3
4 Over the last four decades, women have made substantial inroads into management
5 jobs. But most women are in lower- and middle-management jobs, and few are in top-
6 management jobs (Reskin and Ross 1992; Cohen, Broschak, and Haveman 1998; Carter and
7 Silva 2010). This vertical gender gap occurs even among those with elite educational
8 credentials. Female graduates of highly ranked MBA programs take lower-status jobs than their
9 male counterparts, even after controlling for years of work experience, children living at home,
10 industry, region, and aspirations to be senior executives (Carter and Silva 2010). Moreover,
11 these female MBA graduates lag behind their male counterparts at all stages. This vertical
12 gender gap in management has important implications. Most basically, because women are
13 less likely than men to be in top management jobs, they tend to earn less than men and to have
14 less formal authority than men.

26
27 Human capital theory (Mincer 1970; Becker 1975) predicts that women are less likely
28 than men to be promoted to top management for three related reasons: women acquire fewer
29 of the necessary educational credentials than men, women prefer different kinds of jobs than
30 men, and women accumulate less of the required work experience than men. After discussing
31 the impact of these individual differences on men's and women's advancement into the upper
32 ranks of management, we argue that cultural schemas, specifically gender roles and gender
33 norms, explain most of these gender differences.
34

40

41 Our analysis focuses on managers in the private sector because over four-fifths of the
42 labor force works in the private sector (CPS 2010) and the most powerful and most highly
43 compensated management jobs are in that sector. We analyze data on nationally
44 representative samples, along with the results of published research, to reveal trends over the
45 last four decades – when women began to enter the managerial workforce in large numbers.
46
47
48
49
50
51

52 **The Vertical Gender Gap in Management**

53
54 American women have entered management in increasing numbers. As Figure 1 shows,
55 in 1970, only 13 percent of managers in the private sector were women; in 1998 45 percent
56
57
58
59
60

1
2
3
4 were women, based on estimates from the Current Population Survey (U.S. Census Bureau
5 2010).¹ At that time, women's representation in management almost equalled women's share
6 of the civilian labor force, which was 46 percent (U.S. Census Bureau 2000, Table 646). In
7 recent years, the percentage of female managers in the private sector declined, reaching 41
8 percent in 2010, even though women's share of the civilian labor force rose to 47 percent (U.S.
9 Census Bureau 2011, Table 604).

16 [Figure 1 about here]

17
18 This long-term trend toward gender equality in management, tempered as it is by a
19 recent counter-trend, is not seen at all ranks of management. Instead, women remain
20 disproportionately segregated in lower levels of management and scarce at the top. As Figure 1
21 shows, 12 percent of executives in the private sector were women in 1970; that figure rose to
22 39 percent in 1991 and then dropped to 28 percent in 2010.² The upward trend in women's
23 representation was less strong for executives (12 to 39 percent women, an increase of 225
24 percent) than for managers as a whole (12 to 45 percent women, an increase of 275 percent),
25 and the recent downward trend was more pronounced for executives (39 to 28 percent
26 women, a decline of 28 percent) than for managers as a whole (45 to 41 percent women, a
27 decline of 9 percent). We would like to conduct this trend analysis among Chief Executive
28 Officers (CEOs), but valid data for CEOs does not start until 2003. From 2003 to 2010, the
29 percentage of female CEOs was stagnant, ranging between 24 and 27 percent.
30
31
32
33
34
35
36
37
38
39
40
41
42
43

44 ¹ This figure includes all Census Bureau occupation codes that are relevant to the private sector:
45 occ1990 = 4, 7, 8, 13, 14, 15, 16, 17, 18, 19, 21, and 22. Similar trends are seen when using data from
46 the decennial census and the Equal Employment Opportunity Commission (Cohen, Huffman, and Knauer
47 2009).
48

49 ² Before 2003, the Current Population Survey had a valid count for executives, but not for CEOs (Mary
50 Bowler, U.S. Census Bureau, personal communication, December 2010). Occupation codes were revised
51 between 2002 and 2003, when a valid code for CEO was created (occ=1, which improved on occ1990=4).
52 Before 2003, figures for executives are based on the occupation code "managers n.e.c." ("not elsewhere
53 classified," occ1990=22); most executive-rank employees are in this category and most employees in
54 this category are executives (Mary Bowler, U.S. Census Bureau, personal communication, December
55 2010). After 2003, figures for executives include both managers n.e.c. (occ1990=22) and the new CEO
56 code (occ=1/occ1990=4).
57
58
59
60

