Description

Introduction and state of the art

The invention relates to antibody drug conjugates (ADCs) of kinesin spindle protein inhibitors, to active metabolites of these ADCs, to processes for preparing these ADCs, to the use of these ADCs for the treatment and/or prophylaxis of diseases and to the use of these ADCs for preparing medicaments for treatment and/or prevention of diseases, in particular hyperproliferative and/or angiogenic disorders such as, for example, cancer diseases. Such treatments can be carried out as monotherapy or else in combination with other medicaments or further therapeutic measures.

Cancer diseases are the consequence of uncontrolled cell growth of the most diverse tissues. In many cases, the new cells penetrate into existing tissue (invasive growth), or they metastase into remote organs. Cancer diseases occur in the most diverse organs and often have tissue-specific courses of the disease. The term cancer as a generic term therefore describes a large group of defined diseases of various organs, tissue and cell types.

Tumours in early stages can possibly be removed by surgical and radiotherapy measures. Metastased tumours as a rule can only be treated palliatively by chemotherapeutics. The aim here is to achieve the optimum combination of an improvement in the quality of life and prolonging of life.

Conjugates of binder proteins with one or more active compound molecules are known, in particular in the form of antibody drug conjugates (ADCs) in which an internalising antibody directed against a tumour-associated antigen is covalently attached via a linker to a cytotoxic agent. Following introduction of the ADCs into the tumour cell and subsequent dissociation of the conjugate, either the cytotoxic agent itself or a cytotoxic metabolite formed therefrom is released within the tumour cell

and can unfold its action therein directly and selectively. In this manner, in contrast to conventional chemotherapy, damage to normal tissue is contained in significantly narrower limits [see, for example,. J. M. Lambert, *Curr. Opin. Pharmacol.* 5, 543-549 (2005); A. M. Wu and P. D. Senter, *Nat. Biotechnol.* 23, 1137-1146 (2005); P. D. Senter, *Curr. Opin. Chem. Biol.* 13, 235-244 (2009); L. Ducry and B. Stump, *Bioconjugate Chem.* 21, 5-13 (2010)]. Thus, WO2012/171020 describes ADCs in which a plurality of toxophor molecules are attached via a polymeric linker to an antibody. As possible toxophors, WO2012/171020 mentions, among others, the substances SB 743921, SB 715992 (Ispinesib), MK-0371, AZD8477, AZ3146 and ARRY-520.

The substances mentioned last are kinesin spindle protein inhibitors. Kinesin spindle protein (KSP, also known as Eg5, HsEg5, KNSL1 or KIF11) is a kinesin-like motorprotein which is essential for the bipolar mitotic spindle to function. Inhibition of KSP leads to mitotic arrest and, over a relatively long term, to apoptosis (Tao et al., Cancer Cell 2005 Jul 8(1), 39-59). After the discovery of the first cell-penetrating KSP inhibitor, Monastrol, KSP inhibitors have established themselves as a class of novel chemotherapeutics (Mayer et al., Science 286: 971-974, 1999), and they are subject of a number of patent applications (e.g. WO2006/044825; WO2006/002236; WO2005/051922; WO2006/060737; WO03/060064; WO03/040979; and WO03/049527). However, since KSP unfolds its action only during a relatively short period of time during the mitosis phase, KSP inhibitors have to be present in a sufficiently high concentration during these initial phases.

Summary of the invention

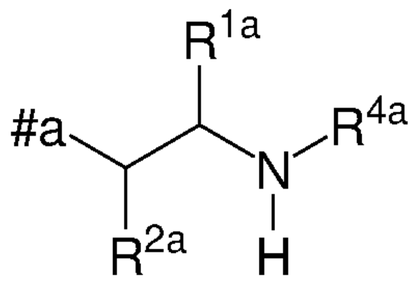
Against this background it is an object of the present invention to provide substances which, after administration at a relatively low concentration, unfold apoptotic action and may therefore be of benefit for cancer therapy.

To achieve this object, the invention provides conjugates of a

binder or derivatives thereof with one or more active compound molecules, the active compound molecule being a kinesin spindle protein inhibitor (KSP inhibitor) attached to the binder via a linker L. The binder is preferably a binder protein or peptide, particularly preferably a human, humanized or chimeric monoclonal antibody or an antigen-binding fragment thereof, in particular an anti-TWEAKR antibody or an antigen-binding fragment thereof or an anti-EGFR antibody or an antigen-binding fragment thereof. Particular preference is given to an anti-TWEAKR antibody which binds specifically to amino acid D in position 47 (D47) of TWEAKR (SEQ ID NO:169), in particular the anti-TWEAKR antibody TPP-2090, or the anti-EGFR antibodies cetuximab or nimotuzumab.

The inventors have found a number of ways to attach the binder to the KSP inhibitor in order to achieve the object mentioned above.

According to the invention, the kinesin spindle protein inhibitors may have the substructure I(sub) below:



I(sub)

#a represents a bond to the remainder of the molecule;

The conjugates according to the invention can have chemically labile linkers, enzymatically labile linkers or stable linkers. Particular preference is given to stable linkers and linkers which can be cleaved by cathepsin.

The invention furthermore provides processes for preparing the conjugates according to the invention, and also precursors and intermediates for the preparation.

