(57) **ABSTRACT**

An oxide film capable of suppressing reflection of a lens is formed under a low temperature. A method of manufacturing a semiconductor device includes forming a metal-containing oxide film on a substrate by performing a cycle a predetermined number of times, the cycle comprising: (a) supplying a metal-containing source to the substrate; (b) supplying an oxidizing source to the substrate; and (c) supplying a catalyst to the substrate.

METHOD OF MANUFACTURING SEMICONDUCTOR DEVICE, SEMICONDUCTOR DEVICE AND SUBSTRATE PROCESSING APPARATUS

CROSS-REFERENCE TO RELATED PATENT APPLICATION

This application claims priority to and the benefit of Japanese Patent Applications No. 2010-261571 filed on Nov. 24, 2010 in the Japanese Patent Office, and is a continuous application of U.S. patent application Ser. No. 13/293,636 filed on Nov. 10, 2011, the entire contents of which are hereby incorporated by reference.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a method of manufacturing a semiconductor device, a semiconductor device, and a substrate processing apparatus.

2. Description of the Related Art

A micro lens configured to collect light for a light receiving element installed on, for example, a semiconductor device, has been used in semiconductor devices such as complementary metal oxide semiconductor (CMOS) image sensors. As the CMOS image sensor is highly integrated, light-collecting efficiency of the lens has been promoted to receive more sufficient incident light through the micro lens.

PRIOR ART DOCUMENTS

Patent Documents

1. Japanese Patent Laid-open Publication No.: 2009-177079

2. U.S. Pat. No. 6,534,395

SUMMARY OF THE INVENTION

In order to improve light-collecting efficiency of a lens, for example, reflection of incident light from a surface of the lens may be suppressed. Since the reflection is more likely to occur as a difference in refractive index between media through which light passes, i.e., air (a low refractive index) and a lens (a high refractive index), increases, the reflection can be suppressed by forming a film of a material having a refractive index therebetween, for example, an oxide film, on the lens to attenuate the difference in refractive index. Such an oxide film has been formed on, for example, a lens formed on a substrate, using a source including a predetermined element and an oxidizing agent.

However, since the refractive index is fixedly determined by a kind of the oxide film and the difference in refractive index between the media is insufficiently attenuated by only installing the oxide film having a predetermined refractive index on the lens, the reflection may be insufficiently suppressed. That is, when an oxide film having a low refractive index closer to the air is selected, reflection at an interface with the lens cannot be easily suppressed, and when an oxide film having a high refractive index closer to the lens is selected, reflection at an interface with the air cannot be easily suppressed. In addition, when the lens is formed of for example, a resin material, since a substantial reactivity between the source and the oxidizing agent cannot be obtained under a low temperature at which no thermal denaturation occurs from the resin material, the oxide film cannot be easily formed.

Therefore, an object of the present invention is to form an oxide film capable of suppressing reflection of a lens under a low temperature.

According to an aspect of the present invention, there is provided a method of manufacturing a semiconductor device, including forming a metal-containing oxide film on a substrate by performing a cycle a predetermined number of times, the cycle including: (a) supplying a metal-containing source to the substrate; (b) supplying an oxidizing source to the substrate; and (c) supplying a catalyst to the substrate.

According to another aspect of the present invention, there is provided a method of manufacturing a semiconductor device, including forming a laminated film wherein a silicon-containing oxide film and a metal-containing oxide film are alternately stacked on a substrate by alternately performing, a predetermined number of times, (a) performing a first cycle a predetermined number of times, the first cycle including: supplying a silicon-containing source to the substrate; supplying an oxidizing source to the substrate; and supplying a catalyst to the substrate to form the silicon-containing oxide film; and (b) performing a second cycle a predetermined number of times, the second cycle including: supplying a metal-containing source to the substrate; supplying an oxidizing source to the substrate; and supplying a catalyst to the substrate to form the metal-containing oxide film.

According to still another aspect of the present invention, there is provided a method of manufacturing a semiconductor device, including: (a) forming a laminated film wherein a silicon-containing oxide film and a metal-containing oxide film are alternately stacked on a substrate by alternately performing, a predetermined number of times, (a-1) performing a first cycle a predetermined number of times, the first cycle including: supplying a silicon-containing source to the substrate; supplying an oxidizing source to the substrate; and supplying a catalyst to the substrate to form the silicon-containing oxide film; and (a-2) performing a second cycle a predetermined number of times, the second cycle including: supplying a metal-containing source to the substrate; supplying an oxidizing source to the substrate; and supplying a catalyst to the substrate to form the metal-containing oxide film; and (b) forming a silicon-containing oxide film on the laminated film by performing a third cycle a predetermined number of times, the third cycle including: supplying a silicon-containing source to the substrate; supplying an oxidizing source to the substrate; and supplying a catalyst to the substrate.

According to a method of manufacturing a semiconductor device, a semiconductor device and a substrate processing apparatus of the present invention, an oxide film capable of suppressing reflection of a lens can be formed under a low temperature.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a perspective view of a substrate processing apparatus in accordance with a first embodiment of the present invention;

FIG. **2** is a view of a process furnace in accordance with the first embodiment of the present invention, particularly showing a cross-sectional view of a process chamber;

FIG. **3** is a view of the process furnace in accordance with the first embodiment of the present invention, particularly showing a cross-sectional view taken along line A-A of the process chamber of FIG. **2**;

FIG. **4** is a flowchart illustrating a substrate processing process in accordance with the first embodiment of the present invention;

FIG. **5** is a gas supply timing chart of the substrate processing process in accordance with the first embodiment of the present invention;

FIGS. **6**A and **6**B are views for explaining a catalyst reaction of the substrate processing process in accordance with the first embodiment of the present invention;

FIG. **7** is a flowchart illustrating a substrate processing process in accordance with a second embodiment of the present invention;

FIG. **8** is a gas supply timing chart of the substrate processing process in accordance with the second embodiment of the present invention;

FIGS. **9**A and **9**B are views for explaining a catalyst reaction of the substrate processing process in accordance with the second embodiment of the present invention;

FIGS. **10**A and **10**B are schematic views showing a refractive index of a lens installed on a semiconductor device in accordance with a reference example and the first embodiment; and

FIGS. **11**A and **11**B are schematic views showing a refractive index of a lens installed on a semiconductor device in accordance with a related art example and the reference example.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

<Inventors' Comments>

First, before describing embodiments of the present invention, some comments from the inventors will be explained.

As described above, a semiconductor device such as a CMOS image sensor is manufactured by forming a light receiving element configured to convert light into an electrical signal, an interconnection configured to process the electrical signal, and so on, on a substrate. For example, a small lens (a micro lens) is installed over the light receiving element to collect light for the light receiving device.

In a conventional semiconductor device shown in FIG. **11**A, incident light **5** which arrives at a resist lens **10**, which is a lens formed of photo resist, partially arrives at a photo diode **30**, which is a light receiving element (a refractive light **7***a*), and is partially reflected (a reflective light **6***a*). Since a difference in refractive index between the air (refractive index: 1.0) and the resist lens **10** (refractive index: 1.6), through which light passes, is large, reflection can easily occur. For this reason, in the conventional semiconductor device, light-collecting efficiency of the resist lens **10** becomes insufficient, and thus, only a weak electrical signal having a large noise ratio may be obtained.

On a semiconductor device according to a reference example shown in FIG. **11**B, for example, a SiO film **20** is formed on a resist lens **10** as one method of suppressing reflection. The difference in refractive index is attenuated by the SiO film **20** (refractive index: 1.45) having a refractive index between the air and the resist lens **10** to somewhat suppress the reflection (reflective light **6***a* and **6***b*) on each film surface.

However, since the refractive index of the oxide film is fixedly determined by a kind of the oxide film such as the SiO film **20**, the reflection cannot be substantially suppressed by a predetermined oxide film only. While the refractive index is adjusted by appropriately selecting the kind of the oxide film to suppress the reflection at the film surface, when the oxide film having a refractive index closer to the air is formed, the reflection at a surface of the resist lens **10** cannot be easily suppressed, and when the oxide film having a refractive index closer to the resist lens **10** is formed, the reflection at an interface with the air cannot be easily suppressed.

In addition, in the semiconductor device according to the reference example, there have been problems involving a temperature upon film forming. The oxide film is formed on the lens of the substrate by supplying a source and an oxidizing source into a process chamber in which the substrate is accommodated and reacting the source and the oxidizing source. However, as described above, when the lens is formed of a resin material such as photo resist, under a temperature at which no thermal denaturation occurs from the resin material, for example, a low temperature equal to or lower than 200° C., reaction between the source and the oxidizing source cannot be sufficiently generated and the oxide film cannot be easily formed.

Therefrom, the inventors have performed research on means for solving these problems. As a result, it has been ascertained that, when an oxide film is formed, reflection can be suppressed by varying a refractive index of the oxide film in a thickness direction. In addition, it has been ascertained that the oxide film can be formed even under a low temperature by supplying catalyst or using plasma. The present invention is based on these discoveries by the inventors.

<First Embodiment>

A configuration of a substrate processing apparatus in accordance with a first embodiment of the present invention will be described below.

(1) Entire Configuration of Substrate Processing Apparatus

FIG. **1** is a perspective view of a substrate processing apparatus **101** of the embodiment.

As shown in FIG. **1**, the substrate processing apparatus **101** in accordance with the embodiment includes a housing **111**. In order to convey a wafer **200**, which is a substrate, into/from the housing **111**, a cassette **110**, which is a wafer carrier (a substrate receiving vessel) configured to receive a plurality of wafers **200**, is used. A cassette loading/unloading port (a substrate-receiving vessel loading/unloading port, not shown), which is an opening through the cassette **110** is conveyed into/from the housing **111**, is installed in the front of the housing **111**. A cassette stage **114** (a substrate-receiving vessel delivery platform) is installed inside the cassette loading/unloading port inside the housing **111**. The cassette **110** is placed on the cassette stage **114** by a conveyance apparatus in a factory (not shown), is configured to be unloaded to the outside of the housing **111** from above the cassette stage **114**.

The cassette **110** is configured to be placed on the cassette stage **114** by the conveyance apparatus in the factory such that the wafer **200** in the cassette **110** is in a vertical posture and a wafer entrance of the cassette **110** is directed upward. The cassette stage **114** is configured such that the cassette **110** is rotated 90° toward a rear side of the housing **111** to place the wafer **200** in the cassette **110** in a horizontal posture, and the wafer entrance of the cassette **110** is directed to the rear side in the housing **111**.