1
2
3
4 The vertical gender gap is most pronounced in the largest firms. From 1992 to 2004,
5 women constituted, on average, 1.3 percent of CEOs in Standard & Poors 1500 firms (Wolfers
6 2006). In 1995, the first year *Fortune* published a combined list for industrial and service firms,
7 there were no female CEOs in the Fortune 500 and just two in the Fortune 501-1000; in 2010,
8 11 Fortune 500 companies had female chief executive officers (CEOs), plus 14 Fortune 501-
9 1000 companies (Catalyst 2010). Thus even today, women constitute a mere 2.5 percent of
10 people at the top of the largest and most powerful private-sector employers.

18

19 **The Impact of Individual Differences between Men and Women**

20
21 Human-capital theory proposes that three differences between men and women explain
22 their differing representation in management, especially in the top ranks: educational
23 attainment, job preferences, and accumulated work experience. We review each in turn.
24
25
26
27

28 **Education.** Higher education is an increasingly critical pathway into top management.
29 An increasing fraction of managers have bachelors' degrees; more and more also have
30 advanced degrees. In 1970, 21 percent of managers in the private sector had bachelors'
31 degrees, while 4 percent also had advanced degrees; in 2010, 35 percent had bachelors'
32 degrees, while 19 percent also had advanced degrees (U.S. Census Bureau 2010). These higher-
33 education credentials have always been far more common among managers than in the
34 population at large. In 1970, 9 percent of Americans had bachelors' degrees, while 3 percent
35 had advanced degrees; in 2010, 21 percent had bachelors' degrees, while 11 percent had
36 advanced degrees (U.S. Census Bureau 2010).
37
38
39
40
41
42
43
44
45

46 Higher education credentials are especially important for top managers in the largest
47 and most powerful firms. Analysis of 2,727 senior managers in 208 large and medium-sized
48 finance and manufacturing firms in 1977 (Useem and Karabel 1986) revealed that 83 percent of
49 senior managers had bachelors' degrees, while 44 percent also had advanced degrees. In that
50 same year, among private-sector firms of all sizes, only 26 percent of managers had bachelors'
51 degrees, while 6 percent also had advanced degrees (U.S. Census Bureau 2010).
52
53
54
55
56
57
58
59
60

1
2
3
4 Over the past 40 years, American women's educational attainment has outpaced men's.
5
6 As Figure 2 shows, women earned 43 percent of bachelors' degrees in 1970-71 (National Center
7
8 for Education Statistics 2011). In 2008-09, women earned 57 percent of bachelors' degrees.
9
10 This trend was evident at all levels: women earned 40 percent of masters' degrees and 14
11
12 percent of doctorates in 1970-71, compared to 60 percent of masters' degrees and 52 percent
13
14 of doctorates in 2008-09. In 2003-04, women constituted 49 percent of all college graduates
15
16 (National Science Foundation 2005). Because women have become more likely than men to
17
18 earn bachelor's degrees, women today must constitute over half of all college graduates in the
19
20 U.S. workforce.
21

22 [Figure 2 about here]
23

24
25 The change in women's educational attainment has been especially rapid in the field of
26
27 business, the training ground for many managers. As Figure 2 shows, women earned 9 percent
28
29 of business BAs and 4 percent of MBAs in 1970-71, compared to 49 percent of business BAs and
30
31 45 percent of MBAs in 2008-09. Thus women are almost as likely as men to earn MBAs, given
32
33 that they constitute 47 percent of the labor force (U.S. Census Bureau 2011, Table 604). The
34
35 remarkable correspondence between Figures 1 and 2 suggests that American women's
36
37 increased educational attainment in the field of business has given them easier entrée into
38
39 management. Through the mid 1990s, the increase in women earning business BAs and MBAs
40
41 paralleled the increase in women in management. But in recent years, trends for women's
42
43 educational attainment and representation in management diverged, as the percentage of
44
45 female managers declined slightly, while the percentage of women earning business BAs and
46
47 MBAs continued to rise.
48

