(54) **Title:** IMAGE PROCESSING METHOD FOR DETERMINING DIMENSIONS OF A PART

FIG. 2

(57) **Abstract:** A high-resolution imaging and processing method and system for determining a geometric dimension of a part is provided. The method includes directing at least one plane of collimated radiation at a surface of a supported part. Each of the planes is occluded by the part to create unobstructed first and second planar portions of the plane of radiation passing by and not blocked by the supported part and to cast a radiation shadow of the supported part. Each of the first and second planar portions has a width and contains an amount of radiation which is representative of a respective geometric dimension of the part to be determined. The method includes increasing the width and decreasing the intensity of the first and second planar portions imaged on first and second predetermined measuring areas, respectively.

WO 2015/026403 A1

IMAGE PROCESSING METHOD FOR DETERMINING DIMENSIONS OF A PART

TECHNICAL FIELD

[0001] This invention relates, in general, to the field of non-contact, optical imaging of parts and, more particularly, to high-resolution methods and systems for optically imaging parts, such as ammunition cases and threaded fasteners, to determine geometric dimensions of the parts.

Overview

[0002] Traditional manual, gauging devices and techniques have been replaced to some extent by automatic inspection methods and systems. However, such automatic inspection methods and systems still have a number of shortcomings associated with them. For example, it is often difficult to “see” or measure smaller details of the parts.

[0003] The assignee of the present application has patented and created several laser inspection instruments that utilize a common laser head to measure parts. These laser heads include typically one or more light sources and sensors that together facilitate precise non-contact measurement of parts. However, there is an ongoing need for laser heads including one or more sensors which increase the accuracy and effective measurement range of laser heads.

[0004] A current laser/sensor configuration of the assignee includes two sensors for each laser light source. The light from a laser is processed through optics to form a line or plane of collimated light. This light passes over the measured part and falls upon the two sensors, one for each side of the part. Each sensor is perpendicular to the collimated light such that one side of a shadow cast by the part falls on each of the two sensors. The sensors are placed as close together as possible but there is still typically a small gap between them. Figure 1 illustrates this configuration.

[0005] Each sensor includes a photo sensor that measures the amount of light it receives. The wider the part, the less light reaches the sensor and vice versa. The correlation between light received and part width is calibrated allowing the part to be measured according to the size of the shadow on the sensors. Because the collimated light is perpendicular to the sensor, the width of the part’s shadow cast on the sensors is the same as the width of the part.

[0006] Figure 9 shows a prior art system of U.S. Patent No. 5,608,530 wherein mirrors are used to change the direction of light passing by a part.

[0007] U.S. Patent No. 4,923,066 discloses an automatic visual inspection system for small arms ammunition which sorts visual surface flaws at high speed according to established standards which can be tailored to fit specific needs.

[0008] U.S. Pat. No. 7,403,872 discloses a method and system for inspecting manufactured parts such as cartridges and cartridge cases and sorting the inspected parts.

[0009] WO 2005/022076 discloses a plurality of light line generators which generate associated beams of light that intersect a part to be inspected.

[0010] U.S. Pat. No. 6,313,948 discloses an optical beam shaper for production of a uniform sheet of light for use in a parts inspection system having a light source including a coherent light generator, a diffractive beam shaper, and lens elements.

[0011] U.S. Pat. No. 6,285,034 discloses an inspection system for evaluating rotationally asymmetric workpieces for conformance to configuration criteria.

[0012] U.S. Pat. No. 6,252,661 discloses an inspection system for evaluating workpieces for conformance to configuration criteria.

[0013] U.S. Pat. No. 6,959,108 discloses an inspection system wherein workpieces to be inspected are consecutively and automatically launched to pass unsupported through the field of view of a plurality of cameras.

[0014] U.S. Pat. No. 4,831,251 discloses an optical device for discriminating threaded workpiece by the handedness by their screw thread profiles.

[0015] U.S. Pat. No. 5,383,021 discloses a non-contact inspection system capable of evaluating spatial form parameters of a workpiece to provide inspection of parts in production.

[0016] U.S. Pat. No. 5,568,263 also discloses a non-contact inspection system capable of evaluating spatial form parameters of a workpiece to provide inspection of parts in production.

[0017] U.S. Pat No. 4,852,983 discloses an optical system which simulates the optical effect of traveling over a large distance on light traveling between reference surfaces.

[0018] U.S. Patent Application Publication No. 2005/0174567 discloses a system to determine the presence of cracks in parts.

