(57) **ABSTRACT**

A system and method for handling quality control data for a manufacturing process among a main computer and a plurality of remote computers, including the steps of establishing a connection between at least one of the remote computers and the main computer via a web browser, inputting quality control data of the manufacturing process from the remote computer into a database of the main computer via the web browser, performing a statistical analysis on the quality control data input into the main computer, and posting results of the statistical analysis on a web site of the main computer accessible to the remote computers through the web browser.

**SYSTEM AND METHOD OF COLLECTING
STATISTICALLY ANALYZING AND
GRAPHICALLY DISPLAYING QUALITY
CONTROL DATA FOR A MANUFACTURING
PROCESS**

**CROSS-REFERENCE TO RELATED
APPLICATIONS**

This application is related to a provisional application
having Ser. No. 60/155,933 filed Sep. 24, 1999.

BACKGROUND OF THE INVENTION

The present invention relates to a system and method of
collecting, statistically analyzing, and graphically displaying
process quality control data for a manufacturing process
within a network and, more particularly, the ability to
accomplish such functions between a single main computer
a plurality of remote computers accessible thereto via a web
browser.

It is well known within the manufacturing environment
for various parameters of a product or process to be quan-
tified and compared with respect to a desired range so as to
maintain quality standards. By utilizing such data in this
manner, it can be determined whether certain factors in the
process should be adjusted. Oftentimes, it is preferred that
the monitoring system perform the statistical process control
in real time, as disclosed in U.S. Pat. No. 5,862,054 to Li and
U.S. Pat. No. 5,691,895 to Kurtzberg et al. It will be seen,
however, that computers used for this purpose have been
interconnected in a typical network configuration. This not
only requires direct connection between the various
computers, but also that each computer have the software
loaded thereon which enables quality control data to be input
and analyzed by a known statistical process control method.

It will be understood that there are several ways of
statistically analyzing quality control data within the manu-
facturing environment, as indicated within U.S. Pat. No.
5,659,467 to Vickers and U.S. Pat. No. 5,355,320 to Erjavic
et al. Additionally, some of these patents disclose different
ways of displaying the information obtained through such
statistical analysis. None of the disclosed prior art
references, however, focuses on an improved manner of
handling the transfer of quality control data between a
plurality of computers which are remotely located or the
minimization of resources required to perform such func-
tions.

Accordingly, it would be desirable for a system and
method to be developed in which a single site or main
computer is able to easily have quality control data for a
manufacturing process input therein from a plurality of
remote computers, whereupon the main computer is able to
apply a statistical process control method thereto and make
the results of such analysis accessible to the remote com-
puters. In this way, parameters of the manufacturing process
can be modified as dictated by the analysis of quality control
data provided by all locations in a more efficient and less
expensive manner. Moreover, none of the remote computers
is required to include the software performing the statistical
analysis thereon, which is particularly relevant when devel-
oping a prototype process.

BRIEF SUMMARY OF THE INVENTION

In accordance with one aspect of the present invention, a
system for handling quality control data for a manufacturing
process between a plurality of computers is disclosed. The

system includes a main computer for analyzing quality
control data of a designated area of the manufacturing
process by means of a statistical process control method,
with the main computer further including memory for stor-
ing a database of quality control data and a processor for
applying the statistical process control method to the quality
control data and posting the results of the statistical analysis
on a web site of the main computer. The system also includes
at least one computer remotely located from the main
computer, with each remote computer further including
communications circuitry for establishing a connection with
the main computer web site by means of a web browser and
an interface for inputting quality control data for a desig-
nated area of the manufacturing process into the web
browser for receipt by the main computer and receiving
results of a statistical analysis of the quality control data
from the main computer web site through the web browser.

In accordance with a second aspect of the present
invention, a method of handling quality control data for a
manufacturing process among a plurality of computer sites
is disclosed. The method includes the steps of establishing a
connection between at least one remote computer and a main
computer via a web browser, inputting quality control data
of the manufacturing process from the remote computer into
a database of the main computer via the web browser,
performing a statistical analysis on the quality control data
input into the main computer, and posting results of the
statistical analysis on a web site of the main computer
accessible through the web browser.

BRIEF DESCRIPTION OF THE DRAWINGS

While the specification concludes with claims particularly
pointing out and distinctly claiming the present invention, it
is believed that the same will be better understood from the
following description taken in conjunction with the accom-
panying drawings in which:

FIG. 1 is a schematic block diagram of the system
disclosed by the present invention;

FIG. 2 is a screen display depicting an exemplary web
page associated with a given netsite, where a plurality of
areas relevant to a designated manufacturing process are
shown;

FIG. 3 is a home web page associated with a designated
area of the manufacturing process shown in the web page of
FIG. 2, from which quality control data can be input to or
received from the main computer depicted in FIG. 1;

FIG. 4 is a web page associated with the inputting of
quality control data to the main computer for certain param-
eters pertaining to the designated area of the manufacturing
process as identified in FIG. 3;

FIG. 5 is a web page associated with the receipt of
graphical displays from the main computer for parameters
related to the designated area of the manufacturing process
as identified in FIG. 3;

FIG. 6 is a web page depicting an exemplary graphical
display for one of the parameters shown in FIG. 5; and,

FIG. 7 is a flow diagram of the functional steps performed
by the system depicted in FIG. 1 in accordance with the
present invention.