49
50 Although overall, women's educational attainment has exceeded men's, educational
51
52 attainment can still help explain the vertical gender gap in management. Educational fields
53
54 continue to be gender-segregated, with women less likely to be in fields that require
55
56 mathematical skill. In 1970, women earned just 18 percent of bachelors' degrees in the fields
57
58 of science, technology, engineering, and mathematics (STEM); in 2004, women earned 38
59
60

1
2
3
4 percent of bachelors' degrees in STEM fields (National Science Foundation 2007). Although
5
6 women's representation among graduates of STEM fields doubled, in 2004, women constituted
7
8 only 25 percent of the STEM workforce (Carrell, Page, and West 2009). Among MBAs, women
9
10 are less likely to acquire expertise in the mathematics-heavy field of finance (Bertrand, Goldin,
11
12 and Katz 2010). Women's under-representation in STEM fields and finance has kept them out
13
14 of pipelines to upper management. Since the 1970s, the top ranks of large American
15
16 corporations have increasingly been filled by people with backgrounds in finance (Fligstein
17
18 1987; Zorn 2004). And since the 1980s, the top ranks of large corporations have increasingly
19
20 been filled by people with backgrounds in production and technology (Ocasio and Kim 1999),
21
22 which usually require education in STEM fields.
23

24
25 Women's access to business education is stratified by institutional prestige, which can
26
27 also help explain why female managers are generally at lower levels than male managers.
28
29 Women constitute a smaller fraction of students in the highest-ranked MBA programs than in
30
31 lower-ranked programs. Only 31 percent of MBA students in the top U.S. business schools are
32
33 female (*Financial Times* 2010), compared to 45 percent across all MBA programs.³ Students
34
35 from top MBA programs have easier access to the best management jobs, due to their schools'
36
37 reputations and their ability to foster ties to other elite students, so the scarcity of women in
38
39 top MBA programs means that women have less easy access to the highest-status positions.
40
41 Thus educational stratification – fewer women in top-ranked MBA programs and more in lower-
42
43 ranked programs – helps maintain gender inequality in management (Lucas 2001).
44

45
46 **Job preferences.** There is some evidence of gender differences in job preferences.
47
48 Longitudinal analysis of high-school seniors' value orientations along three dimensions (concern
49
50 and responsibility for the well-being of others, emphasis on material benefit and competition,
51
52 and concern with finding purpose and meaning in life) revealed substantial and persistent
53
54 gender differences on all three measures (Beutel and Marini 1995). From the mid 1970s
55

56
57 ³ Fifty-six of the top U.S. schools were in this global top-100 list; almost all were in the *Business Week* or
58
59 *US News and World Report* top 50.
60

1
2
3
4 through the early 1990s, young women were consistently more likely than young men to
5
6 express concern and responsibility for the well-being of others, less likely than young men to
7
8 accept materialism and competition (the values that are strongly held in corporate America),
9
10 and more likely than young men to indicate that finding purpose and meaning in life is
11
12 extremely important. There was no evidence that young men's and women's values converged
13
14 over time.
15

16
17 Perhaps more relevant to the question of male vs. female managers' job preferences is a
18
19 pair of studies analyzing data on adult workers from the General Social Survey. The first
20
21 analyzed all workers from 1973 to 1993 (Rowe and Snizek 1995); the second, married workers
22
23 only from 1973 to 1994 (Tolbert and Moen 1998). Both examined preferences for five job
24
25 characteristics: high income, job security, opportunities for advancement, a sense of
26
27 accomplishment, and short hours. Human capital theory would predict that men would prefer
28
29 the first three job characteristics more than women, while women would prefer the last two
30
31 job characteristics more than men. The first study offered little support for human capital
32
33 theory. Men and women had the same rank-order preferences among job characteristics.
34
35 Moreover, gender differences in the ranks assigned to job characteristics were very small. After
36
37 controlling for age, education, marital status, occupational prestige, job satisfaction, spouse's
38
39 work status, and year, there were few differences between men's and women's work values.
40
41 Men were slightly less likely than women to value job security and short hours. Regardless of
42
43 gender, preferences for particular job characteristics depended mostly on age, education, and
44
45 occupational prestige. The second study offered partial support for human capital theory.
46
47 After controlling for age, education, race, occupation, number of children, and time period,
48
49 married men valued promotion opportunities and job security more than married women,
50
51 while married women valued a sense of accomplishment more than married men. Counter to
52
53 human capital theory, there were no significant differences between married men's and
54
55 women's preferences for high incomes or short hours. As in the first study, most statistically
56
57 significant gender gaps in job preferences were small in magnitude. Gender gaps were widest
58
59
60

