(54) Title: SYSTEM AND METHOD FOR MANAGING IN-THEATER DISPLAY ADVERTISEMENTS

(57) Abstract: A library of video advertisements (14) are stored at a clearing house (10) for distribution to a plurality of geographically separated theaters (T1...Tn) along with display schedules of the transmitted video advertisements. A network such as the Internet (12) connects the clearing house to the theaters (T1...Tn). At the theaters (T1...Tn), the transmitted video advertisements are displayed according to the schedules. A log of the displayed advertisements is compiled at each theater and transmitted by the network to the clearing house (10). In addition, one or more parameters representative of attendance and/or demographics at the theater are also transmitted by the network to the clearing house (10).

1 SYSTEM AND METHOD FOR MANAGING
 IN-THEATER DISPLAY ADVERTISEMENTS

5 BACKGROUND OF THE INVENTION

 This invention relates to in-theater display advertisements and, more particularly, to electronic distribution of video display advertisements to geographically separated theaters.

 Video display advertisements are displayed at motion picture
10 theaters prior to the feature film. This activity is a substantial source of revenue for the theater owners. Currently, the advertisements are distributed to the theaters as 35 mm slides carried in carousels. It is costly and inconvenient to deliver the advertisements to the theaters and the order of the
15 display cannot be easily changed.

 SUMMARY OF THE INVENTION

 A library of video advertisements are stored in electronic form at a clearing house for distribution to a plurality of
20 geographically separated theaters along with display schedules of the transmitted video advertisements. A network such as the Internet connects the clearing house to the theaters. At the theaters, the transmitted video advertisements are displayed according to the schedules, which can be changed according to the
25 circumstances. A log of the displayed advertisements is compiled at each theater and transmitted by the network to the clearing house. In addition, one or more parameters representative of attendance and/or demographics at the theaters are also transmitted by the network to the clearing house to audit the
30 effectiveness of the advertisements being displayed.

 BRIEF DESCRIPTION OF THE DRAWINGS

 [To be added in the next draft]

35 DETAILED DESCRIPTION OF THE INVENTION

 In FIG. 1 a clearing house 10 is coupled by a distribution

1 system, preferably the Internet 12, to a plurality of remotely
distributed retail establishments, namely a plurality of motion
picture theaters T_1 to T_n . At clearing house 10, an advertising
source 14 stores still or movie clip video advertisements,
5 preferably in electronic form. Typically, source 14 comprises
a mass storage medium. An electronic clearing house processor
16 controls the operations at clearing house 10. Clearing house
10 gains access to Internet 12 through an input/output port 18.
Port 18 has a bidirectional interface with Internet 12 and
10 receives advertisements from source 14. Port 18 serves to
convert the data it receives or transmits to and from an
appropriate protocol for transmission on the distribution
system, e.g., IP/TCP in the case of the Internet. Processor
16 has a bidirectional connection to source 14 by which
15 processor 16 controls selections of advertisements stored in
source 14 and receives confirmation that the selected
advertisements have been sent to port 18 for distribution over
Internet 12. A RAM 20, which is connected to processor 16,
stores an advertisement display schedule for theaters T_1 to T_n .

20 A real time clock (RTC) 24, which is also connected to
processor 16, provides a time base for operation of the system.
Local clocks (not shown) at theaters T_1 to T_n are synchronized
to RTC 24. Processor 16 is coupled to a report generator 22
Messages from theaters T_1 to T_n are also sent upstream over
25 Internet 12 to clearing house 10. These messages, which may
include a log of the advertisements actually displayed at each
theater, are relayed by port 18 to processor 16. RAM 12 is
coupled to processor 16. The schedule stored in RAM 20
includes times, theaters, and advertisement identification. A
30 report generator 22 is controlled by processor 16.

In operation, schedule 20 includes for each theater
individually the times, theater id's, and advertisement id's.
This data is sent to processor 16 so processor 16 can select the
advertisements at the appropriate times (either real time or
35 delayed time) and send them via port 18 to Internet 12 for
distribution to theaters T_1 to T_n . The advertisements are

1 selected by means of the advertisement id's, which are appended
to the distributed advertisements transmitted to theaters T_1 to
 T_n . Processor 16 appends the theater id's to the advertisements
at port 18 before transmission, so each scheduled advertisement
5 is routed to the scheduled theater either in real time or delayed
time for display at the scheduled time. As a result, the
advertisements and their time of display can be scheduled at
each theater independent of the other theaters. Processor 16
also generates time stamp messages for control of the local
10 clocks at theaters T_1 to T_n . These time stamp messages are
interleaved with the other data transmitted to theaters T_1 to
 T_n over Internet 12.

FIG. 2 illustrates components of the invention at one of
the theaters. The theater gains access to Internet 12 through
15 an input/output port 30. Port 30 has a bidirectional interface
with Internet 12 and receives advertisements from source 14.
Port 30 also serves to convert the data it receives or transmits
to and from an appropriate protocol for transmission on the
distribution system, e.g., IP/TCP in the case of the Internet.
20 Port 30 is connected to a processor 32. A RAM 34, which stores
display schedule data received from clearing house 10, has a
bidirectional connection to processor 32. Another RAM 38, which
stores video advertisements received from clearing house 10 in
electronic form, also has a bidirectional connection to processor
25 32. Processor 32 forwards time stamp messages to a local real
time clock 36, which is synchronized to RTC 24 (FIG. 1).
Processor 32 retrieves video advertisements in electronic form
from RAM 38 in accordance to the display schedule under the
control of local RTC 36 and feeds them to a motion picture
30 projector for interleaving with the feature motion picture
program being displayed. One or more different types of
interactivity sensors 40 are fed to processor 32. Exemplary
interactive sensors are individual seat sensors 82 that detect
when a theater seat is occupied. The outputs of such sensors are
35 coupled by wireless or hardwire to processor 32. A number of
other types of interactivity that can be practiced with the

1 invention are described below.

A log of the displayed advertisements (advertisement id, theater id, and time) is recorded at each theater and stored in display schedule RAM 34. Periodically, this log is retrieved
5 from RAM 34 by processor 32 and transmitted upstream via Internet 12 to clearing house 10, where it is coupled by port 18 to processor 16. Processor 16 compares the logs to the data from schedule 20 and sends the discrepancies to report generator 22.

Assuming the Internet is used to distribute the
10 advertisements to the individual theaters, each theater has its own Internet address (URL) and the data, including theater id's, display schedules, advertisements, time stamps, etc., is transmitted over the Internet according to IP/CTP. If desired each theater T_n in FIG. 1 could comprise a complex of separate
15 theaters in one facility. In this case, there would be a router at each theater to direct the data to the assigned separate theaters according to the theater id.

The invention can be used to perform many functions in a theater. The following are representative of these functions.

20 ***Advertising Scheduling***

Pre-Buying

The advertising agents can view all the scheduled slots and pre book advertising space as is currently industry practice. The system provides the advertising agent with two new alternatives,
25 "Predicted Results" and "Dynamic Buying" booking. These alternatives are not feasible with out automation of the in theater advertising system.

Predicted Results Booking

Predicted Results refers to buying a slot of advertising
30 space that meets a set of criteria for a specific price. The host system assigns the advertisements to slots using the criteria, the in theater system shows the advertisements and collects real-time results used to measure how well the criteria was meet. Based on the degree of the match the advertiser is credited for
35 lack of predicted results or pays the theater a bonus for exceeding the results.

