(54) Titre : DERIVES DU PLASMINOGENE ACTIVABLES PAR LA THROMBINE  
 (54) Title: THROMBIN ACTIVATABLE PLASMINOGEN DERIVATIVES

(57) **Abrégé/Abstract:**

A plasminogen analogue activatable by thrombin to have plasmin activity which contains the cleavage site sequence P4-P3-Pro-Arg-P1'-P2' where P3 is a basic amino acid residue, P4 is a hydrophobic amino acid residue and each of P1' and P2' is independently a non-acidic amino acid residue, said site being cleavable by thrombin between Arg and P1'.

## THROMBIN ACTIVATABLE PLASMINOGEN DERIVATIVES.

This invention is an improvement of the invention disclosed in our  
copening patent application WO-A-9109118, and relates to  
5 plasminogen analogues which are activated by thrombin to have  
fibrinolytic activity or to inhibit blood clot formation. It also relates to  
nucleic acid (DNA and RNA) coding for all or part of such compounds.  
The invention also relates to their preparation, pharmaceutical  
compositions containing them and their use in the treatment of  
10 thrombotic disease.

Plasminogen is a key component of the fibrinolytic system which is the  
natural counterpart to the clotting system in the blood. In the process of  
blood coagulation, a cascade of enzyme activities is involved in  
15 generating a fibrin network which forms the framework of a clot, or  
thrombus. Degradation of the fibrin network (fibrinolysis) is  
accomplished by the action of the enzyme plasmin. Plasminogen is the  
inactive precursor of plasmin and conversion of plasminogen to  
plasmin is accomplished by cleavage of the peptide bond between  
20 arginine 561 and valine 562 of plasminogen. Under physiological  
conditions this cleavage is catalysed by tissue-type plasminogen  
activator (tPA) or by urokinase-type plasminogen activator (uPA).

If the balance between the clotting and fibrinolytic systems becomes  
25 locally disturbed, intravascular clots may form at inappropriate  
locations leading to conditions such as coronary thrombosis and  
myocardial infarction, deep vein thrombosis, stroke, peripheral arterial  
occlusion and embolism. In such cases, the administration of  
fibrinolytic agents has been shown to be a beneficial therapy for the

2145749

2

promotion of clot dissolution. Antithrombotic agents are also useful for the prevention of clot formation.

5 However, the problem with the majority of agents used for fibrinolytic treatment is that at clinically useful doses they are not thrombus specific, as they activate plasminogen in the general circulation. An alternative approach to enhancing fibrinolysis is disclosed in our copending patent application WO-A-9109118, and is based on the use of molecules activatable to have fibrinolytic activity or to inhibit clot formation. The activation is catalysed by one or more endogenous enzymes involved in blood clotting. An advantage of this approach is that thrombus selectivity of fibrinolysis or inhibition of clot formation activity is achieved by way of the thrombus-specific localisation of the activating enzyme. In particular, WO-A-9109118 discloses, *inter alia*, plasminogen analogues activatable to plasmin by cleavage by thrombin.

10 Thrombin (E.C. 3.4.21.5) is a serine protease which catalyses the proteolysis of a number of proteins including fibrinogen (A alpha and B beta chains), Factor XIII, Factor V, Factor VII, Factor VIII, protein C and antithrombin III. The structure required for recognition by thrombin appears to be partially determined by the local amino acid sequence around the cleavage site, but is also determined to a variable extent by sequence(s) remote from the cleavage site. For example, in the fibrinogen A alpha chain, residues P2 (Val), P9 (Phe) and P10 (Asp) are crucial for  $\alpha$ -thrombin-catalysed cleavage at the Arg(16)-Gly(17) peptide bond (Ni, F. et al 1989, Biochemistry 28 3082-3094). WO-A-9109118 discloses that optimum cleavage sites for alpha-thrombin may have the structure

25 (i) P4-P3-Pro-Arg-P1'-P2'

where each of P3 and P4 is independently a residue of a hydrophobic amino acid (such as valine) and each of P1' and P2' is independently a non-acidic amino acid residue, or (ii) P2-Arg-P1'

5 where P2 or P1' is a glycine residue. Accordingly, the thrombin activatable plasminogen analogue compounds disclosed as preferred in WO-A-9109118, and all those specifically exemplified therein, have cleavage sites conforming to the foregoing structures (i) or (ii). The data reported in WO-A-910918 suggests that, of the specifically exemplified thrombin-cleavable plasminogen analogues, that designated T19 is the most effective in the assay systems used. It has a cleavage site based on Factor XIII, Pro (559) and Gly (560) of wild-type plasminogen having been replaced by Val-Glu-Leu-Gln-Gly-Val-Val-Pro. The thrombin cleavage site of T19, the most effective of the compounds specifically exemplified, therefore conforms with the requirements of structure (i) above - preferred according to WO-A-9109118.