1
2
3
4 among young married workers, and there was no evidence that they declined over time; both
5
6 findings are consistent with previous research on high school students (Beutel and Marini
7
8 1989).
9

10 The situation is complicated by the fact that any differences we observe between men's
11 and women's job preferences may not be exogenous; they may instead be due to the jobs men
12 and women currently hold and those they held in the past (Kanter 1977; Brief, Rose, and Aldag
13 1977; Rowe and Snizek 1995). Since women, including women managers, tend to work in
14 lower-status positions than men, women may react by placing less value on their careers
15 (Kanter 1977); if so, women may prefer short hours and a sense of accomplishment more than
16 men. Much evidence supports the hypothesis of endogenous job preferences: after taking into
17 consideration differences between men's and women's jobs, there are no gender differences in
18 attitudes toward work (Brief *et al.* 1977; Bielby and Bielby 1989; Rowe and Snizek 1995). Men
19 and women engaged in similar work have almost equal commitment to work, *and* men and
20 women engaged in similar family roles have almost equal commitment to family (Bielby and
21 Bielby 1989). A study of female finance executives found that the most successful of these
22 women had the strongest devotion to work; indeed, female executives' attitudes toward work
23 were virtually identical to those of their male counterparts (Blair-Loy 2003).
24
25
26
27
28
29
30
31
32
33
34
35
36
37
38

39 **Work experience.** Four decades ago, only 41 percent of American women were in the
40 labor force, compared to 76 percent of American men; by 2009, the figures for men and
41 women had converged slightly: 65 percent of American men and 54 percent of American
42 women were in the labor force (U.S. Census Bureau 2011, Table 586). Married women entered
43 the labor force alongside single women: for single women, labor-force participation rates rose
44 from 57 percent in 1970 to 64 percent in 2009; for married women, these rates rose from 41
45 percent in 1970 to 61 percent in 2009 (U.S. Census Bureau 2011, Table 596). As a result of
46 married women's entry into the labor force, the percentage of two-income couples rose from
47 50 percent in 1986, the earliest year such data are available, to 55 percent in 2009 (U.S. Census
48 Bureau 2011, Table 600). Not only have women entered the labor force in greater numbers,
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 they have increasingly worked full-time: among female workers, the ratio of full-time to part-
5
6 time workers rose from 2.5 in 1972 to 3.3 in 2008 (GSS 2010). Moreover, in more and more
7
8 households with young children, both men and women work: the percentage of working
9
10 married mothers with husbands present and children under 6 rose from 30 percent in 1970 to
11
12 59 percent in 1990 and 62 percent in 2009 (U.S. Census Bureau 2011, Table 598). Taken
13
14 together, these trends indicate that women's lives have come to resemble those of men's:
15
16 women are increasingly likely to work for pay, full-time, even when they have young children
17
18 and husbands present.
19

20
21 Notwithstanding these trends toward gender equality, women tend to accumulate less
22
23 of the work experience that is needed to get into management than men do. We do not have
24
25 good data on work experience, but we do have data on one component of work experience –
26
27 tenure with one's current employer. In 2008, median firm tenure for male workers 20 years
28
29 and older was 4.5 years; median firm tenure for female workers was 4.2 years (U.S. Census
30
31 Bureau 2011, Table 611). To the extent that women take more time out from work than men
32
33 to tend to children, gaps between men's and women's work experience will increase with age.
34
35 We see such a pattern across most age ranges. Median tenure for men aged 25-34 was 2.8
36
37 years; for men aged 35-44, 5.2; for men aged 45-54, 8.2; for men aged 55-64, 10.1. For women,
38
39 median tenure was lower for all age groups, and the gap between men's and women's tenure
40
41 generally widened with age: median tenure for women aged 25-34 was 2.6 years (0.2 years less
42
43 than men); for women aged 35-44, 4.7 years (0.5 years less than men); for women aged 45-54,
44
45 7.0 years (1.2 years less than men); and for women aged 55-64, 9.8 years (0.3 years less than
46
47 men). Such increasing gaps in accumulated experience can help explain the vertical gender gap
48
49 in management (Bertrand, Goldin, and Katz 2010).
50