1

Dynamic Buying Booking

Dynamic Buying refers to the buying a slot of advertising space through auction where the space is sold at the time it is shown. The advertising agent defines sets of criteria (ad business rule) to be meet and the price it is worth if such criteria can be meet. The in theater system collects data real-time which is used to determine which ad's business rules have been met and which ad brings the highest economic value to the theater. All ads are evaluated during the prior slot to determine which ad is shown. All the currently collected data including the following is used in the evaluation:

Tickets Sold; Tacit Viewing; Predicted Eye Ball Count; Minutes Before Feature; Genre Match;; Actual Demographic Matches (Data collected via Dual Addressable Tags described below); Predicted Demographic Matches; Slot Type; Slot Day Code; Slot Time Code; Quiz Available; Time Before Quiz; Time After Quiz; Drawing Available.

Dynamic Matching

Dynamic matching is the process of assigning an advertisement to a time slot. To improve on the process of randomly assign ads to slots, rules or business log is used to determine which slot an ad should be assign to create the most economic value for both the advertiser and the theater operator.

Dynamic Slotting

The ad's and slots are scored based on score rules, then they are matched based on the matching rules, then they are displayed. At the same time the ad is displayed the theater statistics are collected and after the completion of the display of the ad, all statistics are logged. All remaining ads and slots are re-scored during each slotting cycle. All processes are executed concurrently as to allow for efficient processing.

Slotting Cycle

Displaying the advertisement requires the least amount of system resources. While an ad is being displayed, all the necessary processing is performed to determine which ad will be displayed in the next slot.

1

Scoring

Both the content object and the slot object are scored based on the business rules assigned. The slot object supports the following: Slots; Slot Offer Price (The price is calculated based its position in the loop, the actual reach and the number of ad's that match the demographics of its target audience.); Slot Position; Slot Reach; Content; Content Bid Price; Content Demographics; Content; Position; and Content Reach.

5

Matching

The matching agent uses matching business rules to determine which ad to assign to the slot in question.

10

15

20

25

30

35

1 **Audience Derived Data**

Quiz Data Collection

Synchronized with each quiz question is an answer from each respondent. The response or answer is collected via the key pad
5 on response devices attached to the top or back of each auditorium chair. The row and column number of the seat is also collected in addition to the date and time.

Ticket Sales Data Collection

The system is connected electronically to collect the ticket
10 sales for each theater. The data is collected at the beginning of each slot for each screen loop.

People Count

There are three methods for counting the theater population. First, a motion detector counts the number of persons moving in
15 and out of a theater (screen specific) entrance. The device categories the people as possible adult or minor and the data is feed into real-time audience demographics. The counting starts at a specific time before the preview to reduce false counts of persons leaving after the last show or cleaning the theater. This
20 time is part of the schedule.

Second, the number of persons entering the complex is captured using the technology of the first method. In addition, one or more of the following parameters are measured:

Audience = tickets sold for screen

25 C-Factor = Percent of Persons in Concession Lines before Screening

R-Factor = Percent of Persons in Rest Room or Other before Screening

S-Factor = Percent of Persons who Sneak in

30 Concessions = Estimated number of Persons in Concession Lines

Total Audience = Number of Persons that Entered Complex

Eye Balls = Estimated Number of Persons in Theater

Live = Total Number of Tickets sold for a Screening that is Showing

35 LC-Factor = Percent of Persons in Concessions lines while their show is live

1 Complete = Number of Persons in Movies that have Ended
 Pre-Live-Concessions = Concessions - (LC-Factor * Live)⁺ⁿ(each
 theater/screen)

Available = Total-Audience ((complete)⁺ⁿ+(Live / (1+LC-Factor)⁺ⁿ)

5 Audience-Factor = Audience / (Audience)⁺ⁿ

Eye-Balls = Available

In a fashion similar to FIG. 4 coefficients are empirically
 determined, the coefficients are multiplied by the measured
 values, and the products summed to provide a people count.

10 Third, a sensor is attached to each chair to sense if the
 seat is occupied. With reference to theater plan view shown in
 FIG. 6, the sensors could be represented by the asterisks. Each
 seat is coupled by the infrared grid controller to to processor
 32 (FIG. 2) for transmission to clearing house 10.

15 Surveys

As represented in FIG. 6, accurate commercial data such as
 the demographics of the audience are collected in real-time
 through an electronic survey generated by a survey system (4)
 which is projected (3) on the screen. Advertisers can also embed
 20 surveys into the advertisement to collect data specific to the
 advertisements content. The survey answers are collected through
 electronic data collection devices (9). The devices(9) are
 located at the individual seats of the survey subjects in the
 theater. The survey data can be transmitted to cleaning house
 25 10 through the grid controller and the Internet. An electronic
 contest/raffle can be used to increase the audience participation
 in the survey.

30

35

1 Raffle

The degree of a viewers participation in a quiz or survey is tracked real-time by the raffle system(4). The quiz and survey systems(1) send the raffle system(4) electronic raffle tickets
5 when the participant completes a quiz or survey. Each ticket contains the seat row and column number, the data collection devices and an electronically created raffle ticket number. The raffle service randomly draws the number of requested winning tickets. The raffle system send a command to the devices LED is
10 illuminated. The seat location of the winning holders can also be displayed on the projector.

Managing Audience Attention to the Advertisements***Quizzes***

15 The quiz questions increases the audiences attention because the advertisements are integrated into the quiz screen. The audience is also more likely to follow each advertisement in the loop because they do not know when the next quiz question will be displayed. The system can measure and report the degree of
20 attention by dividing the number of persons participating in the quiz and the number of persons seated.

Raffles

Another technique to increase the audiences attention is to reward responses quiz questions and surveys. An electronic raffle
25 ticket can be issued for each desired action from the viewer.

Dual Addressable Data Collections Device

Use of the Dual Addressable Infrared Grid (DAIG) and low power consumption devices that communicate through it provide a significant economic advantage by allowing a low cost means to
30 collect audience reach and demographics data. In addition, the data collection system can be used for activities that increase the audiences attention to the advertisements.

Instead of or in addition to video advertising images, the system could distribute audio advertisements from the clearing
35 house to the theaters for sound reproduction the lobby, auditorium or in the same manner described above.

1 Dual Addressable Infrared Grid 8 (FIG. 6) is used to
determine the location of each device to allow the controller and
in-theater servers to accurately assign the seat column and row
number. It is also used to transmit data to clearing house 10 via
5 processor 32 and the Internet. Reference is made to US Patents
5,299,117 and 5,572,653 for further details about grid controller
8. Each theater complex contains one or more individual
theaters/screens in close proximity to each other.

The device at each seat contains a LED that can be turned on
10 or off via a command from the grid controller. The LED can be
instructed to flash at a rate which is either hard coded or
provided by command from the controller. The LED can be used to
communicate information to either or both the audience and staff.
For example a flashing LED could indicate a winner of a drawing.
15 The device also has a key pad for entry of data by the individual
audience members.