The preparation of the conjugates according to the invention regularly comprises the following steps:

(i) Preparation of a linker precursor which optionally carries protective groups and has a reactive group which is capable of coupling to the binder;

(ii) Conjugation of the linker precursor to the derivative, which optionally carries protective groups, of a low-molecular weight KSP inhibitor (preferably a KSP inhibitor having the substructure I(sub), particularly preferably of formula (Ia) and in particular of formula (IIa), where in these formulae there is as yet no bond to a linker), giving a reactive KSP inhibitor/linker conjugate which optionally carries protective groups;

(iii) Removal of any protective groups present in the KSP inhibitor/linker conjugate and

(iv) Conjugation of the binder to the KSP inhibitor/linker conjugate, giving the binder/KSP inhibitor conjugate according to the invention.

Attachment of the reactive group may also take place after the construction of an optionally protected KSP inhibitor/linker precursor conjugate.

Depending on the linker, succinimide-linked ADCs may, after conjugation, be converted according to Scheme 26 into the open-chain succinamides, which have an advantageous stability profile.

As illustrated above, conjugation of the linker precursor to a low-molecular weight KSP inhibitor may take place by substitution of a hydrogen atom at R^{1a}, R^{2a}, R^{4a} or R^{10} in substructur I(sub), R^{1a}, R^{2a}, R^{3a}, R^{4a}, R^{8a} or R^{10} in formula (Ia), or R^{1}, R^{2}, R^{3}, R^{4}, R^{5} , R^{8} or R^{10} in formula (IIa) by the linker. In the synthesis steps prior to the conjugation, any functional groups present may also be present in protected form. Prior to the conjugation step, these protective groups are removed by known methods of peptide chemistry. Conjugation can take place chemically by various routes, as shown in an exemplary manner in Schemes 7 to 31 in the examples. In particular, it is optionally possible to modify the low-molecular weight KSP

inhibitor for conjugation to the linker, for example by introduction of protective groups or leaving groups to facilitate substitution.

In particular, the invention provides novel low-molecular weight KSP inhibitors which may optionally be conjugated to a binder. These KSP inhibitors or their binder conjugates have the following general formula (IIIa):

Figure 2: A – Schematic diagram of the structure of TWEAKR (SEQ ID NO: 169). The diagram shows the extracellular domain (amino acids 28-80) (SEQ ID NO: 168) including the cysteine-rich domain (36-67), the transmembrane domain – TM (81-101) and the intracellular domain (102-129). TPP-2202 – the complete ectodomain (28-80), fused to the Fc domain of hIgG1. TPP-2203 – extracellular domain with N- and C-terminal truncation (34-68), fused to the Fc domain of hIgG1. Disulphide bridges Cys36-Cys49, Cys52-Cys67 and Cys55-Cys64 are indicated by black bars. N-terminally and C-terminally, TPP-2203 contains two amino acids more and one amino acid more, respectively, than the unmodified cysteine-rich domain to ensure proper folding. TPP-1984 – extracellular domain having C-terminal truncation (28-68), fused to an HIS6 tag. All three constructs show comparable binding to the antibodies according to the invention and PDL-192 (TPP-1104). P4A8 (TPP-1324) binds only to the full-length extracellular domain (TPP-2202).

B – Amino acid sequence of the extracellular domain: It has been published that the amino acid 64 is essential for TWEAK ligand binding; and the amino acid 47 is essential for binding of the antibodies according to the invention, as was determined here.

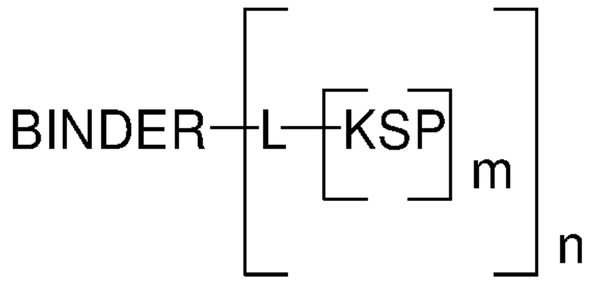
(1 µg/ml), the TWEAKR variant was added at 250 ng/ml, detection was via anti-HIS HRP. Compared to the wild-typ construct, TTP-2090 shows less than 5% binding.

Figure 7: NMR structure of the TWEAKR ectodomain as published by Pellegrini et al. (FEBS 280:1818-1829). TWEAK binding depends on L46 (Pellegrini et al.), TTP-2090 binding depends on D47 and PDL-192 binds to R56. PDL-192 binds opposite the TWEAK ligand binding site, TPP-2090 binds directly to the TWEAK ligand site.

Detailed description of the invention

The invention provides conjugates of a binder or derivative thereof with one or more active compound molecules, the active compound molecule being a kinesin spindle protein inhibitor (KSP inhibitor) attached to the binder via a linker L.

The conjugate according to the invention can be represented by the general formula



where BINDER represents the binder, preferably an antibody, L represents the linker, KSP represents the KSP inhibitor, m represents a number from 1 to 2, preferably 1, and n represents a number from 1 to 50, preferably from 1.2 to 20 and particularly preferably from 2 to 8. Here, m is the number of KSP inhibitors per linker and n a mean of the number of KSP inhibitor/linker conjugates per BINDER. The sum of all KSP present in the conjugate is thus the product of m and n. KSP-L preferably has the formula (I) or (II) shown above. The binder is preferably a binder peptide or protein such as, for example, an antibody. Furthermore, the linker is preferably attached to different amino acids of the binder peptide or protein or derivative thereof. Particular preference is given to binding to different cysteine residues of the binder.