51
52 Since many managers have college degrees, it is worthwhile to assess differences in
53
54 work experience for male and female college graduates. In the first decade after leaving
55
56 college, women tend to have about the same amount of work experience as men; after that
57
58 point, female college graduates tend to work fewer hours than males and female college
59
60

1
2
3
4 graduates are more likely than males to interrupt their careers to raise children (Black *et al.*
5 2008). Thus, over their careers, female college graduates accumulate less work experience
6 than males. But this accumulated experience gap has declined over time, at least for those with
7 elite educational credentials. Among Harvard graduates, spells of women's non-employment,
8 explained by the presence of young children, were longest for 1970 graduates, intermediate for
9 1980 graduates, and shortest for 1990 graduates (Goldin and Katz 2008).
10
11
12
13
14
15
16

17 **Cultural Factors Cause of Individual Differences: Gender Roles and Gender Norms**

18
19 Widely held cultural schemas about what is appropriate for men and women to do
20 (gender norms) and what it is that men and women do well (gender roles) may be the root
21 cause of differences between men's and women's educational attainment, job preferences, and
22 work experience. If so, cultural schemas should explain gender differences in managers' career
23 trajectories. We focus on three cultural schemas that are especially relevant to the vertical
24 gender gap in management: (1) men are better than women at math and science, (2) men
25 belong at work and women belong at home, and (3) men are more natural managers and
26 leaders than women.
27
28
29
30
31
32
33
34
35

36 **Gender and math/science.** Culture can explain women's reluctance to study fields that
37 require mathematical skill and that are gateways to top management jobs. There is only weak
38 evidence of actual gender differences in mathematics skill (Hyde, Fennema, and Lamon 1990;
39 Baker and Jones 1993). Moreover, any gender differences that do exist in *actual* mathematics
40 skill have been attributed to cultural factors, such as women's social status (Penner 2008). But
41 even today, most college students believe men are better at mathematics than women (Nosek,
42 Banaji, and Greenwald 2002).
43
44
45
46
47
48
49

50 Widely held beliefs about competence bias individuals' perceptions of their own
51 competence at career-relevant tasks and so shape their decisions about field of study. In
52 particular, gender stereotypes about math skill affect students' attitudes toward, participation
53 in, and performance in mathematics and science courses (Eccles 1987; Hyde, Fennema, Ryan *et*
54
55
56
57
58
59
60

1
2
3
4 *al.* 1990; Spencer, Steele, and Quinn 1999). Even those female students who believe they are
5 good at math are susceptible to this stereotype (Nguyen and Ryan 2008). Thinking more
6 broadly, if most people – parents, teachers, and students – perceive female students’
7 mathematics skill to be inferior to male students’, female students will be influenced by these
8 widely held stereotypes and will be less likely than male students to study fields that require
9 mathematical skill (Correll 2001, 2004).

10
11
12
13
14
15
16
17 Finally, powerful stereotypes associate careers in science and engineering, which have
18 increasingly led to upper-management jobs, with men and not with women. These stereotypes
19 are held by men and women equally (Smyth, Greenwald, and Nosek 2010) and are reinforced
20 by experience – by men’s domination of science and engineering jobs, which shapes men’s and
21 women’s career choices (Xie and Shauman 2003).

22
23
24
25
26
27 **Gender and work/family.** As married women have entered the workforce in ever
28 greater numbers, Americans have increasingly accepted the idea of married women working.
29 In Gallup Polls, acceptance of married women working was 55 percent in 1969 (Erskine 1971);
30 in the GSS, acceptance of married women working rose to 68 percent in 1972 before dropping
31 to 65 percent in 1977 (Spitze and Huber 1980).⁴ Analysis of related GSS questions between
32 1977 and 1996 revealed that cohort succession and within-cohort attitude shifts led to
33 increasingly positive attitudes about women, including mothers, working (Mason and Lu 1988;
34 Brewster and Padavic 2000). Still, most Americans continue to believe that married women
35 with young children belong at home, not at work. The most recent data we have on this
36 specific gender schema comes from 1994, when 84 percent of Americans approved of married
37 women without children working full-time, but only 11 percent approved of married women
38 with pre-school-age children working full-time; a further 34 percent approved of married
39 women with pre-school-age children working full-time; a further 34 percent approved of married
40 women with pre-school-age children working full-time; a further 34 percent approved of married
41 women with pre-school-age children working full-time; a further 34 percent approved of married
42 women with pre-school-age children working full-time; a further 34 percent approved of married
43 women with pre-school-age children working full-time; a further 34 percent approved of married
44 women with pre-school-age children working full-time; a further 34 percent approved of married
45 women with pre-school-age children working full-time; a further 34 percent approved of married
46 women with pre-school-age children working full-time; a further 34 percent approved of married
47 women with pre-school-age children working full-time; a further 34 percent approved of married
48 women with pre-school-age children working full-time; a further 34 percent approved of married
49 women with pre-school-age children working full-time; a further 34 percent approved of married
50 women with pre-school-age children working full-time; a further 34 percent approved of married
51 women with pre-school-age children working full-time; a further 34 percent approved of married
52 women with pre-school-age children working full-time; a further 34 percent approved of married
53 women with pre-school-age children working full-time; a further 34 percent approved of married
54 women with pre-school-age children working full-time; a further 34 percent approved of married