10 In the absence of cofactors, Factor XI has been reported not to be cleaved by thrombin (Naito, K. and Fujikawa, K (1991), J. Biol. Chem. 266 7353-7358), or to be only slowly cleaved with a  $k_{cat}/K_m=1.6 \times 10^5 M^{-1} min^{-1}$  (Gailani, D. and Broze, G.J. 1991, Science 253, 909-912). The cleavage site sequence of this thrombin substrate differs from the preferred general formulae i) and ii) of WO-A-9109118. In factor XI, a basic amino acid, Lys, is in the P3 position. However, although thrombin cleavage activity at this site in factor XI is very low compared to that of Factor XIII ( $k_{cat}/K_m=1.4 \times 10^5 M^{-1} sec^{-1}$ ; Naski et al., 1991, Biochemistry 30 934-941), it has now been found in accordance with this invention, that plasminogen analogues having a thrombin cleavage sequence with a basic amino acid residue in the P3 position have surprisingly increased activity compared to T19. Such novel analogues are cleaved more

2145749

rapidly by thrombin, and exhibit increased activity in a linked chromogenic assay. More significantly, such analogues are active in a plasma clot lysis assay, which more closely resembles conditions *in vivo*.

5

A further example of a thrombin cleavage site where P3 is a basic amino acid residue is found in single-chain urokinase, where P3 is arginine. Cleavage at this site produces inactive two-chain urokinase (Ichinose et al., (1986) J. Biol. Chem. 261 3486-9). In the absence of cofactors, cleavage of single-chain urokinase by thrombin is also moderately slow, with a  $k_{cat}/K_m=3.8 \times 10^4 M^{-1} sec^{-1}$ ; (de Munk et al., 1990 Fibrinolysis 4 161); however, plasminogen analogues bearing the urokinase cleavage site have now been shown to have increased activity compared to T19.

10

Accordingly, the present invention is an improvement of the invention disclosed in WO-A-9109118 in that it provides a plasminogen analogue which is activatable by thrombin to have plasmin activity (as generally disclosed in WO-A-9109118) but specifically characterised in that it comprises a thrombin-cleavable site sequence P4-P3-Pro-Arg-P1'-P2' wherein P3 is a residue of a basic amino acid, P4 is a residue of a hydrophobic amino acid, and each of P1' and P2' is independently a non-acidic amino acid residue, said site being cleavable by thrombin between Arg and P1'.

15

20

25

Plasminogen has been numbered according to the protein sequencing studies of Sottrup-Jensen et al. (in: Atlas of Protein Sequence and Structure (Dayhoff, M.O., ed.) 5 suppl. 3, p.95 (1978)) which indicated that plasminogen was a 790 amino acid protein and that the site of cleavage was the Arg(560)-Val(561) peptide bond. However, a suitable

2145749

5

plasminogen cDNA useful in this embodiment of the invention and that isolated by Forsgren et al (FEBS Letters 213 254-260 (1987)) code for a 791 residue protein with an extra Ile at position 65. In this specification, the numbering of the amino acids in plasminogen corresponds to that of the cDNA used. There may be polymorphism in the structure of plasminogen and there may be forms of plasminogen in which the numbering of the cleavage site differs but it is intended that such variants be included in the embodiment.

Therefore the term "plasminogen analogue", as used in this specification, means a molecule differing from wild type plasminogen and having the ability to be cleaved or otherwise acted on to form a molecule having plasmin activity.

Plasminogen analogues within the scope of this embodiment of the invention retain the fibrin binding activity of wild type plasminogen to an adequate degree but may have altered inhibition characteristics; preferred plasminogen analogues have a plasma half life which is comparable with that of wild type plasminogen, but this property is not essential.

In the thrombin-cleavable site sequence present in plasminogen analogues according to the invention, the basic amino acid residue P3 may be a lysine or arginine residue; the hydrophobic amino acid residue P4 may be a valine, isoleucine or leucine residue; and each of the non acidic amino acid residues P1' and P2' may independently be a valine or isoleucine residue.

Particular plasminogen analogues within the scope of the invention contain the cleavage site Thr-Thr-Lys-Ile-Lys-Pro-Arg- P1'-P2' , or the

2145749

6

cleavage site Leu-Arg-Pro-Arg, where each of P1' and P2' is independently a non-acidic amino acid residue. As mentioned, P1' and P2' may be isoleucine or valine residues.

5 Specific and preferred compounds according to the invention are plasminogen analogues:

a) in which Pro(559), Gly(560) are replaced by Thr, Thr, Lys, Ile, Lys, Pro and Val(562) is replaced by Ile. In this analogue, amino acid 563 is valine as in the wild type. This mutant has been designated BB10151.

