

Computationally Efficient Bounds for the Sum of Catalan Numbers

Kevin Topley
Email: kevint@ece.ubc.ca

Abstract—Easily computable lower and upper bounds are found for the sum of Catalan numbers. The lower bound is proven to be tighter than the upper bound, which previously was declared to be only an asymptotic. The average of these bounds is proven to be also an upper bound, and empirically it is shown that the average is superior to the previous upper bound by a factor greater than $(9/2)$.

Index Terms—Catalan Numbers, Asymptotic Enumeration, Approximation Bounds; [05A10, 05A16]

I. INTRODUCTION

The Catalan numbers form a sequence of natural numbers that occur in a variety of counting problems [4], [9]. The sum of the first n Catalan numbers has been shown to equal the number of paths starting from the root in all ordered trees with $(n+1)$ edges [5]. The sum of the first n Catalan numbers also equals (a) the sum of the mean maximal pyramid size over all Dyck $(n+1)$ -paths, and (b) the sum of the mean maximal saw-tooth size over all Dyck $(n+1)$ -paths [2].

Although there are numerous closed-form expressions for the k^{th} Catalan number C_k , none of them are especially attractive from a computational standpoint [6]. Determining the sum of the first n Catalan numbers requires computation of C_1, C_2, \dots, C_n [1]; it is thus reasonable to search for an accurate and easily computable approximation to the sum of Catalan numbers. Motivated by its applications and cumbersome expression, we will find computationally efficient upper and lower bounds to the sum of Catalan numbers. The tightness of these approximations is quantified both analytically and empirically.

II. MAIN RESULTS

The k^{th} Catalan number C_k is defined as,

$$C_k = \frac{\binom{2k}{k}}{k+1} = \prod_{i=0}^{k-1} \left(\frac{2k-i}{k-i} \right), \quad k \in \{1, 2, \dots\}. \quad (1)$$

The sum of the first n Catalan numbers is then given by S_n ,

$$S_n = \sum_{k=1}^n C_k. \quad (2)$$

The following asymptotic limit of S_n has been proposed [7],

$$S_n \sim \frac{4^{n+1}}{3\sqrt{\pi n^3}} \doteq u(n). \quad (3)$$

We will prove (3) is actually an upper bound for S_n . Furthermore, we find a more accurate approximation to S_n is given by the following lower bound,

$$S_n > \frac{4^{n+1}}{3(n+1)\sqrt{\pi n}} \doteq \vartheta(n). \quad (4)$$

Specifically, we have the result,

$$\begin{aligned} u(n) > S_n > \vartheta(n) &, \quad \forall n \geq 1 \\ u(n) + \vartheta(n) > 2S_n &, \quad \forall n \geq 8. \end{aligned} \quad (5)$$

Note that the quotient $u(n)/\vartheta(n)$ approaches 1 as n approaches infinity, thus both approximations are asymptotically equal to S_n .

A. Proof of Main Results

The main result (5) is proven here in **Thm.II.4, II.5**. To obtain (5) we require **Lemmas II.1 – II.3**. Let \mathbb{N} to be the set of non-negative integers, and \mathbb{R} the set of real numbers.

Lemma II.1. *The sum of the first n Catalan numbers, S_n (cf. (2)) has a lower bound $\ell_n \doteq 4C_n/3$.*

Proof of Lem.II.1. **Rearranging $S_n > \ell_n$ yields the inequality,**

$$S_n < 4S_{n-1}. \quad (6)$$

We will use the recurrence,

$$C_k = \frac{2(2k-1)}{k+1} C_{k-1} \quad (7)$$

which can be easily obtained from (1) [6]. Applying (7) to the Catalan numbers C_k yields,

$$4C_{k-1} - C_k = \frac{3C_k}{2k-1} > 0, \quad \forall k \in \{1, 2, \dots\}$$

thus we obtain (6). ■

Lemma II.2. *The sum of the first n Catalan numbers, S_n (cf. (2)) has an upper bound u_n (cf.(3)).*

Proof of Lem.II.2. It is shown in [6] that the k^{th} Catalan number C_k has an upper bound,

$$C_k < \frac{2^{2k+1}}{(k+1)\sqrt{\pi(4k+1)}} \doteq \nu(k). \quad (8)$$

Numerical evaluation shows that for $n \in \{1, 2, \dots, 12\}$,

$$S_n < \sum_{k=1}^n \frac{2^{2k+1}}{(k+1)\sqrt{\pi(4k+1)}} < u_n$$

where (8) has been applied to S_n . We now proceed by proving,

$$u_n + \ell_n > 2S_n, \quad \forall n \geq 13. \quad (9)$$

Subtracting ℓ_n from (9) and multiplying by 3 yields,

$$2S_n + 4S_{n-1} < 3u_n. \quad (10)$$

Numerical evaluation verifies (10) for $n = 13$. Next we take (10) as the inductive assumption. It remains to be shown that,