Each loop is started at the scheduled time. Each loop is
comprised of segments or ad windows. At the beginning of each ad
window each business rule in the LOOP BUSINESS RULE set is
20 evaluated to dynamically determine which ad to display in the
current or proceeding window. Business rules are evaluated in
sequential order. Business rules are ordered based on their
economic value. The economic value of the rules are calculated
dynamically prior to the beginning of each ad window.

25 Each ad is associated with a business rule or set of
business rules. The association or linking of an ads rules can
be based on only the ad or on the loop it has been associated or
assigned to. For example the BR may only come into play if the
loops attributes meet the BR criteria

30 ***Dynamic Matching***

Dynamic matching is the process of assigning an
advertisement to a time slot. To improve on the process of
randomly assign ads to slots, rules or business log is used to
determine which slot an ad should be assign to create the most
35 economic value for both the advertiser and the theater operator
Dynamic SlottingThe ad's and slots are scored based on score

1 rules, then they are matched based on the matching rules, then
they are displayed. At the same time the ad is displayed the
theater statistics are collected and after the completion of the
display of the ad, all statistics are logged. All remaining ads
5 and slots are re-scored during each slotting cycle. All processes
are executed concurrently as to allow for efficient processing.
Slotting Cycle

Displaying the advertisement requires the least amount of
system resources. While an ad is being displayed, all the
10 necessary processing is performed to determine which ad will be
displayed in the next slot.

Scoring

Both the content object and the slot object are scored based
on the business rules assigned. The slot object supports

15 Slots

Slot Offer Price: The price is calculated based its position
in the loop, the actual reach and the number of ad's that match
the demographics of its target audience. In FIG. 3, a
plurality of ad agent stations #1, #2, ..., #n are connected to
20 clearing house 10 where processor 16 is programmed to create an
advertising display schedule responsive to the inputs from
stations #1 to #n based on given fixed rate schedules and/or
rules for creating dynamic rate schedules in real time.
Advertisers give the ad agents at stations #1 to #n the
25 information necessary to create the advertising display schedules
and this information is transmitted to clearing house 10 by the
Internet or fixed connection. to which advertisers subscribe and
other inputs including those described below. As described in
FIG. 1, the resulting advertising display schedule is distributed
30 over the Internet 12 to the individual theaters.

In FIG. 4, a number of parameter sensors #1, #2, #3,
etc., measure such parameters as the number of tickets sold, the
particular motion picture being shown, the number of patrons at
the concession stands, the time before the feature that the video
35 advertisement is displayed, etc., at a particular theater during
the display of each video advertisement. The outputs from the

1 sensors are used to predict the actual number of pairs of eyes
viewing the displayed advertisement. This predicted number is
the basis of the fee charged to the advertiser. To this end, a
coefficient is determined for each parameter based on empirical
5 data. The sensors are connected to a processor 50 programmed
to multiple each sensed parameter times its coefficient and to
sum the products of the multiplications to yield a predicted.
The results produced by the processor 50 can also be used to
modify the display schedule stored in RAM 20 to take local
10 theater conditions into account such as the above parameters or
for example audience attentiveness. Audience attentiveness,
interests, or demographics could be measured by encouraging the
audience to respond to a quiz or game displayed on the theater
screen. Instead of being used to modify the display schedule
15 stored in RAM 20, the results produced by the processor 50 could
be used to control one or more other processes at the theater
on a real time basis under the control of a RTC 52 or to generate
reports for use by the advertisers.

FIG. 5 illustrates an arrangement for modifying the
20 advertising display schedule on the fly based on various
conditions in a theater. A ticket counter 40, a real time clock
(RTC) 42, and an attentiveness detector 44 are all coupled to
processor 32. Counter 40 gives a count of theater tickets
purchased or other reliable indication of the number of eye balls
25 in the theater. RTC 42 gives the time of day. Attentiveness
detector, which could use one the approaches described above,
gives a measure of the receptiveness of the audience to the
advertisement being displayed. All three of these factors relate
to the overall effectiveness of an advertisement displayed at the
30 current time. Based on the rate paid by an advertiser, an
appropriate time slot is selected by processor 32 and the
advertisement is retrieved from ad RAM 34 for display by
projector 38.

FIG. 6 illustrates various parts and elements of the
35 present invention for producing interactive and appropriate media
content to be displayed onto a movie theater movie screen 100

1 in an auditorium. The auditorium has patron seats 101 bounded
by walls 102 and arranged in rows and columns as shown. A
digital projector 38 (FIG. 5) is able to project onto screen
100 an image with sufficient resolution, brightness various data
5 and video signals in several aspect ratios as desired. As
compared to the present use of slide film projectors the digital
projector is capable of being connected to a computer interface
and display many different still and moving video and data
signals onto the movie screen. Processor 32 (FIG. 5), including
10 its programs and memory for carrying out the programs, is
represented in FIG. 6 and subsequent FIGs as an In-Theater
Controller 103. The programming that connects In-Theater
Controller 103 to Internet 12 is not represented by the blocks
in Controller 103. The digital projector 38 has an input
15 connection 104 from the In-Theater Controller 103, which has the
capability of displaying various data and video signals. This
is advantageous in that it provides for more efficient
utilization of the media content to be shown, as will become
clearer from a further consideration of the invention. The In-
20 Theater Controller 103 executes a number of programs illustrated
by the blocks, namely a communication system 106 to manage input
and output communication between each system and subsystem
component, a loop management system 108 to control the loop
features such as timing, length and content of the media to be
25 shown via the input connection 104 to the digital projector 38,
an interactive quiz system 112 to control the questions and
answer data in and output, a ticket interface system 114 to
process ticket data and information, a projector control system
116, a log in system 118, a people counter system 120, an
30 advertisement management system 122, interactive patron inputs
from remote wireless transmitters (see FIG. 17) are processed
through the dual addressable infrared grid (DAIG) controller
interface system 124, a cryptologic system 126 is used to encode
data and information, a survey system 128, and data redundancy
35 system 38 used to back-up and monitor data storage and activity.
In In-Theater Controller 103 (FIG. 6), there are other functions

1 such as the ticket interface system 114, projector control system
116, advertisement management system 122, people counter system
120, cryptologic system 126, survey system 128, and all of the
other necessary subsystems working in cooperation to deliver the
5 optimal quiz question, sponsor message and or advertisement to
the movie screen 100 processed by the In-Theater Controller 103
from input from sensors, database and rules.