[0019] U.S. Patent Application Publication No. 2006/0236792 discloses an inspection station for a workpiece including a conveyor, a mechanism for rotating the workpiece, and a probe.

[0020] U.S. Pat. No. 6,289,600 discloses a non-contact measuring device for determining the dimensions of a cylindrical object, such as a pipe.

[0021] U.S. Pat. No. 5,521,707 discloses a non-contact laser-based sensor guided by a precision mechanical system to scan a thread form producing a set of digitized images of the thread form.

[0022] WO 2009/130062 discloses a method and a device for the optical viewing of objects.

[0023] U.S. Pat. Nos. 5,168,458 and 5,170,306 disclose methods and systems for gauging threaded fasteners to obtain trilobular parameters.

[0024] Other U.S. patent documents related to the invention include: U.S. Pat. Nos. 4,315,688; 4,598,998; 4,644,394; 4,852,983; 4,906,098; 5,521,707; 5,608,530; 5,646,724; 5,291,272; 6,055,329; 4,983,043; 3,924,953; 5,164,995; 4,721,388; 4,969,746; 5,012,117; 7,684,054; 7,403,872; 7,633,635; 7,312,607, 7,777,900; 7,633,046; 7,633,634; 7,738,121; 7,755,754; 7,738,088; 7,796,278; 8,054,460; 8,179,434 and U.S. published patent applications 2010/0245850, 2010/0201806, 2012/0293623; 2012/0105429; and 2012/0293789.

[0025] For purposes of this application and for clarity, the photo sensors or photodetectors of this application are drawn as rectangles implying that they are some kind of photocell. In reality, they can be any device that measures intensity of light. Some examples are:

[0026] Area (Photocell): This is a device that generates variable voltages depending on the amount of light it receives. It receives light over an area.

[0027] Line (Linear Sensor Array): Conceptually this is a linear array of photo sensors. Each photo sensor measures the intensity of a point of light and acts independently allowing the sensor to measure both the total amount of light and position of the light that it receives.

[0028] Point (Photodiode): A photo diode is functionally the same as a photocell except that it measures light that falls on a point (or essentially a point) rather than an area.

[0029] Both area and line sensors can be directly substituted for the sensor rectangles in the drawing figures of this application. Point light sensors require more processing. The light passing by the part must somehow be focused onto the point sensor. There are a variety of ways this can be done and one possible configuration is illustrated in Figure 9. For clarity only one sensor on one side is shown in Figure 9 though this can be repeated for all sensors.

SUMMARY OF EXAMPLE EMBODIMENTS

[0030] An object of at least one embodiment of the present invention is to increase the resolution of an imaging and processing method and system for optically determining the geometric dimension of a part.

[0031] In carrying out the above object and other objects of at least one embodiment of the present invention, a high-resolution imaging and processing method of determining a geometric dimension of a part is provided. The method includes the steps of supporting a part having a width and directing at least one plane of collimated radiation at a surface of the part. Each of the planes is occluded by the part to create unobstructed first and second planar portions of the plane of radiation passing by and not blocked by the supported part and to cast a radiation shadow of the supported part. Each of the first and second planar portions has a width and contains an amount of radiation which is representative of a respective geometric dimension of the part to be determined. The method also includes measuring the amount of radiation in each of the first and second planar portions imaged on first and second predetermined measuring areas, respectively, to determine the geometric dimension. The improvement includes increasing the width and decreasing the intensity of the first planar portion imaged on the first predetermined measuring area to produce a first electrical signal proportional to the measurement. The improvement also includes increasing the width and decreasing the intensity of the second planar portion imaged on the second predetermined

measuring area to produce a second electrical signal proportional to the measurement. The improvement further includes processing the electrical signals to determine the geometric dimension with enhanced accuracy.

[0032] The first and second measuring areas may be angled with respect to the width of the part.

[0033] The steps of increasing may include the steps of magnifying the first and second planar portions along the widths.

[0034] The step of magnifying may be performed by a pair of magnifying lenses.

[0035] The method may further include the step of reflecting the first and second planar portions prior to the step of magnifying.

[0036] The step of reflecting may be performed by at least one optical component having reflecting surfaces which are angled with respect to the width of the part.

[0037] The radiation may be visible radiation, laser radiation and/or light radiation.