⁴ The Gallup Poll question was “Do you approve of a married woman earning money in business or industry if she has a husband capable of supporting her?” The GSS added “or disapprove” to this question, so the two surveys are quite comparable.

1
2
3
4 women with pre-school-age children women working part-time and 55 percent preferred they
5 not work at all (Treas and Widmer 2000).
6
7

8 Cultural schemas create behavioral traces that allow us to pinpoint temporal shifts. One
9 behavioral trace of the gender and work/family schema involves use of time for paid work,
10 housework, or leisure. Because traditional gender roles involve women doing more housework
11 and childcare than men, working women who fulfill their expected gender role are forced to
12 take on a “second shift” of housework and childcare after working hours, while working men
13 who fulfill their expected gender role can concentrate more on work or spend more time on
14 leisure (Hochschild 1989). These behavioral traces of traditional gender roles have persisted,
15 even though more married women work and more work full-time. Time-diary studies covering
16 the years 1965, 1975, and 1998 reveal that women continue to do more housework than men,
17 although men increasingly help with core household duties like cooking, cleaning, and child care
18 (Bianchi *et al.* 2000; Sayer 2005). Male-female differences in time use are especially
19 pronounced for parents. Compounding the effect of stable gender roles for time use, especially
20 for parents, is the fact that managers work ever longer hours (Jacobs and Gerson 2004;
21 Collinson and Collinson 2004). A recent survey showed medians of 56 hours per week for male
22 managers and 52 hours per week for female managers; moreover, 29 percent of male
23 managers and 11 percent of female managers worked over 60 hours per week (Brett and Stroh
24 2003). This suggests that female managers experience especially strong work-family time
25 conflicts (Jacobs and Gerson 2004).

43
44

45 In the middle and upper-middle classes, from whose ranks most managers are drawn,
46 there is increasing cultural pressure for mothers to tend their children themselves, rather than
47 working full-time and delegating childcare to nannies, preschools, boarding schools, or
48 babysitters (Epstein 2004; Stone 2007). These mothers are expected to make the switch from
49 managing bureaucracies to managing their children’s increasingly bureaucratized lives: to tutor
50 children after school, help schools raise funds, coach children’s sports teams, and chauffeur
51 children around (Lareau 2003; Lareau and Weininger 2008). There are many journalistic
52
53
54
55
56
57
58
59
60

1
2
3
4 accounts of highly educated and high-achieving women leaving managerial jobs to stay home
5 with their children (*e.g.*, Belkin 2003; Story 2005). But the news media have not just reported
6 on this trend; they have also accentuated it, by excoriating women who hire others to care for
7 their children (*e.g.*, Flanagan 2004). This recent cultural backlash against middle- and upper-
8 middle-class mothers delegating childcare intensifies the already-strong work-family conflicts
9 that female managers experience.
10
11
12
13
14
15