FIG. 17 depicts a data collection remote 95 with a keypad 96
for input of answer choices presented on a movie screen 100 as
10 created by quiz system 112 and In-Theater Controller 103 with
a through input connection 104 to digital projector 38. The
choices selected by the patron are entered into the quiz system
112 by the patron through alphanumeric keys 105 located on the
data collection remote. On the remote a Liquid Crystal Display
15 (LCD) 97 presents information, prompts, or special questions
directly to the patron using the device. Reactions to the
content displayed on the LCD located on the data collection
remote are sent through infra-red transmitter and receiver diodes
98 and 99 located on the data collection remote and the infra-red
20 transmitter and receiver diodes and these radio signals are
detected and received by DAIG 132 then are sent to the DAIG
interface system 124 as data via the Ethernet network 136 to the
communication system 106 in the In-Theater Controller 103 and
processed appropriately, for example as a quiz response the data
25 is processed by the quiz system 112 and quiz services software
140. The data collection remote 100 also includes the ability
to use radio frequency transmitter and receiver 110 as another
means to communicate data and information to the In-Theater
Controller 103 system. Included in FIG. 6 is a electronic sensor
30 82, which permits the detection of a patron in a seat.
Collection of the data regarding which seat is occupied or not
is useful determining how many players are involved in a game,
quiz, the attendance and viewing time of a patron which
contributes to the potential value of advertisements and the
35 price to be charged. The attendance and occupancy census can be
compared to ticket sales or box office receipts and the data

1 stored for use by the business rules systems. Remote 95 could
comprise other handheld device types, such as a portable digital
assistance, cell telephone, their combination and other devices,
remote 95 has data and control inputs 105 used by the game player
5 to direct and respond to video game play as it is projected onto
movie screen 11, activity indicators 76 used to provide visual,
audio and other sensorial feedback and activity to game player
in conjunction with video game play, and wireless data and
control port 77 and wired data and control port 78 used to
10 provide communication with On-Screen Video Game System 9001 as
previously described. Off the shelf industry standard game
devices are interfaced to the On-Screen Video Game System 9001
by physical and electronic interface of wireless control and data
port 77 and wired control and data port 1005 portable adapters
15 to the industry device's existing communication control and data
circuit or ports. Optional video display indicator 97 is used
to display visual content such as game play information and
advertisement. Indicator 97 may be added to industry standard
devices as required. Remote 95 is also used as an input and
20 output device to interact with advertisement and other content
as it is projected on movie screen 11 and on video display
indicator 97. Similarly remote 95 may be used as an input and
output device to interact with audio advertisement as it is
projected via a theater sound system via interface and under
25 control of the In-Theater Controller 103.

Once logged onto the system, game inputs 105 and display 97
and indicator 76 outputs of wireless remote 95 are interactively
communicated via wireless radio signals 123 (FIG. 6) to and from
the dual addressable grid 42 and with the In-Theater Controller
30 14 as described above. Video game play inputs 105 are processed
by the In-Theater Controller 14 and the On-Screen Video Game
System 9001 and ensuing affects are logged and shown on the video
game projected on movie screen 11. Wireless remote display and
indicator data and control commands are communicated from the In-
35 Theater Controller 14 via Internet link 40 via DIAG interface 32
via dual addressable grid 42 via wireless radio signal 44 to

1 wireless remote 95 display 97 and indicator 76 outputs. In
addition to processing ongoing video game interaction and game
activity display, the system constantly tracks remote 95
movements and location. Remote 95 continuously emits a tracking
5 signal from tracker 80. As the wireless tracking signal 44 is
detected and analyzed for strength, direction and proximity by
the dual addressable grid 42, the electronic coordinates of
remote 95 on the dual addressable grid 42 are communicated
through the DIAG interface system 32 via Ethernet 136 to the In-
10 Theater Controller 14, which logs the electronic coordinates
versus time of day and date and creates a tracking record for
device 95 within tracking system 9008. The electronic
coordinates correlate to the physical location of device 95 in
all three physical planes of the theater auditorium. This
15 tracking and mapping process continues for all wireless device
95's while logged onto the system. A similar process is used to
track wired remote 95's. Additionally anything equipped with a
tracker 80 may be tracked by the system.

A grid of wireless infrared transceivers 132 is installed
20 in the ceiling above seats 101 to communicate with infrared
transceivers at the individual seats such as . (Other modes of
wireless communication could be used instead of infrared.) Each
seat is equipped with sensors 82, keyboards, and/or displays
(FIG. 17) so the patron in the seat can communicate with In-
25 Theater Controller 103. The individual transceivers of grid 132
are assigned unique addresses and individual seats 101 are also
assigned unique addresses. Each communication between an
individual transceiver and seat thus includes two addresses to
route signals and locate the source of signals as described in
30 DeTemple et al Patent No. 5,572,653. Each seat sensor could
send a signal indicating that it is occupied and where the patron
is located by row, seat number etc. Grid 132 is connected by
a cable 133 to a DAIG controller 134, which prepares the signals
generated by grid 132 for transmission over an Ethernet network
35 136 to In-Theater Controller 103, such as seat sensors 82 and or
patron input and output devices. Additionally, a patron is able

1 to respond to information such as quizzes that are displayed on
the movie screen 100 by inputting a response which is then
communicated by infrared signaling to the dual addressable grid
132 and DAIG 134 through Ethernet network 136 to the DAIG
5 interface system 124 in In-Theater Controller 103 via
communication system 106 where it is processed in quiz system
112.

In In-Theater Controller 103 (FIG. 6), there are other
functions such as the ticket interface system 114, projector
10 control system 116, advertisement management system 122, people
counter system 120, cryptologic system 126, survey system 128,
and all of the other necessary subsystems working in cooperation
to deliver the optimal quiz question, sponsor message and or
advertisement to the movie screen 100 processed by the In-Theater
15 Controller 103 from input from sensors, database and rules.

The control command, data and video signals for display are
sent to the digital projector 38 from the In-Theater Controller
103 by Ethernet 136. Data and video inputs are collected and
processed using the data and information from sensors, keypads,
20 business rules and database, etc. as described herein.

In FIG. 7 more detail is shown regarding the quiz system
112. The functions of quiz system 112 are controlled by quiz
services software 140, which include applying relevant rules to
the quiz questions being presented to patrons. Specifically,
25 quiz business rules software 142 govern the quiz questions and
answers, which are most appropriate for the particular audience
using parental control categories. The level of difficulty and
how closely the quiz questions are related to the media content
being shown in the auditorium that day or for the movie that the
30 patrons have decided to attend. Elements 144, 148; 150, and 152
represent disk drives or other large storage devices. Having
relevant quiz content that is able to increase the participation
by patrons through interactive feedback using the quiz questions
144 benefits the patrons and sponsoring advertisers because of
35 the increased participation and interest in the quizzes displayed
on screen in the auditorium. More interactions and increased

1 interest by the patrons translates into more awareness, exposures
and recall of the quiz and products(s) being promoted. Each of
the quiz questions from quiz question database 144 is run for a
length of time and from an advertisement loop database 148, which
5 has each advertisement and the know content its running period
for which each advertisement is displayed.

From the advertisement loop database 148 relevant and
appropriate advertisement messages are stored for insertion into
a quiz or other promotional display on the auditorium movie
10 screen 100. The quiz answer database 150 collects and stores
the answers from the audience patrons in the auditorium of the
theater during a quiz activity. The patrons answer quizzes
through input devices communicating to the dual addressable grid
132 and then to the In-Theater Controller 103 to be processed by
15 the quiz system 112 and then stored in the quiz results database
152. As can be seen, quizzes are one of many forms of
interactive communication that are enabled by the invention and
that are able to be changed as desired based upon the quiz
business rules software 142. Quiz system 112 can also be
20 designed to control advertising content. Advertisement business
rules software 146 governs the display of products being
advertised, for example not showing certain goods to specific
audiences. Alcohol and tobacco advertisements would not be
displayed to younger patrons or those attending a movie with a
25 certain rating or family friendly genre.

The architecture of FIG. 7 could also be used to implement
the on-screen video game (OSVG) feature. In this case a OSVG
business rules are substituted for quiz business rules 142, an
OSVG loop is substituted for quiz questions 144 and quiz answers
30 150, and OSVG results is substituted for quiz results 152.