Binders which can be used according to the invention, KSP inhibitors which can be used according to the invention and linkers which can be used according to the invention which can be used in combination without any limitation are described below. In particular, the binders represented in each case as preferred or particularly preferred can be employed in combination with the KSP inhibitors represented in each case as preferred or particularly preferred, optionally in combination with the linkers represented in each case as preferred or particularly preferred.

Particularly preferably, the substitution of the hydrogen atom takes place at R^{1a}, R^{2a}, R^{3a}, R^{4a} or at the pyrrolidine ring formed by R^{2a} and R^{4a}. This conjugation can take place chemically by various routes, as shown in an exemplary manner in Schemes 7 to 31 in the examples. In particular, it is optionally possible to modify the low-molecular weight KSP inhibitor for the conjugation to the linker, for example by introducing protective groups or leaving groups to facilitate substitution (such that in the reaction said leaving group, and not a hydrogen atom, is substituted by the linker). The KSP inhibitor – linker molecules obtained in this manner (where the linker has a reactive group for coupling to the binder) can then

be reacted with the binder to give a binder conjugate according to the invention. In the experimental section, this procedure is illustrated in an exemplary manner by a large number of examples.

By substitution of a hydrogen atom at R^1, R^2, R^3, R^4, R^5 or R^8 or at the pyrrolidine ring (R^{10}) formed by R^2 and R^4, in a manner known to the person of average skill the compound of the formula (IIa) or (II) in which none of the substituents R^1, R^2, R^3, R^4, R^5, R^8 and R^{10} represents -L-#1 may be attached to a linker. This gives conjugates of the formula (IIa) or (II) where one of the substituents R^1, R^2, R^3, R^4, R^5, R^8 or R^{10} represents -L-#1, L represents the linker and #1 represents the bond to the binder or the derivative thereof. If the KSP inhibitor according to formula (IIa) or (II) is conjugated with a binder, one of the substituents R^1, R^2, R^3, R^4 , R^5 , R^8 or R^{10} thus represents -L-#1, where L represents the linker and #1 represents the bond to the binder or the derivative thereof. That is in the case of the

conjugates one of the substituents R^1, R^2, R^3, R^4 , R^5 , R^8 and R^{10} represents -L-#1, where -L-#1 is attached to the binder, for example an antibody. Instead of -L-#1, it is also possible for the group -L-#3 to be present in the compound, where L represents the linker and #3 represents the reactive group for binding to the binder or the derivative thereof. Compounds comprising -L-#3 are reactive compounds which react with the binder or the derivative thereof. #3 is preferably a group which reacts with an amino or thiol group with formation of a covalent bond, preferably with the cysteine residue in a protein. The cysteine residue in a protein may of course be present naturally in the protein, may be introduced by biochemical methods or, preferably, may be generated by prior reduction of disulphides of the binder.

Formula VII

Particular preference is given to the compounds of the formulae

V, VI, VII where R^1 and R^5 represent H or -L-#1; R^2 and R^4 independently of one another represent -L-#1 or H or R^2 and R^4 together (with formation of a pyrrolidine ring) represent $-CH_2-CHR^{10}-$ or $-CHR^{10}-CH_2-$, R^{10} represents H or -L-#1; and R^3 represents CH_2OH, $CH(CH_3)OH$ or -L-#1, where one of the substituents R^1, R^2, R^3, R^4, R^5 and R^{10} represents -L-#1. Especially preferred are the corresponding compounds of the formula VI.

Linkers

The literature discloses various options for covalently coupling (conjugating) organic molecules to binders such as, for example antibodies (see, for example, K. Lang and J. W. Chin. *Chem. Rev.* **2014**, *114*, 4764-4806, M. Rashidian et al. *Bioconjugate Chem.* **2013**, *24*, 1277-1294). Preference according to the invention is given to conjugation of the KSP inhibitors to an antibody via one or more sulphur atoms of cysteine residues of the antibody which are either already present as free thiols or generated by reduction of disulphide bridges, and/or via one or more NH groups of lysine residues of the antibody. However, it is also possible to attach the KSP inhibitor to the antibody via tyrosine residues, via glutamine residues, via residues of unnatural amino acids, via free carboxyl groups or via sugar residues of the antibody. For coupling, use is made of linkers. Linkers can be categorized into the group of the linkers which can be cleaved *in vivo* and the group of the linkers which are stable *in vivo* (see L. Ducry and B. Stump, *Bioconjugate Chem.* 21, 5-13 (2010)). The linkers which can be cleaved *in vivo* have a group which can be cleaved *in vivo*, where, in turn, a distinction may be made between groups which are chemically cleavable *in vivo* and groups which are enzymatically cleavable *in vivo*. "Chemically cleavable *in vivo*" and "enzymatically cleavable *in vivo*" means that the linkers or groups are stable in circulation and are cleaved only at or in the target cell by the chemically or enzymatically different environment therein (lower pH; elevated glutathione concentration; presence of lysosomal enzymes such as cathepsin or plasmin, or glyosidases such as, for example, ß-glucuronidases), thus releasing the low-molecular weight KSP

inhibitor or a derivative thereof. Groups which can be cleaved chemically *in vivo* are in particular disulphide, hydrazone, acetal and aminal; groups which can be cleaved enzymatically *in vivo* are in particular the 2-8-oligopeptide group, especially a dipeptide group or glycoside. Peptide cleavage sites are disclosed in *Bioconjugate Chem.* **2002**, *13*, 855-869, and *Bioorganic & Medicinal Chemistry Letters* 8 (**1998**) 3341-3346 and also *Bioconjugate Chem.* **1998**, *9*, 618-626. These include, for example, valine-alanine, valine-lysine, valine-citrulline, alanine-lysine and phenylalanine-lysine (optionally with additional amide group).

