS cut off levels	Positive MRI (n)		Severe sacriolitis by MRI (n)		MRI scores median (range)
		+ n = 18	− n = 5	+ n = 4	− n = 19	
inactive disease	<1.3	0	0	0	0	NA
moderate activity	1.3–2.1	2	1	1	2	5 (0–16)
high activity	2.1–3.5	7	2	1	8	1 (0–18)
very high activity	>3.5	9	2	2	9	2 (0–12)
		p = NS		p = NS		p = NS

Moderate disease was found in 13%, 39 % had active and 48 % had very active disease. No relationship was found between the different states of disease activity according to ASDAS and MRI findings, including severity of the MRI. Similarly, ASDAS levels were found comparable in groups with/without sacroiliitis by MRI (3.5 ±1.1 vs 3.1±0.9, p=0.5, respectively) and severe sacroiliitis by MRI (3.5 ±1.8 vs 3.4±0.9, p=0.8, respectively). MRI scores were also independent from ASDAS categories.

Conclusion: Besides the clinical benefits of ASDAS, there does not appear to be a relationship between ASDAS and the presence of bone marrow oedema on MRI at the SIJ of axial SpA patients.

Estimation of Optimal Cutt-Off Point of Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Mini-BASDAI. Ruxandra Schiotis[7], Eliza Muñoz Gomariz[3], Juan Mulero[5], Xavier Juanola[4], Janitzia Vazquez-Mellado[1], Percival D. Sampaio-Barros[2] and Eduardo Collantes[6]. [1]Department of Rheumatology, General Hospital of México, México City, [2]Division of Rheumatology, University of São Paulo, [3]Instituto Maimónides de Investigación Biomédica/Hospital Universitario Reina Sofia, Cordoba, Spain, [4]Rheumatology Department, H. U. Bellvitge, Barcelona, [5]Rheumatology Department, Hospital Puerta de Hierro Majadahonda. Madrid, Spain, [6]Rheumatology Department, Hospital Reina Sofía. Córdoba, Spain, [7]University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania

Objective: To estimate the best optimal cut-off point of Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and modified BASDAI (mini-BASDAI) in a large population of patients with ankylosing spondylitis (AS)

Methods: The analysis was performed in two large cohorts of patients from two registries of spondylarthropaties patients: REGISPONSER (Spain) and RESPONDIA (Latin-America). For performing further analyzes patients were divided in two subgroups with and without peripheral arthritis: (1) AS peripheral and (2) AS axial. The optimal cut-off point of the three activity disease indexes was estimated with the ROC curves. The discrimination between active and inactive disease was performed with the area under the curve ROC. The "gold standard" used in our analysis was the physician global assessment obtained on a numerical rating scale (NRS).

Results: The optimal cut-off point for ASDAS, BASDAI and mini-BASDAI were as follows: 2.68; 4.24 and 5.14 respectively. ASDAS cut-off point statistical significantly discriminated active disease compared to BASDAI (P=0.015) and mini- BASDAI (P=0.002). The same tendency of ASDAS cut-off in discriminating active disease was found in both "AS peripheral" and in "AS axial" although, significant statistical difference was encountered only in the "AS axial group"(ASDAS vs BASDAI, P=0.027 and ASDAS vs mini-BASDAI, P=0.040). Higher activity scores were found in "AS peripheral group" for all three studied indexes.

Conclusion: ASDAS is a validated instrument that offers a high discriminatory capacity of active disease when compared with BASDAI and mini-BASDAI, for all presenting AS forms. ASAS should be the preferred score in assessing AS patients in daily practice.

Evaluation of the New ASAS Instrument To Assess Disease Activity, the ASDAS, in Patients with Ankylosing Spondylitis Treated with TNF Blockers over 8 Years. Xenofon Baraliakos[4], Claudia Fritz[2], Joachim Listing[2], Joachim Sieper[1] and Juergen Braun[3]. [1]Charite Campus Benjamin Frankl, Berlin, Germany, [2]German Rheumatism Research Center, [3]Rheumazentrum Ruhrgebiet, Herne, Germany, [4]Rheumazentrum Ruhrgebiet Herne

Background: Currently used clinical parameters for assessment of disease activity (BASDAI) or response to therapy (BASDAI50%, ASAS20% and 40%) in patients with AS mainly rely on patient′s opinion. The Spondyloarthritis International Society (ASAS) has recently developed a new disease activity score, the ASDAS, which includes clinical measures and CRP and has a high discriminatory capacity for assessing disease activity in AS.

Objective: To compare the performance of established tools with the new instrument, the ASDAS, in a longterm clinical of continuous anti-TNF therapy with infliximab in patients with active AS (n=33) after 3, 5 and 8 years.

Methods: According to recent data, an ASDAS <1.3 was considered as 'inactive', 1.3–2.1 as 'moderate', 2.1–3.5 as 'high' and > 3.5 as very high disease activity. An ASDAS change >1.1 was defined as 'minimally important improvement' and ≥2 as 'major improvement', as recently proposed.

Results: The mean BASDAI decreased from 6.4±1.9 at baseline to 2.3±2.0 at 3y (64% decrease), to 2.4±2.0 at 5y (63% decrease), and to 2.6±1.9 (59% decrease) at 8y (all p<0.05). In comparison, the ASDAS decreased from 4.3±0.8 at BL to 1.5±1.0 (65% improved) at 3y, to 1.6±1.0 at 5y and to 1.6±0.9 at 8y (63% decrease).

Overall, a BASDAI < 3 was achieved by 22/33 patients (66.7%) at 3y and by 21/33 patients (63.6%) at 5y and 8y years. In comparison, at 3y, 5y and 8y, an ASDAS<1.3 was found in 15 (46%), in 13 (39%), and in 17 (52%) patients, respectively. An ASDAS between 1.3–2.1 was seen in 11 (33%), in 13 (39%) and 6 (19%) patients after 3y, 5y and 8y, respectively. An ASDAS between 2.1–3.5 was found in 6 (18%), in 9 (27%) and in 9 (27%) after 3y, 5y and 8y, respectively and an ASDAS ≥3.5 was seen in only 1 (3%) patient at all time points. The comparison of different outcome parameters for change is shown in Table 1.

Conclusions: The ASDAS, a new composite disease activity score for AS proposed by the ASAS, was more sensitive than the conventional scores for disease activity and change, confirming recent data on short-term outcomes. More studies are needed to establish the ASDAS as a standard tool for assessment of disease activity in patients with AS in clinical practice.

Response parameter	3 years (n = 33 Pat.)	5 years (n = 33 Pat.)	8 years (n = 33 Pat.)
ASAS 20%	93.9% (31)	81.8% (27)	84.8% (28)
ASAS 40%	72.7% (24)	66.7% (22)	63.6% (21)
BASDAI 50%	66.7% (22)	69.7% (23)	63.6% (21)
ASAS Part. Remission	39.4% (13)	36.4% (12)	24.2% (8)
ASDAS impr. > 1.1	97.7% (32)	90.9% (30)	93.9% (31)
ASDAS impr. ≥ 2.0	72.7% (24)	66.7% (22)	69.7% (23)

Evolution of Familial Spondyloarthritis (SPA) without Radiographic Sacroiliitis over Time: Results of a Prospective Follow Up Study. Nadine Zeboulon-Ktorza[3], Roula Said-Nahal[1], Maria-Antonietta D'Agostino[3] and Maxime Breban[2]. [1]Hôpital Ambroise Paré, Assistance Publique Hôpitaux de Paris, Boulogne-Billancourt, France, [2]Hôpital Ambroise Paré, Assistance Publique Hôpitaux de Paris, Boulogne-Billancourt, France; INSERM Unité 1016; Université Versailles Saint Quentin en Yvelines, F-78000, Versailles, France, [3]Hôpital Ambroise Paré, Assistance Publique Hôpitaux de Paris, Boulogne-Billancourt, France; Université Versailles Saint Quentin en Yvelines, F-78000, Versailles, France

Background: Transversal study of familial SPA shows that all subtypes of SPA, (i.e. ankylosing spondylitis (AS), SPA associated with psoriasis or inflammatory bowel disease (IBD), with or without radiographic sacroiliitis, and undifferentiated SPA (uSPA)) coexist in families, and that longer disease duration correlates with higher frequency of radiographic sacroiliitis (Arthritis Rheum. 2000;3:1356). It was previously suggested that the various subtypes of familial SPA may correspond to different stages of the same disease but this remains as yet unproven. Only longitudinal study could properly address this question.

Material and Methods: The study population consisted of an adult (≥ 16 years) cohort of familial SPA fulfilling Amor's criteria and/or European Spondylarthropathy Study Group criteria, without definite radiographic sacroiliitis at inclusion (i.e. ≥ grade 2 bilateral or ≥grade 3 unilateral, according to the New York modified criteria). Patients underwent thorough clinical evaluation, and a pelvic radiograph at the inclusion and at the end of follow up, which lasted 5 to 15 years. Blinded films were read by 2 expert examinators. Univariate and multivariate logistic regression were performed to identify factors present at inclusion which could predict the evolution of SPA without definite sacroiliitis and evolution of uSPA to a differentiated form, and notably to AS.