$$3u_{n+1} - 2S_{n+1} - 4S_n > 0. \quad (11)$$

Applying the inductive assumption (10) to (11) provides the sufficient condition,

$$3u_{n+1} > 3u_n + 2C_{n+1} + 4C_n. \quad (12)$$

Applying (7) and (8) to the sum $2C_{n+1} + 4C_n$ we obtain the upper bound,

$$2C_{n+1} + 4C_n = 4C_n \left(1 + \frac{2n+1}{\frac{n+2}{3 \cdot 2^{2n+3}}}\right) < \frac{4C_n}{(n+2)\sqrt{\pi(4n+1)}}. \quad (13)$$

Applying (13) to (12) and simplifying yields the sufficient condition,

$$4 \geq \sqrt{\left(\frac{n+1}{n}\right)^3} + \sqrt{\frac{36(n+1)^3}{(n+2)^2(4n+1)}}. \quad (14)$$

By expanding (14) we have,

$$(\mathbf{h}'\mathbf{n})^2 \geq 4(\mathbf{q}'\mathbf{n}\mathbf{r}'\mathbf{n}) \quad (15)$$

where the $\mathbb{R}^{7 \times 1}$ vectors $\mathbf{h}, \mathbf{q}, \mathbf{r}$, and \mathbf{n} , are defined,

$$\begin{aligned} \mathbf{h} &= [-4, -24, -84, -91, 129, 135, 24]' \\ \mathbf{q} &= [0, 0, 0, 36, 108, 108, 36]' \\ \mathbf{r} &= [4, 24, 84, 119, 83, 29, 4]' \\ \mathbf{n} &= [1, n, n^2, n^3, n^4, n^5, n^6]' \end{aligned}$$

Expanding and then simplifying (15) yields,

$$\begin{aligned} \mathbf{j}'\mathbf{N} &\geq 0 \\ \mathbf{j} &= [16, 192, 1248, 4184, 5208, \\ &\quad -16176, -84431, -150414, \\ &\quad -115497, -35634, -1791, 576]' \\ \mathbf{N}_i &= n^{i-1}, \quad i \in \{1, 2, \dots, 12\} \end{aligned}$$

where $\mathbf{N} \in \mathbb{R}^{12 \times 1}$ has i^{th} element \mathbf{N}_i . Denoting the i^{th} element of $\mathbf{j} \in \mathbb{R}^{12 \times 1}$ as \mathbf{j}_i , it is clear that $\mathbf{j}'\mathbf{N} > 0$ for $n = 13$ since $\mathbf{j}_i > 0$ for $i \in \{1, 2, \dots, 5\}$, $\mathbf{j}_i < 0$ for $i \in \{6, 7, \dots, 11\}$, and by numerical evaluation we have,

$$0 < -\sum_{i=6}^{11} (\mathbf{j}_i/13^{12-i}) < \mathbf{j}_{12}.$$

We have shown (9) holds for all integers greater than 12. Lemma II.1 proves $\ell_n < S_n$, thus if $u_n \leq S_n$ then $\ell_n + u_n < 2S_n$, which contradicts (9). ■

Lemma II.3. The sum of the first n Catalan numbers, S_n (cf. (2)) has a lower bound ϑ_n (cf.(4)).

Proof of Lem.II.3. Subtracting ℓ_n from $\vartheta_n < S_n$ and multiplying by 3 yields,

$$3\vartheta_n - 3\ell_n < 4S_{n-1} - S_n. \quad (16)$$

Rearranging (16) and applying Lem.II.1, II.2 yields the sufficient condition,

$$3\vartheta_n \leq 4\ell_{n-1} + 3\ell_n - u_n. \quad (17)$$

It is shown in [6] that the k^{th} Catalan number C_k has a lower bound,

$$C_k > \frac{2^{2k-1}}{k(k+1)\sqrt{\pi/(4k-1)}}. \quad (18)$$

Applying (7) and (18) to the sum $4\ell_{n-1} + 3\ell_n$ we obtain,

$$\begin{aligned} 4\ell_{n-1} + 3\ell_n &= 4C_n \left(\frac{8n-1}{6n-3}\right) \\ &> \frac{2^{2n+1}}{n(n+1)\sqrt{\pi/(4n-1)}} \left(\frac{8n-1}{6n-3}\right). \end{aligned} \quad (19)$$

Substituting (19) as well as the expressions for u_n (cf.(3)) and ϑ_n (cf.(4)) in (17) yields the sufficient condition,

$$\frac{4^{n+1}}{(n+1)\sqrt{\pi n}} \leq \frac{2^{2n+1}}{n(n+1)\sqrt{\pi/(4n-1)}} \left(\frac{8n-1}{6n-3}\right) - \frac{4^{n+1}}{3\sqrt{\pi n^3}}. \quad (20)$$

Simplifying, (20) becomes,

$$\begin{aligned} 4(4n+1)^2(6n-3)^2 \\ < 9n(8n-1)^2(4n-1). \end{aligned} \quad (21)$$

Rearranging (21) yields the equivalent condition $68n^2 > 17n+4$, which holds for all $n \geq 1$. ■

Theorem II.4. For all $n \geq 1$, $u_n > S_n > \vartheta_n$.