10 b) in which Cys(558), Pro(559), Gly(560) are replaced by Ala, Gly, Gln, Lys, Thr, Leu, Arg, Pro; and Cys(566) is replaced with Ala. In this analogue, amino acids 562 and 563 are valine as in the wild type. This mutant has been designated BB10156.

15 c) in which Cys(558), Pro(559), Gly(560) are replaced by Ala, Leu, Arg, Pro; and Cys(566) is replaced with Ala. In this analogue, amino acids 562 and 563 are valine as in the wild type. This mutant has been designated BB10170.

20 d) in which Pro(559), Gly(560) are replaced by Val, Glu, Leu, Gln, Gly, Leu, Arg, Pro. In this analogue, amino acids 562 and 563 are valine as in the wild type. This mutant has been designated BB10171

e) in which Cys(558) Pro(559), Gly(560) are replaced by Ala, Thr, Thr, Lys, Ile, Lys, Pro; Val(562) is replaced by Ile; and Cys(566) is replaced with Ala This mutant has been designated BB10158

25 Plasminogen analogues in accordance with the invention have been defined by particular reference to the nature of their thrombin-cleavable site sequence, since it is the surprising rapidity of cleavage at that site which underlies the improved thrombolytic activity of the compounds. However, it is likely that plasminogen analogues in accordance with the  
30 invention (i.e. containing the now identified novel cleavage site

sequences) may contain other modifications (as compared with wild type plasminogen) which may be one or more additions, deletions or substitutions at sites more or less remote from the cleavage site, without losing the benefit of rapid cleavage. An example of such a modification would be the addition, removal, substitution or alteration of one or more kringle domains to alter fibrin binding activity or reduce  $\alpha$ 2-antiplasmin binding. A specific example would be mutation of the lysine-binding site located on Kringle 1 to interfere with the binding of  $\alpha$ 2-antiplasmin to this site. Such variants may be resistant to inhibition by  $\alpha$ 2-antiplasmin. Preferred embodiments include BB10189, BB10190 and BB10192, which are the plasminogen analogues BB10153, BB010170 and BB10171 respectively with the additional mutations of Asp 137> Ser and Asp 139> Ser.

Another example would be mutation to prevent disulphide bond formation between Cys (558) and Cys (566), for example by replacing one or both of the cysteines with alanine residues, in order to remove the constraint put on the cleavage site by the disulphide bond formed between the cysteine residues. Of the preferred embodiments described above, variants BB10156, BB10158 and BB10170 have such open-loop modifications.

An example of a modification involving deletion would be lys-plasminogen variants of a plasminogen analogue in which the amino terminal 68, 77 or 78 amino acids have been deleted. Such variants may have enhanced fibrin binding activity as has been observed for lys-plasminogen compared to wild-type glu-plasminogen (Bok, R. A. and Mangel, W. F. 1985, Biochemistry 24 3279-3286). A further example involving deletion would be variants of a

plasminogen analogue in which the kringle 1 or kringle 1-4 domains have been deleted to impair  $\alpha$ 2-antiplasmin binding. Such variants may be resistant to inhibition by  $\alpha$ 2-antiplasmin. Deletion of kringles 1-4 would also alter the fibrin binding and pharmacokinetic properties of the molecule.

For the highly clot selective analogue of plasminogen of the present invention it may be preferred to introduce a mutation in the serine protease domain that interferes with plasmin inhibitor binding (SEQ ID2 depicts the serine protease domain of wild-type plasmin, and references herein to that domain, where numbered, use the numbering of SEQ ID2). This mutation could be in a position analogous to that shown to prevent inhibitor binding to tissue plasminogen activator (Madison, E. L. et al 1989 Nature 339 721-724) or could be in another position which prevents inhibitor binding to plasminogen; such modifications are described in co-pending patent application PCT/GB 9301632, which discloses endopeptidases of the chymotrypsin superfamily which exhibit resistance to serine protease inhibitors. Such resistance is provided by a modification in the endopeptidase or its precursor which induces one of the following

- a) a conformational change in the local fold of the protease;
- b) a change in the relative orientations of the protease and inhibitor on forming a complex;
- c) a change in the steric bulk of the protease in the region of the inhibitor,
- d) a change in the electrostatic potential field in the region of the inhibitor binding site; or
- e) any combination of the above.