Results: Of the initial cohort consisting of 150 non-radiographic SPA followed more than 5 years, analysis were performed on 83 patients (68.7% of females; 93.7% HLA-B27+; 71.1% of uSPA, 25.3% with psoriasis, 3.6% with IBD) with available pelvic radiograph at the end of follow up. At inclusion, age (mean ± SD) was 43.1 ± 13.5 years and disease duration was 14.8 ± 12.1 years. The mean duration of follow up was 8.3 ± 2.2 yrs. At the end of follow-up, definite radiographic sacroiliitis (i.e. AS) was detected in 21.7% of the patients (7.2% with psoriasis). Of the remaining patients, 21.7% had psoriasis, 9.6% IBD and 47.0% had uSPA. Of 59 initial uSPA, 20 (33.4%) developed a differentiated form of SPA: 13 (65.0%) AS (1 with psoriasis), 4 (20.0%) non-radiographic SPA with psoriasis, 3 (15.0%) non-radiographic SPA with IBD. The only factor at inclusion that was moderately but significantly associated with a higher risk to develop radiographic sacroiliitis was a disease duration < 10 years: Odds Ratio = 0.26 (95% Confidence Interval 0.09–0.77).

Conclusion: This prospective study conducted on familial SPA without definite radiographic sacroliiitis at inclusion shows for the first time that a

substantial proportion of them develop AS and that uSPA tends to evolve to differentiated form over time. This validates the hypothesis that distinct subtypes of familial SPA correspond to different stages of the same disorder.

Frequency of Iridocyclitis at Onset in a Large Series of Patients with Early Psoriatic Arthritis. Fabrizio Cantini[2], Carlotta Nannini[2], Emanuele Cassarà[2], Olga Kaloudi[2], Massimo Susini[1] and Laura Niccoli[2]. [1]Ophthalmology Unit, Hospital of Prato, Prato, Tuscany, Italy, [2]Rheumatology Unit, Hospital of Prato, Prato, Tuscany, Italy

Background: The occurrence of iridocyclitis (IC) in early psoriatic arthritis (PsA) has been rarely assessed [1,2].

Objective: Primary end-point was to evaluate the frequency of IC at onset in a large cohort of p. with early PsA.

Methods: We evaluated the frequency of IC in a clinical series of consecutive, new outpatients with early PsA observed between January 2000 and December 2009. All p. met the CASPAR criteria for PsA and had a disease duration ≤12 months. The demographic and clinical information were stored in a computed database. At baseline sex, age at diagnosis, date of diagnosis, articular and extra-articular manifestations, laboratory assessments [erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), HLA B27], radiological evaluation (sacro-iliac joints X-ray, and MRI), were assembled. The following clinical patterns were considered: peripheral PsA (oligoarthritis ≤4 and polyarthritis ≥5 involved joints), axial PsA (Calin's criteria for inflammatory spinal pain, radiographic or MRI evidence of sacroiliitis), mixed (concomitant axial and peripheral features). IC diagnosis was accepted in presence of typical ocular signs/symptoms and ophthalmology examination. Therapy was standardized as previously reported[3]. P. were followed by the same rheumatologist, and follow-up visits were scheduled at baseline and every 4 months. Control visit intervals were shortened in the case of urgent clinical problems, and all p. were instructed to call the centre in presence of worsening of previous arthritis, additional joint involvement, extra-articular manifestations onset, adverse events (AEs).

Results: 242 p., 137 (57%) women and 105 (43%) men with a mean age of 50.33±11.7 ys and a mean duration of symptoms of 9.38±3.1 months were studied. Peripheral pattern was observed 132 (51%) p., axial in 41 (17%) and mixed in 69 (28%). Mean ESR and CRP were 31±18 mm/h and 1.83±2.28 mg/dl respectively. A total number of 26 episodes of IC were recorded at diagnosis in 22 (9%) p., 17 (77.3%) females and 5 (22.7%) males; 11 (50%) p. had peripheral PsA, 2 (9.1%) axial and 9 (40.9%) mixed; 5/22 (22.7%) p. were B27 positive. IC recurred in 2/22 (9%) p. over the follow up. Mean follow-up duration was 4.6±3.5 years. Multiple logistic regression analysis did not disclose any significant association with IC for all demographic, clinical, and laboratory variables.

Conclusion: IC occurred in 9% of 242 p. with early PsA. This frequency is higher than previously reported. IC was not associated with the PsA clinical pattern and B27 positivity.

Hip Involvement Concerns 18% of Spondyloarthritis Patients, Is Often Bilateral and Total Joint Replacement Leads to Good Functional Results in These Patients. Vincent Burki, Simon Paternotte, Muriel Elhai, Isabelle Fabreguet, Eugenie Koumakis, Magali Meyer, Judith Payet, Fanny Roure, Laure Gossec and Maxime Dougados. Paris Descartes University, Cochin Hospital, Paris, France

Background: Hip involvement is a common but little studied feature of spondyloarthritis (SpA).

Objective: To study the prevalence and clinical features of hip involvement, in a cohort of patients with spondylarthritis (SpA) in a tertiary care center.

Methods: *Study design*: retrolective single center observational study in 2010 (COSPA). *Patients*: definite SpA (Amor's criteria). Each patient underwent direct interview by a physician. *Data collection*: prevalence of hip involvement, and if present, the date of appearance, the localization and nature of the pain, treatments performed (intra-articular injections, surgery) and outcomes of total joint replacement (TJR). *Analysis*: descriptive analysis.

Results: To date, 148 consecutive SpA patients were assessed: 26/148 patients (18%) suffered from SpA-associated hip involvement; median age 44.2 (range 25.9–69.4) years, median symptom duration 23.5 (5–51) years, 22 (85%) were men, 22/24 (92%) were B27 positive. 22/26 (85%) of patients with hip involvement had been treated by anti TNF at data collection versus 65/120 (54%) of other patients. Hip involvement appeared during the first 5 years of disease duration in 68% and during the first 10 years in 81%. Prevalence varied according to SpA predominant manifestation: more frequent in axial patients (20%, 22/110), than in peripheral disease (14%, 4/29). Hip involvement was bilateral in 46% (12/26) and unilateral in 54% (14/26); 11 patients (46%) received intra articular corticoid injections (of which, 23% were triamcinolone hexacetonide). In all, 9 patients (6% of the whole group and 36% of patients with hip involvement) had a TJR; the median delay between first hip symptoms and TJR was 36 months (range 0–27 years). After a median follow-up of TJR of 101 months (range 2– 27 years), TJR was considered as having a good function in 100% and only 22% (2/9) patients had TJR complications with a second TJR of the hip for both of them.

Conclusion: Hip involvement occurs in 18% of our SpA patients; hip involvement seems to start usually in the first 10 years of the disease (81% of our patients) with almost equal bilateral or unilateral involvement. TJR is still the best treatment at the moment for serious destruction, with good results even if corticoid intra articular injections are used to retard it.

HLA-Cw*06 Allele Increases the Duration of Time between the Onset of Psoriasis and Psoriatic Arthritis. Lihi Eder[2], Vinod Chandran[2], Fawnda Pellett[2], Sutha Shanmugarajah[2], Hua Shen[3], Richard Cook[3] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto Psoriatic Arthritis Clinic, Toronto Western Hospital, [3]University of Waterloo

Aim: Most of the patients with psoriatic arthritis (PsA) develop arthritis following the onset of the skin disease, with a mean duration of approximately 7 years. It was suggested recently that the risk of developing PsA remains constant after the diagnosis of psoriasis. We aimed to investigate whether the rate of PsA after the onset on psoriasis is constant and whether it is affected by clinical and genetic factors.

Methods: We performed a retrospective cohort analysis of patients with PsA and psoriasis without arthritis. The PsA patients were part of a large single centre longitudinal cohort. The psoriasis patients were recruited from a recently established prospective cohort of psoriasis without arthritis. They were assessed annually by a rheumatologist to rule out PsA. Only patients that developed arthritis after the onset of psoriasis were included. We analyzed the rate of PsA cases per year from the onset of psoriasis. Patients with psoriasis alone were censored at their last visit to the clinic. Parametric survival analysis was used to determine the probability model that predicts the risk of developing PsA after the onset of psoriasis. The following variables were tested for their effect on the interval of time from psoriasis to PsA: HLA-C*06, HLA-B*27, gender, type I vs. II psoriasis.

Results: 438 patients with psoriasis and 769 patients with PsA were included in the study. The mean age at onset of psoriasis and PsA were 26.8±14.7 and 37.3±13.3 years. The sex ratio was 1.3:1 (male: female). The proportion of type I psoriasis was 82.8%. 36% of the participants were carriers of HLA-Cw*06 allele and 11% of the participants were carriers of HLA-B*27 allele. The mean time from the onset of psoriasis to development of PsA was 12.2±10.7 years. The estimated annual probability of PsA was fit with an exponential probability model, suggesting that the risk of developing PsA over time was constant. Tests for trend did not suggest any evidence of departure from a constant hazard. HLA-Cw*06 carriers were associated with longer intervals of time between psoriasis and development of PsA (Relative Risk 0.54, 95% Confidence Interval 0.37–0.78, p=0.001). HLA-B*27, type of psoriasis and gender were not found to affect the time interval between psoriasis and PsA.