[0038] Further in carrying out the above object and other objects of at least one embodiment of the present invention, a high-resolution imaging and processing system for determining a geometric dimension of a part with enhanced accuracy is provided. The system includes a support for supporting a part having a width and at least one transmitter-receiver pair. Each pair includes a radiation source for directing a plane of collimated radiation at the part so that the part occludes each plane of radiation to create unobstructed first and second planar portions of the plane of radiation passing by and not blocked by the supported part. Each of the unobstructed first and second planar portions has a width and contains an amount of radiation which is representative of a respective geometric dimension of the part to be determined. Each pair further includes a receiver module for measuring the amount of radiation present in each of the unobstructed first and second planar portions imaged on first and second predetermined measuring areas, respectively, to determine the geometric dimension. The improvement includes a means or mechanism for increasing the width and decreasing the intensity of the first and second planar portions imaged on the first and second measuring areas, respectively, to produce first and second electrical signals proportional to the

measurements. The improvement also includes at least one processor to process the electrical signals to determine the geometric dimension with enhanced accuracy.

[0039] First and second photodetectors may have the first and second predetermined measuring areas, respectively. Each of the photodetectors may be angled with respect to the width of the part wherein the effective widths of the photodetectors are reduced.

[0040] The receiver module may include a pair of magnifying optical components to magnify the planar portions along the widths and first and second photodetectors may have the first and second measuring areas, respectively.

[0041] The magnifying optical components may include a pair of magnifying lenses.

[0042] The photodetectors may comprise at least one of photocells, linear sensor arrays and photodiodes.

[0043] The receiver module may include at least one optical component having reflecting surfaces which are angled with respect to the width of the part to reflect the planar portions prior to magnifying.

[0044] The system may further includes an actuator mechanism for moving each transmitter-receiver pair in unison relative to the part to scan the at least one plane of collimated radiation in a scanning direction at a surface of the part.

[0045] The radiation may be laser radiation, light radiation and/or visible radiation.

BRIEF DESCRIPTION OF THE DRAWINGS

[0046] For a more complete understanding of the present invention, and for further features and advantages thereof, reference is made to the following description taken in conjunction with the accompanying drawings, in which:

[0047] Figure 1 is a top plan schematic view illustrating a method and prior art method and system for measuring a geometric dimension of a part;

[0048] Figure 2 is a top plan schematic view illustrating a method and system for determining a geometric dimension of a part utilizing at least one embodiment of the present invention;

[0049] Figure 3 is a top plan schematic view of a cylindrical part illuminated with collimated light and a pair of angled photo sensors or detectors of at least one embodiment of the present invention;

[0050] Figure 4a is a top plan schematic view, partially broken away, of a part and collimated radiation with a non-rotated sensor;

[0051] Figure 4b shows a dimension of the part and shadow cast on an angled sensor with associated calculations;

[0052] Figure 5 is a top plan schematic view of another embodiment for spreading or magnifying collimated light passing by a part;

[0053] Figure 6 is a top plan schematic view of yet another embodiment wherein the sensor is substantially parallel to the generated collimated light;

[0054] Figure 7 is a top plan schematic view of yet another embodiment wherein the angled sensors are staggered;

[0055] Figure 8 is a view similar to the view of Figure 7 wherein two adjacent sensors overlap in the shadow cast by the part to eliminate any gap between the sensors; and

[0056] Figure 9 is a top plan schematic view of a prior art point sensor system.

DETAILED DESCRIPTION

[0057] As required, detailed embodiments of the present invention are disclosed herein; however, it is to be understood that the disclosed embodiments are merely exemplary of the invention that may be embodied in various and alternative forms. The figures are not necessarily to scale; some features may be exaggerated or minimized to show details of particular components. Therefore, specific structural and functional details disclosed herein are not to be interpreted as

limiting, but merely as a representative basis for teaching one skilled in the art to variously employ the present invention.

[0058] In general, and as described below, at least one embodiment of the present invention provides a high-resolution imaging and processing method and system for determining a geometric dimension of a part such as a manufactured part. The part, such as a threaded fastener, has a length, a width, a part axis and an outer peripheral surface which extends 360° around the part.

[0059] Referring now to Figure 2, a part such as a threaded bolt may be supported by a chuck or fixture of a part holder, as described in detail in U.S. Pat. No. 7,812,970. The head of the bolt is supported by and disposed within the fixture. The threads of the bolt may be optically inspected in an embodiment of the method and system of the present invention. Other parts, such as ammunition cases can be supported in a similar or slightly different fashion. Alternatively, such parts can travel down a track and the rest of the system can be stationary.