**DETAILED DESCRIPTION OF THE
INVENTION**

Referring now to the drawings in detail, wherein identical
numerals indicate the same elements throughout the figures,
FIG. 1 depicts schematically a system, generally represented

by the numeral **10**, for handling quality control data for a manufacturing process between a main computer **12** and a plurality of computers **14** located remotely from main computer **12**. It will be understood that main computer **12** functions to analyze quality control data within a designated area of a manufacturing process by means of a statistical process control method. Remote computers **14** are utilized within system **10** to input quality control data into main computer **12** for analysis, as well as access the statistical analysis of such quality control data from main computer **12**.

Contrary to typical networks of computers utilized for statistical process control purposes, main computer **12** and remote computers **14** are not necessarily connected at all times. Moreover, system **10** of the present invention is able to minimize cost and operating delays by having only main computer **12** responsible for performing the statistical analysis of quality control data which is input from all remote computers **14**. This is particularly advantageous when the manufacturing process for a prototype is involved since the commitment of resources to system **10** is less than an entire network of computers connected at all times and each having the software for the statistical process control method operational thereon.

With respect to system **10**, it will further be seen that main computer **12** includes memory **16** for storing a database of quality control data therein. A processor **18** in main computer **12** functions, among other things, to apply the statistical process control method to the quality control data and post the results of the statistical analysis on a web site (identified generally by the numeral **20** and discussed in greater detail hereinafter) run by main computer **12**. Each remote computer **14** includes communications circuitry **22** for establishing a connection with web site **20** of main computer **12** by means of a web browser run by a processor **24**. In addition, remote computers **14** include an interface **26** for inputting quality control data for a designated area of the manufacturing process into the web browser for receipt by main computer **12**, as well as for receiving results of the statistical analysis of the quality control data from main computer web site **20** through the web browser.

As seen in FIG. 2, main computer web site **20** typically includes a home page **28** depicting various information about a particular manufacturing process. Such categories of information may include, for example, certain information pertaining to lot processing or other technical matters as indicated at **30** and **32**. In conjunction with the present invention, one category **34** of information preferably involves certain areas of the manufacturing process which has one or more parameters incorporated therein. It will be appreciated that each area of the manufacturing process has an identifier **36** associated therewith which is linked to a specific web home page **38** therefor. As a particular identifier **36** is clicked, specific web home page **38** appears, as depicted in FIG. 3 for the "Dielectrics" area.

It will be noted that while specific area web home page **38** may include other information, such as contact information, it primarily is utilized to access other web pages **44** and **46** (see FIGS. 4 and 5) linked to identifiers **40** and **42**, which permit inputting of quality control data to main computer **12** and accessing of charts or other graphical displays depicting the statistical analysis of quality control data performed by main computer **12**, respectively. Although not shown in a separate figure, specific area web home page **38** may also enable access to the raw quality control data in the database stored in main computer memory **16** through a linked identifier **48**. In this way, remote computer **14** is able to download the quality control data in the database and perform its own statistical analysis as desired.

It will be seen from FIG. 4 that web page **44** preferably includes one or more tables **50** and **52**, respectively, to identify the parameters involved and a normal range therefor as relating to the manufacturing process. As further seen therein, one or more form based queries **54** and **56** are provided to identify basic information from the inputting source/remote computer (e.g., name and date), one or more form based queries **58** and **60** are provided to identify certain important factors or parameters related to the parameter designated, and one or more other form based queries **62**, **64** and **66** are provided to identify any other significant factor pertaining to the designated parameter, results of the manufacturing process, and a comments section. It is also preferred that separate buttons **68** and **70** be provided on web page **44** to update the quality control database in main computer **12** and reset the menu of queries located thereon, respectively.

It will be understood that processor **18** of main computer **12** collects the quality control data transmitted from web page **44** through the web browser and then stores it in memory **16**. In order to secure the accurate transmission of quality control data, it is preferred that such data be encoded by the web browser prior to collection by main computer **12** and decoded by the web browser prior to storage in main computer memory **16**.

FIG. 5 depicts web page **46** as including a plurality of identifiers **72** thereon linked with an associated control chart so that clicking on a particular identifier **72** causes a web page **74** containing such control chart **76** to appear (see FIG. 6). In this way, each remote computer **14** is able to access a graphical display of the pertinent quality control data through the web browser.