Conclusions: The risk of developing PsA over time among psoriasis patients is constant. HLA-Cw*06 allele doubles the duration of time between the onset of psoriasis and PsA.

Hypertension and Diabetes Significantly Enhance the Risk for Cardiovascular Disease in Patients with Psoriasic Arthritis (PsA). Maria Helena Sampaio Favarato[1], Carla Gonçalves Saad[2], Célio Roberto Gonçalves[2], Percival Degrava Sampaio-Barros[2] and Claudia Goldenstein-Schainberg[2]. [1]Rheumatology, HC-FMUSP, São Paulo, Brazil, [2]Rheumatology, HC-FMUSP

New evidence has lightened the linkage between psoriatic arthritis (PsA) and the development of atherosclerosis and cardiovascular disease (CVD) events.

Objective: To describe the prevalence of cardiovascular events and associated risk factors among patients with PsA from a tertiary hospital.

Methods: Retrospective evaluation of medical records from all current patients who fulfilled the CASPAR criteria for PsA attending a specialized spondyloarthritis clinic at a universitary tertiary hospital.

Results: 158 PsA patients, 48.73% females and 51.27% males, aged 53.67 ± 13.89 yrs (52.61± 14.96yrs for women and 54.69 ± 12.80yrs for men, p= 0.34). Mean joint disease duration was 13.7 ± 8,92yrs. Cutaneous psoriasis preceded articular involvement in 53%, was concomitant in 38% and followed joint disease in 9%. Polyarticular subtype was the most common presentation accounting for 42% of PsA patients, while peripheral olygoarticular involvement occured in 20%, axial + peripheral polyarticular in 18%; pure axial disease in 12% and axial + peripheral olygoarticular in 8% of cases. According to drug therapy, 32 (20%) were under the action of anti-TNFagents, 94 (60%) were taking metothrexate, 18 (11%) leflunomide, 13 (8%) sulfasalazine, 5 (3%) other immunossupressors and 4 (2.5%) chloroquine; 85 (54%) were using NSAIDs and 21 (13%) were on low-dose prednisone. Over half patients (87patients, 55%) had arterial hypertension (AH) and 23% (36) had diabetes mellitus (DM). Statins were being used by 32% (51) cases. Lipid profile was similar for men and women revealing total cholesterol mean levels of 186.5±38.6mg/dl, LDL=112.3±30.6mg/dl, HDL= 47, 89 ± 14,6 and total triglycerides = 127.4±65.6mg/dl. Mean CRP levels was 9,13 ± 16,25. Remarkably, 14% (n=XX) PsA patients have had CVD, namely cerebrovascular or coronary heart disease. Sex, age, disease duration, joint involvement subtype, CRP and lipids levels were similar among patients with and without CVD. Notably, the prevalences of AH and DM were significantly higher ($p<0.001$) in the group of PsA patients who have had CVD, conferring an odds ratio of 5.44 for AH, of 3.27 for DM and of 8,32 for both.

Conclusion: We have shown for the first time that despite psoriasis has recently been recognized as an independent CV risk factor, traditional risk factors such as AH and DM are important in the enhancement of the incidence of CVD in PsA patients. Therefore, early recognition and specific treatment of AH and/or DM is mandatory in order to prevent CVD in PsA patients

Identification of the Clinical Features That Can Distinguish between Psoriatic Polyenthesitis and Fibromyalgia. Antonio Marchesoni[6], Valentina Varisco[6], Fabiola Atzeni[7], Antonio Spadaro[3], Ennio Lubrano[5], Salvatore D'Angelo[10], Alberto Cauli[4], Carlo Salvarani[8], Giuseppe Provenzano[2], Raffaele Scarpa[9], Daniela Melchiorre[1], Piercarlo Sarzi Puttini[7], Ignazio Olivieri[10], Mariangela Atteno[9], Monica Montepane[3], Gabriele De Marco[6], Laura Rotunno[6] and Maria Manara[6]. [1]AOUC University of Florence, Italy, [2]CTO Hospital, Palermo, Italy, [3]Department of Clinical and Medical Therapy, Sapienza-University of Rome, Italy, [4]Department of Medical Sciences, University of Cagliari, Italy, [5]Fondazione Maugeri, IRCCS, Telese Terme, Italy, [6]G.Pini Orthopedic Institute, Milan, Italy, [7]L. Sacco University Hospital, Milan, Italy, [8]Reggio Emilia Hospital, Italy, [9]Rheumatology Research Unit, University Federico II Naples, Italy, [10]San Carlo Hospital of Potenza, Italy

Background and Purpose: As polyenthesitic psoriatic arthritis (PsA) is sometimes hard to distinguish from fibromyalgia (FM), secondary FM in PsA patients and PsA in FM patients can be misdiagnosed. The purpose of this study was to identify which clinical features can help distinguish between polyenthesitic PsA and FM.

Materials and Methods: This was a multicentre cross-sectional study carried out by 10 Italian tertiary Rheumatologic (8 recruiting PsA patients and 2 FM patients) centres from January 2009 to September 2009. All of the consecutives patients with PsA (CASPAR criteria) and FM (ACR criteria) who accepted to participate to the study were enrolled in it. For each patient all of the standard clinical and laboratory data, including the questionnaires for PsA and FM, were collected. For the statistical analysis, Student's t test, χ^2 test, Fisher's exact test, univariate and multivariate logistic regression, and Receiving Operating Characteristic (ROC) curves, were used as appropriate.

Results: Two-hundred-sixty-two PsA patients (122 females and 140 males, mean age 51.9±12.8, mean disease duration 10.1±9.2 years) and 96 FM patients (89 females and 7 males, mean age 50.6±1.8, mean disease duration 5.4±4.1 years) were enrolled in this study. Eighteen (6.9%) PsA patients met the classification criteria for FM. Tender and swollen joint counts, dactylitis count, ESR and CRP, and response to NSAIDs were significantly higher in the PsA group. Inflammatory back pain, HAQ values, and PtGA scores were comparable in the two groups. Enthesitis score, tender point count, morning stiffness, VAS pain by patient, and all of the typical symptoms of FM (headache, irritable bowel syndrome, sleep disturbances, paresthesias, anxiety, depression, Raynaud's phenomenon) were significantly associated with FM. However, using the univariate logistic regression, the ORs of morning stiffness, anxiety, and depression were not statistically different between the two groups. The ROC curves showed that 6 or more FM-associated symptoms (sens. 93%, spec. 86%) and 8 ore more tender points (sens. 93%, SPEC 82%) had the best performance in identifying FM patients. The multivariate logistic regression (table 1) showed that 6 or more FM-associated symptoms, 8 or more tender points, and no response to NSAIDs were significantly predictive of FM.

Table 1. Multivariate logistic regression of the main features associated with FM

Feature	OR	95% IC	p
Female gender	0.88	0.23–3.40	0.853
FIQ	1.01	0.98–1.03	0.624
VAS pain	1.00	0.97–1.02	0.798
FM symptoms ≥6	20.05	7.15–56.23	0.000
Enthesitis score ≥3	0.53	0.20–1.44	0.212
Tender points ≥8	16.49	4.62–58.86	0.000
No response to NSAIDs	6.37	1.52–26.71	0.011

Conclusions: Number of FM-associated symptoms, number of tender points, and response to NSAID can help distinguish between polyenthesitic PsA and FM.

Background: Susceptibility to SPA has been shown to be largely genetically determined but the contribution of environmental factors to

disease evolution has not yet been elucidated. The objective of this study was to prospectively investigate the impact of several environmental factors on disease activity.

Methods: The study population consisted of a dedicated cohort of adult (age ≥ 18 years) SPA patients fulfilling Amor's criteria. The follow up period extended over 3 years (December 2005 to October 2008). Patients were asked to log on a secured website every 3 months and to complete a standardized auto-questionnaire. They notified if they were exposed since the previous connexion to environmental factors suspected of being non-specific stimulants of inflammatory response, such as infections (respiratory tract infection, gastroenteritis, urinary tract infection), stressful or traumatic life events and vaccinations. Outcome variables included the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), the patient global assessment (PGA), and the Bath Ankylosing Functional Index (BASFI) (rated each from 0 to 10). Univariate and multivariate analysis were performed using a standard generalized estimating equation approach for repeated measures adjusting on the outcome measurement collected at the previous connexion. This model assesses the variation of the outcome following the exposure to environmental factors.

Results: Two hundred and sixty two patients (57% of females) were included in the analysis (2078 patient-connexions). Mean Age (± SD) was 43.6 ± 10.5 years and disease duration was 16.8 ± 11.3 years. The mean total number of connexions per patient was 8.0 ± 2.0. The mean time between two connexions was 4,1 ± 2,4 months. Occurrence of life events were followed by an average increase of 0.4 points (95% confidence interval [CI] 0.3–0.6) on the BASDAI score ($p<0.0001$) (consecutive to an increase of the score of each question), of 0.6 points (95% CI 0.4–0.8) of the PGA ($p<0.0001$) and of 0.4 points (95% CI 0.2–0.6) on the BASFI score ($p<0.0001$). A moderately significant link between vaccination and disease activity was found with the BASDAI rising by 0.3 points (95% CI 0.0–0.6) ($p=0.028$). There was no relationship with disease activity for any of the other investigated events.