2145749

9

5 A preferred embodiment is BB10158 with the A4 mutation (Glu606 to Lys) described in PCT/GB 9301632 (BB10199). This mutation is designed to interrupt ionic interactions on the surface of plasminogen, interfering with binding to antiplasmin. Mutagenesis was carried out using a 24 base oligonucleotide 5'CTT GGG GAC TTC TTC AAG CAG TGG3', designed to convert Glu606 to Lys. Other preferred embodiments have, either singly or in combination, mutations at Glu606, Glu623, Phe583, Met585 or Lys 607. The Glu606 and Glu623 mutations were exemplified in PCT/GB 9301632. An example of this embodiment is 10 BB10153 which is the plasminogen analogue BB10151 with the additional mutations of Glu606 to Lys and Glu623 to Lys.

15 Other plurally-modified plasminogen analogues in accordance with the invention may include one or more modifications to prevent, reduce or alter glycosylation patterns. Plasminogen analogues incorporating such modifications may have a longer half-life, reduced plasma clearance and/or higher specific activity.

20 Preferred features of plasminogen analogues within the scope of the invention also apply, where appropriate, to other compounds of the invention, mutatis mutandis.

25 The plasminogen analogues of the first aspect of the invention can be synthesised by any convenient route. According to a second aspect of the invention there is provided a process for the preparation of such a plasminogen analogue, the process comprising coupling successive amino acid residues together and/or ligating oligopeptides. Although proteins may in principle be synthesised wholly or partly by chemical means, it is preferred to prepare them by ribosomal translation,

2145749

10

preferably in vivo, of a corresponding nucleic acid sequence. The protein may be glycosylated appropriately.

5 It is preferred to produce proteins of the invention by using recombinant DNA technology. DNA encoding a naturally occurring plasminogen may be obtained from a cDNA or genomic clone or may be synthesised. Amino acid substitutions, additions or deletions are preferably introduced by site-specific mutagenesis. DNA sequences encoding plasminogen analogues may be obtained by procedures  
10 familiar to those skilled in the art of genetic engineering.

The process for producing proteins using recombinant DNA technology will usually include the steps of inserting a suitable coding sequence into an expression vector and transferring the vector into a host cell.  
15 Therefore, according to a third aspect of the invention, there is provided synthetic or recombinant nucleic acid coding for a proteinaceous compound as described above. The nucleic acid may be RNA or DNA and may be in the form of a vector, such as a plasmid, cosmid or phage. The vector may be adapted to transfect or transform prokaryotic (for  
20 example bacterial) cells and/or eukaryotic (for example yeast or mammalian) cells. A vector will comprise a cloning site and usually at least one marker gene. An expression vector will have a promoter operatively linked to the sequence to be inserted in the cloning site, and, preferably, a sequence enabling the protein product to be secreted.

25 The plasminogen analogues of the invention may be expressed using a vector of the type described in WO-A-9109118, which comprises a first nucleic acid sequence coding for a protein or embodying a cloning site, operatively linked to a second nucleic acid sequence containing a strong  
30 promoter and enhancer sequence derived from human

2145749

cytomegalovirus, a third nucleic acid sequence encoding a polyadenylation sequence derived from SV40 and a fourth nucleic acid sequence coding for a selectable marker expressed from an SV40 promoter and having an additional SV40 polyadenylation signal at the 3' end of the selectable marker sequence.

It is to be understood that the term "vector" is used in this specification in a functional sense and is not to be construed as necessarily being limited to a single nucleic acid molecule. So, for example, the first, second and third sequences of the vector defined above may be embodied in a first nucleic acid molecule and the fourth sequence may be embodied in a second nucleic acid molecule.

This vector enables the plasminogen analogues to be expressed and secreted into the cell culture medium in a biologically active form without the need for any additional biological or chemical procedures.

According to a third aspect of the invention, there is provided a process for the preparation of nucleic acid encoding the plasminogen analogues described above, the process comprising coupling successive nucleotides together and/or ligating oligo- and/or poly-nucleotides.

In a further aspect of the invention, there is provided a cell or cell line transformed by nucleic acid and/or a vector as described above. Suitable cells or cell lines to be transformed include both prokaryotic (for example *Escherichia coli*) and eukaryotic cells, such as yeast cells (including *Saccharomyces cerevisiae* and *Pichia pastoris*) and mammalian cells. Mammalian cells which grow in continuous culture and which can be transfected or otherwise transformed by standard techniques are preferred. Examples of suitable cells include Chinese hamster ovary (CHO) cells, mouse myeloma cell lines such as NS0 and

2145749

12

P3X63-Ag8.653, COS cells, HeLa cells, BHK cells, melanoma cell lines such as the Bowes cell line, mouse L cells, human hepatoma cell lines such as Hep G2, mouse fibroblasts and mouse NIH 3T3 cells. CHO cells are particularly preferred as hosts for the expression of plasminogen and plasminogen analogues.

Transformation may be achieved by any convenient method; electroporation is particularly suitable.