A cassette shelf **105** (a substrate receiving vessel placing shelf) is installed at a substantially center portion in the housing **111** in a forward-backward direction. The cassette shelf **105** is configured to store a plurality of cassettes **110** in multiple rows and multiple columns. A transfer shelf **123**, in which the cassette **110** conveyed by a wafer transfer mechanism **125** (described later) is received, is installed at the

cassette shelf **105**. In addition, a preliminary cassette shelf **107** is configured to be installed over the cassette **114** to store a preliminary cassette **200**.

A cassette conveyance apparatus **118** (a substrate receiving vessel conveyance apparatus) is installed between the cassette stage **114** and the cassette shelf **105**. The cassette conveyance apparatus **118** includes a cassette elevator **118***a* (a substrate receiving vessel elevation mechanism) configured to go up/down with holding the cassette **110**, and a cassette conveyance mechanism **118***b* (a substrate receiving vessel conveyance mechanism), which is a conveyance mechanism that is horizontally movable while holding the cassette **110**. With a continuous operation of the cassette elevator **118***a* and the cassette conveyance mechanism **118***b*, the cassette **110** is configured to be conveyed to a predetermined position of the cassette shelf **105** other than the cassette stage **114** and the transfer shelf **123**, i.e., between the preliminary cassette shelf **107** and the transfer shelf **123**.

A wafer transfer mechanism **125** (a substrate transfer mechanism) is installed behind the cassette shelf **105**. The wafer transfer mechanism **125** includes a wafer transfer apparatus **125***a* (a substrate transfer apparatus) configured to horizontally rotate or straightly move the wafer **200**, and a wafer transfer apparatus elevator **125***b* (a substrate transfer apparatus elevation mechanism) configured to raise/lower the wafer transfer apparatus **125***a*. In addition, the wafer transfer apparatus **125***a* includes tweezers **125***c* (a substrate holder) configured to hold the wafer **200** in a horizontal posture. With a continuous operation of the wafer transfer apparatus **125***a* and the wafer transfer apparatus elevator **125***b*, the wafer **200** is picked up from the cassette **110** on the transfer shelf **123** to be charged on a boat **217** (a substrate holder, described later) (wafer charging), or the wafer **200** is discharged from the boat **217** (wafer discharging), receiving the wafer **200** into the cassette **110** on the transfer shelf **123**.

The process furnace **202** is installed at a rear upper side of the housing **111**. An opening is formed at a lower end of the process furnace **202**, and configured to be opened/closed by a furnace port shutter **147** (a furnace port opening/closing mechanism). In addition, a configuration of the process furnace **202** will be described later.

A transfer chamber **124**, which is a space for charging/discharging the wafer **200** from the cassette **110** on the transfer shelf **123** to the boat **217** (the substrate holder), is installed under the process furnace **202**. A boat elevator **115** (a substrate holder elevation mechanism), which is an elevation mechanism configured to raise/lower the boat **217** to load/unload the boat **217** into/from the process furnace **202**, is installed in the transfer chamber **124**. An arm **128**, which is a connecting tool, is installed at an elevation frame of the boat elevator **115**. A seal cap **219**, which is a furnace port cover configured to vertically support the boat **217** and to hermetically close the lower end of the process furnace **202** when the boat **217** is raised by the boat elevator **115**, is installed on the arm **128** in a horizontal posture.

The boat **217** includes a plurality of holding members, and is configured to hold a plurality of wafers **200** (for example, about 25 to 125) in a multi-stage in a state where the plurality of wafers **200** are concentrically aligned in a vertical direction and held in a horizontal posture.

A clean unit **134***a* including a supply fan and an anti-vibration filter is installed over the cassette shelf **105**. The clean unit **134***a* is configured to flow clean air of a purified atmosphere into the housing **111**.

In addition, a clean unit (not shown) including a supply fan for supplying clean air and an anti-vibration filter is installed at a left end of the housing **111** opposite to the wafer transfer apparatus elevator **125***b* and the boat elevator **115**. The clean air injected from the clean unit is suctioned into an exhaust apparatus (not shown) to be exhausted to the outside of the housing **111**, after flowing through the wafer transfer apparatus **125***a* and the boat **217**.

(2) Operation of Substrate Processing Apparatus

Hereinafter, an operation of the substrate processing apparatus **101** in accordance with the embodiment will be described.

First, the cassette **110** is placed on the cassette stage **114** such that the cassette **110** is loaded through the cassette loading/unloading port (not shown) by the conveyance apparatus in the factory, the wafer is in a vertical posture, and the wafer entrance of the cassette **110** is directed upward. Then, the cassette **110** is rotated 90° toward a rear side of the housing **111** by the cassette stage **114**. As a result, the wafer **200** in the cassette **110** is in a horizontal posture, and the wafer entrance of the cassette **110** is directed to a rear side in the housing **111**.

Next, the cassette **110** is automatically conveyed and delivered to a designated shelf position of the cassette shelf **105** (except for the transfer shelf **123**) or the preliminary cassette shelf **107** by the cassette conveyance apparatus **118**, temporarily stored, and then, transferred to the transfer shelf **123** from the cassette shelf **104** or the preliminary cassette shelf **107** or directly conveyed to the transfer shelf **123**.

When the cassette **110** is transferred to the transfer shelf **123**, the wafer **200** is picked up from the cassette **110** through the wafer entrance by the tweezers **125***c* of the wafer transfer apparatus **125***a* to be charged to the boat **217** at a rear side of the transfer chamber **124** by a continuous operation of the wafer transfer apparatus **125***a* and the wafer transfer apparatus elevator **125***b* (wafer charging). The wafer transfer mechanism **125**, which delivered the wafer **200** to the boat **217**, returns to the cassette **110**, and then charges the next wafer **200** to the boat **217**.

When a predetermined number of wafers **200** are charged to the boat **217**, the furnace port shutter **147** closing the lower end of the process furnace **202** is opened. Next, as the seal cap **219** is raised by the boat elevator **115**, the boat **217** holding the group of the wafer **200** is loaded into the process furnace **202** (boat loading). After the loading, arbitrary processing is performed on the wafer **200** in the process furnace **202**. Such processing will be described later. After the processing, the wafer **200** and the cassette **110** are unloaded to the outside of the housing **111** in reverse sequence of the above sequence.

(3) Configuration of Process Furnace

Next, a configuration of the process furnace **202** in accordance with the embodiment will be generally described with reference to FIGS. **2** and **3**. FIG. **2** is a configuration view of the process furnace **202** of the substrate processing apparatus **101** shown in FIG. **1**, particularly showing a cross-sectional view of a process chamber **201**. In addition, FIG. **3** is a cross-sectional view taken along line A-A of the process chamber **201** shown in FIG. **2**.

(Process Chamber)

The process furnace **202** in accordance with the embodiment is configured as a batch-type vertical hot-wall process furnace. The process furnace **202** includes a reaction tube **203** and a manifold **209**. The reaction tube **203** is formed of a heat resistant material such as quartz (SiO_2) or silicon carbide (SiC), and has a cylindrical shape with an upper end closed and a lower end opened. The manifold **209** is faulted of a metal material such as SUS, and has a cylindrical shape with upper and lower ends opened. The reaction tube **203** is vertically supported from the lower end side thereof by the manifold **209**. The reaction tube **203** is disposed concentrically with the manifold **209**. An O-ring **220**, which is a sealing

member, is installed between the reaction tube **203** and the manifold **209**. A lower end of the manifold **209** is configured to be hermetically sealed by the seal cap **219** when the boat elevator **115** is raised. An O-ring **220***b*, which is a sealing member configured to hermetically seal the inside of the process chamber **201**, is installed between the lower end of the manifold **209** and the seal cap **219**.

The process chamber **201** in which the wafer **200**, which is a substrate, is accommodated is formed in the reaction tube **203** and the manifold **209**. The boat **217**, which is a substrate holder, is configured to be inserted into the process chamber **201** from a lower side thereof. Inner diameters of the reaction tube **203** and the manifold **209** are configured to be larger than a maximum outline of the boat **217** to which the wafer **200** is charged.

The boat **217** is formed of a heat resistant material such as quartz or silicon carbide, and is configured to hold the plurality of wafers **200** in a multi-stage in a state where the plurality of wafers **200** are concentrically aligned and held in a horizontal posture. In addition, an insulating member **218** formed of a heat resistant material such as quartz or silicon carbide is installed at a lower part of the boat **217** to reduce heat transfer from a heater **207** (described later) to the seal cap **219**. Further, the insulating member **218** may be constituted by a plurality of insulating plates formed of a heat resistant material such as quartz or silicon carbide, and an insulating plate holder configured to support the plates in a horizontal posture in a multi-stage.

The seal cap **219**, which is a furnace port cover configured to hermetically close a lower end opening of the reaction tube **203**, is installed under the reaction tube **203**. The seal cap **219** abuts the lower end of the reaction tube **203** from a vertical lower side thereof. The seal cap **219** is formed of a metal material such as SUS and has a disc shape. An O-ring **220***b*, which is a seal member in contact with the lower end of the manifold **209**, is installed at an upper surface of the seal cap **219**.

A rotary mechanism **267** configured to rotate the boat **217** is installed at the seal cap **219** opposite to the process chamber **201**. A rotary shaft **255** of the rotary mechanism **267** is connected to the boat **217** through the seal cap **219** to rotate the boat **217**, thus rotating the wafer **200**. The seal cap **219** is configured to be vertically raised/lowered by the boat elevator **115**, which is an elevation mechanism vertically installed outside the reaction tube **203** such that the boat **217** can be loaded/unloaded into/from the process chamber **201**.

The heater **207**, which is a heating unit having a cylindrical shape concentric with the reaction tube **203**, is installed at an outer circumference of the reaction tube **203**. The heater **207** is supported by a heater base (not shown), which is a holding plate, to be installed vertically. In addition, the heater **207** functions as an activation mechanism configured to activate a gas using heat.

A temperature sensor **263**, which is a temperature detector, is installed in the reaction tube **203**, and a conduction state to the heater **207** is adjusted based on temperature information detected by the temperature sensor **263** such that a temperature in the process chamber **201** becomes a desired temperature distribution. The temperature sensor **263** has an L shape similar to nozzles **400***a*, **400***b*, **400***c* and **400***d* (described later), and is installed along an inner wall of the reaction tube **203**.