Conclusion: This prospective study conducted in a large cohort of SPA patients shows for the first time a link between stressful events and disease activity. This may offer insights into pathogenesis and approaches to disease management.

Increased Risk of Cardiovascular Disease in Patients with Active Ankylosing Spondylitis. Inger J. Berg, Anne G. Semb, Hanne Dagfinrud, Camilla Fongen, Sella A. Provan and Tore K. Kvien. Dep of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

Background: Several inflammatory rheumatic diseases are associated with an increased risk of cardiovascular disease (CVD). There are also some studies suggesting a higher risk of CVD in patients with ankylosing spondylitis (AS).

The aim of this study was to compare prevalence of CVD and levels of Augmentation index (AIx), a surrogate markers for CVD risk, between a cohort of AS patients and a population control group. Comparisons were made between patients with high and low disease activity.

Methods: 161 patients with AS and 134 controls were examined in 2008–2010. The AS patients derived from the 5-year longitudinal follow-up of a cohort of hospital-recruited patients diagnosed according to the New York classification criteria. The control population was randomly selected by Statistics Norway. AIx estimation was performed using the Sphygmocor apparatus. BASDAI score was calculated from the standard questionnaire. Statistical analyses were preformed in SPSS ver 14.0 using bivariate tests as appropriate. The risk of CVD and levels of CVD risk markers were explored across levels of BASDAI (dichotomized at the median) and compared to controls in logistical and linear regression models adjusted for age, sex and smoking habit.

Results: The groups were comparable regarding demographic data (AS vs controls): age (51.2 vs 53.1 $p=0.18$), gender/male (62.7% vs 57.9% $p=0.41$) and smoking (56.4% vs 60.2% $p=0.52$), but as expected there were significant differences regarding ESR (17 vs 8 $p<0.001$). Total cholesterol was significant lower in the AS group (5.43 vs 5.75 $p=0.01$).The subgroup analyses are presented in Figure 1.

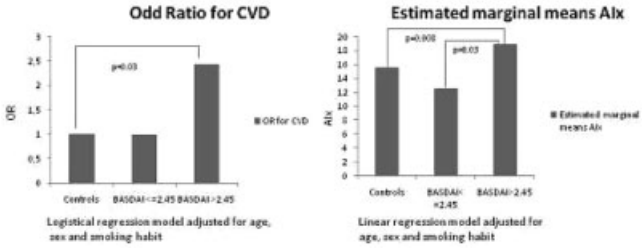

Figure 1. OR for CVD and levels of AIx compared across AS disease activity and population controls.

Conclusion: We found significantly higher OR for established CVD among patients with active AS despite the total AS group having significantly lower total cholesterol. The increased risk of CVD was further confirmed by a significantly increased AIx in patients with high BASDAI. The results indicate that there might be a higher risk of CVD in the AS patient with the most active disease. These findings will be investigated in further analysis.

535

Increased Risk of Gastrointestinal Complications among Persons with Ankylosing Spondylitis: A Population-Based Study from Québec, Canada. Adrian R. Levy[3], Shelagh M. Szabo[3], Walter P. Maksymowych[4], Sumati Rao[1], Diane V. Lacaille[2] and Mary Cifaldi[1]. [1]Abbott, [2]Arthritis Research Ctr Canada, Vancouver, BC, Canada, [3]Oxford Outcomes, [4]University of Alberta, Edmonton, AB, Canada

Purpose: Individuals with ankylosing spondylitis (AS) may be at increased risk of developing gastrointestinal (GI) complications as a result of at least two pathways. First, both subclinical and manifest GI inflammation is frequently observed in persons with AS. Second, the symptoms of AS are often treated with non-steroidal anti-inflammatory drugs; an unintended consequence of these medications is increased risk of GI ulcers. However, the magnitude of increased risk of GI complications in AS and the demographics of patients at more pronounced risk is not well-characterized. Published studies of the excess risks of GI disorders among persons with AS have been clinic-, and not population-, based. The objective was to estimate the age- and sex-specific risk of GI disorders in a population-based cohort of persons with AS compared to a cohort of persons without AS.

Methods: A retrospective cohort study was conducted using the population-based administrative physician-billing database maintained by the Régie de l'Assurance Maladie du Québec. The cohort included individuals with at least one International Classification of Diseases 9th Revision, (ICD-9) billing code for AS between 1996 and 2006. The comparison cohort was a 1% random sample of individuals without AS. GI complications were defined according to ICD code, and included: ulcer-related GI complications (hemorrhage, ulcer, esophagitis, gastritis, or duodenitis); inflammatory GI diseases (Crohn's or colitis); and other GI complications (irritable bowel or diverticulitis). We calculated incidence rates per person-year and age- and sex-adjusted incidence rate ratios (IRRs) with 95% confidence intervals (CIs) compared to the comparison cohort.

Results: Among 8,616 persons with AS, 55% were male and median age at diagnosis was 42.5 years. Age-specific incidence of GI complications increased with age from 43 to 59 per 1000 person-years among males aged 20–39, and >60 years, respectively; and from 52 to 58 per 1000 person-years among females aged 20–39, and >60 years, respectively. There seemed to be a trend of decreasing IRRs (95% CI) with increasing age; among men, from 1.7 (1.6–1.8) for those 20–39 years, to 1.5 (1.4–1.6) for those >60 years; and, among women, from 1.7 (1.6–1.8) for those 20–39 years to 1.3 (1.2–1.4) for those >60 years. Ulcer-related GI events were the most frequent complication (incidence rate, 32 per 1000 person-years) followed by other GI events (27 per 1000 person-years), and inflammatory GI diagnoses (25 per 1000 person-years). Age- and sex-adjusted IRRS were: hemorrhage: 1.9 (1.7–2.2); ulcer: 2.0 (1.9–2.2); esophagitis: 1.7 (1.6–1.8); gastritis: 1.8 (1.7–1.9); Crohn's: 4.6(4.1–5.0); Colitis: 1.8 (1.7–1.9); irritable bowel: 2.3 (2.1–2.5); and diverticulitis: 1.6 (1.5–1.8).

Conclusions: Individuals with AS are at increased risk for many types of GI complications. The excess risk may be more pronounced among younger

individuals. Ulcer-related GI complications were the most common and the increased risk among persons with AS was highest for inflammatory GI diseases. These data support a policy of routine assessment of GI disorder among patients with AS.

Inflammation in an Individual Joint Predicts Damage to That Joint in Psoriatic Arthritis. Vinod Chandran[3], Lynne Creswell[1], Vernon T. Farewell[1] and Dafna D. Gladman[2]. [1]MRC Biostatistics Unit, Cambridge, UK, [2]Toronto Western Hospital, Toronto, ON, Canada, [3]University of Toronto Psoriatic Arthritis Clinic, Toronto Western Hospital

Background: Psoriatic arthritis (PsA) leads to progressive joint damage and disability. Predictors for joint damage progression have been identified. However, these analyses were based on total joint counts in the individual patient and not on the presence of swelling, tenderness or damage at the individual joint level. We aimed to identify predictors of damage to individual joints in the hands and feet of patients with PsA, in particular those that capture previous activity.

Methods: Data from 705 patients followed prospectively at a large PsA clinic between 1978 and 2006 were available for analysis. Data from 511 patients who had no clinical damage in their hand joints [wrists, MCP, PIP and DIP (total 30)] at clinic entry were included in the analysis of the hand joints; data from 552 patients who had no clinical damage observed in the joints of the feet [ankles, MTP, IP (total 22)] at clinic entry contributed data to the analysis of the foot joints. An active joint was defined as a joint with either tenderness or swelling. Clinical damage was determined by the presence of a limitation of range of movement of >20% of the range not related to the presence of joint effusion, the presence of joint deformities, subluxation, flail joints or ankylosis. Logistic regression was used to relate the probability of a joint developing damage, within a specified time interval after the most recent clinic visit, to potential predictor variables. The predictor variables considered encompassed the history of disease activity of the joint and elsewhere, previous damage and the timing of clinical assessments.

Results: 511 patients (286 males, median age 41 years, PsA duration 3 years, active joint count in hands 2) with no hand damage at clinic entry and 552 patients (310 males, median age 41 years, PsA duration 3 years, active joint count in feet 2) with no foot damage at clinic entry were included in the analysis of the hand and foot joints, respectively. The results of the multivariate analyses are given in tables 1 and 2.

Table 1. Results for the Final Multivariate Model for Damage to Hand Joints

	Explanatory Variable	Odds Ratio (95% CI)	P
Joint specific activity variables	EWMA	1.40 (1.25, 1.56)[1]	<0.001
	PROP	1.33 (1.20, 1.48)[1]	<0.001
	Swelling at any visit	1.63 (1.35, 1.97)	<0.001
Global activity variable	Swelling in the same hand at any of most recent 3 visits	1.55 (1.30, 1.84)	<0.001
Damage variables	Damage in the symmetric joint	2.24 (1.79, 2.80)	<0.001
	Damage in an adjacent joint	1.53 (1.22, 1.91)	<0.001

EWMA = Exponentially Weighted Moving Average; PROP = proportion of visits with activity observed in the joint
Symmetric joint = equivalent joint on the opposite hand/foot
Adjacent joint = a joint of the same type (MCP, PIP or DIP) of an adjacent finger
[1] The odds ratio for the EWMA and PROP are presented in a form that describes the multiplicative effect on the odds of damage developing caused by an increase of 0.25.