Plasminogen analogues of the present invention may be used for the prophylaxis and/or treatment of conditions caused by an imbalance between clotting and fibrinolysis, the method comprising administering to a patient an effective amount of the plasminogen analogue. Therefore, according to a further aspect of the invention, there is provided a plasminogen analogue as disclosed herein, for use in medicine, particularly in the prophylaxis and/or treatment of conditions caused by an imbalance between clotting and fibrinolysis, where it is desired to produce local fibrinolytic and/or anticoagulant activity. Such conditions include myocardial and cerebral infarction, arterial and venous thrombosis, thromboembolism, post-surgical adhesions, thrombophlebitis and diabetic vasculopathies and coagulation imbalances associated with cancer.

The invention also provides the use of a plasminogen analogue as disclosed herein in the preparation of a thrombolytic, antithrombotic or thrombolytic antithrombotic agent.

Furthermore, there is also provided a pharmaceutical or veterinary composition comprising one or more plasminogen analogues as disclosed herein and a pharmaceutically or veterinarily acceptable

carrier. Such a composition may be adapted for administration orally, by intravenous or intramuscular injection or by infusion. Suitable injectable compositions include preparations of sterile plasminogen analogue(s) in isotonic physiological saline and/or buffer and may also include a local anaesthetic to alleviate the pain of injection. Similar compositors may be used for infusion. Where the compound is to be administered as a topical treatment, it may be formulated as a cream, ointment or lotion in a suitable base.

The compounds of the invention may be supplied in unit dosage form, for example as a dry powder or water-free concentrate in a hermetically sealed container such as an ampoule or sachet.

The quantity of material to be administered will depend on the amount of fibrinolysis or inhibition of clotting required, the required speed of action, the seriousness of the thromboembolic position and the size of the clot. The precise dose to be administered will, because of the very nature of the condition which compounds of the invention are intended to treat, be determined by the physician. As a guideline, however, a patient being treated for a mature thrombus will generally receive a daily dose of a plasminogen analogue of from 0.01 to 10 mg/kg of body weight either by injection in for example up to 5 doses or by infusion.

25

The following figures and examples of the invention are offered by way of illustration, and not by way of limitation. In the drawings referred to in the examples:

Figure 1 shows the rate of cleavage of BB10151 (T51) by thrombin;

Figure 2 shows the results of a chromogenic assay comparing the activation of BB10151 (T51) and T19 by thrombin;

Figure 3 shows the clot lysis activity of BB10151 (T51).

5

Example 1 - Construction Expression and Purification of BB10151

The isolation of plasminogen cDNA and construction of the vectors pGWH and pGWHgP have been described in WO-A-91/09118. In pGWHgP, transcription through the plasminogen cDNA can initiate at the HCMV promoter/enhancer and the selectable marker gpt is employed.

10

The techniques of genetic manipulation, expression and protein purification used in the manufacture of the modified plasminogen example to follow, are well known to those skilled in the art of genetic engineering. A description of most of the techniques can be found in one of the following laboratory manuals: "Molecular Cloning" by T. Maniatis, E.F. Fritsch and J. Sambrook published by Cold Spring Harbor Laboratory, Box 100, New York, or "Basic Methods in Molecular Biology" by L.G. Davis, M.D. Dibner and J.F. Battey published by Elsevier Science publishing Co Inc, New York.

15

20

Additional and modified methodologies are detailed in the methods section below.

25

BB10151 is a plasminogen analogue in which the amino acid residues Pro(559), Gly(560) are replaced by Thr, Thr, Lys, Ile, Lys, Pro and Val(562) is replaced by Ile to produce a cleavage loop cleavable by thrombin (Seq. ID. 1). This site is based on a potential thrombin cleavage site in factor

30

XI. The procedures used in this example are essentially as described in WO-A-9109118 Examples 2 and 3, with the mutagenesis reaction carried out on the 1.87kb KpnI to HincII fragment of plasminogen cloned into the bacteriophage M13mp18. Single stranded template was prepared and the mutation made by oligonucleotide directed mutagenesis. In this case a 48 base long oligonucleotide

(5'CACCCCCCTACGATTCTAGGTTTAATTTTAGTTGTACATTTCTTCGGC3')

(SEQ.ID. 4) was used to direct the mutagenesis.

Plasmid DNA was introduced into CHO cells by electroporation using 800 V and 25  $\mu$ F. Selective medium containing 250  $\mu$ l/ml xanthine, 5  $\mu$ g/ml mycophenolic acid, 1x hypoxanthine-thymidine (HT)) was added to the cells 24 hours post transfection and the medium was changed every two to three days. Plates yielding gpt-resistant colonies were screened for plasminogen production using an ELISA assay. Cells producing the highest levels of antigen were re-cloned and the best producers scaled up into flasks with production being carefully monitored. Frozen stocks of all these cell lines were laid down. Producer cells were scaled up into roller bottles to provide conditioned medium from which plasminogen protein was purified using lysine SEPHAROSE 4B. (The word SEPHAROSE is a trade mark.) The cell line used to produce this mutant protein was 123.C6.