Proof of Thm.II.4. The result is a combination of Lem.II.2, II.3. ■

Theorem II.5. For all $n \geq 8$, $u_n + \vartheta_n > 2S_n$.

Proof of Thm.II.5. Numerical evaluation shows that for $n \in \{8, 9, \dots, 12\}$,

$$2S_n < 2 \sum_{k=1}^n \frac{2^{2k+1}}{(k+1)\sqrt{\pi(4k+1)}} < u_n + \vartheta_n$$

where (8) has been applied to S_n . We now show that $\vartheta_n > \ell_n$, thus the result follows from (9). Apply (8) to ℓ_n ,

$$\ell_n < \frac{2^{2n+3}}{3(n+1)\sqrt{\pi(4n+1)}}.$$

It suffices to then show,

$$\frac{2^{2n+3}}{3(n+1)\sqrt{\pi(4n+1)}} < \frac{4^{n+1}}{3(n+1)\sqrt{\pi n}}$$

which simplifies to $1 > 0$. ■

III. NUMERICAL RESULTS

In this section we evaluate how the new estimate (4) improves the approximation of the asymptotic limit (3). Consider the ratio of the errors in approximation,

$$\delta(n) = \frac{S_n - \vartheta(n)}{u(n) - S_n}. \quad (22)$$

The error in the approximation to S_n by $\vartheta(n)$ is lower than that obtained from $u(n)$ by a factor of $1/\delta(n)$. Accordingly, values of $\delta(n)$ near zero imply (4) is a significantly better estimate than (3); note that (5) implies $\delta(n) \in [0, 1)$ for integers $n \geq 8$. In Fig.1 the ratio $\delta(n)$ is plotted for integers $n \in [8, 9, \dots, 50]$. At $n = 28$ the ratio $\delta(n)$ drops below $(2/3)$, which is plotted as a horizontal line.

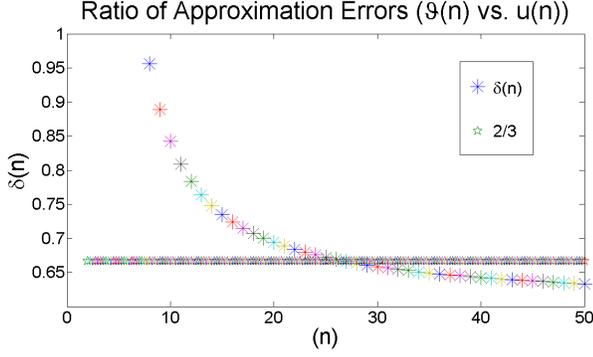

Figure 1. Ratio of the errors in approximation to S_n associated with the estimates $\vartheta(n)$ and $u(n)$. At $n = 28$ the ratio $\delta(n)$ drops below $(2/3)$.

To put our results in context, we compare $\delta(n)$ with a similar measure used in [6]. The upper bound (8) was proven in [6] to approximate C_k at least 3 times as well as the previously established estimate $v(k) \doteq 4^k / ((k+1)\sqrt{\pi k})$ [3],

$$(\nu(k) - C_k) \leq \frac{1}{3}(\nu(k) - C_k).$$

From Fig.1 we find $\delta(n)$ drops below $(2/3)$ for $n \geq 28$, thus our estimate ϑ_n improves the established estimate u_n comparably to the improvement of ν_k over v_k that was proven in [6].

In [6] both a lower and upper bound on the k^{th} Catalan number C_k was established. In the numerical results presented in [6] it was found that the average of the lower and upper bound significantly improved the approximation of C_k . This motivates us to consider taking the average of the lower bound $\vartheta(n)$ (cf.(4)) and upper bound $u(n)$ (cf.(3)) as an approximation to S_n . Define $\mu(n) \doteq \frac{1}{2}(\vartheta(n) + u(n))$. In Fig.2 we plot the ratio of errors in approximation,

$$\zeta(n) = \frac{\mu(n) - S_n}{u(n) - S_n}.$$

From Fig.2 we find that the ratio $\zeta(n)$ approaches $(1/5)$ from below as $n \rightarrow \infty$. In Fig.1, the ratio $\delta(n)$ (cf.(22)) approaches a value larger than $(3/5)$ from above as n

grows, thus we have $\zeta(n) < (1/3)\delta(n)$ and, consequently, the average $\frac{1}{2}(\vartheta(n) + u(n))$ improves the estimate of $\vartheta(n)$ by a factor greater than 3.