Because the handling of quality control data in system **10** occurs via the web browser, main computer **12** and remote computers **14** are connectable via an Intranet or the Internet. While an Intranet has inherent security built into it, use of the Internet preferably requires certain security measures to determine whether, for example, a remote computer **14** (or user thereof) is authorized to input quality control data into main computer memory **16** or even access the statistical analysis of such quality control data as described above. This can be accomplished by means of known security precautions, including, but not limited to, passwords or the like. Of course, such security measures should be taken immediately upon connection of remote computer **14** and main computer **12** before any other functions are permitted.

In order to better exhibit the steps of the process undertaken by system **10** for purposes of the present invention, the flow chart of FIG. 7 is provided herewith. As seen therein, remote computer **14** first establishes connection with main computer **12** over an Intranet or the Internet via a web browser (block **100**). Thereafter, the web browser preferably queries remote computer **14** to determine whether it is authorized to input quality control data and/or access the statistical analysis performed for quality control data stored in main computer memory **16** (decision block **102**). If the response to such query is negative, the web browser causes remote computer **14** to be disconnected (block **104**). Otherwise, provided remote computer **14** is authorized to input or receive information from main computer web site **20**, the web browser next determines which identifier **36** is selected (block **106**) and provides a home web page **38** specific thereto (block **108**).

Upon depiction of web page **38**, the web browser next determines which identifier **40**, **42** or **48** is selected (block **110**) and provides an appropriate web page associated

5

therewith (block 112). Afterward, remote computer 14 is able to input quality control data to the database of main computer 12, access raw quality control data from the database of main computer 12, or access control charts 76 reflecting the statistical analysis of the quality control data in the database of main computer 12.

Having shown and described the preferred embodiment of the present invention, further adaptations of the system and method for collecting, statistically analyzing, and graphically displaying process control data can be accomplished by appropriate modifications by one of ordinary skill in the art without departing from the scope of the invention. In particular, it will be noted that the particular statistical process control method (e.g., SPC or SPC charts) or web browser implemented is not critical the present invention.

What is claimed is:

1. A system for handling quality control data for a manufacturing process between a plurality of computers, comprising:

(a) a main computer for analyzing quality control data of a designated area of said manufacturing process by means of a statistical process control method, said main computer further comprising:

(1) memory for storing a database of quality control data; and

(2) a processor for applying said statistical process control method to said quality control data and posting the results of the statistical analysis on a web site;

(b) at least one computer remotely located from said main computer, each remote computer comprising:

(1) communications circuitry for establishing a connection with said main computer web site by means of a web browser; and

(2) an interface for inputting quality control data for a designated area of said manufacturing process into said web browser for receipt by said main computer and receiving results of a statistical analysis of said quality control data from said main computer web site through said web browser.

2. The system of claim 1, wherein said main computer processor collects said quality control data from said web browser and stores said quality control data in said memory.

3. The system of claim 1, wherein said main computer processor links a graphical display of said statistical analysis results with an identifier on a web page of said main computer web site.

4. The system of claim 1, wherein said main computer and said remote computers are connectable via an Intranet.

5. The system of claim 1, wherein said main computer and said remote computers are connectable via the Internet.

6. The system of claim 1, wherein said quality control data is input into said web browser by completing a plurality of form based queries on a web page of said main computer web site linked to a designated area of said manufacturing process.

6

7. The system of claim 2, wherein said quality control data is encoded prior to collection of said quality control data from said web browser.

8. The system of claim 7, wherein said quality control data is decoded prior to storing said quality control data in said database.

9. The system of claim 1, said main computer processor further verifying the origin of said quality control data as a proper remote computer prior to storing said quality control data in said database.

10. A method of handling quality control data for a manufacturing process among a plurality of computers, comprising the following steps:

(a) establishing a connection between at least one remote computer and a main computer via a web browser;

(b) inputting quality control data of said manufacturing process from said remote computer into a database of said main computer via said web browser;

(c) performing a statistical analysis on said quality control data input into said main computer; and

(d) posting results of said statistical analysis on a web site of said main computer accessible through said web browser.

11. The method of claim 10, said quality control data inputting step further comprising:

(a) collecting said quality control data from said web browser; and

(b) storing said quality control data in said database of said main computer.

12. The method of claim 10, said posting step further comprising the step of linking a graphical display of said statistical analysis results with an identifier on said web site.

13. The method of claim 10, said performing step further comprising application of a statistical process control method to said quality control data.

14. The method of claim 10, wherein said remote computer and said main computer are connected via an Intranet.

15. The method of claim 10, wherein said remote computer and said main computer are connected via the Internet.

16. The method of claim 10, said quality control data inputting step further comprising the step of completing a plurality of form based queries on a web page of said main computer web site linked to a designated area of said manufacturing process.

17. The method of claim 11, said quality control data inputting step further comprising the step of encoding said quality control data prior to said collecting step.

18. The method of claim 17, said quality control data inputting step further comprising the step of decoding said quality control data prior to said storing step.

19. The method of claim 10, further comprising the step of verifying the origin of said quality control data as a proper remote computer prior to said inputting step.
