

US009524334B2

(12) United States Patent

Wilson et al.

(54) USING DISTINGUISHING PROPERTIES TO CLASSIFY MESSAGES

- (71) Applicant: **Dell Software Inc.**, Round Rock, TX (US)
- Inventors: Brian K. Wilson, Palo Alto, CA (US);
 David A. Koblas, Los Altos, CA (US);
 Arno A. Penzias, San Francisco, CA (US)
- (73) Assignee: **DELL SOFTWARE INC.**, Round Rock, TX (US)
- (*) Notice: Subject to any disclaimer, the term of this patent is extended or adjusted under 35 U.S.C. 154(b) by 0 days.
- (21) Appl. No.: 14/938,573
- (22) Filed: Nov. 11, 2015

(65) **Prior Publication Data**

US 2016/0078124 A1 Mar. 17, 2016

Related U.S. Application Data

- (63) Continuation of application No. 13/912,055, filed on Jun. 6, 2013, now Pat. No. 9,189,516, which is a continuation of application No. 13/015,526, filed on Jan. 27, 2011, now Pat. No. 8,484,301, which is a continuation of application No. 11/926,819, filed on Oct. 29, 2007, now Pat. No. 7,882,189, which is a continuation of application No. 10/371,987, filed on Feb. 20, 2003, now Pat. No. 8,266,215.

(57) ABSTRACT

A system and method are disclosed for classifying a message. The method includes receiving the message, identifying in the message a distinguishing property; generating a signature using the distinguishing property; and comparing the signature to a database of signatures generated by previously classified messages.

14 Claims, 5 Drawing Sheets

USING DISTINGUISHING PROPERTIES TO CLASSIFY MESSAGES

CROSS REFERENCE TO RELATED APPLICATIONS

The present application is a continuation and claims the priority benefit of U.S. patent application Ser. No. 13/912, 055 filed Jun. 6, 2013, issuing as U.S. Pat. No. 9,189,516, which is a continuation and claims the priority benefit of Ser. ¹⁰ No. 13/015,526 filed Jan. 27, 2011, now U.S. Pat. No. 8,484,301, which is a continuation and claims the priority benefit of U.S. patent application Ser. No. 11/926,819 filed Oct. 29, 2007, now U.S. Pat. No. 7,882,189, which is a continuation and claims the priority benefit of U.S. patent application Ser. No. 10/371,987 filed Feb. 20, 2003, now U.S. Pat. No. 8,266,215, the disclosures of which are incorporated herein by reference.

The present application is related to U.S. patent application Ser. No. 10/371,977 filed Feb. 20, 2003, now U.S. Pat. ²⁰ No. 7,299,261, the disclosure of which is incorporated herein by reference.

FIELD OF THE INVENTION

The present invention relates generally to message classification. More specifically, a system and method for classifying messages that are junk email messages (spam) are disclosed.

BACKGROUND OF THE INVENTION

People have become increasingly dependent on email for their daily communication. Email is popular because it is fast, easy, and has little incremental cost. Unfortunately, 35 these advantages of email are also exploited by marketers who regularly send out large amounts of unsolicited junk email (also referred to as "spam"). Spam messages are a nuisance for email users. They clog people's email box, waste system resources, often promote distasteful subjects, 40 and sometimes sponsor outright scams

There have been efforts to block spam using spamblocking software in a collaborative environment where users contribute to a common spam knowledge base. For privacy and efficiency reasons, the spam-blocking software 45 generally identifies spam messages by using a signature generated based on the content of the message. A relatively straightforward scheme to generate a signature is to first remove leading and trailing blank lines then compute a checksum on the remaining message body. However, spam 50 senders (also referred to as "spammers") have been able to get around this scheme by embedding variations—often as random strings—in the messages so that the messages sent are not identical and generate different signatures.

Another spam-blocking mechanism is to remove words 55 that are not found in the dictionary as well as leading and trailing blank lines, and then compute the checksum on the remaining message body. However, spammers have been able to circumvent this scheme by adding random dictionary words in the text. These superfluous words are sometimes 60 added as white text on a white background, so that they are invisible to the readers but nevertheless confusing to the spam-blocking software.