16 Because cultural schemas affect the amount of time men and women spend at work
17 rather than home, they affect the type and amount of work experience men and women
18 accumulate. The persistence of the gender gap in housework and childcare creates role
19 conflicts for working women, especially those with children. Women may try to “balance” work
20 and family by choosing jobs with lower time commitments and greater flexibility, by working
21 fewer hours, and by staying at home when their children are very young. Thus, traditional
22 expectations about gender roles at work vs. home, especially for married women with young
23 children, may explain why female managers accumulate less work experience than their male
24 counterparts, and so may help explain the vertical gender gap in management. This conclusion
25 is supported by research showing that women in management often got there by foregoing
26 marriage and children altogether: female managers are less likely to be married than their
27 male counterparts (Davidson and Burke 2000). And a study of female executives in finance
28 showed that after women have children, their choices of career trajectories – to pursue senior-
29 management positions, stay at home, or work part-time – are influenced by two conflicting
30 cultural schemas, family devotion and work devotion (Blair-Loy 2003). The work devotion
31 schema characterizes the culture of the finance industry; it demands that executives put the
32 firm and clients first by working long hours. The family devotion schema characterizes children
33 as vulnerable and in need of attention, particularly from their mothers. Women who try to
34 have it both ways and go part-time are marginalized for their lack of devotion to the firm and
35 cut off from promotion to upper management.

Gender and management. Cultural schemas about men and women at work also shape perceptions of who should be in positions of corporate leadership, and so may explain the dearth of female managers in the top managerial ranks. People who score high on three of the “big five” personality traits – conscientiousness, extraversion, and openness to experience – are more likely to become leaders and to be effective leaders (Judge *et al.* 2002).⁵ Men and women exhibit similar level of extraversion, openness to experience, and conscientiousness, although there are differences between men and women on subcomponents of extraversion and openness to experience (Costa, Terracciano, and McCrae 2001). Therefore, personality differences cannot explain women’s under-representation among the leaders of private companies. Perhaps differences in interpersonal skills can. People who have greater emotional intelligence, meaning greater ability to perceive emotions, understand emotions, use emotions to facilitate thought, and regulate emotions (Mayer *et al.* 2001) may be more likely to be leaders. Women tend to score higher than men on emotional intelligence (Brackett *et al.* 2006), so if this skill helps people get into formal leadership positions, we would expect women to *outnumber* men among managers. This is especially likely in the top ranks because senior management jobs have a large symbolic component (Selznick 1957; Pfeffer 1981). In sum, little evidence suggests that differences between men and women in personality traits and interpersonal skills can explain women’s under-representation in top management; instead, such differences are due to cultural factors.

52
53
54
55
56
57
58
59
60

Powerful stereotypes associate managerial roles with men and not with women. Put simply, when people “think manager,” they “think male” (Schein 2001). Such stereotypes are reinforced by experience; the fact that men dominate the ranks of management, especially at the top, contributes to this stereotype (Marini and Brinton 1984). Because of this stereotype,

⁵ Conscientiousness involves achievement orientation and dependability. Extraversion involves sociability, assertiveness, activity, and positive emotions. Openness to experience involves creativity, nonconformity, autonomy, and unconventional qualities. The personality traits that have not been empirically linked to leadership are neuroticism and agreeableness. Neuroticism involves poor emotional adjustment and negative emotions, while agreeableness involves caring, trusting, compliant, and gentle qualities.

1
2
3
4 people expect managers to do things that are typically associated with masculinity, such as
5
6 competing with peers, imposing their wishes on subordinates, behaving assertively, and
7
8 standing out from the group (Miner 1993; Atwater *et al.* 2004). That is why people who assess
9
10 “men,” “women,” and “successful managers” rate managers and men as similar on many
11
12 individualistic and agentic characteristics, such as being competitive, self-confident, aggressive,
13
14 and ambitious (Schein 2001; Sczesny 2003). In contrast, ratings of women and managers are
15
16 similar on only a few communal characteristics, such as being intuitive and helpful.
17

18
19 Because cultural schemas constrain behavior, men and women exhibit different
20
21 leadership styles, despite having similar personality traits. Women are “outsiders” to
22
23 management and must negotiate two roles – woman and manager – and reconcile the
24
25 communal qualities people prefer in women with the agentic qualities that people expect in
26
27 managers. As a result, female managers are more likely than male managers to have
28
29 democratic, participative, and collaborative styles (Eagly and Johnson 1990). But the gender
30
31 gap in managerial style is narrower among more senior managers. Moreover, between-gender
32
33 differences are small compared to within-gender variation.
34