As shown in FIG. 14, a point of sale is located in a
theater for the concession of items such as popcorn, candy and
beverages. Each concession area usually has a point of sale
(POS) device 160 where each item sold is recorded. With the
35 sale of each item a database of the sales is established on the
point of sale device. These database records are then

1 transmitted to via Ethernet network 136 to the In-Theater
Controller 103 to be stored in an appropriate database and file
format for processing of the information as it relates to the
advertisement management system 122. Advertising management
5 system 122 is programmed to project the most relevant
advertisements onto the screen(s) through the use of the loop
management system 108 and communication system 106 to display
advertising images onto the screen using the digital projector
38. The quiz system 112 may be employed to offer a prize of
10 popcorn for the patron with the most correct answers to the
quizzes and/or each patron that participates. The increase of
the number of popcorn buckets sold simulates the demand for
others to purchase popcorn. The system operates to communicate
and stimulate demand for a concession and/or sponsors of goods
15 or services. The In-Theater Controller 103 is also connected via
Ethernet network 136 to the theater's box office 162 for ticket
sales information. As tickets are sold for each movie being
shown in the auditoriums, the data is stored for collection on
the In-Theater Controller 103 and within the ticket interface
20 system 114. This data is processed in the In-Theater Controller
103 to optimally select and present advertisements relevant to
the genre, audience and inputs gathered by the In-Theater
Controller 103 from various databases and sensors. As one
example, patrons may enjoy a specific genre of movies and the
25 next coming attraction is added into the advertisement loop
being shown under control of communication system 106 and loop
management system 108. This advertisement is processed by the
projector control system 116 to be sent to the digital projector
38 via the input connection 104 for display onto the screen in
30 an auditorium.

Electronic signage units (ESU) 65 display information to
patrons in various locations, such as the vestibule, movie screen
100 and or auditorium entrances. As illustrated, this
information is distributed to the locations by dual addressable
35 infrared grid 132. In this case, grid 132 would extend outside
the auditorium proper to the vestibule and other areas to be

1 accessed by grid 132. Alternatively it could be distributed by
hard wire (eg, Ethernet network 136). ESU's 65 displays static
and/or full motion video images under control of the
communication system 106 and In-Theater Controller 103 based upon
5 relevant and appropriate input of sensors, rules and databases
being processed.. Each of the ESU's 65 is able to receive and
send data as detected from tickets, patrons, identification
badges or other devices permitted by the communication system 106
to send and receive data and signals from the dual addressable
10 grid 132 or ESU's 65 equipped with transmitters. The
information and data collected is useful to create advertisement
business rules 146 and quiz business rules 142 and other
interactive content for display onto the movie screen 100 in an
auditorium of patrons.

15 Tracking hardware 166 in the form of infrared transmitters
communicate with the dual addressable grid 132. The
transmitters are installed on moveable persons or things within
the theater to track their movement and verify their location.
The signals representing the individual transmitters and their
20 locations are send to In-Theater processor 103 where the
information is compiled for transmission to clearing house 10,
for use in selecting the ads to be displayed on screen 100, or
for security purposes. For example the correct ticket needs to
be purchased for a specific showing of a movie. Motion Picture
25 AA (MPAA) ratings can be enforced when a ticket for a movie
that has one rating inappropriate for the one in which the
patron is seated for viewing. R rated movies would not be
appropriate for G rated ticketed patrons. The tickets themselves
or the patron ID such as a frequent movie attendance cards have
30 the ability to communicate to the dual addressable grid 132 to
indicate that the patron may not belong in the auditorium for the
movie or content being displayed. The ability to monitor and
enforce MPPA ratings increases the likelihood that a parent would
permit an adolescent to attend theater showing R rated movies.
35 The tickets or cards would communicate through radio signals 44
to the dual addressable grid 132 and then the data is sent by

1 Ethernet network 136 to the communication system 106 and
processed by the In-Theater Controller 103. The data about the
kinds and types of concessions, volume, etc is collected and
linked to the patrons that are able to be distinguished by
5 either data collection from admission tickets or through input
and interactivity by participation with the quiz system 112,
sensors 40, quiz questions 144, or DAIG interface system 124, as
processed by the In-Theater Controller 103, and reaction to the
content, images displayed on the screens and Ethernet network 136
10 throughout the theater. In this case, grid 132 would also
extend outside the auditorium proper to the vestibule and other
areas to be accessed by grid 132.

With the use of a movie tap (MT) 164 a patron may enjoy a
movie and order a copy thereof immediately rather than waiting
15 for the movie to be mass distributed in the future. The movie
tap functions as method to deliver a recording of the theater
interactivity from quiz system 112 and content and images
displayed on the movie screen 100, including the ability to
replay or view activity recorded through input devices through
20 the dual addressable grid 42. For example a group game or quiz
event is recorded for the use of the patron that participated or
others seeking to experience the event at another time and place.
The patron can replay the quizzes at home by using the movie tap
164 to deliver a CD or DVD. A distinguishing feature of the
25 movie tap 164 is that it will deliver the media content from the
format it was presented into the format desired by the patron,
for example the movie being shown is a film and the movie tap 164
deliver it in a DVD format.

The theater location is connected to corporate and other
30 stakeholders over the Internet 12 through a website at
clearinghouse 10 (FIG. 1) that features the use of a virtual
private network (VPN). The VPN interfaces and connects to
content databases 170 that contain media, images and data for
use in all the projection and display components. All of these
35 elements are accessible through a virtual private network 74
accessed over the Internet 78, typically a transmission control

1 Internet protocol TCP/IP network communication means for sending
and receiving files. Each of the files sent over the Internet
78 between clearinghouse 10 and the In-Theater Controller 103 may
be encrypted and controlled by the cryptologic system 126.
5 Stakeholders, including the theater corporation, receive up to
the minute status reports of concession sales broken down into
time increments as collected by POS 160, attendance receipts
from the box office, patron demographics from quiz answers 150,
10 and logs of the advertisements actually displayed at the theaters
and the time of display, advertisement, promotion and sales event
information. The invention permits the make up of the audience
to be understood and content, images and information presented
on screen to become dynamically monitored and modified on a real-
time basis when desired.

15 In-Theater Controller 103 sends image files from databases
170 via the input connection 104 to the digital projector 38 for
illumination onto the auditorium movie screen 100 so corporate
and other stakeholders are able to direct their content
submissions to the individual theater or chain of theaters and
20 or specific auditorium movie screen 100, which can be influenced
by input from each of the sources connected to the system via the
Internet 12. For example input from individual and aggregated
consumer household(s) 172 is able to influence when a movie,
content, contest or program is available for viewing in a
25 theater, the location of the event, or showing times. In
addition, consumer households 172 and in theater patrons and
provide the inputs to create a database of consumer interest
and activity for analysis to optimize theater operational
efficiencies. In other words, the right movie is shown the right
30 number of times at the best time of day for maximum patronage to
the theater.

In summary, the Internet 12 connects all aspects of the
theater operation--In-Theater processor 103, content databases,
170, and consumer households 172-- through website 168 to
35 exchange data and video images among these constituencies.