The existing spam-blocking mechanisms have their limitations. Once the spammers learn how the signatures for the 65 messages are generated, they can alter their message generation software to overcome the blocking mechanism. It

would be desirable to have a way to identify messages that cannot be easily overcome even if the identification scheme is known. It would also be useful if any antidote to the identification scheme were expensive to implement or would incur significant runtime costs.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention will be readily understood by the 10 following detailed description in conjunction with the accompanying drawings, wherein like reference numerals designate like structural elements, and in which:

FIG. **1** is a block diagram illustrating a spam message classification network according to one embodiment of the present invention.

FIG. **2** is a flowchart illustrating how to extract the distinguishing properties and use them to identify a message, according to one embodiment of the present invention.

FIG. **3** is a flowchart illustrating how a user classifies a message as spam according to one embodiment of the present invention.

FIG. **4** is a flowchart illustrating how the distinguishing properties are identified according to one embodiment of the present invention.

FIG. **5** is a flowchart illustrating the details of the email address identification step shown in FIG. **4**.

DETAILED DESCRIPTION

It should be appreciated that the present invention can be implemented in numerous ways, including as a process, an apparatus, a system, or a computer readable medium such as a computer readable storage medium or a computer network wherein program instructions are sent over optical or electronic communication links. It should be noted that the order of the steps of disclosed processes may be altered within the scope of the invention.

A detailed description of one or more preferred embodiments of the invention is provided below along with accompanying figures that illustrate by way of example the principles of the invention. While the invention is described in connection with such embodiments, it should be understood that the invention is not limited to any embodiment. On the contrary, the scope of the invention is limited only by the appended claims and the invention encompasses numerous alternatives, modifications and equivalents. For the purpose of example, numerous specific details are set forth in the following description in order to provide a thorough understanding of the present invention. The present invention may be practiced according to the claims without some or all of these specific details. For the purpose of clarity, technical material that is known in the technical fields related to the invention has not been described in detail so that the present invention is not unnecessarily obscured.

An improved system and method for classifying mail messages are disclosed. In one embodiment, the distinguishing properties in a mail message are located and used to produce one or more signatures. The signatures for junk messages are stored in a database and used to classify these messages. Preferably, the distinguishing properties include some type of contact information.

FIG. 1 is a block diagram illustrating a spam message classification network according to one embodiment of the present invention. The system allows users in the network to collaborate and build up a knowledge base of known spam messages, and uses this knowledge to block spam messages. A spam message is first received by a mail device **100**. The

mail device may be a mail server, a personal computer running a mail client, or any other appropriate device used to receive mail messages. A user reads the message and determines whether it is spam.

If the message is determined to be spam, the spam-⁵ blocking client 108 on the mail device provides some indicia for identifying the message. In one embodiment, the indicia include one or more signatures (also referred to as thumbprints) based on a set of distinguishing properties extracted from the message. The signatures are sent to a spamblocking server 102, which stores the signatures in a database 104. Different types of databases are used in various embodiments, including commercial database products such as Oracle databases, files, or any other appropriate storage that allow data to be stored and retrieved. In one embodiment, the database keeps track of the number of times a signature has been identified as spam by other users of the system. The database may be located on the spam-blocking server device, on a network accessible by server 102, or on $_{20}$ a network accessible by the mail devices. In some embodiments, the database is cached on the mail devices and updated periodically.

When another mail device **106** receives the same spam message, before it is displayed to the user, spam-blocking 25 client software **110** generates one or more signatures for the message, and sends the signatures along with any other query information to the spam-blocking server. The spamblocking server looks up the signatures in the database, and replies with information regarding the signatures. The infor-30 mation in the reply helps mail device **106** determine whether the message is spam.

Mail device **106** may be configured to use information from the spam-blocking server to determine whether the message is spam in different ways. For example, the number 35 of times the message was classified by other users as spam may be used. If the number of times exceeds some preset threshold, the mail device processes the message as spam. The number and types of matching signatures and the effect of one or more matches may also be configured. For 40 example, the message may be considered spam if some of the signatures in the signature set are found in the database, or the message may be determined to be spam only if all the signatures are found in the database.

Spammers generally have some motives for sending spam 45 messages. Although spam messages come in all kinds of forms and contain different types of information, nearly all of them contain some distinguishing properties (also referred to as essential information) for helping the senders fulfill their goals. For example, in order for the spammer to 50 ever make money from a recipient, there must be some way for the recipient to contact the spammer. Thus, some type of contact information is included in most spam, whether in the form of a phone number, an address, or a URL. Alternatively, certain types of instructions may be included. These 55 distinguishing properties, such as contact information, instructions for performing certain tasks, stock ticker symbols, names of products or people, or any other information essential for the message, are extracted and used to identify messages. Since information that is not distinguishing is 60 discarded, it is harder for the spammers to alter their message generation scheme to evade detection.