Mainly, the process chamber **201** is constituted by the reaction tube **203**, the manifold **209** and the seal cap **219**, and the process furnace **202** is constituted by the heater **207**, the reaction tube **203**, the manifold **209** and the seal cap **219**.

(Nozzle)

A first nozzle **400***a*, a second nozzle **400***b*, a third nozzle **400***c* and a fourth nozzle **400***d* are installed at a lower portion of the reaction tube **203** in the process chamber **201** to pass through a sidewall of the manifold **209**. Each of the nozzles **400***a*, **400***b*, **400***c* and **400***d* is constituted as an L-shaped long nozzle.

Specifically, the nozzles **400***a*, **400***b*, **400***c* and **400***d* are installed in a vertical posture in an arc-shaped space between the inner wall of the reaction tube **203** and the wafer **200** from a lower portion to an upper portion of the inner wall of the reaction tube **203** upward in a stacking direction of the wafers **200**. Gas supply holes **401***a*, **401***b*, **401***c* and **401***d* configured to supply a gas are installed at side surfaces of the nozzles **400***a*, **400***b*, **400***c* and **400***d*, respectively. The gas supply holes **401***a*, **401***b*, **401***c* and **401***d* are opened toward a center of the reaction tube **203**. The plurality of gas supply holes **401***a*, **401***b*, **401***c* and **401***d* are installed from the lower portion to the upper portion of the reaction tube **203**, each of which has the same opening area at the same opening pitch.

In addition, as shown in FIG. **3**, the nozzles **400***a*, **400***b*, **400***c* and **400***d* are installed at positions opposite to the temperature sensor **263**, for example, with the wafer **200** interposed therebetween. However, in FIG. **2**, in order to show structures of the nozzles **400***a*, **400***b*, **400***c* and **400***d*, for the sake of convenience, the third nozzle **400***c* and the fourth nozzle **400***d* and their subsidiary gas supply pipes **410***c* and **410***d* are shown at a right side of the drawing opposite to the first nozzle **400***a* and the second nozzle **400***b*.

(First Processing Source Supply Part) A downstream end of a first processing source gas supply pipe **410***a* configured to supply a Si-containing gas, which is a first processing source including silicon (Si) as a first element, for example, hexachlorodisilane (HCD: Si_2Cl_6) gas, is connected to an upstream end (a lower portion) of the first nozzle **400***a*. An HCD supply source (not shown) configured to supply a liquid source, which is in a liquid phase at room temperature, a liquid mass flow controller **411***a*, which is a flow rate controller (a flow rate control unit), a valve **412***a*, which is an opening/closing valve, an evaporator **415***a*, and a valve **413***a*, which is an opening/closing valve, are installed at the first processing source supply pipe **410***a* in a sequence from an upstream side thereof.

A downstream end of a carrier gas supply pipe **420***a* configured to supply a carrier gas such as nitrogen (N_2) gas supplied into the process chamber **201** with HCD gas generated in the evaporator **415***a* is connected to the evaporator **415***a*. A carrier gas supply source (not shown), a mass flow controller **421***a*, which is a flow rate controller (a flow rate control unit), and a valve **422***a*, which is an opening/closing valve, are installed at the carrier gas supply pipe **420***a* in a sequence from the upstream side thereof. When the valve **412***a* is opened and liquid HCD whose flow rate is controlled by a liquid mass flow controller **411***a* is supplied into the evaporator **415***a*, the evaporator **415***a* is configured to heat the supplied HCD to generate a vaporized gas of the HCD. From the state in which the HCD gas is generated in the evaporator **415***a*, the valve **422***a* is opened, the carrier gas whose flow rate is controlled by the mass flow controller **421***a* is supplied into the evaporator **415***a*, and the valve **413***a* is opened, such that the HCD gas can be supplied into the process chamber **201** with the carrier gas.

A downstream end of a purge gas supply pipe **430***a* configured to supply a purge gas such as N_2 gas is connected to the first processing source supply pipe **410***a* at a lower side of the valve **413***a*. A purge gas supply source (not shown), a mass flow controller **431***a*, which is a flow rate controller (a flow rate control unit), and a valve **432***a*, which is an opening/

closing valve, are installed at the purge gas supply pipe **430**_a_ in a sequence from the upstream side thereof. As the valve **432**_a_ is opened, the purge gas can be supplied into the process chamber **201** from the purge gas supply source while controlling a flow rate by the mass flow controller **431**_a_. For example, after completion of supply of the HCD gas, as the purge gas is supplied while exhausting the inside of the process chamber **201**, the HCD gas remaining in the process chamber **201** can be eliminated.

A first processing source supply part configured to supply a first processing source into the process chamber **201** is mainly constituted by the first processing source supply pipe **410**_a_, the HCD supply source, the liquid mass flow controller **411**_a_, the valve **412**_a_, the evaporator **415**_a_, the valve **413**_a_, the carrier gas supply pipe **420**_a_, the carrier gas supply source, the mass flow controller **421**_a_, the valve **422**_a_, the first nozzle **400**_a_ and the gas supply hole **401**_a_.

(Second Processing Source Supply Part)

A downstream end of a second processing source supply pipe **410**_b_ configured to supply a Ti-containing gas as a second processing source including titanium (Ti) as a second element, for example, tetrachlorotitanium ($TiCl_4$) gas, is connected to an upstream end (a lower portion) of the second nozzle **400**_b_. A $TiCl_4$ supply source (not shown) configured to supply $TiCl_4$ as a liquid source, which is liquid at room temperature, a liquid mass flow controller **411**_b_, which is a flow rate controller (a flow rate control unit), a valve **412**_b_, which is an opening/closing valve, an evaporator **415**_b_, and a valve **413**_b_, which is an opening/closing valve, are installed at the second processing source supply pipe **410**_b_ in a sequence from the upstream side thereof.

A downstream end of a carrier gas supply pipe **420**_b_ configured to supply a carrier gas such as N_2 gas supplied into the process chamber **201** with $TiCl_4$ gas generated in the evaporator **415**_b_ is connected to the evaporator **415**_b_. A carrier gas supply source (not shown), a mass flow controller **421**_b_, which is a flow rate controller (a flow rate control unit), and a valve **422**_b_, which is an opening/closing valve, are installed at the carrier gas supply pipe **420**_b_ in sequence from the upstream side thereof. Similar to the case of the first processing source, as the respective parts are operated, the $TiCl_4$ gas generated in the evaporator **415**_b_ can be supplied into the process chamber **201** with the carrier gas.

A downstream end of a purge gas supply pipe **430**_b_ configured to supply a purge gas such as N_2 gas is connected to the second processing source supply pipe **410**_b_ at a downstream side of the valve **413**_b_. A purge gas supply source (not shown), a mass flow controller **431**_b_, which is a flow rate controller (a flow rate control unit), and a valve **432**_b_, which is an opening/closing valve, are installed at the purge gas supply pipe **430**_b_ in a sequence from the upstream side thereof. Similar to the case of the purge gas, as the respective parts are operated, the purge gas can be supplied into the process chamber **201**, and thus, the $TiCl_4$ gas remaining in the process chamber **201** can be eliminated.

A second processing source supply part configured to supply a second processing source into the process chamber **201** is mainly constituted by the second processing source supply pipe **410**_b_, the $TiCl_4$ supply source, the liquid mass flow controller **411**_b_, the valve **412**_b_, the evaporator **415**_b_, the valve **413**_b_, the carrier gas supply pipe **420**_b_, the carrier gas supply source, the mass flow controller **421**_b_, the valve **422**_b_, the second nozzle **400**_b_ and the gas supply hole **401**_b_.

(Oxidizing Source Supply Part)

A downstream end of an oxidizing source supply pipe **410**_c_ configured to supply an oxidizing source such as an oxygen (O) containing gas, for example, vapor (H_2O gas), is connected to an upstream end (a lower portion) of the third nozzle **400**_c_.

A H_2O gas supply source (not shown) configured to supply H_2O gas, a mass flow controller **411**_c_, which is a flow rate controller (a flow rate control unit), and a valve **412**_c_, which is an opening/closing valve, are installed at the oxidizing source supply pipe **410**_c_ in a sequence from the upstream side thereof. Meanwhile, when the H_2O gas is supplied, oxygen (O_2) gas and hydrogen (H_2) gas may be supplied into a pyrogenic furnace to generate H_2O gas.

A downstream end of an inert gas supply pipe **420**_c_ configured to supply an inert gas such as N_2 gas is connected to a downstream side of the valve **412**_c_. An inert gas supply source (not shown), a mass flow controller **421**_c_, which is a flow rate controller (a flow rate control unit), and a valve **422**_c_, which is an opening/closing valve, are installed at the inert gas supply pipe **420**_c_ in sequence from the upstream side thereof. As the valves **412**_c_ and **422**_c_ are opened, the H_2O whose gas flow rate is controlled by the mass flow controller **412**_c_ can be supplied into the process chamber **201** with the inert gas, which is a carrier gas whose flow rate is controlled by the mass flow controller **422**_c_.

In addition, in a state in which the valve **422**_c_ is opened with the valve **412**_c_ closed and the flow rate is controlled by the mass flow controller **421**_c_, the inert gas is supplied into the process chamber **201** as a purge gas so that the H_2O gas, etc., remaining in the process chamber **201** can be eliminated. Further, similar to the case of the first processing source and the second processing source, the purge gas supply pipe configured to supply the purge may be installed separately from the inert gas supply pipe **420**_c_ configured to supply the carrier gas.

The oxidizing source supply part configured to supply the oxidizing source into the process chamber **201** is mainly constituted by the oxidizing source supply pipe **410**_c_, the H_2O gas supply source, the mass flow controller **411**_c_, the valve **412**_c_, the inert gas supply pipe **420**_c_, the inert gas supply source, the mass flow controller **421**_c_, the valve **422**_c_, the third nozzle **400**_c_ and the gas supply hole **401**_c_.

(Catalyst Supply Part)

A downstream end of a catalyst supply pipe **410**_d_ configured to supply a catalyst such as ammonia (NH_3) gas is connected to an upstream end (a lower portion) of the fourth nozzle **400**_d_. An NH_3 gas supply source (not shown) configured to supply NH_3 gas, a mass flow controller **411**_d_, which is a flow rate controller (a flow rate control unit), and a valve **412**_d_, which is an opening/closing valve, are installed at the catalyst supply pipe **410**_d_ in a sequence from the upstream side thereof.