In FIG. 15 a separating wall 200 lies between a

1 conventional projection booth 202 and a theater auditorium 204,
where the patrons are seated for the showing of the film onto a
movie screen 206. The projected images pass through a clear
glass window 208 located in the separating wall 200. An image
5 injector 210 has an electronic display panel located at one of
three positions directly in the path of the film projector's
light source 212. The three positions are inside the
projector's lens housing 214 at position 216a, after the lens
housing 214 nearer the glass window 208 at position 216b, or
10 behind the lens housing 214, but in front of the projector
aperture plate and film track mechanism 218 at position 216c.
The image injector 210 receives control and data via control and
data lines 220 from the image injector controller 222, which
receives its control and data via control and data line 224 from
15 the In-Theatre Controller 103 (FIG. 6). The In-Theatre
Controller 103 is connected to input sources 226, which comprise
files of advertisements stored in RAM 34 (FIG. 5), via data and
control lines 228. The In-Theatre Controller 103 controls the
selection of the data and images forwarded via the image
20 controller 222 to the electronic display panel. Thus, an
electronic image is projected onto the movie screen 206 using the
existing projector housing 214 and lens and the existing light
source 212.

An exemplary construction of a conventional lens housing
25 214 is shown in FIG. 16A. Lens housing 214 incorporates
multiple industry standard lens combinations such as lens
sections 232, 234, and 236. Each theater auditorium has its own
dimensions and screen size, thus the projector's lens housing 214
and lens sections 232-236 must be configured to project the
30 proper image onto the movie screen 206. Once set, typical lens
configurations rarely change, varying only by film aspect ratio.
When the electronic display panel is at position 216a, the image
injector 210 utilizes the conventional lens housing 214 modified
to substitute lens sections 238 and 240 for lens section 236.
35 A support ring 241, which holds electronic display panel labeled
242 is disposed in lens housing 214 between lens section 234 and

1 lens section 238, as illustrated in FIG. 16B, and extends across
the light path is lens housing 214, as illustrated in FIG. 16C.
A cable 244 extends outside lens housing 214 to connect the
electronic display panel 242 to controller 222. The electronic
5 display panel 242 is capable of 100% transparency when an
advertisement is not being displayed, in order to pass the
motion picture film image through the lens system and through the
window 208 onto the movie screen 206.

The invention contemplates several ways to insure that the
10 light path from light source 212 through the lens to screen 100
is not obstructed by any images projected by the feature film
being shown. One way is to unload the feature film from the
projector reels while the advertisements are being displayed.
Another way is to splice one or more sections of blank film into
15 the feature film carried by the projector reels and synchronize
the display of the advertisements with the blank film sections.

When an advertisement is being displayed, an image thereof
is formed on the electronic display panel 242 and projected onto
screen 206. The electronic display and logic circuit and cable
20 assembly 3113 is optionally retractable depending upon lens 2113
configuration in order to ensure standard films can be shown.
The projection of film or digital images is under control of the
display schedule of the In-Theater Controller 103.

This adaptation is an advance in state of the art image
25 projection because the image injector 91 enables operators to
project traditional film and digital content onto existing movie
screens 100 by using the existing light source 06 and other
installed projector subsystems. This negates the need to
purchase expensive digital content only projection systems whose
30 very installation also eliminates the operator's choice to show
traditional film only releases. The image injector enables
theater operators to alternate between and combine their choice
of digital content and traditional film projections. This
enables the operator to offer and secure additional revenue from
35 multiple forms of new and old entertainment content. The
projector injector 91 protects the operator's current equipment

1 investment, expands useful equipment life, and adds here-to-
unaffordable digital projection capability.

FIG. 18 is an illustration of an example of the image output
of the In-Theater Controller 103 and quiz system 112 sent to the
5 digital projector 38 and shown on the movie screen 100. The
example quiz advertisement image 300 shows a question 301 above
the example quiz screen answer choices 302, these choices are the
ones to be entered onto the data collection remote 100 using the
alphanumeric keys 105 located on the keypad 96. In this example
10 the advertisement is for a personal computer.

FIG. 19 shows the example of a In-Theater Controller 103
directing the display of an image through the input connection
104 to the digital projector 38 in order to display an image on
the movie screen 100 in the auditorium of a theater. The first
15 frame is blank except for the copyright legend in small print,
the first frame 320 with copyright is then followed by the second
frame which displays the sponsor frame 122 then the a larger
first advertisement 324 image then a second advertisement 326
image, a third advertisement 328 and then a fourth advertisement
20 330, then a fifth advertisement 332 and finally a sixth
advertisement 334 image frame, progressively each frame is shown
and the content in the frames and sponsorships are changeable as
desired through the In-Theater Controller 103 sending the image
signals to the input connection 104 on the digital projector 38.
25 Each frame is able to have different sponsors or advertisements
and the advertisements and images may be presented as a slide
show or as full motion video as these signals are controlled by
the In-Theater Controller 103 as connected to the digital
projector 38. This is a great advancement over the use of a
30 slide carousel and a great cost savings for theater's that desire
to have digital advertising images efficiently projected instead
of a feature film using an existing light source.

FIG. 21 shows a flow chart for the Advertising, Quiz and
Survey process steps in the flow of the processing and logic for
35 displaying a particular advertisement or image based upon
specific data feed from the input databases and compared to the

1 actual input of the activity or characteristics of the audience,
theater or content being show as the main feature, etc.
Specifically, from the starting state of the processor or machine
the routine moves to block 401, which represents the
5 initialization of the screen loop, i.e., the actual images to be
displayed on screen; block 402 represents the retrieval of the
loop schedule, i.e., pre-established or dynamic loops of images
to be shown are retrieved for displaying on screen at the
appropriate time and sequence, e.g., previews, intermission and
10 trailer (end of feature); block 403 represents a wait until loop
start time, i.e., the prescheduled or dynamically configured
images are in a waiting state ready to be displayed upon cue for
either a trailer or feature event; block 404 represents a
trailer or feature start decision point, i.e., yes display feature
15 if it does not display then the processor sleeps and awaits
another trailer or feature starting event the advertisement loop
or quiz activity ends just before the feature starts and after
the loop plays upon the trailer activity; block 405 represents
processor sleeps until another trailer or feature point arrives
20 to start the loop; block 406 represents the end of file routine
decision, i.e., if yes the appropriate loop is retrieved or
created to be shown; block 407 represents next record is read;
block 408 represents decision process by the logic for static or
dynamic advertisement inserts decision; block 409 represents
25 processing of data inputs that are collected from real time
(live) sensors such as seat sensors and other communication
inputs to the system; block 410 represents the ratings or
responses or appropriateness based upon the audience, venue, time
of day, audience characteristics an or past behaviors or history
30 and number, quantity and type of audience demographics are rated
or scores kept to compare the advertisements performance or
audience appreciation or retention is compiled as a score for
that time slot or genre slot; block 411 represents advertisements
scored based upon inputs from data collection devices and sales
35 or responses to the advertisements call to action; block 412
represents each advertisement is compared for appropriateness for

1 being shown at a specific slot time, for example new automobile
advertisements can be shown to the appropriate audience that the
car is created for or specifically the demographic the auto
should or may appeal to, or adult products can be advertised
5 during R movies and for PG movies general merchandise is more
appropriate or based upon the sales attributable to the audience
or group; block 413 represents that each advertisement may be
classified as a display advertisement, part of a quiz or survey
requiring input from the audience members which in turn adds to
10 the data for an advertisement; block 414 represents that an
advertisement is loaded to be projected as an image; block 415
represents in this case an advertisement is shown; block 416
represents selection of a quiz with or without an advertisement
or sponsorship; block 417 represents loading of a quiz; block 418
15 represents display and start a quiz routine; block 419 represents
that a survey is selected; block 420 represents that a survey is
loaded; block 421 represents display and start of the survey on
the screen as an image; and block 422 represents the activity
about the audience and inputs being logged into the database for
20 statistical analysis.