#### Example 2 - Construction of BB10153

BB10153 is a derivative of BB10151 containing two additional mutations (Glu606 to Lys and Glu623 to Lys) to impair binding of  $\alpha$ 2-antiplasmin. The 663bp EcoRV to Sph I fragment of BB10151 (cloned in pUC - see

2145749

Example 1) was removed and replaced with the equivalent 663bp fragment from the antiplasmin resistant mutant A3A4. Construction of this is described in example 5 of PCT/GB9301632. The 24 base oligonucleotide 5'CTT GGG GAC TTC TTC AAG CAG TGG3' (SEQ ID 3),  
5 was used to convert Glu-606 to Lys and the 27 base oligonucleotide 5'GTTCGAGATTCACTTTTTGGTGTGCAC3' (SEQ ID 5) was used to convert Glu623 to Lys. The full length plasminogen was then cloned into the expression vector pGW1H prior to the insertion of the gpt selection marker as described in WO-A-9109118 Example 2.

10

Example 3 - Construction of BB10156, BB10158 & BB10170

The DNA encoding plasminogen mutant BB10150 was used as the template for production of BB10156, BB10158 & BB10170. BB10150 is a plasminogen analogue in which the amino acid residues Pro(559), Gly(560) are replaced by Val, Val, Pro and has the additional mutations Cys(558) to Ala and Cys(566) to Ala to prevent disulphide bond formation. The opened cleavage loop sequence of BB10150 is shown in Seq. I.D. 6. BB10150 was made by mutagenesis using two  
15 oligonucleotide primers (5' CTAGGTACAACCGCTTTCTTCGGCT 3' (Seq. I.D. 7) and 5' GGTGGGCCACCGCCCCCCCCAC 3' (Seq. I.D. 8) and  
20 the 1.87kb KpnI to HincII fragment of mutant T13 (see patent application WO-A-9109118, Example 13 and Seq. I.D. 9) cloned into M13.

25

Plasminogen analogues BB10156, BB10158 and BB10170 were all constructed by site specific mutagenesis using the previously described mutant BB10150 in M13 as the template so that they all have the same Cys to Ala mutations at residues 558 and 566. BB10156 is a plasminogen analogue in which the amino acid residues Pro(559), Gly(560) are  
30 replaced by Gly, Gln, Lys, Thr, Leu, Arg, Pro (Seq. I.D. 10). BB10158 is a

plasminogen analogue in which the amino acid residues Pro(559), Gly(560) are replaced by Thr, Thr, Lys, Ile, Lys, Pro and Val(562) is replaced by Ile (Seq. I.D. 11). BB10170 is a plasminogen analogue in which the amino acid residues Pro(559), Gly(560) are replaced by Leu, Arg, Pro (Seq. I.D. 12). The oligonucleotides used to prime each mutagenesis are shown below:-

MUTANT                      OLIGONUCLEOTIDE SEQUENCE

BB10156      (Seq.I.D. 13)

5' CAACCCTAGGTCTAAGTGTTTTCTGACCCGCTTTCTTCG 3'

BB10158      (Seq. I.D. 14)

5' CAACCCTAGGTTTGATCTTCGTTGTCGCTTTCTTCG 3'

BB10170      (Seq. I.D. 15)

5' CACAACCCTAGGTCTAAGCGCTTTCTTCGG 3'

In each case, following DNA sequencing, the mutation was cloned directly into the pGW1Hg.plasminogen expression vector using the restriction enzymes HindIII and SplI. These sites had previously been introduced at the extreme 5' end of plasminogen and at 1850 respectively via mutagenesis; the plasminogen amino acid coding sequence was not affected by this procedure.

Example 4 - Construction of BB10169 and BB10171

BB10169 is a plasminogen analogue in which the amino acid residues Pro(559), Gly(560) are replaced by Val, Glu, Leu, Gln, Gly, Ile, Lys Pro and Val(562) is replaced by Ile (Seq. I.D. 16). BB10169 was made by oligonucleotide directed mutagenesis of BB10151 in M13 using the 42 base oligonucleotide

2145749

5' GATTCTAGGTTTAATGCCCTGCAGTTCCACACATTTCTTCGG 3'  
(Seq. I.D. 17) followed by cloning into pGW1Hg plasminogen using  
HindIII and SplI. BB10171 is a plasminogen analogue in which the  
amino acid residues Pro(559), Gly(560) are replaced by Val, Glu, Leu,  
5 Gln, Gly, Leu, Arg, Pro (Seq. I.D. 18). The single stranded M13 from  
BB10169 was used as the template for the construction of BB10171.  
Mutagenesis was primed using the 39 base oligonucleotide  
5' CACCCCCCTACCACTCTGGGTCTCAGGCCCTGCAGTTCC 3' (Seq.  
I.D. 19) and, following DNA sequencing, was cloned into the expression  
10 vector using HindIII and SplI.