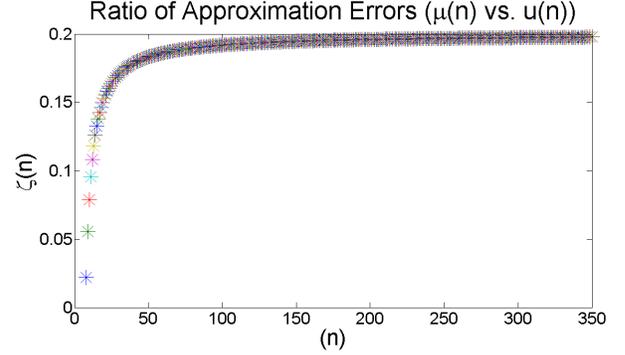

Figure 2. Ratio of the errors in approximation to S_n associated with the estimates $\mu(n)$ and $u(n)$. The ratio $\zeta(n)$ approaches $(1/5)$ from below as $n \rightarrow \infty$.

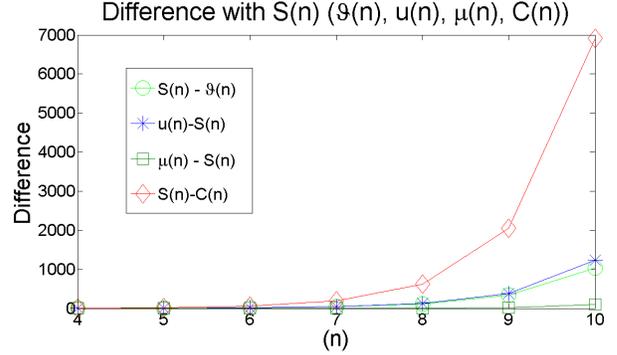

Figure 3. Difference between S_n and $\{\vartheta(n), u(n), \mu(n), C_n\}$.

In Fig.3, we plot the difference between S_n and the estimates $\{\vartheta(n), u(n), \mu(n), C_n\}$. Clearly C_n is significantly smaller than S_n , whereas both the upper bound $u(n)$ and lower bound $\vartheta(n)$ provide relatively similar approximations to S_n , albeit $\vartheta(n)$ remains the better estimate. The average $\mu(n)$ is empirically shown to be the best estimator of S_n among the set $\{\vartheta(n), u(n), \mu(n), C_n\}$, as was suggested by Fig.1, 2. Note that (5) implies $\mu(n)$ is also an upper bound to S_n .

IV. FUTURE WORK

It is possible to obtain an asymptotic approximation to S_n that is arbitrarily tight by utilizing the following recurrence relation proposed in [8],

$$(n+1)S_n + (1-5n)S_{n-1} = 2(1-2n)S_{n-2}. \quad (23)$$

Specifically, by substituting the sum S_n in (23) with a p^{th} degree polynomial in $(1/n)$ and upper bound (3) coefficient,

$$S_n \approx u(n) \left(\sum_{r=0}^p \left(\frac{c_r}{n} \right)^r \right), \quad (24)$$

or even more accurately by a p^{th} degree polynomial in $(1/n)$ and lower bound (4) coefficient,

$$S_n \approx \vartheta(n) \left(\sum_{r=0}^p \left(\frac{m_r}{n} \right)^r \right) \quad (25)$$

we can iteratively solve for $\{c_r : r \in \{1, 2, \dots, p\}\}$ (resp. m_r) and obtain an asymptotic estimate for S_n that becomes arbitrarily tight as p approaches infinity. For $p = 0$, Fig.1 illustrates that (25) yields an estimate of S_n that is at least $(3/2)$ times tighter than that of (24). For $p = 1$ it can be shown that this ratio increases to 2. Such approximations require an increasing number of computations and thus do not benefit from the relative simplicity of (3) and (4). An interesting project might consider how increasing the value of p in (24)–(25) will affect the error ratio between the two estimates, particularly in regard to the extra computational costs.

V. CONCLUSION

We have proven upper and lower bounds on the sum of Catalan numbers, S_n , where previously only an asymptotic limit had been proposed [7]. The lower bound was proven to be a better approximation to S_n than the upper bound, and empirical evidence shows this improvement is at least by a factor of $(3/2)$. The improvement of the lower bound over the previously established upper bound was shown to be comparable to the improvement in approximation of the k^{th} Catalan number that was presented in [6]. Motivated by the results presented in [6], the average of these bounds was considered. The average proved to be an upper bound to S_n , and, empirically, it was found that the average provided a significant improvement on both the upper and lower approximations. Specifically, the average improved the lower bound by a factor greater than 3, and improved the upper bound by a factor greater than $(9/2)$.