Table 2. Results for the Final Multivariate Model for Damage to Foot Joints

	Explanatory Variable	Odds Ratio (95% CI)	p
Joint specific activity variables	Activity at any visit	1.48 (1.27, 1.72)	<0.001
	Swelling at any visit	1.44 (1.17, 1.78)	0.001
Global activity variables	Activity in the feet at any of the three most recent visits	1.56 (1.32, 1.78)	<0.001
	Activity in the other toe joint at any visit	2.14 (1.85, 2.46)	<0.001
Damage variable	Damage in the symmetric joint	1.53 (1.14, 2.06)	0.005

The analyses of the hand and foot joints demonstrated that the activity (tenderness and/or swelling) history of the specific joint is associated with subsequent damage. For the joints of the feet, activity observations elsewhere, in particular in the same toe, were also shown to be associated with subsequent damage. Moreover, the longer the patient is in clinic and longer the time between visits, the more likely that joint damage is observed.

Conclusions: Both joint tenderness and swelling are important predictors of joint damage in PsA. Frequent and regular follow-up assessments may contribute to the prevention of joint damage.

Inflammatory Bowel Disease Markers in the Stool of Patients with Ankylosing Spondylitis Compared to Healthy Controls. Franziska Matzkies[1], Dermot McGovern[2], Stephen Targan[2] and Michael H. Weisman[3]. [1]Cedars Sinai, San Bruno, CA, [2]Cedars Sinai, Los Angeles, CA, [3]Cedars-Sinai Medical Center, Los Angeles, CA

Background: Past and current research continues to uncover relationships between Ankylosing Spondylitis (AS) and inflammatory bowel disease (IBD). AS patients have a high frequency of asymptomatic chronic gut inflammation. IBD and AS share key genetic and pathogenetic features. In both diseases the mucosal integrity is disrupted, leading to increased permeability, exposure to dietary/infectious antigens, and subsequent loss of tolerance to bowel flora and priming of inflammatory T-cells. Since T cells reactive to bacterial antigens have also been detected in the joints of AS patients, it is tempting to hypothesize the gut might play an important role in the pathogenesis of AS.

Advances in IBD research have identified fecal Calprotectin (fCAL), a neutrophil-derived protein that can be quantified in the feces, as a marker of bowel inflammation that correlates with the histological degree of inflammation. We propose that patients with AS will have increased levels of fecal calprotectin in their stool compared to healthy controls (HC) even in the absence of any clinical symptoms.

Methods: 41 consecutive patients with established AS were selected from our cohort and 42 HC were recruited. AS patients or HC that used NSAIDS within 2 days of the collection and AS patients currently on humira or infliximab or with a prior diagnosis of IBD were excluded. Stool samples were sent to Genova diagnostics; fCAL was measured by ELISA and a cut of 50μg/ml was used for a sample to be called positive.

Results: 17 AS patient (40%) and 3 HC (7%) had positive fCAL levels in their stool. Average fCAL level in AS was 112μgr/ml vs 26μgr/ml in HC. Results were statistically significant with p less than 0.001. When fCAl positive and negative AS patients were compared no statistical significant differences were found in regards to age, gender, disease duration, NSAIDs use, HLA-B27 positivity, prior uveitis or peripheral arthritis. More Enbrel use (58% vs 36%), higher BASDAI (3.4 vs 2.9), BASFI (35 vs 24) and BASRI (6.6 vs 5.6) scores were observed in the fCAL positive AS group compared to the negative AS group. However none of these parameters were statistically significantly different between the two groups.

Conclusion: fCAL was found at significant higher levels in patients with AS compared to HC. These AS patients did not possess typical symptoms or had a prior diagnosis of IBD and were not treated with medications that would influence bowel inflammation. Increased levels of fCAL therefore truly represent subclinical inflammation of the bowel in this cohort of AS patients. fCAL is a noninvasive, stable, reliable, and reproducible test for IBD inflammation. It therefore can be studied to evaluate subclinical bowel inflammation in large cohort of patients. Currently, there are no serologic or other biological markers in AS that are associated with clinical phenotypes, genetic associations, or treatment response. Further studies utilizing fCAL might prove to have pathophysiological significance with regard to genetic associations and environmental triggers.

Influence of Fc-Gamma Receptor IIA (CD32) and IIIA (CD16) Polymorphisms on the EULAR Response to Anti-Tumor Necrosis Factor-alpha Therapy in Psoriatic Arthritis: A Longitudinal Study with 2 Years Follow-Up. Julio Ramirez[7], José Luis Fernández-Sueiro[6], Raquel López-Mejías[1], Carlos Montilla[5], Belen Suarez[2], Raimon Sanmartí[4], Concepción Moll[3], Francisco Blanco[6], Francisco Lozano[1] and Juan D. Cañete[3]. [1]Servicio de Inmunología, Hospital Clínic y Universidad de Barcelona, Barcelona, Spain, [2]Servicio de Inmunología, Hospital Clínic y Universidad de Barcelona, Barcelona, Spain, [3]Servicio de Reumatología, Hospital Clínic e IDIBAPS, Barcelona, Spain, [4]Servicio de Reumatología, Hospital Clinic e IDIBAPS, Barcelona, Spain, [5]Servicio de Reumatología, Hospital Clinico de Salamanca, Salamanca, Spain, [6]Servicio de Reumatología, Hospital Juan Canalejo, La Coruña, Spain, [7]Servicio Reumatología, Hospital Clinic e IDIBAPS, Barcelona, Spain

Introduction: Therapies targeting tumor necrosis factor (TNF)-alpha have shown to be very efficacious in psoriatic arthritis (PsA). However, around 40% of patients do not achieve a satisfactory response to treatment. This heterogeneity in the response might be partly due to the high/low affinity polymorphisms of the Fc-IgG receptors, which are expressed on the cell membrane of platelets and myeloid cells and might produce differences in the rate of clearance of TNF-blockers and therefore in their clinical effects.

Objective: To assess the influence of FCGR2A-R131H and FCGR3A-F158V polymorphisms on the clinical response to anti-TNF-alpha therapy in patients with PsA.

Methods: Patients fulfilling the CASPAR criteria for PsA, non-responsive to methotrexate (≥15 mg/week) and starting anti-TNF-alpha therapy were included. The efficacy of therapy was evaluated according to EULAR response criteria at 3,6,9,12 and 24 months. FCGR2A-R131H and FCGR3A-F158V polymorphisms were genotyped by allele-specific PCR and PCR sequence-based typing, respectively. Differences in the clinical response with respect to the FCGR2A-R131H and FCGR3A-F158V polymorphisms were calculated using the chi^2 test.

Results: 111 PsA patients were included and treated with the following TNF-blockers: 53.2% etanercept, 33.3% infliximab and 13.5% adalimumab. Fifty- one percent were male (median age at inclusion 46.3 years, disease duration 13.3 years, PCR 2.48 mg/dl and DAS 4.67).

More than 85% of patients achieved a EULAR response during the 24 month follow-up. Globally, more than 60% of patients achieved a good EULAR response (63.1% at 3 and 6 months, 60.7% at 9 months, 61% at 12 months and 73.8% at 24 months). Significantly-more patients with high affinity FCGRIIA polymorphisms (HH and HR) achieved a EULAR response at month 6 compared with patients with low affinity polymorphism (RR).

No other significant differences were found in EULAR responses at any time during follow-up between patients with high (HH and HR for CD32, VV and VF for CD16) and low (RR for CD 32 and FF for CD 16) affinity polymorphisms.

Conclusions: The effect of FCGR2A-R131H and FCGR3A-F158V polymorphisms on the response to TNF-blockers in PsA is mild and seems to be contrary to that previously found in patients with rheumatoid arthritis (RA).

Possible explanations for these findings might be the different pathogenesis of PsA and RA and the complexity of the interactions between Fc-Ig receptors and TNF-blockers over time. However, given that therapeutic responses to anti-TNF-alpha agents are substantially higher and better sustained over time in PsA compared with RA, the effect of polymorphisms on response to this therapy might be lower in PsA than in RA.

539

Intestinal Microsporidiosis: High Risk in Rheumatic Diseases Patients under Anti-TNF Therapy Combined with Methotrexate. Nadia E. Aikawa[3], Aline O. Twardowsky[5], Jozelio Carvalho[5], Clovis Silva[4], Ivan Silva[2], Ana Medeiros[5], Carla Gonçalves[5], Julio Moraes[5] and Eloisa Bonfa[1]. [1]Faculdade Medicina, Sao Paulo, Brazil, [2]Rheumatology Division (CEDMAC) and Infectology Division, Faculdade de Medicina da Universidade de Sao Paulo, [3]Rheumatology Division (CEDMAC) and Pediatric Rheumatology Unit, Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil, [4]Rheumatology Division (CEDMAC) and Pediatric Rheumatology Unit, Faculdade de Medicina da Universidade de Sao Paulo, [5]Rheumatology Division (CEDMAC), Faculdade de Medicina da Universidade de Sao Paulo

Background: Microsporidiosis are among the most frequent opportunistic intestinal diseases in immunocompromised subjects. However, there are scarce studies regarding the relevance of microsporidia and other intestinal parasites in high risk rheumatic diseases patients.