Example 5 - Construction and Expression of BB10189, BB10190 and  
BB10191

15 Plasminogen analogues BB10189, BB10190 and BB10191 have the  
kringle 1 double mutation Asp(137) to Ser, Asp(139) to Ser to disable the  
lysine binding site. The mutation was performed in the BB10153,  
BB10170 and BB10171 backgrounds (see examples 2, 3 & 4) using the 28  
base long oligonucleotide

20 5' CCCTGCGGAGAGTTGGATGGATTCCTGC 3' (Seq. I.D. 20).

The mutation was then cloned into pGW1Hg.plasminogen using the  
restriction enzymes HindIII and SplI.

Example 6 - Construction of BB10181

25 BB10181 has the cleavage site sequence of BB10170 and an additional  
mutation of Phe(583) to Arg to interfere with the binding of  $\alpha$ 2-  
antiplasmin. BB10181 was constructed via an intermediate BB10150-

2145749

19

based construct using M13 containing full length BB10150 as the template and the oligonucleotide

5' GAAGTGCATTCTCTCCTCGTACGAAG 3' (Seq. I.D. 21) as the primer. The mutated BB10150 gene was then cloned into pGW1Hg using the restriction enzymes HindIII and SmaI. The BB10181 expression vector was then made from this intermediate by replacing the HindIII to SplI fragment from this plasmid with the corresponding portion from BB10170 (see example 3).

Example 7 - Construction of BB10186

BB10186 has the cleavage site sequence of BB10171 and an additional mutation of Met(585) to Arg to interfere with the binding of  $\alpha$ 2-antiplasmin. BB10186 was made in a similar manner to that described in example 6 above for BB10181. The intermediate BB10150 construct was made using the 25 base long oligonucleotide 5' CCACAGAAGTGTCTTCCAAACCTCG 3' (Seq. I.D. 22) followed by cloning into pGW1Hg. BB10186 was then made by a fragment switch using the HindIII to SplI fragment from BB10171 (see example 4).

Example 8 - Construction of BB10199

BB10199 has the cleavage site sequence of BB10158 and an additional mutation of Glu(606) to Lys to interfere with the binding of  $\alpha$ 2-antiplasmin. BB10199 was made essentially as described in PCTGB 9301632 examples 2 & 3. The KpnI to EcoRV fragment of BB10158 (see example 3 above) was used to replace the corresponding fragment of a BB10151 Glu(606) to Lys construct cloned into pUC and was then cloned into the final expression vector as described in PCTGB 9301632.

## Example 9 - Cleavage of BB10151

5 Plasminogen mutants (12.5 $\mu$ g) were incubated with 2.8 $\mu$ g thrombin as described in Method 1. The time course of cleavage of the plasminogen mutants was determined by quantitative gel scanning; 50% cleavage times for T19 and BB10151 were 9 and 3 minutes respectively. Gel scan data for cleavage of BB10151 are shown in Figure 1.

## Example 10 - Activation of BB10151

10 Purified BB10153` protein was assayed for activation using the linked chromogenic assay (see Method 2.1). Results of this assay are shown in Figure 2 in which the increase in absorbance at 405nm with time demonstrates that plasmin activity is generated upon incubation of  
15 BB10151 with thrombin. T19 is shown for comparison and was found to be approximately 2 times less potent than BB10151 in this assay.

## Example 11- Plasma Clot Lysis

20 The ability of BB10153 and T19 to lyse a plasma clot was determined as described in Method 2.2 and the results of such an assay are shown in Figure 3. BB10151 (20 $\mu$ g/ml) was able to cause complete lysis of the clot whereas T19 did not lyse the clot at concentrations up to 150 $\mu$ g/ml. Thus BB10153 was found to be at least 7 times more active than T19 at  
25 inducing lysis of a plasma clot.