A downstream end of an inert gas supply pipe **420**_d_ configured to supply an inert gas such as N_2 gas is connected to a downstream side of the valve **412**_d_. An inert gas supply source (not shown), a mass flow controller **421**_d_, which is a flow rate controller (a flow rate control unit), and a valve **422**_d_, which is an opening/closing valve, are installed at the inert gas supply pipe **420**_d_ in a sequence from the upstream side thereof. Similar to the case of the oxidizing source, as the respective operations are executed, the NH_3 gas can be supplied into the process chamber **201** with the inert gas, which is a carrier gas.

In addition, as the inert gas is supplied into the process chamber **201** as a purge gas, the NH_3 gas remaining in the process chamber **201** can be eliminated. Further, similar to the case of the first processing source or the second processing source, the purge gas supply pipe configured to supply the

purge gas may be installed separately from the inert gas supply pipe **420***d* configured to supply the carrier gas.

The catalyst supply part configured to the catalyst into the process chamber **201** is mainly constituted by the catalyst supply pipe **410***d*, the NH_3 gas supply source, the mass flow controller **411***d*, the valve **412***d*, the inert gas supply pipe **420***d*, the inert gas supply source, the mass flow controller **421***d*, the valve **422***d*, the fourth nozzle **400***d* and the gas supply hole **401***d*.

(Exhaust Part)

A gas exhaust pipe **231** configured to exhaust an atmosphere in the process chamber **201** is installed at the reaction tube **203**. A vacuum pump **246**, which is a vacuum exhaust apparatus, is connected to the gas exhaust pipe **231** via a pressure sensor **245**, which is a pressure detector (a pressure detection part) configured to detect a pressure in the process chamber **201** and an automatic pressure controller (APC) valve **243**, which is a pressure regulator (a pressure regulation part), and is configured such that the pressure in the process chamber **201** is vacuum-exhausted to a predetermined pressure (a level of vacuum). The APC valve **243** is an opening/closing valve capable of opening/closing the valve to perform vacuum exhaust/vacuum exhaust stoppage of the inside of the process chamber **201** and adjusting a valve opening angle to adjust the pressure.

In addition, as shown in FIG. **3**, the gas exhaust pipe **231** is installed at, for example, a lower sidewall of the reaction tube **203** between the first nozzle **400***a* and the temperature sensor **263**. However, in FIG. **2**, in order to show structures of the gas exhaust pipe **231**, the APC valve **243**, the vacuum pump **246** and the pressure sensor **245**, for the sake of convenience, the configuration including the gas exhaust pipe **231** is shown at a right side of the drawing opposite to the first nozzle **400***a* and the second nozzle **400***b*.

The exhaust part is mainly constituted by the gas exhaust pipe **231**, the APC valve **243**, the vacuum pump **246** and the pressure sensor **245**.

(Control Unit)

The controller **280**, which is a control unit, is connected to the liquid mass flow controllers **411***a*, **411***b* and **411***c*, the mass flow controllers **421***a*, **431***a*, **421***b*, **431***b*, **421***c*, **431***c*, **411***d* and **421***d*, the valves **412***a*, **413***a*, **422***a*, **432***a*, **412***b*, **413***b*, **422***b*, **432***b*, **412***c*, **413***c*, **422***c*, **432***c*, **412***d* and **422***d*, the APC valve **243**, the pressure sensor **245**, the vacuum pump **246**, the heater **207**, the temperature sensor **263**, the rotary mechanism **267**, the boat elevator **115**, and so on. The controller **280** controls the flow rate adjusting operations of various gases by the liquid mass flow controllers **411***a*, **411***b* and **411***c* and the mass flow controllers **421***a*, **431***a*, **421***b*, **431***b*, **421***c*, **431***c*, **411***d* and **421***d*, the opening/closing operations of the valves **412***a*, **413***a*, **422***a*, **432***a*, **412***b*, **413***b*, **422***b*, **432***b*, **412***c*, **413***c*, **422***c*, **432***c*, **412***d* and **422***d*, the pressure regulating operations based on the opening/closing of the APC valve **243** and the pressure sensor **245**, the temperature control operation of the heater **207** based on the temperature sensor **263**, the start/stop of the vacuum pump **246**, the rotational speed adjusting operation of the rotary mechanism **267**, the elevating operation of the boat elevator **115**, and so on.

(4) Substrate Processing Process

Next, the substrate processing process in accordance with the embodiment will be described. The substrate processing process in accordance with the embodiment, which is one process of a process of manufacturing a semiconductor device such as a CMOS image sensor, is performed by the process furnace **202**, and similar to FIG. **10***b*, which will be described in detail, a silicon titanium oxide (SiTiO) film **21** having a high refractive index and a silicon oxide (SiO) film **20** having a low refractive index are sequentially formed on the resist lens **10**. In addition, the SiO film is a silicon oxide film having an arbitrary composition ratio including SiO_2.

A film forming method includes a chemical vapor deposition (CVD) method in which a plurality of gases containing a plurality of elements constituting a film to be formed are simultaneously supplied, and an atomic layer deposition (ALD) method in which a plurality of gases containing a plurality of elements constituting a film to be formed are alternately supplied. Then, the silicon oxide (SiO) film, etc., is formed by controlling supply conditions such as a gas supply flow rate, a gas supply time, a plasma power, and so on, upon the gas supply.

In these film forming methods, for example, supply conditions are controlled such that a composition ratio of the film becomes $N/Si \approx 1.33$, which is a stoichiometric composition, when a titanium nitride (SiN) film is formed, and a composition ratio of the film becomes $O/Si \approx 2$, which is a stoichiometric composition, when a silicon oxide (SiO) film is formed.

In addition, supply conditions may be controlled such that a composition of a film to be formed becomes another predetermined composition ratio different from a stoichiometric composition. That is, the supply conditions may be controlled such that at least one element among the plurality of elements constituting the film to be formed exceeds the stoichiometric composition more than another element. As described above, the film forming may be performed while controlling a ratio of the plurality of elements constituting the film to be formed (the composition ratio of the film).

Further, the term "metal film" means a film formed of a conductive material containing metal atoms, and includes, in addition to a conductive metal mono-film formed of a metal monomer, a conductive metal nitride film, a conductive metal oxide film, a conductive metal oxynitride film, a conductive metal complex film, a conductive metal alloy film, a conductive metal silicide film, and so on. For example, the titanium nitride layer is a conductive metal nitride film.

Hereinafter, the substrate processing process in accordance with the embodiment will be described in detail with reference to FIGS. **4** and **5**. FIG. **4** is a flowchart of the substrate processing process performed by the process furnace **202**. In addition, FIG. **5** is a timing chart showing each gas supply timing when supply of the respective gases is alternately repeated according to the embodiment. In the following description, operations of the respective parts constituting the process furnace **202** shown in FIG. **2** are controlled by the controller **280**.

<Substrate Loading Process S**101**>

First, the plurality of wafers **200** on which the resist lenses **10** are previously formed are charged to the boat **217** (wafer charging). Then, the boat **217** on which the plurality of wafers **200** are held is raised by the boat elevator **115** to be loaded into the process chamber **201** (boat loading). In this state, the seal cap **219** seals the lower end of the manifold **209** via the O-ring **220***b*. In the substrate loading process S**101**, the valves **432***a* and **432***b* of the purge gas supply pipes **430***a* and **430***b* and the valves **422***c* and **422***d* of the inert gas supply pipes **420***c* and **420***d* may be opened to continuously supply the purge gas such as N_2 gas into the process chamber **201**.

<Pressure Reduction Process S**102** and Temperature Increase Process S**103**>

Next, the valves **432***a*, **432***b*, **422***c* and **422***d* are closed, and the inside of the process chamber **201** is exhausted by the vacuum pump **246**. At this time, as an opening angle of the APC valve **243** is adjusted, the inside of the process chamber **201** is under a predetermined pressure. In addition, the tem-

perature in the process chamber **201** is controlled by the heater **207** such that the wafer **200** arrives at a desired temperature, for example, room temperature to 200° C., more preferably, room temperature to 150° C., for example, 100° C. At this time, a conduction state to the heater **207** is feedback controlled based on temperature information detected by the temperature sensor **263** such that the inside of the process chamber **201** arrives at a desired temperature distribution. Then, the boat **217** is rotated by the rotary mechanism **267** to initiate rotation of the wafer **200**.

<Lower Layer Oxide Film Forming Process S**104***a* to S**106**>

Next, processes S**104***a* to S**106** of FIG. **4** are performed to form a SiTiO film **21**, which is a lower layer oxide film (a high refractive index oxide film), on the resist lens **10** formed on the wafer **200** (see FIG. **10**B). The lower layer oxide film forming process S**104***a* to S**106** includes a first cycle process of setting processes S**104***a* to S**104***d* as one cycle and performing the cycle a predetermined number of times S**104***e*, and a second cycle process of setting processes S**105***a* to S**105***d* as one cycle and performing the cycle a predetermined number of times S**105***e*. The first cycle process S**104***a* to S**104***e* and the second cycle process S**105***a* to S**105***e* are set as one set, and the set is performed with a predetermined combination a predetermined number of times (S**106**), forming the SiTiO film **21**. In addition, the SiTiO film **21** is a complex oxide film of Si and Ti having an arbitrary composition ratio. Hereinafter, the first cycle process S**104***a* to S**104***e* and the second cycle process S**105***a* to S**105***e* will be described in detail.

<First Processing Source and Catalyst Supply Process S**104***a*>

In the first processing source and catalyst supply process S**104***a* of the first cycle process S**104***a* to S**104***e*, HCD gas, which is a first processing source, and NH_3 gas, which is a catalyst, are supplied into the process chamber **201**.

Specifically, first, before initiating supply of the HCD gas, the HCD gas is previously generated in the evaporator **415***a*. That is, the valve **412***a* is opened, and liquid HCD is supplied into the evaporator **415***a* while controlling a flow rate by the liquid mass flow controller **411***a*, generating the HCD gas. When the HCD gas is supplied, the valve **422***a* is opened, and the carrier gas is supplied into the evaporator **415***a* while controlling a flow rate by the mass flow controller **421***a*. In addition, the valve **413***a* is opened, and the generated HCD gas is supplied into the process chamber **201** with the carrier gas.

In addition, the valves **412***d* and **422***d* are opened, and the NH_3 gas is supplied into the process chamber **201** with the inert gas, which is a carrier gas, while controlling flow rates by the mass flow controllers **411***d* and **421***d*, respectively.