Linkers which are stable *in vivo* are distinguished by a high stability (less than 5% metabolites after 24 hours in plasma) and do not have the chemically or enzymatically *in vivo* cleavable groups mentioned above.

The linker -L- preferably has one of the basic structurs (i) to (iv) below:

(i) $-(CO)_m$-SG1-L1-L2-

(ii) $-(CO)_m$ -L1-SG-L1-L2-

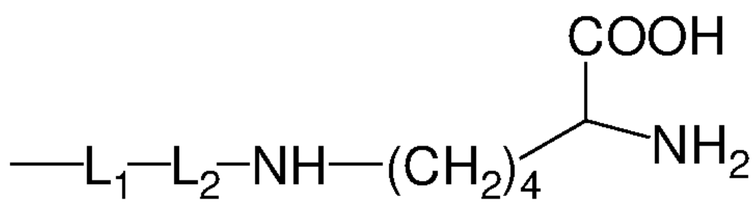
(iii) $-(CO)_m$ -L1-L2-

(iv) $-(CO)_m$ -L1-SG-L2

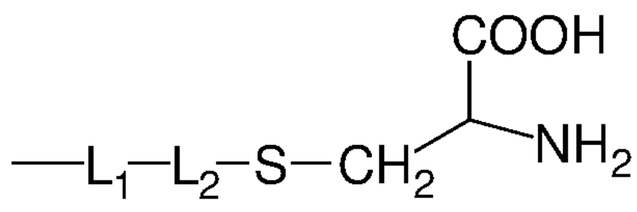
where m is 0 or 1; SG is a (chemically or enzymatically) *in vivo* cleavable group (in particualar disulphide, hydrazone, acetal and aminal; or a 2-8-oligopeptide group which can be cleaved by cathepsin or plasmin), SG1 is an oligopeptide group or preferably a dipeptide group, L1 independently of one another represent *in vivo* stable organic groups, and L2 represents a coupling group to the binder or a single bond. Here, coupling is preferably to a cysteine residue or a lysine residue of the binder. Alternatively, coupling can be to a tyrosine residue, glutamine residue or to an unnatural amino acid of the binder.

The unnatural amino acids may contain, for example, aldehyde or keto groups (such as, for example, formylglycine) or azide or alkyne groups (see Lan & Chin, Cellular Incorporation of Unnatural Amino Acids and Bioorthogonal Labeling of Proteins, Chem.Rev. 2014, 114, 4764-4806).

Particular preference according to the invention is given to the basic linker structure (iii), in particular when the binder is an anti-TWEAKR antibody or an anti-EGFR antibody. Via metabolization, the administration of a conjugate according to the invention having a basic linker structure (iii) and coupling of the linker to a cysteine or lysine residue of the binder protein or peptide leads to cysteine or lysine derivatives of the formulae below:



;



where L1 is in each case attached to the low-molecular weight KSP inhibitor, for example a compound of the formula (I), (IIa), (II), (III), (IIIa), (IIIb), (IIIc), (IIId), (IIIe) or (IV).

Preference according to the invention is also given to the basic linker structures (ii) and (iv), in particular when attachment is at position (iii), in particular when group L1 has one of the following structures:

(a) $-NH-(CH_2)_{0-4-}(CHCH_3)_{0-4}-CHY^5-CO-Y^7$, where Y^5 represents H or NHY^6, where Y^6 represents H or $-COCH_3$, and Y^7 represents a single bond or $-NH-(CH_2)_{0-4}-CHNH_2-CO-$, so that after cleavage the corresponding structure $-NH-(CH_2)_{0-4-}(CHCH_3)_{0-4}-CHY^5-COOH$ or $-NH-(CH_2)_{0-4-}(CHCH_3)_{0-4}-CHY^5-CO-NH-(CH_2)_{0-4}-CHNH_2-COOH$ is obtained.

(b) $-CH_2-S_x-(CH_2)_{0-4}-CHY^5-CO-$, where x is 0 or 1, and Y^5 represents H or NHY^6, where Y6 represents H or $-COCH_3$, such that after cleavage the corresponding structure $-CH_2-S_x-(CH_2)_{0-4}-CHY^5-COOH$ is obtained.

This embodiment is preferred when L1 is attached in each case to the low-molecular weight KSP inhibitor, for example a compound of the formula (I), (IIa), (II), (III), (IIIa), (IIIb), (IIIc), (IIId), (IIIe) or (IV), in particular at position R_4. The binder is preferably an anti-TWEAKR antibody or an anti-EGFR antibody.