Purpose: To evaluate microsporidiosis and other intestinal pathogenic parasites in patients with rheumatic diseases under disease modifying anti-rheumatic drugs (DMARDs) and biological agents therapies and to investigate possible associations between these parasitoses, disease activity and drugs.

Methods: 98 consecutive rheumatic diseases patients [47 rheumatoid arthritis (RA), 31 ankylosing spondylitis (AS), 11 psoriatic arthritis (PsA) and 9 juvenile idiopathic arthritis (JIA)] and 92 socio-economic-matched healthy controls were enrolled. Stool parasitological analysis and culture were performed in all participants. Three stool samples from each subject were collected in different days. Stools were evaluated using microscopic examination for detection of pathogenic protozoan oocysts, cysts, helminthic eggs and larvae. GRAM-Chromotrope for Microsporidium and intestinal Coccidia, Leishman staining for *Blastocystis hominis and* fecal leukocytes, Kinyoun procedure and capture-ELISA for *Cryptosporidium sp*., *Cyclospora cayetanensis* and *Isospora belli*, and Kato-Katz for *Schistosoma mansoni* were also performed. Clinical manifestations, disease activity data and treatments were also analyzed.

Results: The mean of current age (44.2±14.3 vs. 43.75±14.29 years, $p=0.8155$), frequencies of Caucasian race and socio-economic classes were comparable in patients and controls ($p>0.05$). Of note, the frequency of microsporidia was significantly higher in rheumatic diseases compared to controls (36% vs. 4%, $p<0.0001$), as well as in RA (32% vs. 4.4%, $p<0.0001$), EA (45% vs. 4%, $p<0.0001$), PsA (40% vs. 4%, $p<0.0001$) and JIA patients (56% vs. 4%, $p=0.0002$). Regarding the other pathogenic parasites, only *Giardia lamblia* was more often observed in EA patients *versus* controls (9.7% vs. 0%, $p=0.0149$). The frequency of methotrexate/anti-TNF therapy was higher in patients with pathogenic parasites compared to those without these parasitosis (77% vs. 54%, $p=0.0249$), in spite of similar mean duration of anti-TNF therapy in both groups (12.3 ± 9.9 vs. 15 ± 11.1months, $p= 0.2231$) and disease activity parameters ($p>0.05$). Gastrointestinal symptoms occurred in a similar frequency in patients with and without pathogenic parasitosis ($p>0.05$) and none had disseminated disease. All patients and controls were treated with albendazole for microsporidia infection and metronidazole for giardiasis.

Conclusion: We have identified that microsporidiosis is a frequent opportunistic infection in rheumatic diseases patients under concomitant methotrexate and anti-TNF treatment regardless of the gastrointestinal symptoms and therefore investigation for microsporidia is highly recommended for early diagnosis. This drug combination seems to play an important role in host defense probably by inhibiting inflammatory mediators.

Involvement of the Anterior Chest Wall in Patients with Spondyloarthritis: Relationships between Clinical Symptoms and Imaging Features. Roberta Ramonda[2], Alessandro Lo Nigro[2], Mariagrazia Lorenzin[2], Valentina Modesti[2], Federico Angelini[1], Carla Campana[2], Paola Frallonardo[2] and Leonardo Punzi[2]. [1]Radiology Unit, University of Padova, [2]Rheumatology Unit, University of Padova

Background: The anterior chest wall (ACW) is frequently affected in spondylarthritis (SpA), although its involvement is underestimated. The wide range of disorders found in this anatomic region renders the conventional radiology frequently inadequate for the diagnosis. Plain radiography appears of limited value, due to the difficulty of multiplanar evaluation of ACW joints and a poor sensitivity in revealing the first pathological changes. Bone scintigraphy (BS) is sensitive in showing the articular involvement pattern, but its specificity is considered low. New diagnostic methods, such as magnetic resonance imaging (MRI), appear potentially more effective to study the initially changes found in early SpA.

Objectives: The aim of this study was to compare the reliability of two different sensitive methods, such as BS and MRI, in assessing the involvement of ACW in patients with early SpA.

Methods: Out of 105 consecutive patients (pts) with early (≤ 1 year) SpA attending the Rheumatology Unit of the Padova University, from January 2008 to April 2010, 31 (29.5%, 17 F, mean age 46.2±12.6 yrs) complained of symptoms (pain and/or tenderness) in the ACW and so were submitted to BS and targeted MRI. Eighteen pts (58.1%) were affected with psoriatic

arthritis (PsA), 5 (16.1 %) with ankylosing spondylitis (AS) and 8 (25.8%) with undifferented SpA (USpA).

Results: At clinical examination, the right sternocostoclavicular (SCCJ) was involved in 28 pts (90.3%), the left SCCJ in 25 pts (80.7 %) and the sternum in 4 pts (12.9%). Out of the 31 pts with clinical symptoms BS was positive in 26 (83.8%) and MRI in 18 (58.1%). At BS, the most frequently involved joints were the left and right SCCJ, respectively in 16 pts (51.6%); and in 19 pts (61.2%), followed by the sternum, found in 12 pts (38.7 %). MRI too showed a more frequent involvement of SCCJ, found in 17 pts (54.8%), while the sternum was involved only in 6 pts (19.4%). Main changes reflecting early signs of active disease such as bone edema with synovial hyperaemia were observed in 11 pts (35.5%), endoarticular swelling in 1 (3%), increase of thickness of capsular structure in 12 pts (38.7%) and erosions in 5 (16.1%); among other signs, marginal bone irregularities were found in 5 pts (16.1%), osteoproductive processes in 6 (19.4%), and osteophytes in 2 (6.5%). The concordance between symptoms and imaging was more evident for BS (26 pts, 83.8 %) than for MRI (18 pts, 58.1 %).

Conclusions: The ACW involvement in early SpA is not so rare and it is mainly found in female pts. Both two imaging methods seem useful to investigate ACW symptoms. The BS confirms its higher sensitivity and, although less specific, it can reveal a subclinical involvement. MRI may give information useful for the therapeutic approach, revealing type and extent of articular involvement, in particular the presence of bone erosions.

541

Long Term Profile of Cytokine, Metalloproteinase and Cartilage Biomarkers in Psoriatic Arthritis Patients Treated with Biologic Therapy. Jose Luis Fernandez-Sueiro, J. C. Fernández-Lopez, N. Oreiro-Villar, S. Pertega-Diaz, J. A. Pinto and FJ Blanco. Complejo Hospitalario Universitario La Coruña, La Coruña, Spain

Objective: to assess the cytokine, metalloproteinase (MMP) and cartilage biomarkers (CB) profile in long term psoriatic arthritis (PsA) patients treated with biologic therapy.

Patients and Methods: PsA patients met CASPAR criteria. Biologic therapy was started following the recommendations of the Spanish Society of Rheumatology. Patients were evaluated just before starting therapy and then every 12 weeks until last evaluation. In each visit SJC, TJC, VAS patient, physician, total pain, morning stiffness, HAQ, ESR and CRP was performed. Serum and blood was taken just before starting therapy and then every 12 weeks. For this study we analysed serum samples before starting therapy and at the last evaluation. We determined by ELISA the following: IL-1b, IL-6, IL-10, TNFa, MMP-1, MMP-3, C2C and CPII. All determinations were performed with commercial kits following the manufacturer's instructions. For the statistical analysis, Mann-Whitney test and Wilcoxon signed-rank tests were used.

Results: 38 PsA patients started the study, 19 were females. The mean age was 43.1±10.6 years; mean time of evolution was 8.2±4.8 years, mean time of follow up 47.6±15.2 months. 16 patients (42.1%) were treated with infliximab (INFx) and 22 (57.9%) were treated with etanercept (ETA) at start, in the last visit 9 patients were on INFX, 21 with ETA and 4 with adalimumab. 28 patients (73.7%) had peripheral disease and 10 patients (26,3%) had "mixed" disease. Basal clinical features were as follows: TJC 11.7±7.4, SJC 5.6±4.1, morning stiffness 39.9±24.2 minutes, VAS pain 63.5±18.0mm, VAS patient 64.8±17.6mm, VAS physician 52.0±10.7mm, HAQ 1.4±0.7, ESR 29.0±23.9 mm1/h, CRP 3.0±6.7 mg/dl.

With respect to the first visit, at last visit there was a significant monthly decrease in IL-6, MMP3 (ng/ml) and C2C and an increase in CPII/C2C.

Table I. Average monthly change of Cytokine, metalloproteinase and cartilage biomarkers from basal to last visit.