It is advantageous that messages other than those sent by the spammer are not likely to include the same contact information or instructions. Therefore, if suitable distin- 65 guishing properties are identified, the risk of a false positive classification as spam can be diminished. 4

In some embodiments, spam-blocking server **102** acts as a gateway for messages. The server includes many of the same functions as the spam-blocking client. An incoming message is received by the server. The server uses the distinguishing properties in the messages to identify the messages, and then processes the messages accordingly.

FIG. 2 is a flowchart illustrating how to extract the distinguishing properties and use them to identify a message, according to one embodiment of the present invention. First, a message is received (200). The distinguishing properties in the message are identified (202), and one or more signatures are generated based on the distinguishing properties (204). The signatures are looked up in a database (206). If the signatures are not found in the database, then the system proceeds to process the message as a normal message, delivering the message or displaying it when appropriate (208). Otherwise, if matching signatures are found in the database, some appropriate action is taken accordingly (210). In an embodiment where the process takes place on a mail client, the action includes classifying the message as spam and moving it to an appropriate junk folder. In an embodiment where the process takes place on a mail server, the action includes quarantining the message so it is recoverable by the administrator or the user.

Sometimes, a spam message is delivered to the user's inbox because an insufficient number of signature matches are found. This may happen the first time a spam message with a distinguishing property is sent, when the message is yet to be classified as spam by a sufficient number of users on the network, or when not enough variants of the message have been identified. The user who received the message can then make a contribution to the database by indicating that the message is spam. In one embodiment, the mail client software includes a "junk" button in its user interface. The user can click on this button to indicate that a message is junk. Without further action from the user, the software automatically extracts information from the message, submits the information to the server, and deletes the message from the user's inbox. In some embodiments, the mail client software also updates the user's configurations accordingly. For instance, the software may add the sender's address to a blacklist. The blacklist is a list of addresses used for blocking messages. Once an address is included in the blacklist, future messages from that address are automatically blocked.

FIG. 3 is a flowchart illustrating how a user classifies a message as spam according to one embodiment of the present invention. A spam message is received by the user (300). The user selects the message (302), and indicates that the message is junk by clicking on an appropriate button or some other appropriate means (304). The software identifies the distinguishing properties in the message (306), and generates a set of signatures based on the distinguishing properties (308). The signatures are then submitted to the database (310). Thus, matching signatures can be found in the database for messages that have similar distinguishing properties. In some embodiments, the mail client software then updates the user's configurations based on the classification (312). In some embodiments, the sender's address is added to a blacklist. The message is then deleted from the user's inbox (314).

FIG. **4** is a flowchart illustrating how the distinguishing properties are identified according to one embodiment of the present invention. Since most spammers would like to be contacted somehow, the messages often include some sort of contact information, such as universal resource locators (URL's), email addresses, Internet protocol (IP) addresses, telephone numbers, as well as physical mailing addresses. In this embodiment, the distinguishing properties of the message include contact information.

The message is preprocessed to remove some of the non-essential information (400), such as spaces, carriage 5 returns, tabs, blank lines, punctuations, and certain HTML tags (color, font, etc.).

Distinguishing properties are then identified and extracted from the message. Since spammers often randomly change the variable portions of URL's and email addresses to evade detection, the part that is harder to change-the domain name-is included in the distinguishing properties while the variable portions are ignored. The domain name is harder to change because a fee must be paid to obtain a valid domain name, making it less likely that any spammer would register 15 for a large number of domain names just to evade detection. The software scans the preprocessed message to identify URL's in the text, and extracts the domain names from the URL's (402). It also processes the message to identify email addresses in the text and extracts the domain names embed-20 ded in the email addresses (404).

Telephone numbers are also identified (406). After preprocessing, phone numbers often appear as ten or eleven digits of numbers, with optional parentheses around the first three digits, and optional dashes and spaces between the 25 numbers. The numbers are identified and added to the distinguishing properties. Physical addresses are also identified using heuristics well known to those skilled in the art (408). Some junk messages may contain other distinguishing properties such as date and location of events, stock 30 ticker symbols, etc. In this embodiment, these other distinguishing properties are also identified (410). It should be noted that the processing steps are performed in different order in other embodiments. In some embodiments, a subset of the processing steps is performed.