Representative examples of other plasminogen analogues of the invention were compared for plasma clot lysis activity at a concentration of 40  $\mu$ g /ml and the results in Table 1 show that they possess similar activity to BB10151

30

2145749

21

Table 1

Plasminogen Analogue	Time for 50% clot lysis (min)
BB10151	4.5
T19	not lysed
BB10158	12.5
BB10199	6
BB10153	4.1
BB10171	4.4
BB10156	6.6
BB10170	3.1

Methods1. Cleavage Analysis

Plasminogen analogues are assessed for susceptibility to cleavage by thrombin using SDS PAGE under reducing conditions. Typical incubation volumes of 0.125 ml in 100mM Tris HCl pH 7.4 consist of plasminogen analogue, at the concentration shown in the examples, and thrombin, at the concentration shown in the examples. Incubations are performed at 37°C. Control incubations are performed under the same conditions in the absence of thrombin. The activation reactions were stopped by precipitating the protein by the addition of trichloroacetic acid to a final concentration of 20% and standing at 4°C for >4 hours. The precipitates were then pelleted, washed with acetone and resuspended in SDS PAGE sample buffer (0.1m Tris pH6.8, 10% glycerol, 1% SDS, 0.5% mercaptoethanol and 0.05% bromophenol blue). The samples were analysed either on 8-25% gradient gels or 12% gels.

The resulting gels were analysed using a SHIMADZU Gel Scanner which scans the gel and calculates the concentration of protein in bands by determining the area under the peaks. (The word SHIMADZU is a trade mark.) The rate of cleavage of plasminogen was thus determined by measuring the disappearance of the plasminogen band at approximately 92kDa and the appearance of the plasmin heavy chain band at approximately 66kDa.

## 2. Activation Analysis

### 2.1 Linked Chromogenic Assay

Plasminogen analogue and thrombin are incubated together in the presence of the chromogenic substrate S2251 and plasmin produced by activation directly cleaves the S2251 leading to an increase in absorbance at 405nm. The assay is performed in a total volume of 880 $\mu$ l in a buffer containing 50mM Tris HCl, 0.1mM EDTA, 0.005% Triton X100<sup>\*</sup> and 0.1% HSA. S2251 is added to a final concentration of 0.35mg/ml and the plasminogen analogue concentration used is 3  $\mu$ g/ml. The thrombin concentration used is 4.55 NIHU/ml. Aliquots of 100 $\mu$ l of the reaction are removed during incubation at 37°C and added to 25 $\mu$ l 4% acetic acid, in microtitre plates, to stop the reaction. At the completion of the time course the plates are read on a microplate reader at a wavelength of 405nm.

### 2.2 In Vitro Plasma Clot Lysis Assay

A mixture of 50 $\mu$ l rabbit plasma (anticoagulated with 3.8% trisodium citrate), 50 $\mu$ l APTT reagent (Instrumentation Labs) and an appropriate volume of plasminogen analogue in 0.1M Tris HCl pH 7.4 is made up to

\* trade-mark

23

200µl with the same buffer in a well of a 96 well microtitre plate. A separate well contains 4.4µl 500mM CaCl<sub>2</sub> mixed with 50.6µl of the same buffer. The plate is incubated at 37°C for 30 minutes and clotting is initiated by transferring 50µl of the CaCl<sub>2</sub> to the well containing plasminogen analogue. Progress of clot formation and dissolution is followed by measuring the absorbance at 405nm (620nm reference) at timed intervals during continued incubation at 37°C for 1 hour.

**The embodiments of the invention in which an exclusive privilege or property is claimed are as follows:**

1. A plasminogen analogue activatable by thrombin to have fibrinolytic plasmin activity,  
5 which contains the cleavage site sequence

P4-P3-Pro-Arg-P1'-P2'

and where P3 is a basic amino acid residue, P4 is a hydrophobic amino acid residue and each of P1' and P2' is independently a non-acidic amino acid residue, said site being cleavable by thrombin between Arg and P1'.

- 10 2. A plasminogen analogue as claimed in claim 1 wherein the basic amino acid residue P3 is a lysine or arginine residue; the hydrophobic amino acid residue P4 is valine, isoleucine or leucine, and the non-acidic amino acid residues P1' and P2' are each independently valine, isoleucine or leucine.

- 15 3. A plasminogen analogue as claimed in claim 1 which contains the cleavage site sequence Thr-Thr-Lys-Ile-Lys-Pro-Arg-Ile-Val.

4. A plasminogen analogue as claimed in claim 1 where the cleavage site sequence is formed so that the sequence corresponding to Pro(559)-Gly(560) of wild-type plasminogen is replaced by Thr-Thr-Lys-Ile-Lys-Pro, and Val(562) is replaced by Ile.

- 20 5. A plasminogen analogue as claimed in claim 4 in which, in addition to said cleavage site sequence, the amino acid residues corresponding to Glu(606) and Glu(623) of the said wild-type plasminogen are each replaced by a lysine residue.

6. A pharmaceutical of veterinary composition comprising a plasminogen analogue as claimed in any one of claims 1 to 5 together with a pharmaceutically or veterinarily acceptable carrier.