	Last visit-Basal visit		
	Mean	SD	p*
IL-1β*	0.0004	0.0263	0.923
IL-6*	−0.1639	0.2292	**<0.001**
IL-10*	0.023	0.075	0.111
TNFα*	−0.433	2.814	0.423
MMP-1†	−0.018	0.061	0.091
MMP-3†	−0.450	0.655	**<0.001**
C2C†	−0.230	0.256	**<0.001**
CPII†	0.318	2.583	0.478
CPII/C2C	0.086	0.134	**0.001**
ESR‡	−0.05	0.41	0.456
CRP#	−0.05	0.20	0.161

* pg/ml, †ng/ml, ‡mml [a]hour, # mg/dl

22 (64.7%) patients reached an ACR20, in these patients there was a significant decrease in IL-6, MMP-3 and C2C and an increase in CPII/C2C values with regard to basal levels.

Table II. Average monthly change of Cytokine, metalloproteinase and cartilage biomarkers from basal to last visit according to ACR20 response.

	ACR20 responders (n = 22)			ACR20 non responders (n = 12)		
	Last visit-Basal visit			Last visit-Basal visit		
	Mean	SD	p	Mean	SD	p
IL-1β*	0.003	0.029	0.583	−0.005	0.020	0.408
IL-6*	−0.212	0.255	**0.001**	−0.068	0.128	0.107
IL-10*	0.028	0.092	0.165	0.014	0.022	**0.043**
TNFα*	−0.837	3.255	0.264	0.577	0.409	0.005
MMP-1†	−0.025	0.064	**0.083**	−0.006	0.056	0.715
MMP-3†	−0.566	0.605	**<0.001**	−0.239	0.717	0.273
C2C†	−0.232	0.246	**<0.001**	−0.227	0.285	**0.019**
CPII†	−0.054	1.721	0.884	0.999	3.685	0.368
CPII/C2C	0.074	0.129	**0.014**	0.109	0.145	**0.025**
ESR‡	−0.075	0.481	0.473	−0.014	0.264	0.856
CRP#	−0.075	0.248	0.173	−0.003	0.013	0.405

*pg/ml, †ng/ml, ‡mm1 [a]hour, # mg/dl

In non responders (n=12), there were differences but not at the same level of significance. According to the pattern of joint involvement, there were basal differences in the levels of MMP-3 (peripheral 6.10±3.68 vs "mixed" 3.34±2.04, p=0.031).

Conclusion: In the long term follow up of PsA patients treated with biologic therapy, IL-6, MMP-3 and C2C decrease whereas CPII/C2C increases, however these changes are more profound if patients clinically respond to therapy as assessed by ACR20. In this long term follow up study, IL-6, MMP-3 as well as CPII/C2C seems good markers of synovial inflammation and cartilage metabolism.

Myocardial Infarction and Cardiovascular Risk Profile in Ankylosing Spondylitis. A Systematic Review and Meta-Analysis. Sylvain Mathieu[3], Laure Gossec[2], Maxime Dougados[1] and Martin Soubrier[3]. [1]Hospital Cochin, Paris, France, [2]Rhumatologie B, Hôpital Cochin, Paris, France, Paris, France, [3]Rhumatologie, CHU Gabriel Montpied, Clermont-Ferrand, France

Background: Rheumatoid arthritis (RA) is associated with increased cardiovascular risk. In ankylosing spondylitis (AS) there is little information on cardiovascular risks, especially that of myocardial infarction (MI) risk.

Objectives: To assess the incidence of MI and the cardiovascular risk profile in AS patients.

Methods: A literature review of publications up to August 2009 was performed using Pubmed, Embase, the Cochrane Collaboration and congress abstracts. All observational studies reporting MI and all case/control studies assessing traditional (blood pressure, glycemia, metabolic syndrome, body mass index (BMI), lipid profile) and newer cardiovascular risk factors (intima-media thickness (IMT)) in AS patients and healthy controls were included. Myocardial infarction risks were calculated by metaproportion (inverse of the variance method) and for 100 patient-years (pyrs) of exposure. To assess the MI risk in AS, a meta-analysis was performed using Mantel-Haenszel's method. For continuous variables, the differences between AS patients and controls were expressed by standardized mean difference using inverse of variance method.

Results: Eight longitudinal studies were included (N patients=3279). In control groups (N=82735), 1318 MI were observed (4.6 % (95%CI [0.01, 0.10])). A total of 224 MI were reported in the 3279 AS patients during a mean follow-up of 22 years. In AS patients, the incidence of MI was about 7.0 % (95% CI [0.05, 0.10]) i.e, 0.35/100 pyrs. Meta-analysis of the three longitudinal studies comparing occurrence of MI in AS patients (146/2266) and healthy controls (1318/82745) showed no significant increase in MI in AS patients: risk ratio = 1.88 (0.83–4.28). Fifteen case/control studies and nine abstracts were included (N patients=1214 and N controls=1000). AS patients were characterized by a higher weighted mean intima-media thickness (0.61±0.12 vs. 0.54±0.10 mm; p=0.008), a significant decrease in levels of triglycerides, of total cholesterol and of HDL cholesterol compared with healthy controls. The risk of metabolic syndrome was higher in AS

patients: RR= 2.13 (95% CI [1.46, 3.06]), but without differences in level of glycemia or in BMI. No difference was evidenced in blood pressure, levels of homocysteinemia, of LDL cholesterol and atherogenic index (total cholesterol/HDL cholesterol).

Conclusion: AS patients appear at higher risk of MI compared to controls. This could be due to an atherogenic lipid profile or to systemic inflammation. Management of cardiovascular risk factors and control of systemic inflammation should be taken into account in AS.

National Survey of Patients with Psoriatic Arthritis in Spain: Disease Activity, Pharmacological Therapy and Impact on Quality of Life. Juan D. Cañete[1], Julio Ramírez[2] and Rosario Rodríguez[3]. [1]Arthritis Unit, Rheumatology Dpt. Hospital Clinic and IDIBAPS, Barcelona, Spain, [2]IDIBAPS, Barcelona, Spain, [3]Medical Dept, Sanofi-Aventis Spain, Barcelona, Spain

Objective: To evaluate disease activity, pharmacological treatment and the impact on functional capacity and quality of life of psoriatic arthritis in Spain.

Methods: Cross-sectional, multicenter, national survey. The following data were collected: age, sex, type of psoriasis, swollen and tender joint counts (SJ 44/TJ 46), ESR (mm/1hour), CRP (mg/dL), DAS28, Psoriasis Global Assessment (PGA), Physician Global Assessment (PhyGA), Patient Global Assessment (PatGA), pharmacological therapy (AINEs, glucocorticoids, DAMARDs, and anti-TNFalfa therapy), Visual Analogue Scale (VAS) of pain, Disease impact as measured by VAS in the personal, occupational and social spheres, Health Assessment Questionary (HAQ) and Dermatology Life Quality Index (DLQI).

Results: 214 patients with psoriatic arthritis fulfilling CASPAR criteria from 54 Spanish rheumatology outpatient clinics were included. Fifty-six per cent were male and the mean age was 52 years (mean (95%CI:50.1;53.8)). Seventy-eight percent of patients had type I and 22% type II psoriasis. Patient had the following clinical and functional parameters: TJC:3.2 (2.6;3.7); SJC:2.4 (2;2.9) ESR:20.6 mm/1h (18.4–22.8); CRP:5.3 mg/dL (3.7;6.8); DAS28 3.1 (2.9;3.3); PhyGA:24.7(21.4; 27.9); PatGA:29.2 (25.3;33.2); VAS of global pain:29.7(25.5;33.8). 24% of patients had a moderate-severe extent of PsA as measured by PGA.

Disease impact as measured by VAS in the personal, occupational and social spheres, were 26.2(22.1;30.3), 27.9(23;32.8) and 23.2(19.1:27.3), respectively, with females reporting more significant involvement than males in the personal sphere (31.2(25;37.4) vs 22.1 (16.7;27.5); $p<0.03$). The global HAQ was 0.61 (0.52;0.7), being significantly higher en females than in males (0.84 (0.71;0.97) vs 0.42 (0.31–0.54), respectively; $p<0.00001$). Global DLQ was 3.5 (2.8;4.2), with youngest patients (18–29 years) reporting greater involvement (27% marked moderate to very severe affectation; $p<0.05$, Fisher test).

Regarding pharmacological therapies, 98.6% of patients were taken drugs for treatment of psoriatic arthritis; 58% AINE; 21% oral glucocorticoids (≤5 mg of prednisolone), 86.2% DMARDs (96% methotrexate and/or leflunomide, and 10% these drugs in combination) and 26.2% TNFalfa blockers. Of 173 patients from whom DAS28 was avalaible, 38% were en remission (DAS28<2.6); 23% had low disease activity (DAS28>2.6<3.2) and 39% had moderate or high activity (DAS28>3.2).

Conclusions: This observational national survey on psoriatic arthritis is the first trying to reflect treatment, clinical activity of disease and quality of life of patients with psoriatic arthritis in Spain. Globally it suggests that despite most patients are treated with DMARDs and one quarter with TNFalfa blockers, almost 40% of patients still exhibit moderate-high disease activity and 25% had moderate-high skin involvement. Furthermore, although the impact of the disease on functional capacity and psoriasis-related quality of life is globally mild-moderate, the group constituted by females and people of <30 years suffered a greater impact, suggesting we need to intensify the treatment of their joint and skin involvement.