FIG. 22 is the software or firmware routine for
communication with input devices and software routines between
system components such as In Theater Processor 103, audience
communication devices etc. Specifically, block 425 represents
25 start of the processor acting on a software routine or the "on"
activity or "awake"; block 426 represents routine or processor
"awake" no activity so the time out moves the unit to sleep and
periodically awakes to check for a start signal; block 427
represents the system as been either not awakened for a set
30 number of cycles or move to a power saving off when idling for
a extended length of time without an interrupt;
block 428 represents that the host provides a wake up call to
start activity; block 429 represents decisions of logging into
the host computer for communications with other devices or
35 peripherals; block 432 represents initialize communication with
the host, i.e., the host and remote are beginning the

1 communication handshake, agreeing on communication style, error
correction and rate to transmit and receive data; block 433
represents that the communication begins; block 434 represents
that the host logs on with the remote device communicating;
5 block 435 represents the decision that the log on procedure
either failed or succeeded; block 430 represents a
synchronization condition for data transfer, and timers for
events and wait status are set; block 431 represents that system
synchronization settings are inputted; block 436 represents a
10 failure to log on, retry count exceeded as set; block 437
represents failed log attempts so an alert is sent for display
to the operator; and
block 438 represents input setting for sleep cycle or power
saving controls.

15 FIG. 23 displays the flow chart and process of
communication with audience communication devices via the
infrared grid 132 or other means that tie the inputs back to
In-Theater Processor 103 or other system data and database
collection features. Specifically, block 450 represents the
20 start of the processor acting on a software routine or the "on"
activity or "awake"; block 451 represents the infrared grid
receiver or other input means from the audience communication
devices being powered "on" and active ready to transmit or
receive communications; block 452 represents searching for a
25 carrier signal, i.e., for an open line or open channel to carry
the data; block 453 represents the decision of whether there
is a transmission being sent or received; block 454 represents
a Yes decision, transmission being communicated so an address
must be detected as to the source of the transmission or
30 destination of the signal and data; block 455 represents the
decision of whether the detected address matches the data
collection device, terminal address of the devices known to be
active registered or in the systems database; block 456
represents that addresses match and data can begin to be
35 sent; block 457 represents that the last key pressed is read

1 for a cue to check the seat occupied detector to be certain the
patron is in the sit or it is occupied;
block 458 represents that the seat occupied sensors detection
status is noted; block 459 represents that the results are
5 sent to the host; block 460 represents that the receiver is
powered down after the transmission and communication activity
to save power; block 461 represents that an adjustable delay
occurs before power is reduced to sleep or wait status of the
communicating devices; and the loop back to block 451
10 represents that as each device is processed, the next address
is looked up in the database and compared with the address of
the device for a match; if there is a match the cycle is
repeated; .block 462 represents that receiver power is turned
off while there is no transmission, or in a sleep or power save
15 mode so that any interrupt awakes the unit; and block 463
represents that there is a time delay in the cycle of shutting
down progressively.

20 FIG. 24 is an illustration of the disclosed system elements
of the On-Screen Video Game System 9001. The invention expands
the theater auditorium into an entertainment gaming center
whereby the auditorium's movie screen 11 displays video game
and game player activity, replacing the traditional CRT, or the
like, display. Video games are projected onto the movie screen
25 11 by projector 10 under the control of the In-Theater
Controller 14 via control and data line 12. Game player remote
95 activity and physical location and movement is tracked,
integrated into the video game play and displayed on the movie
screen 11 by the In-Theater Controller 14. The number of
30 remotes 95, each having a unique device identification number,
thus game players, each also having their unique player
identification number, on movie screen 11, addressable by the
wireless dual addressable grid 42 is 1,000,000. All remote 95
35 location and movement is tracked in three-dimensions and
correlated in time by the system via the wireless dual

1 addressable grid 42. A key element of the solution enables
multiple same game - video game players, utilizing remote 95,
or the like, to interactively compete against one another on
the same single video display, movie screen 11. Another key
5 element of the solution enables concurrent display of multiple
video games being played by multiple players using remote 95,
or the like, through the split screening of movie screen 11.
Theater audio sound system 20001 is interfaced to the In-
Theater Controller 14 to provide video game and content sound
10 reproduction.

10 Communication interface from the On-Screen Video Game
System 9001 to remote 95 may be wireless, direct-wired and/or
both, depending upon the remote 95 and the video game. For
wireless remote 95 interface, the In-Theater Controller 14
15 communicates data and control information to and from the
remote 95 via Ethernet network 40 via DIAG interface system 32
via wireless dual addressable grid 42 via wireless radio
signals 44 to wireless remote control and data connection port
77. For wired remote 95 interface the In-Theater Controller
20 14 communicates data and control information to and from the
remote 95 via Ethernet network 40 to control and data
connection line 79 to wired remote control and data connection
port 78.

25 FIG. 25 is an illustration of the disclosed elements of the
On-Screen Video Game System's ID Verification Devices 11001.
To enter a theater auditorium and play a video game, a game
player must log onto and be positively verified in real-time by
the solutions Loggin System 118 (FIG. 24). This ensures only
eligible game players compete in the video game projected on
30 the movie screen 11. The ID Verification Devices 11001
subsystem communicates with passive RF-ID sensors 11002,
biometric sensors 11003, other sensors 11004, keyboards 11005,
magnetic stripe readers 11006, and other physical devices 11007
and via control and data line 79 via Internet link 40 with the
In-Theater Controller 14 and Loggin System 118. One
35 authorization and verification scenario would have the passive

1 RF-ID sensor 11002 automatically recognize the unique RF-ID
identification tag number implanted in the game player's
identification card, or secured to his remote 95, or imbedded
in an admission ticket, or the like. The game player would
5 then enter his unique personal identification number on a
keyboard 11005 and the information would be communicated via
data and control line 79 via theEthernet 136 to the In-Theater
Controller 14, where the Loggin System 118 would validate and
authorize game play for the game player. Another scenario
10 would have the game player insert his finger, or the like, into
a biometric sensor 11003 and then enter his unique personal
identification number on a keyboard 11005. This information
would be communicated via data and control line 79 via
theEthernet 136 to the In-Theater Controller 14, where the
15 Loggin System 118 would validate and authorize the game play
for the game player. Still another scenario would have the
game player actively swiping his identification card through a
magnetic stripe reader 11006 and entering his unique personal
identification number on a keyboard 11005. This information
20 would be communicated via data and control line 79 via
theEthernet 136 to the In-Theater Controller 14, where the
Loggin System 118 would validate and authorize the game play
for the game player. Still other scenarios would utilize
various combinations of the above ID Verification Devices 11001
25 in order to create real-time, positive verification and
authorization of game players.