FIG. 5 is a flowchart illustrating the details of the email address identification step shown in FIG. 4. First, the message is scanned to find candidate sections that include top-level domain names (500). The top-level domain refers to the last section of an address, such as .com, .net, .uk, etc. 40 An email address includes multiple fields separated by periods. The top-level domain determines which fields form the actual domain name, according to well-known standards. For example, the address user1@server1.mailfrontier.com has a domain name that includes two fields (mailfrontier- 45 .com), while as user2@server1.mailfrontier.co.uk has a domain name that includes three fields (mailfrontier.co.uk). Thus, the top-level domain in a candidate section is identified (502), and the domain name is determined based on the top-level domain (504).

The presence of any required characters (such as @) is checked to determine whether the address is a valid email addresses (506). If the address does not include the require characters, it is invalid and its domain name should be excluded from the distinguishing properties (514). If the 55 required characters are included in the address, any forbidden characters (such as commas and spaces) in the address are also checked (508). If the address includes such forbidden characters, it is invalid and its domain name may be excluded from the distinguishing properties (514).

Sometimes, spammers embed decoy addresses-fake addresses that have well-known domain names-in the messages, attempting to confuse the spam-blocking software. In some embodiments, the decoy addresses are not included in the distinguishing properties. To exclude decoy 65 addresses, an address is checked against a white list of well-known domains (510), and is excluded from the dis-

tinguishing properties if a match is found (514). If the address is not found in the white list, it belongs to the distinguishing properties (512).

In some embodiments, a similar process is used to identify URL's. The domain names of the URL's are extracted and included in the distinguishing properties, and decoy URL's are discarded. Sometimes, spammers use numerical IP addresses to hide their domain names. By searching through the message for any URL that has the form http://x.x.x.x where the x's are integers between 0-255, these numerical IP addresses are identified and included in the distinguishing properties. More crafty spammers sometimes use obscure forms of URL's to evade detection. For example, binary numbers or a single 32 bit number can be used instead of the standard dotted notation. Using methods well-known to those skilled in the art, URL's in obscure forms can be identified and included in the distinguishing properties. In some embodiments, physical addresses, events, and stock quotes are also identified.

Once the distinguishing properties have been identified, the system generates one or more signatures based on the distinguishing properties and sends the signatures to the database. The signatures can be generated using a variety of methods, including compression, expansion, checksum, or any other appropriate method. In some embodiments, the data in the distinguishing properties is used directly as signatures without using any transformation. In some embodiments, a hash function is used to produce the signatures. Various hash functions are used in different embodiments, including MD5 and SHA. In some embodiments, the hash function is separately applied to every property in the set of distinguishing properties to produce a plurality of signatures. In one embodiment, any of the distinguishing properties must meet certain minimum byte requirement for 35 it to generate a corresponding signature. Any property that has fewer than a predefined number of bytes is discarded to lower the probability of signature collisions.

The generated signatures are transferred and stored in the database. In one embodiment, the signatures are formatted and transferred using extensible markup language (XML). In some embodiments, the signatures are correlated and the relationships among them are also recorded in the database. For example, if signatures from different messages share a certain signature combination, other messages that include the same signature combination may be classified as spam automatically. In some embodiments, the number of times each signature has been sent to the database is updated.

Using signatures to identify a message gives the system greater flexibility and allows it to be more expandable. For 50 example, the mail client software may only identify one type of distinguishing property in its first version. In later versions, new types of distinguishing properties are added. The system can be upgraded without requiring changes in the spam-blocking server and the database.

An improved system and method for classifying a message have been disclosed. The system identifies the distinguishing properties in an email message and generates one or more signatures based on the distinguishing properties. The signatures are stored in a database and used by spamblocking software to effectively block spam messages.

60

Although the foregoing invention has been described in some detail for purposes of clarity of understanding, it will be apparent that certain changes and modifications may be practiced within the scope of the appended claims. It should be noted that there are many alternative ways of implementing both the process and apparatus of the present invention. Accordingly, the present embodiments are to be considered 5

15

as illustrative and not restrictive, and the invention is not to be limited to the details given herein, but may be modified within the scope and equivalents of the appended claims.