If the linker is attached to a cysteine side chain or a cysteine residue, L2 is preferably derived from a group which reacts with the sulphhydryl group of the cysteine. These include haloacetyls, maleimides, aziridines, acryloyls, arylating compounds, vinylsulphones, pyridyl disulphides, TNB thiols and disulphide-reducing agents. These groups generally react in an electrophilic manner with the sulphhydryl bond, forming a sulphide (e.g. thioether) or disulphide bridge. Preference is given to stable sulphide bridges. L2 is preferably

$\#^1$ denotes the point of attachment to the sulphur atom of the binder,

It is preferred when x=1 and R^{22} represents COOH.

In a conjugate according to the invention or in a mixture of the conjugates according to the invention, the bonds to a cysteine residue of the binder are present, to an extent of preferably more than 80%, particularly preferably more than 90% (in each case based on the total number of bonds of the linker to the binder), particularly preferably as one of the two structures of the formula A3 or A4. Here, the structures of the formula A3 or A4 are generally present together, preferably in a ratio of from 60:40 to 40:60, based on the number of bonds to the binder.

The remaining bonds are then present as the structure

Here, #1 is the bond to the KSP inhibitor and #2 is the bond to the coupling group to the binder (e.g. L2).

A straight-chain or branched hydrocarbon chain of arylen groups and/or straight-chain and/or branched and/or cyclic alkylene groups generally comprises a α,ω-divalent alkyl radical having the respective number of carbon atoms stated. Examples which may be mentioned as being preferred are: methylene, ethane-1,2-diyl (1,2-ethylene), propane-1,3-diyl (1,3-propylene), butane-1,4-diyl (1,4-butylene), pentane-1,5-diyl (1,5-pentylene), hexane-1,6-diyl (1,6-hexylene), heptane-1,7-diyl (1,7-hexylene), octane-1,8-diyl (1,8-octylene), nonane-1,9-diyl (1,9-nonylene), decane-1,10-diyl (1,10-decylene). However, the alkylene groups in the hydrocarbon chain may also be branched, i.e. one or more hydrogen atoms of the straight-chain alkylene groups mentioned above may optionally be substituted by C_{1-10}-alkyl groups, thus forming side chains. The hydrocarbon chain may furthermore contain cyclic alkylene groups (cycloalkanediyl), for example 1,4-cyclohexanediyl or 1,3-cyclopentanediyl. These cyclic groups may be unsaturated. In particular, aromatic groups (arylene groups), for example phenylene, may be present in the hydrocarbon group. In turn, in the cyclic alkylene groups and the arylene groups, too, one or more hydrogen atoms may optionally be substituted by C_{1-10}-alkyl groups. In this way, an

optionally branched hydrocarbon chain is formed. This hydrocarbon chain has a total of 0 to 100 carbon atoms, preferably 1 to 50, particularly preferably 2 to 25 carbon atoms.

The side chains, if present, may be substituted by $-NHCONH_2$, -COOH, -OH, $-NH_2$, NH-$CNNH_2$, sulphonamide, sulphone, sulphoxide or sulphonic acid.

The hydrocarbon chain may be interrupted once or more than once by one or more of the groups -O-, -S-, -SO-, SO_2, -NH-, -CO-, -NHCO-, -CONH-, -NMe-, -NHNH-, $-SO_2NHNH-$, -CONHNH- and a 5- to 10-membered aromatic or non-aromatic heterocycle having up to 4 heteroatoms selected from the group consisting of N, O and S, -SO- or $-SO_2-$ (preferably ).

Further examples of L1 are given in Table C, in which this group is highlighted in a box.

Examples of a linker moiety L1 are given in Tables A and A‘

below. The table furthermore states with which group L2 these examples of L1 are preferably combined, and also the preferred coupling point (R^1-R^5) and the preferred value for m, this is whether there is a carbonyl group in front of L1 or not (cf. §-(CO)m-L1-L2-§§). These linkers are preferably coupled to a cysteine residue. The first column furthermore states the example numbers for the cetuximab ADCs in which the linkers in question are used, but which likewise apply in each row for ADCs with other antibodies. If L2 is a succinimide or derived therefrom, this imide may also be fully or partially in the form of the hydrolysed open-chain succinamide, as described above. Depending on L1, this hydrolysis to open-chain succinamides may be more or less pronounced or not present at all.

Particular preference is given to an anti-TWEAKR antibody which binds specifically to amino acid D in position 47 (D47) of TWEAKR (SEQ ID NO:169), in particular the anti-TWEAKR antibody TPP-2090, or the anti-EGFR antibodies cetuximab or nimotuzumab.

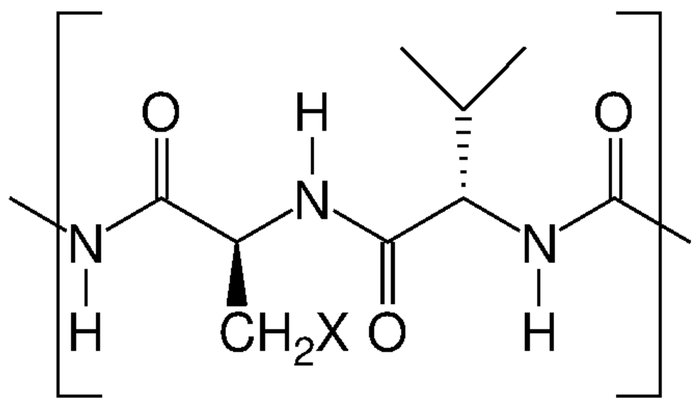
Preference according to the invention is furthermore given to the basic structure (i), (ii) or (iv), where SG1 or SG represents a group which can be cleaved by cathepsin and L1 and L2 have the meanings given above. Particular preference is given to the following groups:

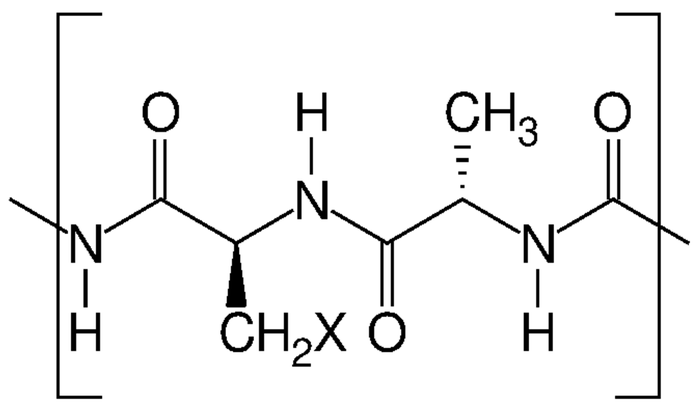
- -Val-Ala-CONH- (hereby cleavage of the amide bond at the C-terminal amide of alanine)
- -NH-Val-Lys-CONH- (cleavage of the amide bond at the C-terminal amide of lysine)
- -NH-Val-Cit-CONH- (cleavage of the amide bond at the C-terminal amide of citrulline)
- -NH-Phe-Lys-CONH (cleavage of the amide bond at the C-terminal amide of lysine)

- -NH-Ala-Lys-CONH- (cleavage of the amide bond at the C-terminal amide of lysine)
- -NH-Ala-Cit-CONH- (cleavage of the amide bond at the C-terminal amide of citrulline)

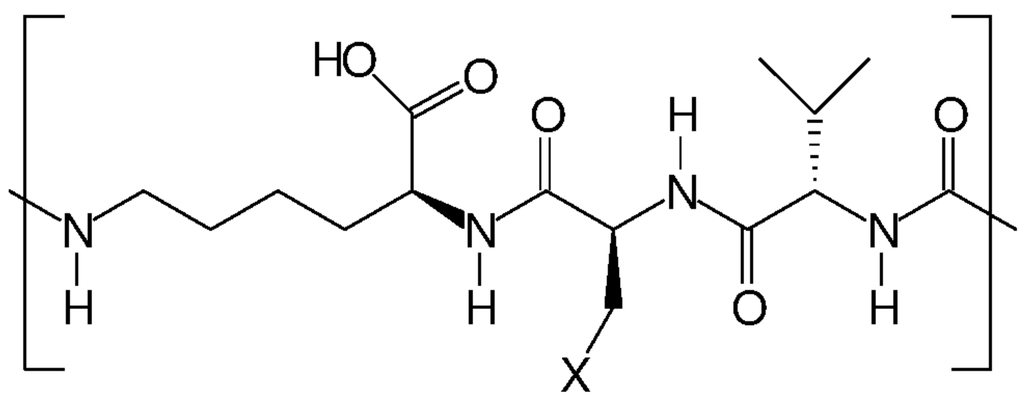
SG1 or SG is particularly preferably



or



or



where X represents H or a C_{1-10}-alkyl group which may optionally be substituted by $-NHCONH_2$, -COOH, -OH, NH_2, $-NH-CNNH_2$ or sulphonic acid.

Table C below gives examples of a linker moiety -SG1-L1- or -L1-SG-L1-, where SG1 and SG are groups which can be cleaved by cathepsin. Table C furthermore states with which group L2 these examples of -SG1-L1- and -L1-SG-L1- are preferably combined, and also the preferred coupling point (R^1-R^5) and the preferred

value for m, thus whether there is a carbonyl group in front of L1 or not (cf. §-(CO)m-L1-L2-§§). These linkers are preferably coupled to a cysteine residue. The first column furthermore states the example numbers, given in an exemplary manner for cetuximab ADCs, in which corresponding linkers are used. They apply in the same manner to the corresponding ADCs with other antibodies. The L1 group is highlighted in a box. However, these groups L1 can be replaced by one of the groups L1 given for formula §-(CO)m-L1-L2-§§ above. If L2 is a succinamide or derived therefrom, this amide may also be fully or partially in the form of the hydrolysed open-chain succinamide, as described above.

following structure, where X1, X2 and X3 have the meanings given above, L4 has the same meaning as L1, AK1 represents an antibody attached via a cysteine residue and n is a number from 1 to 10. Depending on the linker, succinimide-linked ADCs may, after conjugation, be converted into the open-chain succinamides, which have an advantageous stability profile.

This reaction (ring opening) can be carried out at pH 7.5 to 9, preferably at pH 8, at a temperature of from 25°C to 37°C, for example by stirring. The preferred stirring time is 8 to 30 hours.

In the above formulae, X_1, X_2, X_3 have the same meaning as in formula (II), SG1 and L1 have the same meaning as described above and L2, L3 and L4 have the same meaning as L1; R and K have the same meaning as described above. AK1 is an antibody coupled via a cysteine residue, and AK2 is an antibody coupled via a lysine residue. With particular preference, AK1 and AK2 are anti-TWEAKR antibodies, in particular antibodies which bind specifically to amino acid D in position 47 (D47) of TWEAKR (SEQ ID NO:169), in particular the anti-TWEAKR antibody TPP-2090.