[0060] As shown in Figure 2, the system includes at least one transmitter-receiver pair, and preferably, a plurality of such pairs. Each pair includes a radiation source for directing a plane of collimated radiation at the supported part so that the part occludes each plane of radiation to create unobstructed first and second planar portions of the plane of radiation passing by and not blocked by the supported part. Each of the unobstructed first and second planar portions has a width and contains an amount of radiation which is representative of a respective geometric dimension of the part to be determined. Each pair further also includes a receiver module for measuring the amount of radiation present in each of the unobstructed first and second planar portions imaged on first and second predetermined measuring areas, respectively, to determine the geometric dimension.

[0061] The system may further include an actuator mechanism such as a linear drive under control of a system controller for moving an optical head and each supported transmitter-receiver pair in unison relative to the supported part to scan the at least one plane of collimated radiation in a scanning direction at a surface of the part. However, it is to be understood that the supported part may move relative to the transmitter-receiver pair. For example, the part may travel down a track relative to stationary transmitter-receiver pairs.

[0062] The system may further include one or more processors under control of the system controller to process the resulting sets of 2-D profile signals to obtain measurements of the parts as described in U.S. Patent No. 7,812,970. As shown in Figure 2, the system may also include sensors including a linear encoder, a user interface and a display as described in U.S. Patent No. 7,812,970.

[0063] There are at least two types of improvements to the methods and systems of the prior art described herein:

[0064] 1) Improvements to magnify (or spread out) the image of the part. Magnifying or splitting the image of a part allows measurements to be calculated more accurately.

[0065] 2) Improvements to increase the area covered by sensors. The effective sizes of the photo sensors or detectors are increased to accommodate such magnified or split part images.

Sensor Design Improvements to Magnify Part Images

[0066] A new sensor design is best described in multiple parts because each part adds an improvement to the sensor design. Each of the parts can be implemented separately but may be combined in a single design as described herein.

[0067] At least one embodiment of the present invention increases the sensitivity of the laser sensors. The current sensor design measures using a 1:1 part-width-to-shadow ratio. By increasing the ratio (i.e. magnifying the image) to 1:X($x > 1$) the shadow of the part will be magnified so that small details in the part will produce large details in the part's shadow. This will allow the sensors to produce more accurate and consistent measurements.

[0068] There are multiple ways in which the (shadow) image of a part can be magnified in a way that is suitable for detailed measurements.

Using Angled Photo Sensors or Detectors

[0069] The design change is to rotate the sensors so that they are at a more than 90 degree angle to the collimated light. This has the effect of elongating (magnifying) the shadow as illustrated in Figure 3.

[0070] Figure 3 illustrates the angle as rotated 45 degrees from perpendicular. However, a rotation of any angle will magnify the shadow. The more the sensor is rotated the more the shadow is multiplied though there are obvious problems as the rotation angle approaches 90 degrees.

[0071] Calculations show that the amount of shadow magnification is $1/\cos$ (rotation angle). This is illustrated in Figures 4a and 4b.

[0072] The following table shows some example angle vs. magnification for selected angles.

Angle (degrees)	Magnification
30	1.15
45	1.41
60	2.0

Using Optics

[0073] This method of magnifying a part image uses optical elements in the form of lenses. The image of the part passes through a magnifying lens and then to a suitable sensor or sensors. Figure 5 illustrates this configuration. For clarity only one side of the sensor configuration is shown in Figure 5.

Combinations

[0074] The previous image magnification methods can be combined in any order to increase the magnification. Figure 6 illustrates one possible combined configuration. In Figure 6, the image of the part is magnified 2x by angling the mirror (assuming a rotation of 60 degrees) plus an additional magnification from the magnifying lens.

[0075] A gist of at least one embodiment of the present invention is to spread out (magnify) at least one laser line segment or plane of collimated radiation so it can be measured in greater detail using multiple photo-diodes. Magnification of the line segment can be done either by angling

mirrors/detectors or through the use of magnifying optics. It is not strictly necessary to magnify the line segment in order to use multiple photo-diodes. The line segment could simply be split into multiple sub-segments and each sub-segments sent to a photo-diode. In this embodiment, multiple photo-diodes are used in order to measure with greater resolution.

Photo Sensor or Detector Design Improvements to Increase Measurement Width

[0076] The above-described improvements increase the measurement capacity of receiver modules which include sensors or photodiodes by allowing wider parts to be measured.

[0077] Angling the sensors has the benefit of increasing the sensitivity of the sensor by magnifying the shadow but has the downside of reducing the effective width of the sensor. The following table shows the magnitude of this effect for selected angles.