When the HCD gas and the NH_3 gas are supplied into the process chamber **201**, an opening angle of the APC valve **243** is adjusted to bring the inside of the process chamber **201** to a predetermined pressure, for example, 10 Torr. A flow rate ratio of the HCD gas and the NH_3 gas is a ratio of a flow rate (sccm) of the HCD gas/a flow rate (sccm) of the NH_3 gas, for example, 0.01 to 100, more preferably 0.05 to 10. A supply time of the HCD gas and the NH_3 gas is, for example, 1 second to 100 seconds, more preferably, 5 seconds to 30 seconds. When a predetermined time elapses, the valves **412***a*, **413***a*, **422***a* and **412***d* are closed, and supply of the HCD gas and the NH_3 gas into the process chamber **201** is stopped. In addition, the valve **422***d* is kept open.

As described above, the HCD gas and the NH_3 gas supplied into the process chamber **201** pass over the wafer **200** to be exhausted through the gas exhaust pipe **231**. When the HCD gas passes over the wafer **200**, the HCD gas is chemisorbed to a surface of the resist lens **10** on the wafer or a surface of a Si-containing layer formed by adsorbing HCD molecule (or decomposed matters thereof) on the resist lens **10**, forming the Si-containing layer.

The NH_3 gas accelerates formation of the Si-containing layer by chemosorption of the HCD gas. That is, as shown in FIG. **6**A, the NH_3 gas, which is a catalyst, is reacted with an OH-bond of a surface of, for example, the resist lens **10** or the Si-containing layer, weakening a bonding force between 0-H. Hydrogen (H), a bonding force of which is weakened, is reacted with chlorine (Cl) of the HCD gas to separate hydrogen chloride (HCl) gas, and HCD molecules (a halide), from which Cl is lost, is chemisorbed with the surface of the resist lens **10**, etc. The NH_3 gas weakens the bonding force between 0-H because N atoms having lone electron pairs in the NH_3 molecules function to pull H. Since the NH_3 gas has an acid dissociation constant (hereinafter referred to as pKa), which is an index of a force pulling H, of about 9.2, the force pulling H is relatively strong.

<Exhaust Process S**104***b*>

As described above, after a predetermined time has elapsed to stop supply of the HCD gas and the NH_3 gas, the APC valve **243** is opened to exhaust an atmosphere in the process chamber **201**, eliminating the remaining HCD gas, NH_3 gas, decomposed matters after reaction (an exhaust gas), and so on. In addition, in a state in which the valve **422***d* is opened, the valve **432***a* is opened, and the purge gas is supplied into the process chamber **201** while controlling a flow rate by the mass flow controllers **431***a* and **421***d*. At this time, the valves **432***b* and **422***c* may be further opened, and the purge gas may be supplied through the purge gas supply pipe **430***b* or the inert gas supply pipe **420***c*. Accordingly, the effect of eliminating the remaining gas from the inside of the process chamber **201** can be further improved. After a predetermined time elapses, the valves **432***a* and **422***d* are closed and the exhaust process S**104***b* is terminated.

<Oxidizing Source and Catalyst Supply Process S**104***c*>

After removing the remaining gas in the process chamber **201**, the H_2O gas, which is an oxidizing source, and the NH_3 gas, which is a catalyst, are supplied into the process chamber **201**. That is, the valves **412***c* and **422***c* are opened, and the H_2O gas is supplied into the process chamber with the inert gas, which is a carrier gas, while controlling flow rates by the mass flow controllers **411***c* and **421***c*. In addition, in the same sequence as the first processing source and catalyst supply process S**104***a*, the NH_3 gas is supplied into the process chamber **201** with the inert gas, which is a carrier gas.

When the H_2O gas and the NH_3 gas are supplied into the process chamber **201**, the pressure in the process chamber **201** is, for example, 10 Torr. In addition, for example, a ratio of a flow rate (sccm) of the H_2O gas/a flow rate (sccm) of the NH_3 gas is 0.01 to 100, more preferably, 0.05 to 10. At this time, it is more preferable that mass percent concentrations of the H_2O gas and the NH_3 gas are substantially equal to each other. The supply time of the gases may be, for example, 1 second to 100 seconds, more preferably, 5 seconds to 30 seconds. When a predetermined time elapses, the valves **412***c* and **412***d* are closed, and supply of the H_2O gas and the NH_3 gas into the process chamber **201** is stopped. In addition, the valves **422***c* and **422***d* are kept open.

As described above, the H_2O gas and the NH_3 gas supplied into the process chamber **201** pass over the wafer **200** to be exhausted through the gas exhaust pipe **231**. When passing over the wafer **200**, the H_2O gas surface-reacts with the Si-containing layer, etc., formed on the resist lens **10**, and the Si-containing layer, etc., is oxidized to be converted into a

SiO layer. In addition, the SiO layer is a silicon oxide layer having an arbitrary composition ratio including SiO_2.

The NH_3 gas accelerates the surface reaction of the H_2O gas with the Si-containing layer. That is, as shown in FIG. **6**B, the NH_3 gas, which is a catalyst, reacts with an O—H bond included in the H_2O gas to weaken the bonding force between O—H. H, a bonding force of which is weakened, reacts with Cl included in the Si-containing layer on the resist lens **10** to separate hydrogen chloride (HCl) gas, and O of the H_2O gas, from which H is lost, is added to Si, from which Cl is separated.

<Exhaust Process S**104***d*>

After stopping supply of the H_2O gas and the NH_3 gas, the APC valve **243** is opened to exhaust the atmosphere in the process chamber **201**, and the remaining H_2O gas, NH_3 gas, decomposed matters after reaction (exhaust gas), etc., are eliminated. In addition, the inert gas, which is a purge gas, is supplied into the process chamber **201** while controlling flow rates by the mass flow controllers **421***c* and **421***d* via the valves **422***c* and **422***d* in an open state. At this time, another purge gas supply pipe may be used. After a predetermined time elapses, the valves **422***c* and **422***d* are closed to stop the exhaust process S**104***d*.

<Process of Performing Predetermined Number of Times S**104***e*)>

The processes S**104***a* to S**104***d* are set as one cycle and the cycle is performed a predetermined number of times, forming the SiO layer on the resist lens **10** of the wafer **200** to a predetermined film thickness, for example, 2.0 Å to 10,000 Å. FIG. **5** shows an example in which the cycle is performed p times. A horizontal axis of FIG. **5** represents elapsed time, and a vertical axis of FIG. **5** represents a gas supply timing of each gas. From the above, the first cycle process S**104***a* to S**104***e* is terminated.

As described above, in each of the first processing source and catalyst supply process S**104***a* and the oxidizing source and catalyst supply process S**104***c*, since the NH_3 gas is used as a catalyst, chemisorption of the HCD gas can be accelerated even under a low temperature, and surface reaction of the H_2O gas can also be accelerated. As described above, as the SiO layer is formed under a low temperature, thermal denaturation of the resist lens **20** can be suppressed and occurrence of bad resist lenses **10** can be reduced.

<Second Processing Source and Catalyst Supply Process S**105***a*>

In the second processing source and catalyst supply process S**105***a* of the second cycle process S**105***a* to S**105***e*, $TiCl_4$ gas, which is a second processing source, and NH_3 gas, which is a catalyst, are supplied into the process chamber **201**.

Specifically, first, before initiating supply of the $TiCl_4$ gas, the $TiCl_4$ gas is previously generated in the evaporator **415***b*. That is, the valve **412***b* is opened, and liquid $TiCl_4$ is supplied into the evaporator **415***b* to generate the $TiCl_4$ gas while controlling a flow rate of the liquid mass flow controller **411***b*. When the $TiCl_4$ gas is supplied, the valve **422***b* is opened, and the carrier gas is supplied into the evaporator **415***b* while controlling a flow rate by the mass flow controller **421***b*. In addition, the valve **413***b* is opened, and the generated $TiCl_4$ gas is supplied into the process chamber **201** with the carrier gas. Further, in a sequence similar to the first processing source and catalyst supply process S**104***a*, the NH_3 gas is supplied into the process chamber **201** with the inert gas, which is a carrier gas.

The pressure, supply amount and supply time of the gas, etc., when the $TiCl_4$ gas and the NH_3 gas are supplied into the process chamber **201** may be the same as in the first processing source and catalyst supply process S**104***a*. When a predetermined time elapses, the valves **412***b*, **413***b*, **422***b* and **412***d* are closed, and supply of the $TiCl_4$ gas and the NH_3 gas into the process chamber **201** is stopped. In addition, the valve **422***d* is kept open.

Similar to the first processing source and catalyst supply process S**104***a*, chemisorption of the $TiCl_4$ gas is accelerated by the NH_3 gas, and a Ti-containing layer is formed on a surface of the SiO layer, a surface of the already formed Ti-containing layer, etc.

<Exhaust Process S**105***b*>

After stopping supply of the $TiCl_4$ gas and the NH_3 gas, the APC valve **243** is opened to exhaust the atmosphere in the process chamber **201** and the remaining $TiCl_4$ gas or NH_3 gas, decomposed matters after reaction (exhaust gas), etc., are eliminated. In addition, the valve **432** is further opened in a state in which the valve **422***d* is opened, and the purge gas is supplied into the process chamber **201** while controlling a flow rate by the mass flow controller **431***b* and **421***d*. At this time, another purge gas supply pipe, etc., may be used. After a predetermined time elapses, the valves **432***b* and **422***d* are closed to stop the exhaust process S**105***b*.

<Oxidizing Source and Catalyst Supply Process S**105***c*>

In a sequence and processing conditions similar to the oxidizing source and catalyst supply process S**104***c*, the H_2O gas and the NH_3 gas are supplied into the process chamber **201**. The Ti-containing layer, etc., is oxidized by a reaction similar to the oxidizing source and catalyst supply process S**104***c* to be converted into a TiO layer. In addition, the TiO layer is a titanium oxide layer, which is a metal oxide layer, having an arbitrary composition ratio including TiO_2.

<Exhaust Process S**105***d*>

In a sequence similar to the exhaust process S**104***d*, the atmosphere in the process chamber **201** is exhausted to eliminate the remaining H_2O gas, etc. In addition, the purge gas is supplied into the process chamber **201**.

<Process S**105***e* of Performing Predetermined Number of Times>

The processes S**105***a* to S**105***d* are set as one cycle and the cycle is performed a predetermined number of times. The TiO layer is formed on the SiO layer of the wafer **200** to a predetermined film thickness, for example, 2.0 Å to 10,000 Å. FIG. **5** shows an example in which the cycle is performed q times. From the above, the second cycle process S**105***a* to S**105***e* is terminated.