Binders

In the broadest sense, the term "binder" is understood to mean a molecule which binds to a target molecule present at a certain target cell population to be addressed by the binder/active compound conjugate. The term binder is to be understood in its broadest meaning and also comprises, for example, lectins, proteins capable of binding to certain sugar chains, and phospholipid-binding proteins. Such binders include, for example, high-molecular weight proteins (binding proteins), polypeptides or peptides (binding peptides), non-peptidic (e.g. aptamers (US5,270,163) review by Keefe AD., et al., Nat. Rev. Drug Discov. 2010; 9:537-550), or vitamins) and all other cell-binding molecules or substances. Binding proteins are, for example, antibodies and antibody fragments or antibody mimetics such as, for example, affibodies, adnectins, anticalins, DARPins, avimers, nanobodies (review by Gebauer M. et al., Curr. Opinion in Chem. Biol. 2009; 13:245-255; Nuttall S.D. et al., Curr. Opinion in Pharmacology 2008; 8:608-617). Binding peptides are, for example, ligands of a ligand/receptor pair such as, for example, VEGF of the ligand/receptor pair VEGF/KDR, such as transferrin of the ligand/receptor pair transferrin/transferrin

receptor or cytokine/cytokine receptor, such as TNFalpha of the ligand/receptor pair TNFalpha/TNFalpha receptor.

The literature also discloses various options of covalent coupling (conjugation) of organic molecules to antibodies. Preference according to the invention is given to the conjugation of the toxophores to the antibody via one or more sulphur atoms of cysteine residues of the antibody and/or via one or more NH groups of lysine residues of the antibody. However, it is also possible to bind the toxophor to the antibody via free carboxyl groups or via sugar residues of the antibody.

A "target molecule" in the broadest sense is understood to mean a molecule which is present in the target cell population and which may be a protein (for example a receptor of a growth factor) or a non-peptidic molecule (for example a sugar or phospholipid). It is preferably a receptor or an antigen.

The term "extracellular" target molecule describes a target molecule, attached to the cell, which is located at the outside of a cell, or the part of a target molecule which is located at the outside of a cell, i.e. a binder may bind on an intact cell to its extracellular target molecule. An extracellular target molecule may be anchored in the cell membrane or be a component of the cell membrane. The person skilled in the art is aware of methods for identifying extracellular target molecules. For proteins, this may be by determining the transmembrane domain(s) and the orientation of the protein in the membrane. These data are usually deposited in protein databases (e.g. SwissProt).

The term "cancer target molecule" describes a target molecule which is more abundantly present on one or more cancer cell species than on non-cancer cells of the same tissue type. Preferably, the cancer target molecule is selectively present on one or more cancer cell species compared with non-cancer cells of the same tissue type, where selectively describes an at least two-fold enrichment on cancer cells compared to non-cancer cells of the same tissue type (a "selective cancer target

molecule"). The use of cancer target molecules allows the selective therapy of cancer cells using the conjugates according to the invention.

The binder can be attached to the linker via a bond. Attachment of the binder can be via a heteroatom of the binder. Heteroatoms according to the invention of the binder which can be used for attachment are sulphur (in one embodiment via a sulphhydryl group of the binder), oxygen (according to the invention by means of a carboxyl or hydroxyl group of the binder) and nitrogen (in one embodiment via a primary or secondary amine group or amide group of the binder). These heteroatoms may be present in the natural binder or are introduced by chemical methods or methods of molecular biology. According to the invention, the attachment of the binder to the toxophor has only a minor effect on the binding activity of the binder with respect to the target molecule. In a preferred embodiment, the attachment has no effect on the binding activity of the binder with respect to the target molecule.

In accordance with the present invention, the term "antibody" is to be understood in its broadest meaning and comprises immunoglobulin molecules, for example intact or modified monoclonal antibodies, polyclonal antibodies or multispecific antibodies (e.g. bispecific antibodies). An immunoglobulin molecule preferably comprises a molecule having four polypeptide chains, two heavy chains (H chains) and two light chains (L chains) which are typically linked by disulphide bridges. Each heavy chain comprises a variable domain of the heavy chain (abbreviated VH) and a constant domain of the heavy chain. The constant domain of the heavy chain may, for example, comprise three domains CH1, CH2 and CH3. Each light chain comprises a variable domain (abbreviated VL) and a constant domain. The constant domain of the light chain comprises a domain (abbreviated CL). The VH and VL domains may be subdivided further into regions having hypervariability, also referred to as complementarity determining regions (abbreviated CDR) and regions having low sequence variability (framework region,

abbreviated FR). Typically, each VH and VL region is composed of three CDRs and up to four FRs. For example from the amino terminus to the carboxy terminus in the following order: FR1, CDR1, FR2, CDR2, FR3, CDR3, FR4. An antibody may be obtained from any suitable species, e.g. rabbit, llama, camel, mouse or rat. In one embodiment, the antibody is of human or murine origin. An antibody may, for example, be human, humanized or chimeric.

The term "monoclonal" antibody refers to antibodies obtained from a population of substantially homogeneous antibodies, i.e. individual antibodies of the population are identical except for naturally occurring mutations, of which there may be a small number. Monoclonal antibodies recognize a single antigenic binding site with high specificity. The term monocvlonal antibody does not refer to a particular preparation process.