Angle (degrees)	Effective Width Reduction Factor
30	0.87
45	0.71
60	0.50

[0078] Rotating the sensor 60 degrees doubles the sensitivity but also cuts in half the maximum width of parts that can be measured.

[0079] One solution to this is to use multiple sensors that are staggered to increase the width of shadows that can be measured. This is illustrated in Figure 7.

[0080] Staggering the sensors causes the shadow of the part to spill over to a lower adjacent sensor if it is wider than the previous sensor. The electrical signal outputs from the sensors are added together to form the net measurement. Any number of sensors can be combined in the

staggered formation allowing the maximum width of measureable parts to be limited only by the number of staggered sensors rather than the width of a single sensor.

Photo Sensor or Detector Design Improvement to Eliminate the “Gap” Between Sensors

[0081] This improvement increases the measurement capacity of the sensor by allowing narrower parts to be measured.

[0082] The prior art typically includes a gap between adjacent photo sensors or detectors. This imposes a lower limit on the size of parts that can be measured. However, this gap can be eliminated by moving the left and right sensors so that they overlap with respect to the parts as shown in Figure 8. By overlapping the sensors the lower limit is eliminated so the optical instrument will be able to measure any part that can be placed such that each side of its shadow falls on each side of the sensors.

[0083] Because the sensors are overlapped there is no gap between for the sensors. All parts of the shadow must fall on the sensors. However, the part is only measureable if one side of the part falls on each side of the sensors.

Summary

[0084] This application describes improvements for photo sensors and/or detectors used in various inspection and sorting instruments. Multiple improvements can be implemented in any combination or together for maximum benefit. These improvements include:

[0085] 1) Angle the sensors with respect to the collimated light. This increases measurement resolution by magnifying or spreading out the collimated light. The collimated light can also be optically magnified. Also, the collimated light can be optically split and imaged on multiple photo detectors.

[0086] 2) Use multiple sensors in a staggered formation to extend the maximum size of a part that can be measured.

[0087] 3) Overlap the sensors on each side to eliminate the present gap between sensors. With this change there is no lower limit to the width of parts that can be measured.

[0088] While exemplary embodiments are described above, it is not intended that these embodiments describe all possible forms of the invention. Rather, the words used in the specification are words of description rather than limitation, and it is understood that various changes may be made without departing from the spirit and scope of the invention. Additionally, the features of various implementing embodiments may be combined to form further embodiments of the invention.

WHAT IS CLAIMED IS:

1. A high-resolution imaging and processing method of determining a geometric dimension of a part, the method including the steps of supporting a part having a width, directing at least one plane of collimated radiation at a surface of the part wherein each of the planes is occluded by the part to create unobstructed first and second planar portions of the plane of radiation passing by and not blocked by the supported part and to cast a radiation shadow of the supported part wherein each of the first and second planar portions has a width and contains an amount of radiation which is representative of a respective geometric dimension of the part to be determined, and measuring the amount of radiation in each of the first and second planar portions imaged on first and second predetermined measuring areas, respectively, to determine the geometric dimension, the improvement comprises:

increasing the width and decreasing the intensity of the first planar portion imaged on the first predetermined measuring area to produce a first electrical signal proportional to the measurement;

increasing the width and decreasing the intensity of the second planar portion imaged on the second predetermined measuring area to produce a second electrical signal proportional to the measurement; and

processing the electrical signals to determine the geometric dimension with enhanced accuracy.

2. The method as claimed in claim 1, wherein the first and second measuring areas are angled with respect to the width of the part.

3. The method as claimed in claim 1, wherein the steps of increasing includes the steps of magnifying the first and second planar portions along the widths.

4. The method as claimed in claim 3, wherein the step of magnifying is performed by a pair of magnifying lenses.

5. The method as claimed in claim 3, further comprising the step of reflecting the first and second planar portions prior to the step of magnifying.

6. The method as claimed in claim 5, wherein the step of reflecting is performed by at least one optical component having reflecting surfaces which are angled with respect to the width of the part.