As described above, even when the TiO layer is formed using the $TiCl_4$ gas, the NH_3 gas may be used as a catalyst in each of the second processing source and catalyst supply process S**105***a* and the oxidizing source and catalyst supply process S**105***c*, accelerating chemisorption of the $TiCl_4$ gas even under a low temperature and also accelerating surface reaction of the H_2O gas. As described above, when the TiO layer is formed under a low temperature, thermal denaturation of the resist lens **10** can be suppressed to reduce occurrence of a bad resist lens **10**.

<Process S**106** Performed Predetermined Number of Times>

In the process S**106** performed a predetermined number of times, the first cycle process S**104***a* to S**104***e* and the second cycle process S**105***a* to S**105***e* are set as one set, and the set is performed with a predetermined combination a predetermined number of times (for example, p times and q times, respectively), forming the SiTiO film **21** on the resist lens **10** of the wafer **200** to a predetermined film thickness, for example, 50 Å to 20,000 Å (see FIG. **10**B).

Since a refractive index of the TiO layer is 2.2, which is relatively higher than 1.45—a refractive index of the SiO—as described above, the SiTiO film **21** formed by depositing the

SiO layer and the TiO layer can obtain a high refractive index closer to the resist lens **10** than in the SiO film formed on its own. In addition, the SiTiO film **21** having a predetermined refractive index may be formed by arbitrarily adjusting a deposition ratio of the TiO layer with respect to the SiO layer. The deposition ratio may be adjusted by the combination, i.e., the number of times each cycle process is performed. For example, when the number of times the first cycle process S**104***a* to S**104***e* is performed is 3 (p=3) and the number of times of the second cycle process S**105***a* to S**105***e* is performed is 2 (q=2), the SiTiO film **21** having a refractive index of 1.55 can be obtained. In addition, when p=3 and q=1, the refractive index becomes 1.50. The refractive index of the SiTiO film **21** is selected within a range of more than a refractive index of air to less than a refractive index of the resist lens **10**.

In addition, in a state in which the arbitrary combination is maintained, as the first cycle process S**104***a* to S**104***e* and the second cycle process S**105***a* to S**105***e* are set as one set and the number of times the set is performed is varied, the film thickness of the SiTiO film **21** can be controlled in a state in which a predetermined refractive index is maintained. Further, the first cycle process S**104***a* to S**104***e* and the second cycle process S**105***a* to S**105***e* may be performed in an arbitrary sequence, and the lower layer oxide film forming process S**104***a* to S**106** may be initiated from an arbitrary process or may be terminated at an arbitrary process. For example, the lower layer oxide film forming process S**104***a* to S**106** may be initiated from the second cycle process S**105***a* to S**105***e* and may be terminated at the second cycle process S**105***a* to S**105***e*.

<Upper Layer Oxide Film Forming Process S**107***a* to S**107***e*>

Next, the processes S**107***a* to S**107***d* are set as one cycle and the cycle is performed a predetermined number of times S**107***e*, forming the SiO film **20** on the SiTiO film **21** of the wafer **200** as an upper layer oxide film (a low refractive index oxide film) (see FIG. **10**B). Each process of the processes S**107***a* to S**107***d* is performed in a sequence and processing conditions similar to each process of the processes S**104***a* to S**104***d*. Since these processes are performed a predetermined number of times, the SiO film **20** is formed on the SiTiO film **21** to a predetermined film thickness, for example, 50 Å to 10,000 Å. At this time, the refractive index of the SiO film **20** is within a range of more than the refractive index of air to less than the refractive index of the SiTiO film **21**. FIG. **5** shows an example in which the cycle is performed r times.

As described above, in this embodiment, the SiO film **20** having a relatively low refractive index is formed on the SiTiO film **21** having a relatively high refractive index to gradually reduce the refractive index in a thickness direction from the resist lens **10** to the air. Accordingly, in comparison with the case of forming only the SiO film **20**, a difference in refractive index between the media can be further attenuated to further suppress the reflection.

<Temperature Reduction Process S**108** and Normal Pressure Returning Process S**109**>

When the SiTiO film **21** and the SiO film **20** are formed to a desired film thickness, power supply to the heater **207** is stopped, and the boat **217** and the wafer **200** are cooled to a predetermined temperature. While reducing the temperature, the valves **432***a*, **432***b*, **422***c* and **422***d* are kept open, and supply of the purge gas into the process chamber **201** from the purge gas supply source (not shown) is continued. Accordingly, the inside of the process chamber **201** is substituted by the purge gas, and the pressure in the process chamber **201** returns to a normal pressure.

<Substrate Unloading Process S**110**>

When the wafer **200** is cooled to a predetermined temperature and the inside of the process chamber **201** returns to a normal pressure, in reverse sequence of the above sequence, the film-formed wafer **200** is unloaded from the process chamber **201**. In addition, when the boat **217** is unloaded, the valves **432***a*, **432***b*, **422***c* and **422***d* are opened, and the purge gas may be continuously supplied into the process chamber **201**. Therefore, the substrate processing apparatus in accordance with the embodiment is terminated.

(5) Effects According to the Embodiment

According to the embodiment, the following one or more effects are provided.

(a) According to the embodiment, the SiTiO film **21** and the SiO film **20** are formed on the resist lens **20** formed on the wafer **200** in sequence. At this time, the refractive index of the SiTiO film **21** is controlled within a range of more than the refractive index of air to less than the refractive index of the resist lens **10**, and the refractive index of the SiO film **20** is within a range of more than the refractive index of air to less than the refractive index of the SiTiO film **21**.

As described above, as the refractive index can be varied when the oxide film is formed and the refractive index is gradually reduced in a thickness direction from the resist lens **10** to the air, a difference in refractive index between the media can be attenuated to suppress reflection of the resist lens **10**, improving light-collecting efficiency. FIG. **10**B shows a shape in which the refractive index is attenuated to suppress reflection (reflective light **6***a*, **6***b* and **6***c*) of surfaces of the respective films.

(b) In addition, according to the embodiment, the SiO film **20** is combined with the SiTiO film **21** having a relatively high refractive index. Accordingly, in comparison with the case in which only the SiO film **20** having a relatively low refractive index is formed, since light can easily enter the photo diode **30** even when the light enters in a side direction, light collection from a wider angle becomes possible.

In a semiconductor device according to reference example, on which only the SiO film **20** is formed, as show in FIG. **10**A, since the refractive index of the SiO film **20** is low, light collection from the wide angle may become difficult. That is, since refraction of incident light **2** in the SiO film **20** is shallow (refractive light **7***b*), the light is deviated from the photo diode **30** as much as the light enters in a side direction.

However, in this embodiment, since the SiTiO film **21** having a relatively high refractive index is combined with the SiO film **20**, as shown in FIG. **10**B, the incident light **5** can reach the photo diode **30** from a wider angle (refractive light **7***a*), improving light collecting efficiency.

(c) In addition, according to the embodiment, the first cycle S**104***a* to S**104***e* and the second cycle S**105***a* to S**105***e* are set as one set and the set is performed with a predetermined combination a predetermined number of times (S**106**), forming the SiTiO film **21**. Accordingly, a deposition ratio of the TiO layer with respect to the SiO layer can be adjusted to obtain the SiTiO film **21** having a predetermined refractive ratio.

(d) Further, according to the embodiment, since the first cycle S**104***a* to S**104***e* and the second cycle S**105***a* to S**105***e* are set as one set and the number of times the set is performed is varied, the film thickness of the SiTiO film **21** can be controlled. At this time, when the predetermined combination is maintained, the refractive index of the SiTiO film **21** can be maintained at a predetermined value.

(e) Furthermore, according to the embodiment, the SiTiO film **21** and the SiO film **20** are formed using the NH_3 gas, which is a catalyst. In addition, at this time, the heating

temperature of the wafer **200** is 200° C. or less, more preferably, 150° C. or less. Using the catalyst, even under the low temperature, chemisorption of the HCD gas and the $TiCl_4$ gas can be accelerated and surface reaction of the H_2O gas can also be accelerated. That is, since only the oxide film such as the SiTiO film **21** and the SiO film **20** are mainly formed, the film can be formed using the catalyst under the low temperature. Accordingly, thermal denaturation of the resist lens **10** can be suppressed and occurrence of a bad resist lens **10** can be reduced, improving properties thereof

(f) Further, according to the embodiment, the SiTiO film **21** and the SiO film **20** are continuously formed in the same process chamber **201**. Accordingly, efforts such as conveyance of the wafer **200** to another process furnace in the middle of the process can be omitted. In addition, since no wafer **200** is exposed to the air in the middle of the process, an oxide film of a better quality can be formed.

Furthermore, in this embodiment, while the example in which the NH_3 gas is used as a catalyst is described, the catalyst is not limited to ammonia but may be another material such as pyridine.

<Second Embodiment>

Hereinafter, a substrate processing process in accordance with a second embodiment will be described. Unlike the embodiment in which the refractive index is gradually varied in two steps, in the substrate processing process in accordance with the embodiment, a SiTiO film is formed such that a refractive index is gradually reduced in a thickness direction from a surface thereof in contact with a resist lens **10** to an opposite surface in contact with air, not forming a SiO film **20**. In addition, in this embodiment, an example in which pyridine (C_5H_5N) gas is used as a catalyst will be described.

(1) Substrate Processing Process

Hereinafter, the substrate processing process in accordance with the embodiment will be described in detail with reference to FIGS. **7** and **8** in detail. The substrate processing process in accordance with the embodiment is also performed using the process furnace **202** of FIGS. **2** and **3**, and operation of the respective parts is controlled by the controller **280**. However, since the pyridine is in a liquid phase at room temperature, an apparatus of the embodiment includes a catalyst supply pipe **410***d*, an evaporator (not shown), and so on.

<Substrate Loading Process S**201** to Temperature Increase Process S**203**>

A substrate loading process S**201**, a pressure reduction process S**202** and a temperature increase process S**203** shown in FIG. **7** are performed in the same sequence as the corresponding processes S**101** to S**103** of the above embodiment.

<Deposition Oxide Film Forming Process S**204***a* to S**206**>

Next, processes S**204***a* to S**206** of FIG. **7** are performed to form a SiTiO film, which is a deposition oxide film, on a resist lens **10** formed on the wafer **200**. In the deposition oxide film forming process S**204***a* to S**206**, a first cycle process S**204***a* to S**204***e* and a second cycle process S**205***a* to S**205***e* are set as one set and the set is performed with a predetermined combination a predetermined number of times (S**206**), forming the SiTiO film.