What is claimed is:

1. A method for classifying messages, the method comprising:

- receiving an electronic message over a communication network; and
- executing instructions stored in memory, wherein execu- 10 tion of the instructions by a processor:
 - scans the received electronic message to identify candidate sections that include top-level domains, wherein the scanned candidate sections include the body of the received electronic message,
 - identifies one or more top-level domain names in each candidate section, wherein at least one of the identified top-level domain names is part of an email address
 - verifies that the email address associated with the at 20 least one top-level domain name from the electronic message is valid based on detected presence of required characters,
 - identifies that the email address associated with the at least one top-level domain name from the electronic 25 message does not include any forbidden characters,
 - characterizes the electronic message as having one or more distinguishing features based on the verification that the email address includes the required characters and the identification that the email 30 address does not include the forbidden characters, wherein the distinguishing features include at least email addresses that have the required characters and that lack the forbidden characters,
 - generates a signature for the characterized electronic 35 message based on a set of distinguishing features; and
- storing the generated signature for the electronic message in memory for comparison to subsequently received electronic messages. 40

2. The method of claim 1, wherein the generated signature corresponds to the received electronic message characterized as being spam.

3. The method of claim 2, wherein the generated signatures for spam are stored in a database that includes other 45 having embodied thereon a program executable by a prosignatures associated with electronic messages characterized as being spam.

4. The method of claim 3, wherein the spam database includes information related to how many times a particular signature has been associated with an electronic message 50 characterized as being spam.

5. The method of claim 1 further comprising excluding email addresses associated with the received electronic message characterized as being decoys.

6. The method of claim 5, wherein the exclusion of decoy 55 email addresses is performed by comparing the verified one or more email addresses against a list of well-known domains.

7. The method of claim 1, wherein the identified candidate sections further includes URLs. 60

8. The method of claim 7, wherein the URLs have identifiable IP addresses that are characterized as one or more distinguishing features for the received electronic message.

9. The method of claim 1, wherein generation of the 65 signature includes transformation of the set of distinguishing features via compression, expansion, or checksum.

10. The method of claim 1, wherein generation of the signature is based on the use of the set of distinguishing features without any transformation.

11. The method of claim 1, wherein generation of the signature is performed using a hash function.

12. The method of claim 1 further comprising correlating the stored signatures thereby obtaining one or more relationships that is used to characterize subsequently received electronic messages.

- 13. A system for classifying messages, comprising:
- a user device that receives electronic messages over a communication network;
- a processor that executes instructions stored in memory to:
 - scan the received electronic messages from the mail device to identify candidate sections that include top-level domains, wherein the scanned candidate sections include the body of the received electronic message
 - identify one or more top-level domains in each candidate section, wherein at least one of the identified top-level domain names is part of an email address,
 - verify that an email address associated with the at least one top-level domain name from the electronic message is valid based on detected presence of required characters,
 - identify that the email address associated with the electronic message does not include any forbidden characters,
 - characterize the electronic message as having one or more distinguishing features based on the verification that the email address has the required characters and the identification that the email addresses does not include the forbidden characters, wherein the distinguishing features include at least email addresses that have the required characters and that lack the forbidden characters, and
 - generate a signature for the characterized electronic message based on a set of distinguishing features; and
- a server that stores the generated signature for the electronic message for comparison to subsequently received electronic messages.

14. A non-transitory computer-readable storage medium, cessor to perform a method for classifying messages, the method comprising:

- receiving an electronic message over a communication network; and
- scanning the received electronic message to identify candidate sections that include top-level domains, wherein the scanned candidate sections include the body of the received electronic message;
- identifying one or more top-level domain names in each candidate section, wherein at least one of the identified top-level domain names is part of an email address;
- verifying that the email address associated with the at least one top-level domain name from the electronic message is valid based on detected presence of required characters:
- identifying that the email address associated with the at least one top-level domain name from the electronic message does not include any forbidden characters;
- characterizing the electronic message as having one or more distinguishing features based on the verification that the email address includes the required characters and the identification that the email address does not

10

include the forbidden characters, wherein the distinguishing features include at least email addresses that have the required characters and that lack the forbidden characters;

generating a signature for the characterized electronic 5 message based on a set of distinguishing features; and

storing the generated signature for the electronic message in memory for comparison to subsequently received electronic messages.