35
36 Women who embrace the “think manager – think male” stereotype are less likely to
37
38 aspire to managerial positions (van Vianen and Keizer 1996; Davies, Spencer, and Steele 2005).
39
40 Even women who reject this stereotype and aspire to management may perform more poorly
41
42 than comparable men, due to stereotype threat (for a review of research on stereotype threat,
43
44 see Steele, Spencer, and Aronson [2002]). If women are not expected to be managers,
45
46 especially not top managers, and if women are aware that others believe this stereotype, then
47
48 women are at risk of confirming this stereotype. Simply being aware of this stereotype may
49
50 create concerns about fulfilling it, which may hinder task performance. Stereotype threat has
51
52 been shown to diminish female MBA students’ performance in many managerial tasks, such as
53
54 negotiating (Kray, Thompson, and Galinsky 2001).
55

56
57 When those who evaluate potential managers for promotion embrace the stereotype of
58
59 managers as male, they are less likely to perceive female candidates for managerial jobs –
60

1
2
3
4 especially at the top, where women are rare – as positively as their male rivals (Eagly and Karau
5 2002). To be promoted to upper management, one must demonstrate competence. But
6
7 surveys and laboratory experiments alike reveal that people perceive men as more competent
8
9 than women (*e.g.*, Heilman *et al.* 1989; Lucas 2003). Even when women enter management
10
11 positions, they are in a double bind: as women, they are expected to be communal,
12
13 collaborative, and democratic, but as managers, they are expected to be agentic and
14
15 authoritative. The situation is complicated by the fact that higher-ranking managerial jobs tend
16
17 to involve greater uncertainty – more about strategy and less about tactics to achieve a
18
19 strategic goal. Such uncertainty should accentuate decision makers' reliance on gender as an
20
21 indicator of competence (Gorman and Kmec 2009).
22
23
24

25 26 **Conclusion**

27
28 Widely held cultural expectations about what men and women can and should do –
29
30 gender stereotypes about who can do mathematics, who should work and who should care for
31
32 children and the home, and who should lead – are the basic cause of observed gender
33
34 differences in educational attainment, job preferences, and work experience. Figure 3 shows
35
36 our causal model. It makes clear that research on the vertical gender gap in management that
37
38 seeks to show effects of education, job preferences, or work experience must account for these
39
40 cultural factors. If cultural factors are ignored, any observed effects of these factors can be
41
42 dismissed as spurious. And as Figure 3 indicates, the individual differences that human capital
43
44 theory focuses on have common cultural origins; therefore, their effects cannot be entirely
45
46 separated. In addition, the cultural schemas we highlight feed stereotypes about men as
47
48 managers that prevent women from aspiring to or getting into management positions,
49
50 especially at the top.
51

52 [Insert Figure 3 about here]

53
54
55 Our basic conclusion is that, contrary to human-capital theory, it's not all about choices.
56
57 Instead, choices – including what field to study, how much education to get, whether or not to
58
59
60

1
2
3
4 work, how much to work, and what kind of job is most desirable – are constrained by culture.
5
6 We risk sounding unoriginal by echoing Duesenberry's (1960, 233) quip that "Economics is all
7
8 about how people make choices. Sociology is all about why they don't have any choices to
9
10 make." But we take this risk because our point is one that many scholars seem to have
11
12 forgotten. We read a plethora of studies that take behavioral indicators of "managerial" talent
13
14 (*e.g.*, mathematics test scores, years of experience) at face value and ignore the power of
15
16 culture to drive men and women to display different amounts of such talent.
17

18 **Policy implications.** If the root cause of the vertical gender gap in management is
19
20 culture, then corporate or public policies that seek to reduce this gap must focus on culture. In
21
22 general, to change culture, you have to change people's hearts and minds. Therefore, culture is
23
24 arguably the hardest thing to change through policy. In the United States, policies that target a
25
26 single group like women have been subject to backlash and retrenchment (Skocpol 1991;
27
28 Alesina and Glaeser 2006). Americans simply refuse to pay for something that does not benefit
29
30 them (Korpi and Palma 1998). One way around that is to nest policies that benefit women
31
32 within policies that benefit *both* men and women. For instance, family-friendly policies could
33
34 place a ceiling on working hours for all salaried workers (*e.g.*, 50 hours per week) or mandate
35
36 on-site employer-sponsored childcare for workplaces over a certain size, while education
37
38 policies could create programs, available to both sexes, to foster student participation in
39
40 science and mathematics programs in secondary schools as well as colleges.