Performance of Different Criteria Sets for Inflammatory Back Pain in Patients with Axial Spondyloarthritis with and without Radiographic Sacroiliitis. Dilek Solmaz[3], Servet Akar[3], Ozgul Gunduz[3], Feride Yuksel[1], Gercek Can[3], Vedat Gerdan[3], Yesim Akkoc[2], Merih Birlik[3], Fatos Onen[3] and Nurullah Akkoc[3]. [1]Internal Medicine, Dokuz Eylul University Faculty of Medicine, [2]Physical Therapy and Rehabilitation, Ege University Faculty of Medicine, [3]Rheumatology, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey

Background: The most prominent clinical feature of axial spondyloarthritis (SpA), is inflammatory back pain (IBP). Therefore it is of crucial impaortance to recognize inflammatory back pain for an early diagnosis of axial SpA, including ankylosing spondylitis (AS). Up to now several criteria sets have been proposed to define inflammatory back pain (IBP). Assessment of SpondyloArthritis International Society (ASAS) has just recently published new criteria set for diagnosing IBP. In the present study we evaluated the performance of the new ASAS criteria for IBP in comparison to Calin and Berlin criteria in patients with axial SpA using a control group of patients with chronic mechanical low back pain (MLBP).

Patients and Methods: The study sample included a total of 214 patients [117 male (54,7%); mean age42,6±12,2] with a diagnosis axial SpA based on clinical and radiologic findings and 44 patients with a diagnosis of chronic (>3 moths) MLBP based upon the treating physician's clinical judgment (MLBP group). Among patients with axial SpA, 70 patients had active sacroiliitis (SI) on MRI as defined by ASAS (SI on MRI group) and 144 patients had radiographic SI as defined by the modified New York criteria (AS group). A face to face interview by using a standardized questionnaire addressing all the components of inflammatory back pain included in Calin, Berlin and new ASAS criteria sets was performed by the same trained physicain. Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) were measured. Data about HLA B27 status, erythrocyte sedimentation rate and C reactive protein (CRP) levels were obtained from the patients charts if available.

Results: There were significantly more male patients ($p<0,001$) in the AS group (%66) than in the SI on MR (%31,4) and also than in the MLBP group (%36,4). Some demographic and clinical features in the patient groups are shown in Table 1.

Table 1. Demographic and clinical features in the study groups

	AS group (n = 144)	SI on MRI group (n = 70)	MLBP group (n = 44)
Males, n (%)	95 (66)	22 (31)	16 (36,4)
Age, mean ± SD	42,3 ± 11,6	43,1 ± 12,7	43,6 ± 11,6
Age at onset of back pain, mean ± SD	24,7 ± 7,4	27,8 ± 7,4	29,7 ± 9,6
Education Level, mean ± SD (years)	9,5 ± 3,8	10,4 ± 4,2	9,0 ± 4,2
BASDAI, mean ± SD	3,4 ± 2,2	4,8 ± 2,6	3,2 ± 2,4
BASFI, mean ± SD	2,7 ± 2,6	3,1 ± 2,4	2,2 ± 2,0
CRP, mean ± SD	12,9 ± 14,5	8,2 ± 14,3	3,6 ± 3,7
HLA-B27 positivity	72%	36%	7–11%*

*HLA-B27 positivity reported in the general Turkish population in previous publications.

Among the criteria sets, Calin criteria showed the best sensitivity (92%), and Berlin criteria showed the best specificity (84%) in the differentiation of inflammatory back pain from chronic mechanical back pain. If the morning stiffness component of Calin's criteria set was defined as longer than30 minutes, the specificity improved (75%), but at a price of loss in sensitivity (84,5%). The performance of different criteria sets in different patient groups are shown in Table 2.

Table 2. Performance of different criteria sets in different patient groups

	Calin		Calin 30		Berlin		ASAS	
	AS	SI on MRI	AS	SI on MRI	AS	SI on MRI	AS	SI on MRI
Sensitivity (%)	95,1	88,5	88,0	75,7	74,3	78,5	77,0	72,8
Specificity (%)	50,0	50,0	75,0	75,0	84,0	84,0	72,7	72,7
+LR (%)	1,9	1,7	3,5	3,0	4,6	4,9	2,8	2,6
−LR (%)	0,09	0,2	0,1	0,2	0,3	0,2	0,3	0,3
Odds Ratio	19,5	7,7	24	9,3	15,2	19,3	8,9	7,1

Conclusion: New ASAS criteria for IBP did not seem to perform better in differentiating IBP from chronic mechanical back pain, than the existing criteria sets in patients followed at a rheumatology outpatient clinic.

Pregnancy in Ankylosing Spondylitis Is Associated with Fluctuation in Back Pain but Return to Baseline Postpartum: A Case Control Study. Nai Lee Lui[1], Adele Carty[4], Nigil Haroon[3], Sutha Shanmugarajah[4], Hua Shen[2], Richard J. Cook[2], Dafna D. Gladman[5] and Robert D. Inman[6]. [1]Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, [2]Department of Statistics and Actuarial Science, University of Waterloo, Canada, [3]Division of Rheumatology, Toronto Western Hospital, Toronto, ON, Canada, [4]Division of Rheumatology, Toronto Western Hospital, Toronto, Canada, [5]Toronto Western Hospital, Toronto, ON, Canada, [6]Toronto Western Hospital, Toronto, ON, Canada

Objective: Previous studies of pregnancy in ankylosing spondylitis (AS) have not included a control group in order to control for pregnancy-related effects on back pain in general. We performed a case control study to evaluate the impact of pregnancy in patients with AS.

Methods: A questionnaire was developed and mailed to female AS patients in a longitudinal AS clinic and to a group of female psoriasis patients as controls. Patients with psoriatic arthritis were excluded. The questionnaire consisted of clinical data on AS (age of symptom onset and diagnosis of AS, analgesics use), numerical rating scale (NRS) for pain and stiffness for the periods pre-, during and post-pregnancy, and the Roland-Morris questionnaire, a disease-specific validated questionnaire with 24 items inquiring about the severity of symptoms and functional impairment due to back pain.

Results: Nineteen female AS patients (with 35 pregnancies) and 33 psoriasis controls (with 77 pregnancies) completed the questionnaire. AS patients experienced significantly more back pain compared to controls in all three trimesters based on the Roland-Morris questionnaire (mean values for 1st, 2nd, 3rd trimesters; 6.4, 9.7, 11.7 for AS *vs* 0.4, 1.4, 4.5 for controls; $p<0.001$ for the 1st and 2nd trimesters and $p=0.001$ for the 3rd trimester).

In the 1st trimester, there was a significant improvement in pain and stiffness in the AS patients ($p= 0.002$ and 0.016 respectively) compared to baseline pre-pregnancy levels. However, in the 2nd and 3rd trimesters, AS patients experienced significantly more pain and stiffness. The first month postpartum showed trend towards less pain ($p=0.072$) and stiffness ($p=0.108$) in the AS patients, but worsening of symptoms ensued from the second to the sixth month post partum. At six months postpartum the level of pain and stiffness had returned to baseline pre-pregnancy levels.

No increase in flares of psoriasis, uveitis, peripheral arthritis or inflammatory bowel disease was reported during pregnancy. Most AS patients who performed stretching exercises prior to their pregnancies continued with their exercise regime during their pregnancies ($p=0.005$). Seven patients did not perform stretching exercises due to fear of complication to pregnancy ($p=0.023$). Most AS patients refrained from analgesic medications during their pregnancies ($p=0.028$) for fear of adverse effects on the fetus ($p<0.001$). Back pain did not hinder breast feeding.

Conclusion: The improvement in back pain and stiffness in the 1st trimester could be related to the high levels of human chorionic gonadotropin (HCG) hormone in the 1st trimester of pregnancy. Previous hormonal reports have found HCG to possess significant analgesic effects. The worsening of symptoms in the 2nd and 3rd trimesters was seen both in AS and controls and likely reflects biomechanical loading of the low back with later stages of pregnancy. AS patients appear to return to baseline levels of back pain and stiffness post partum, suggesting that pregnancy does not substantially aggravate disease activity in AS.

546

Prevalence and Characteristics of Uveitis in US Veterans with Seronegative Spondyloarthropathy. Hashem Monshie-Vahabzadeh[4], Saloomeh Vahadat[4], J. Steuart S. Richards[4], Andreas Reimold[1], Jessica Walsh[2] and Gail S. Kerr[3]. [1]Dallas VA Medical Center, Dallas, TX, [2]Salt Lake City VA Medical Center, Salt Lake City, UT, [3]VA Medical Center Washington DC, Washington, DC, [4]VA Medical Center Washington, DC, Washington, DC

Purpose: Acute anterior uveitis (AAU) is recognized as the most common extra-articular manifestation of ankylosing spondylitis (AS) occuring in up to 41% of cases but is less frequently in other spondyloarthopathies (SpA), and is more prevalent in SpA patients who are HLA-B27 positive. Herein we describe the frequency, demographic and clinical associations of AAU in a cohort of US veterans enrolled in the PULSAR registry (Program to Understand the Long Term Outcomes of SpA).