7. The method as claimed in claim 1, wherein the radiation is visible radiation.

8. The method as claimed in claim 1, wherein the radiation is laser radiation.

9. The method as claimed in claim 1, wherein the radiation is light radiation.

10. A high-resolution imaging and processing system for determining a geometric dimension of a part with enhanced accuracy, the system including a support for supporting a part having a width and at least one transmitter-receiver pair, each pair including a radiation source for directing a plane of collimated radiation at the part so that the part occludes each plane of radiation to create unobstructed first and second planar portions of the plane of radiation passing by and not blocked by the supported part wherein each of the unobstructed first and second planar portions has a width and contains an amount of radiation which is representative of a respective geometric dimension of the part to be determined and wherein each pair further includes a receiver module for measuring the amount of radiation present in each of the unobstructed first and second planar portions imaged on first and second predetermined measuring areas, respectively, to determine the geometric dimension, the improvement comprises:

means for increasing the width and decreasing the intensity of the first and second planar portions imaged on the first and second measuring areas, respectively, to produce first and second electrical signals proportional to the measurements; and

at least one processor to process the electrical signals to determine the geometric dimension with enhanced accuracy.

11. The system as claimed in claim 10, wherein first and second photodetectors have the first and second predetermined measuring areas, respectively, each of the photodetectors being angled with respect to the width of the part wherein the effective widths of the photodetectors are reduced.

12. The system as claimed in claim 10, wherein the receiver module includes a pair of magnifying optical components to magnify the planar portions along the widths and first and second photodetectors have the first and second measuring areas, respectively.

13. The system as claimed in claim 12, wherein the magnifying optical components include a pair of magnifying lenses.

14. The system as claimed in claim 12, wherein the photodetectors comprise at least one of photocells, linear sensor arrays and photodiodes.

15. The system as claimed in claim 12, wherein the receiver module includes at least one optical component having reflecting surfaces which are angled with respect to the width of the part to reflect the planar portions prior to magnifying.

16. The system as claimed in claim 11, wherein the photodetectors comprise at least one of photocells, linear laser arrays and photodiodes.

17. The system as claimed in claim 10, wherein the radiation is laser radiation.

18. The system as claimed in claim 10, wherein the radiation is light radiation.

19. The system as claimed in claim 10, wherein the radiation is visible radiation.

20. The system as claimed in claim 10 further comprising an actuator mechanism for moving each transmitter-receiver pair in unison relative to the part to scan the at least one plane of collimated radiation in a scanning direction at a surface of the part.

FIG. 8

INTERNATIONAL SEARCH REPORT

14/054031-21-00-2014
International application No.
PCT/US14/34857

A. CLASSIFICATION OF SUBJECT MATTER
 IPC(8) - G01B 11/08, 11/24; G06K 7/10 (2014.01)
 USPC - 356/602; 250/559.2
 According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED
 Minimum documentation searched (classification system followed by classification symbols)
 IPC(8) - G01B 11/08, 11/24; G06K 7/10; G02B 26/00; G01N 21/86; G06T 17/00 (2014.01)
 USPC - 356/602; 250/559.2, 559.24; 235/462.14, 462.22; 345/428

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)
 MicroPatent (US Granted, US Applications, EP-A, EP-B, WO, JP, DE-G, DE-A, DE-T, DE-U, GB-A, FR-A); DialogPro (Derwent, INSPEC, NTIS, PASCAL, Current Contents Search, Dissertation Abstracts Online, Inside Conferences); IEEE.org; Google; Google Scholar; IP.com, Proquest.com; KEYWORDS: geometric, dimension, part, laser radiation, magnifying lens, reflective surface

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X --- Y	US 5,608,530 A (GATES, D) March 04, 1997; figures 3-6, 8-10; column 2-3; lines 4-23, 16-33, 31-68, 57-68	10-17 ----- 18-20
Y	US 2009/0103107 A1 (NYGAARD, M) April 23, 2009; abstract; figures 1, 51; paragraphs [0037, 0050, 0120, 0129, 0580, 0582, 0590, 0592, 0600]	1-9, 18-19
Y	US 6,971,578 B2 (TSIKOS, C) December 06, 2005; figures 4A, 5A, 6A, 1B3, 1113, 1113A-1113B; columns 4, 10, 29, 53-54, 64, 129; lines 1-10, 3-18, 34-68; 48-64, 63-68	1-9, 20

Further documents are listed in the continuation of Box C.

* Special categories of cited documents:	"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A" document defining the general state of the art which is not considered to be of particular relevance	"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"E" earlier application or patent but published on or after the international filing date	"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"&" document member of the same patent family
"O" document referring to an oral disclosure, use, exhibition or other means	
"P" document published prior to the international filing date but later than the priority date claimed	

Date of the actual completion of the international search 26 July 2014 (26.07.2014)	Date of mailing of the international search report 27 AUG 2014