<First Cycle Process S**204***a* to S**204***e*>

The first cycle process S**204***a* to S**204***e* is performed in a sequence and processing conditions similar to the first cycle process S**104***a* to S**104***e* in accordance with the embodiment. At this time, pyridine gas is used as a catalyst. Similar to the NH_3 gas, the pyridine gas functions to pull H (pKa=5.7) because an N atom of a pyridine molecule has a lone electron pair. Accordingly, as shown in FIGS. **9**A and **9**B, a bonding force of a surface of the resist lens **10** or the Si-containing layer or an O—H bond in the H_2O gas is weakened, and thus, chemisorption of the HCD gas is accelerated and surface reaction of the H_2O gas is also accelerated.

Accordingly, the SiO layer is formed on the resist lens **10** of the wafer **200** to a predetermined film thickness, for example, 2.0 Å to 1,000 Å. FIG. **8** shows an example in which the cycle is performed in times.

<Second Cycle Process S**205***a* to S**205***e*>

The second cycle process S**205***a* to S**205***e* is performed in a sequence and processing conditions similar to the second cycle process S**105***a* to S**105***e* in accordance with the embodiment. The pyridine gas is used as a catalyst. Accordingly, the TiO layer is formed on the SiO layer of the wafer **200** to a predetermined film thickness, for example, 2.0 Å to 1,000 Å. FIG. **8** shows an example in which the cycle is performed n times.

<Process S**206** of Performing Predetermined Number of Times>

In the process S**206** performed a predetermined number of times, the first cycle process S**204***a* to S**204***e* and the second cycle process S**205***a* to S**205***e* are set as one set and the set is performed with a predetermined combination (for example, m times and n times, respectively) a predetermined number of times, forming the SiTiO film on the resist lens **10** of the wafer **200** to a predetermined film thickness, for example, 2.0 Å to 2,000 Å.

Here, in this embodiment, as the deposition ratio of the TiO layer with respect to the SiO layer is gradually reduced, the SiTiO film is formed such that the refractive index is gradually reduced in a thickness direction from a surface thereof in contact with the resist lens **10** to an opposite surface in contact with air. Specifically, as the number of times the second cycle process S**205***a* to S**205***e* is performed with respect to the number of times the first cycle process S**204***a* to S**204***e* is performed, i.e., a value of n with respect to a value of m, is gradually reduced, the first cycle process S**204***a* to S**204***e* and the second cycle process S**205***a* to S**205***e* are set as one set and the set is performed a predetermined number of times. At this time, the refractive index of the SiTiO film is varied within a range of a refractive index of air to less than a refractive index of the resist lens **10**.

In addition, a performing sequence of the first cycle process S**204***a* to S**204***e* and the second cycle process S**205***a* to S**205***e* is arbitrary. For example, the deposition oxide film forming process S**204***a* to S**206** may be initiated from the second cycle process S**205***a* to S**205***e* and may be terminated at the first cycle process S**204***a* to S**204***e*.

As described above, in this embodiment, the refractive index may be gradually reduced in a thickness direction from the resist lens **10** to the air and a difference in refractive index between the media may be attenuated, suppressing reflection of the resist lens **10**.

<Temperature Reduction Process S**208** to Substrate Unloading Process S**210**>

A temperature reduction process S**208**, a normal pressure returning process S**209** and a substrate unloading process S**210** are performed in a sequence similar to the corresponding processes S**108** to S**110** of the embodiment. From the above, the substrate processing process in accordance with the embodiment is terminated.

(2) Effects According to the Embodiment

The embodiment has the same effects as the above embodiment.

(a) In addition, according to the embodiment, the SiTiO film is formed such that the refractive index is gradually reduced in the thickness direction from the surface in contact with the resist lens **10** to the opposite surface in contact with the air. Accordingly, the difference in refractive index

between the media can be further attenuated to suppress reflection of the resist lens **10**.

(b) Further, according to the embodiment, the SiTiO film is formed using the pyridine, which is a catalyst. Accordingly, particles are reduced.

As described above, when the NH_3 gas is used as a catalyst, as the NH_3 gas and the HCD gas are simultaneously supplied, a reaction between the NH_3 gas and the HCD gas partially occurs so that NH_4Cl is generated as a byproduct, generating particles (see FIG. **6**A).

However, in this embodiment, since the pyridine (pKa) gas having a smaller acid dissociation constant pKa than the NH_3 gas and low reactivity with a group **17** element such as Cl is used as a catalyst, generation of byproducts can be suppressed and particles can be reduced.

<Third Embodiment>

Hereinafter, a substrate processing process in accordance with a third embodiment of the present invention will be described below. The substrate processing process in accordance with the embodiment is distinguished from the above embodiment in that plasma is used instead of the catalyst to activate the H_2O gas, which is an oxidizing source, improving reactivity.

In the substrate processing process in accordance with the embodiment, in addition to the configuration shown in FIGS. **2** and **3**, a process furnace having a mechanism configured to generate plasma is used. The mechanism mainly includes a buffer chamber, which is a gas distribution space, installed at an inner wall of the reaction tube **203**, a pair of rod-shaped electrodes installed in the buffer chamber, and a radio frequency power source connected to the rod-shaped electrodes via an adapter, none of which are shown. The H_2O gas, which is an oxidizing source, is supplied into the buffer chamber through a third nozzle **400***c* disposed in the buffer chamber and connected to a downstream end of the oxidizing source supply pipe **410***c*, and a high frequency power is applied to the rod-shaped electrodes from the high frequency power source via the adapter, so that the H_2O gas in a plasma state is supplied into the process chamber **201**.

The substrate processing process in accordance with the embodiment is performed using the process furnace including the configuration as follows. That is, in the process corresponding to the first processing source and catalyst supply process S**104***a*, S**107***a* and S**204***a* or the second processing source and catalyst supply process S**105***a* and S**205***a* in accordance with the embodiment, chemisorption of each source is accelerated by the catalyst similar to the above embodiment, without converting the first processing source or the second material into a plasma state. In addition, in the oxidizing supply process performed in response to each of the source and catalyst supply processes, the H_2O gas in a plasma state is supplied into the process chamber **201** to accelerate surface reaction by the H_2O gas, without supplying the catalyst.

As described above, in this embodiment, the H_2O gas in a plasma state may be supplied into the process chamber **201** to accelerate surface reaction by the H_2O gas under a low temperature, even when the catalyst is not used.

<Other Embodiments>

Hereinabove, although embodiments of the present invention have been specifically described, the present invention is not limited thereto but various modifications may be made without departing from the teaching of the present invention.

For example, in the embodiments, while the photo resist is used as a lens material, in addition to a photosensitive resin such as the photo resist, a resin having plasticity or curability with respect to heat or light may be used, specifically, acryls, phenols, styrenes, etc. A refractive index of the acryls is 1.5. These resins may be transparent resins through which light having a predetermined wavelength such as visible light passes. In addition, for example, an inorganic material such as glass or quartz (SiO_2) may be used as a lens material.

Further, in the embodiment, while supply of the oxidizing source and supply of the first processing source or the second processing source are alternately performed, when a complex oxide film is formed, the oxidizing source may be supplied at predetermined intervals during alternate supplies of the first processing source and the second processing source a predetermined number of times.

Furthermore, in addition to the HCD gas, silicon-based chloride gases such as dichlorosilane (DCS: SiH_2Cl_2) gas, trichlorosilane ($SiHCl_3$) gas, tetrachlorosilane ($SiCl_4$) gas, or octachlorotrisilane (Si_3Cl_8) gas, fluoride gases, boromide gases, and iodide gases may be used as the Si-containing gas, which is a first element. In addition, the first element may be an element other than Si, or may include a plurality of elements.

Further, in addition to $TiCl_4$ gas, various titanium-based chloride, fluoride, boromide and iodide gases may be used as a Ti-containing gas, which is a second element. Furthermore, in addition to Ti, hafnium (Hf), zirconium (Zr), etc., may be used as the second element as long as the predetermined refractive index can be obtained when a complex oxide film is formed in combination with the first element such as Si. For example, refractive indices of a HfO layer and a ZrO layer are 2.3 and 2.2, respectively. The second element may include a plurality of elements.

In addition, in addition to the H_2O gas, hydrogen peroxide (H_2O_2) gas, a mixed gas of hydrogen (H_2) gas and ozone (O_3) gas, mixed gas plasma of hydrogen (H_2) gas and oxygen (O_2) gas, etc., may be used as an O-containing gas, which is an oxidizing source. When the catalyst is used as in the embodiment, the gases may be used as the oxidizing source as long as the gases containing elements with different electro-negativities among molecules have electrical deviation. The O_2 gas or O_3 gas with no electrical deviation may be used when the plasma is used as in the third embodiment.

Further, in addition to the NH_3 gas or the pyridine gas, a gas having a relatively high pKa such as trimethylamine [$N(CH_3)_3$, pKa=9.8] gas, methylamine [$H_2N(CH_3)$, pKa=10.6] gas or triethylamine [$N(C_2H_5)_3$, pKa=10.7] gas, or a gas having a relatively low pKa similar to the pyridine gas, such as heterocycle to which N is bonded, for example, aminopyridine ($C_5H_4N—NH_2$, pKa=6.9), picoline [$C_5H_4N(CH_3)$, pKa=6.1], piperazine [$C_4H_{10}N_2$, pKa=5.7], lutidine [$C_5H_3N(CH_3)_2$, pKa=7.0], etc., may be used as the catalyst.

<Preferred Aspects of the Invention>

Hereinafter, preferred aspects of the present invention will be additionally stated.

An aspect of the present invention provides a method of manufacturing a semiconductor device, including:

(a) forming a lower layer oxide film on a lens formed on a substrate using a first processing source containing a first element, a second processing source containing a second element, an oxidizing source and a catalyst, the lower layer oxide film having a refractive index greater than that of air and less than that of the lens; and

(b) forming an upper layer oxide film on the lower layer oxide film using the first processing source, the oxidizing source and the catalyst, the upper layer oxide film having a refractive index greater than that of the air and less than that of the lower layer oxide film.

Preferably, at least one of the process (a) and the process (b) may include heating the substrate to a temperature ranging from room temperature to 200° C.

More preferably, at least one of the process (a) and the process (b) may include heating the substrate to a temperature ranging from room temperature to 150° C.