Game player logon authorization will not be finalized via
Loggin System 118 unless the game player has paid for or pre-
authorized funds transfer for game play payment. If Loggin
30 System 118 determines the game player has established play
credits based on previous game play, pre-payment or payment via
Ticket Interface System 9009, game player verification and
authorization is granted via the In-Theater Controller 14 via
theEthernet 136 via data and control line 79 to ID Verification
35 Device 11001 to other physical device 11007; e.g., a federal
regulation E printing device. If Loggin System 118 determines

1 the game player needs to pay, game player verification and
authorization is not granted and the game player is advised at
physical device 11007; e.g., a federal regulation E printing
device. At this time the game player is also directed back to
5 the theater's ticket office to make payment or prompted for
payment method, such as a credit card, debit card, or other
authorized electronic payment type. Game player inputs a
secure electronic payment authorization request via ID
Verification Device 11001 and communicated via data and control
10 line 79 via the Ethernet 136 via the In-Theater Controller 14
via Login System 118 via Ticket Interface System 9010,
formatted for a appropriate electronic funds transaction and
transmitted via Comm. System 1009 via the appropriate external
financial authorization network. Upon receipt of electronic
15 funds transfer authorization via Comm. System 1009, the Login
System 118 stores game player payment information, authorizes
play, and communicates required electronic funds transaction
and game authorization status via the In-Theater Controller 14
via Ethernet 136 via data and control line 79 to ID Verification
20 Device 11001 to other physical device 11007; e.g., a federal
regulation E printing device.

Upon authorization a game player is electronically linked
to the remote 95 he is using to play the video game. The On-
Screen Video Game System 9001 then assigns a unique IP address
25 to the game player based on this linkage and this unique IP
address is utilized to identify ongoing game player tracking
and video game play. This is done for all game players. This
identification and game play tracking process is a key element
of this invention because it also extends movie screen 11 video
30 game play to non-theater auditorium-based, remote IP address
game players. These authorized remote IP address game players,
connect to the In-Theater Controller 14 via Internet, LAN
(local area network), or other means, and they are identified
and tracked by their device's (computer, PDA, cell phone, etc.)
35 unique IP address, similar to how Internet-based and LAN-based
computer-to-computer video games are currently executed. For

1 example, a remote Personal Computer-based game player and his
game play will be linked by his computer's IP address through
the Internet through In-Theater Controller 14 through Comm.
System 9009, to the On-Screen Video Game System 9001. As the
5 In-Theater Controller 14 projects the video game onto the movie
screen 11, it includes the interaction of all IP address based
game players, both in-theater auditorium players and, in this
example, a remote PC-based remotes. Additionally, utilization
of IP addresses to identify game players enables multiple game
10 players to compete on multiple movie screens 100 via the
Internet, LAN, or other interconnection of multiple In-Theater
Controller's 14 that are executing and running the same video
game on their respective On-Screen Video Game Systems 9001;
e.g., single or multiple game players on one movie screen 11
15 can compete with any number of other game players on any number
of movie screens 100 or on other displays, such as a remote
PC's monitor. Additionally the video and audio advertisement
content and processes detailed in other sections of this
disclosure can be used with video games.

20 Another element of the invention as illustrated in FIG. 26
is derived by the utilization of the dual addressable grid 42
and the In-Theater Controller 14 with multiple Screen Video
Controllers 1214, multiple projectors 10, and multiple movie
screens 100 to create a three dimensional player-centric
25 immersed video game space within a single theater auditorium or
space. Each wall, the ceiling and the floor are outfitted with
movie screens 100 covering their entire area, creating a six-
sided or cubed enclosure. The dual addressable grid 42 is
integrated with the ceiling movie screen 110. A Screen Video
30 Controller 1214 is assigned to a projector 10, and a projector
10 is assigned to each of the six movie screens 100. Each
Screen Video Controller 1214 communicates video game and game
play content from its On-Screen Video Game System 9001 via
control and data line 12 to its assigned projector 10, which
35 projects the video game and game play content onto its assigned
movie screen 11. Each of six movie screens 100 display

1 different video game and game play images in order to create a
player-centric perception of surround or immersed video. The
On-Screen Video Game Systems 9001 in each Screen Video
Controller 1214 is dedicated to deliver only the appropriate
5 player-centric immersed video game and game play content
applicable to the location of its assigned movie screens11;
e.g.: the ceiling movie screen 110 displays only video game and
game play images that would be perceived as such by a game
player if he were looking upward; the forward movie screen 11F
10 displays only video game and game play images that would be
perceived as such by a game player if he were looking forward;
the floor, rear, right and left movie screens 100B, 100A, 100R,
and 100L, respectively display only video game and video play
images that would be perceived as such by a game player if he
15 were looking to the floor, to the rear, to the right, or to the
left, respectively. The In-Theater Controller 14 used in this
player-centric immersed video game solution performs all of the
functions previously detailed for other In-Theater Controllers
14, excluding direct control of a projector. Additionally the
20 player-centric In-Theater Controller 14 processes all video
game and video game player IP addresses identification and
tracking information, synchronizes it for each Screen Video
Controller 1214, and communicates it to the Screen Video
Controllers 1214 via data and control line 1240, Ethernet 136,
25 or other suitable communication link, in order that each Screen
Video Controllers 1214 may process and project synchronized
video game and video game player activity on its assigned movie
screen 11 via control and data lines 12 and assigned projector
10. Further the player-centric In-Theater Controller 14 system
30 can connect via Internet, LAN, or other means to unlimited
other multiple player-centric In-Theater Controller's 14 in
order to enable multiple local and remote game players to
compete in multiple six-sided three dimensional player-centric
immersed video game spaces. Additionally the video and audio
35 advertisement content and processes detailed in other sections
of this document can be used with player-centric video games.

1

WHAT IS CLAIMED IS:

5

1. A method for displaying video advertisements at a plurality of geographically separated theaters, the method comprising the steps of:

storing a library of video advertisements at a clearing house remote from the theaters;

10

connecting the clearing house to the theaters through a network;

transmitting video advertisements to the theaters over the network;

15

transmitting display schedules of the transmitted video advertisements to the theaters over the network; and

displaying the transmitted video advertisements at the theater according to the schedules.

20

2. The method of claim 1, in which the connecting step connects the clearing house to the theaters through the Internet.

25

3. The method of claim 1, in which the step of transmitting display schedules transmits a different display schedule to each theater.

30

4. The method of claim 1, in which the step of transmitting video advertisements transmits a different set of video advertisements to each theater.

5. The method of claim 1, additionally comprising the step of compiling a log of the video advertisements actually displayed at each theater.

35

1

6. The method of claim 5, in which the log preparing step includes the time of display in the log.

5

7. The method of claim 5, additionally comprising the step of transmitting the logs to the clearing house.

10

8. The method of claim 7, additionally comprising the step of comparing the logs with display schedules to detect discrepancies.

9. The method of claim 1, additionally comprising the step of measuring one or more parameters representative of attendance at the theaters.

15

10. The method of claim 1, additionally comprising the step of measuring one or more parameters representative of audience demographics at the theaters.

20

11. The method of claim 9, additionally comprising the step of transmitting the one or more parameters representative of attendance to the clearing house over the network.

25

12. The method of claim 10, additionally comprising the step of transmitting the one or more parameters representative of audience demographics to the clearing house over the network.