Preferably, the first element may contain at least silicon, and the second element may contain one of at least titanium, hafnium and zirconium.

Preferably, the lens may include a transparent resin as a major material.

Preferably, the process (a) may include:

(a-1) performing one or more times a first cycle including supplying the first processing source and the catalyst into a process chamber accommodating the substrate; exhausting the process chamber; supplying the oxidizing source and the catalyst into the process chamber; and exhausting the process chamber;

(a-2) performing one or more times a second cycle including supplying the second processing source and the catalyst into the process chamber accommodating the substrate; exhausting the process chamber; supplying the oxidizing source and the catalyst into the process chamber; and exhausting the process chamber; and

(a-3) performing a combination of the steps (a-1) and (a-2), and the process (b) may include: performing one or more times a third cycle including supplying the first processing source and the catalyst into the process chamber accommodating the substrate; exhausting the process chamber; supplying the oxidizing source and the catalyst into the process chamber; and exhausting the process chamber.

Another aspect of the present invention provides a semiconductor device including: a lens; a lower layer oxide film disposed on the lens, the lower layer oxide film having a refractive index greater than that of air and less than that of the lens and being formed using a first processing source containing a first element, a second processing source containing a second element, an oxidizing source and a catalyst; and an upper layer oxide film disposed on the lower layer oxide film, the upper layer oxide film having a refractive index greater than that of the air and less than that of the lower layer oxide film and being formed using the first processing source, the oxidizing source and the catalyst.

Still another aspect of the present invention provides a substrate processing apparatus including: a process chamber configured to accommodate a substrate, the substrate having a lens disposed thereon;

a heating part configured to heat the substrate;

a first processing source supply part configured to supply a first processing source containing a first element into the process chamber;

a second processing source supply part configured to supply a second processing source containing a second element into the process chamber;

an oxidizing source supply part configured to supply an oxidizing source into the process chamber;

a catalyst supply part configured to supply a catalyst into the process chamber;

an exhaust part configured to exhaust an atmosphere in the process chamber; and

a control unit configured to control the heating part, the first processing source supply part, the second processing source supply part, the oxidizing source supply part, the catalyst supply part and the exhaust part to form a lower layer oxide film on the lens using the first processing source, the second processing source, the oxidizing source and the catalyst, the lower layer oxide film having a refractive index greater than that of air and less than that of the lens, and to form an upper layer oxide film on the lower layer oxide film using the first processing source, the oxidizing source and the catalyst, the upper layer oxide film having a refractive index greater than that of the air and less than that of the lower layer oxide film.

Yet another aspect of the present invention provides a method of manufacturing a semiconductor device, including: forming a deposition oxide layer on a lens formed on a substrate using a first processing source containing a first element, a second processing source containing a second element, an oxidizing source and a catalyst, the deposition oxide layer having a refractive index equal to or greater than that of air and equal to or less than of the lens,

wherein, in the forming the deposition oxide layer, the deposition oxide layer is formed such that the refractive index in the deposition oxide layer is gradually reduced from a surface thereof in contact with the lens to a surface opposite to the lens and in contact with the air.

Preferably, the forming the deposition oxide layer may include: (a) performing m times a first cycle including supplying the first processing source and the catalyst into the process chamber accommodating the substrate, exhausting the atmosphere in the process chamber, supplying the oxidizing source and the catalyst into the process chamber, and exhausting the atmosphere in the process chamber; (b) performing n times a second cycle including supplying the second processing source and the catalyst into the process chamber accommodating the substrate, exhausting the atmosphere in the process chamber, supplying the oxidizing source and the catalyst into the process chamber, and exhausting the atmosphere in the process chamber; and (c) performing the steps (a) and (b) with a combination a predetermined number of times, and

the deposition oxide layer is formed such that the refractive index in the deposition oxide layer is gradually reduced from a surface thereof in contact with the lens to a surface opposite to the lens and in contact with the air by gradually reducing a value of n with respect to a value of m.

Yet another embodiment of the present invention provides a semiconductor device including: a lens; and a deposition oxide film formed on the lens using a first processing source containing a first element, a second processing source containing a second element, an oxidizing source and a catalyst, wherein the deposition oxide film has a refractive index equal to or greater than that of air and equal to or less than that of the lens, and is configured such that the refractive index in the deposition oxide film is gradually reduced from a surface thereof in contact with the lens to a surface opposite to the lens and in contact with the air.

Yet another aspect of the present invention provides a substrate processing apparatus including: a process chamber configured to accommodate a substrate, the substrate having a lens disposed thereon; a heating part configured to heat the substrate; a first processing source supply part configured to supply a first processing source containing a first element into the process chamber; a second processing source supply part configured to supply a second processing source containing a second element into the process chamber; an oxidizing source supply part configured to supply an oxidizing source into the process chamber; a catalyst supply part configured to supply a catalyst into the process chamber; an exhaust part configured to exhaust an atmosphere in the process chamber; and a control unit configured to control the heating part, the first processing source supply part, the second processing source supply part, the oxidizing source supply part, the catalyst supply part, and the exhaust part to form a deposition oxide film having a refractive index equal to or greater than that of air and equal to or less than that of the lens on the lens using the first processing source, the second processing source, the oxidizing source and the catalyst, wherein the control unit

controls the heating part, the first processing source supply part, the second processing source supply part, the oxidizing source supply part, the catalyst supply part, and the exhaust part such that the refractive index in the deposition oxide film is gradually reduced from a surface thereof in contact with the lens to a surface opposite to the lens and in contact with the air.

Yet another aspect of the present invention provides a method of manufacturing a semiconductor device, including: forming a lower layer oxide film on a lens formed on a substrate using a first processing source containing a first element, a second processing source containing a second element and an oxidizing source in a plasma state, the a lower layer oxide film having a refractive index greater than that of air and less than of a lens; and

forming an upper layer oxide film on the lower layer oxide film using the first processing source and the oxidizing source in a plasma state, the upper layer oxide film having a refractive index greater than that of the air and less than that of the lens.

Yet another aspect of the present invention provides a method of manufacturing a semiconductor device, including: forming a deposition oxide film on a lens formed on a substrate using a first processing source containing a first element, a second processing source containing a second element, and an oxidizing source in a plasma state, the deposition oxide film having a refractive index equal to or greater than that of air and equal to or less than of the lens,

wherein, in the forming the deposition oxide film, the deposition oxide film is formed such that the refractive index in the deposition oxide film is gradually reduced from a surface thereof in contact with the lens to a surface opposite to the lens and in contact with the air.

Yet another aspect of the present invention provides a semiconductor device including: a lens; and an oxide film disposed on the lens, the oxide film having a refractive index equal to or greater than that of air and equal to or less than that of the lens,

wherein the oxide film is formed by depositing a silicon oxide layer; and a metal oxide layer containing one of at least titanium, hafnium and zirconium and having a refractive index greater than that of the silicon oxide layer.

Preferably, the oxide film may be configured such that the refractive index of the oxide film can be controlled by controlling a deposition ratio between the silicon oxide layer and the metal oxide layer.

Preferably, the oxide film may be configured such that the refractive index of the oxide film is gradually increased or decreased by gradually increasing or decreasing a deposition ratio of the metal oxide layer with respect to the silicon oxide layer.

Preferably, the oxide film may be formed at a temperature of 100° C. or less.

Preferably, the lens may be a lens for a CMOS image sensor installed over a light receiving element.

What is claimed is:

1. A method of manufacturing a semiconductor device, comprising forming a laminated film wherein a silicon-containing oxide film and a metal-containing oxide film are alternately stacked on a substrate by alternately performing, a predetermined number of times,

(a) performing a first cycle a predetermined number of times, the first cycle comprising: supplying a silicon-containing source to the substrate; supplying an oxidizing source to the substrate; and supplying a catalyst to the substrate to form the silicon-containing oxide film; and

(b) performing a second cycle a predetermined number of times, the second cycle comprising: supplying a metal-containing source to the substrate; supplying an oxidizing source to the substrate; and supplying a catalyst to the substrate to form the metal-containing oxide film.

2. The method according to claim 1, wherein the steps (a) and (b) are alternately performed in the step of forming the laminated film to gradually decrease a stacking ratio of the metal-containing oxide film with respect to the silicon-containing oxide film.

3. The method according to claim 1, wherein the silicon-containing source comprises at least one selected from a group consisting of chloride, fluoride, bromide and iodide.

4. The method according to claim 1, wherein the silicon-containing source comprises at least one selected from a group consisting of hexachlorodisilane, dichlorosilane, trichlorosilane, tetrachlorosilane and octachlorotrisilane.

5. The method according to claim 1, wherein the metal-containing source comprises at least one selected from a group consisting of chloride, fluoride, bromide and iodide.

6. The method according to claim 1, wherein the oxidizing source comprises at least one selected from a group consisting of H_2O, H_2O_2, a mixed gas of H_2 and O_3 and a mixed gas of H_2 and O_2.

7. The method according to claim 1, wherein the catalyst comprises at least one selected from a group consisting of ammonia, pyridine, trimethylamine, methylamine, triethylamine, aminopyridine, picoline, piperazine and lutidine.

8. The method according to claim 1, wherein the metal-containing source comprises at least one selected from a group consisting of titanium, hafnium, and zirconium.

9. The method according to claim 1, wherein the substrate is heated to a temperature ranging from room temperature to 200° C. in at least one of the steps (a) and (b).

10. The method according to claim 1, wherein the substrate is heated to a temperature ranging from room temperature to 150° C. in at least one of the steps (a) and (b).

11. A method of manufacturing a semiconductor device, comprising:

(a) forming a laminated film wherein a silicon-containing oxide film and a metal-containing oxide film are alternately stacked on a substrate by alternately performing, a predetermined number of times, (a-1) performing a first cycle a predetermined number of times, the first cycle comprising: supplying a silicon-containing source to the substrate; supplying an oxidizing source to the substrate; and supplying a catalyst to the substrate to form the silicon-containing oxide film; and (a-2) performing a second cycle a predetermined number of times, the second cycle comprising: supplying a metal-containing source to the substrate; supplying an oxidizing source to the substrate; and supplying a catalyst to the substrate to form the metal-containing oxide film; and

(b) forming a silicon-containing oxide film on the laminated film by performing a third cycle a predetermined number of times, the third cycle comprising: supplying a silicon-55 containing source to the substrate; supplying an oxidizing source to the substrate; and supplying a catalyst to the substrate.