The term "intact" antibody refers to antibodies comprising both an antigen-binding domain and the constant domain of the light and heavy chain. The constant domain may be a naturally occurring domain or a variant thereof having a number of modified amino acid positions.

The term "modified intact" antibody refers to intact antibodies fused via their amino terminus or carboxy terminus by means of a covalent bond (e.g. a peptide bond) with a further polypeptide or protein not originating from an antibody. Furthermore, antibodies may be modified such that, at defined positions, reactive cysteines are introduced to facilitate coupling to a toxophor (see Junutula et al. Nat Biotechnol. 2008 Aug;26(8):925-32).

The term "human" antibody refers to antibodies which can be obtained from a human or which are synthetic human antibodies. A "synthetic" human antibody is an antibody which is partially or entirely obtainable *in silico* from synthetic sequences based on the analysis of human antibody sequences. A human antibody can be encoded, for example, by a nucleic acid isolated from a

library of antibody sequences of human origin. An example of such an antibody can be found in Söderlind et al., Nature Biotech. 2000, 18:853-856.

The term "humanized" or "chimeric" antibody describes antibodies consisting of a non-human and a human portion of the sequence. In these antibodies, part of the sequences of the human immunoglobulin (recipient) are replaced by sequence portions of a non-human immunoglobulin (donor). In many cases, the donor is a murine immunoglobulin. In the case of humanized antibodies, amino acids of the CDR of the recipient are replaced by amino acids of the donor. Sometimes, amino acids of the framework, too, are replaced by corresponding amino acids of the donor. In some cases the humanized antibody contains amino acids present neither in the recepient nor in the donor, which were introduced during the optimization of the antibody. In the case of chimeric antibodies, the variable domains of the donor immunoglobulin are fused with the constant regions of a human antibody.

The term complementarity determining region (CDR) as used herein refers to those amino acids of a variable antibody domain which are required for binding to the antigen. Typically, each variable region has three CDR regions referred to as CDR1, CDR2 and CDR3. Each CDR region may embrace amino acids according to the definition of Kabat and/or amino acids of a hypervariable loop defined according to Chotia. The definition according to Kabat comprises, for example, the region from about amino acid position 24 – 34 (CDR1), 50 – 56 (CDR2) and 89 – 97 (CDR3) of the variable light chain and 31 – 35 (CDR1), 50 – 65 (CDR2) and 95 – 102 (CDR3) of the variable heavy chain (Kabat et al., Sequences of Proteins of Immunological Interest, 5th Ed. Public Health Service, National Institutes of Health, Bethesda, MD. (1991)). The definition according to Chotia comprises, for example, the region from about amino acid position 26 – 32 (CDR1), 50 – 52 (CDR2) and 91 –96 (CDR3) of the variable light chain and 26 – 32 (CDR1), 53 – 55 (CDR2) and 96 – 101 (CDR3) of the variable heavy chain (Chothia and Lesk; J Mol Biol 196: 901-917 (1987)). In some cases, a CDR may comprise amino acids from

a CDR region defined according to Kabat and Chotia.

Depending on the amino acid sequence of the constant domain of the heavy chain, antibodies may be categorized into different classes. There are five main classes of intact antibodies: IgA, IgD, IgE, IgG and IgM, and several of these can be divided into further subclasses. (Isotypes), e.g. IgG1, IgG2, IgG3, IgG4, IgA1 and IgA2. The constant domains of the heavy chain, which correspond to the different classes, are referred to as [alpha/α], [delta/δ], [epsilon/ε], [gamma/γ] and [my/μ]. Both the three-dimensional structure and the subunit structure of antibodies are known.

The term "functional fragment" or "antigen-binding antibody fragment" of an antibody/immunoglobulin is defined as a fragment of an antibody/immunoglobulin (e.g. the variable domains of an IgG) which still comprise the antigen binding domains of the antibody/immunoglobulin. The "antigen binding domain" of an antibody typically comprises one or more hypervariable regions of an antibody, for example the CDR, CDR2 and/or CDR3 region. However, the "framework" or "skeleton" region of an antibody may also play a role during binding of the antibody to the antigen. The framework region forms the skeleton of the CDRs. Preferably, the antigen binding domain comprises at least amino acids 4 to 103 of the variable light chain and amino acids 5 to 109 of the variable heavy chain, more preferably amino acids 3 to 107 of the variable light chain and 4 to 111 of the variable heavy chain, particularly preferably the complete variable light and heavy chains, i.e. amino acids 1 - 109 of the VL and 1 to 113 of the VH (numbering according to WO97/08320).

"Functional fragments" or "antigen-binding antibody fragments" of the invention encompass, non-conclusively, Fab, Fab', F(ab')2 and Fv fragments, diabodies, Single Domain Antibodies (DAbs), linear antibodies, individual chains of antibodies (single-chain Fv, abbreviated to scFv); and multispecific antibodies, such as bi and tri-specific antibodies, for example, formed from antibody fragments C. A. K Borrebaeck, editor (1995) Antibody

Engineering (Breakthroughs in Molecular Biology), Oxford University Press; R. Kontermann & S. Duebel, editors (2001) Antibody Engineering (Springer Laboratory Manual), Springer Verlag. Antibodies other than "multispecific" or "multifunctional" antibodies are those having identical binding sites. Multispecific antibodies may be specific for different epitopes of an antigen or may be specific for epitopes of more than one antigen (see, for example WO 93/17715; WO 92/08802; WO 91/00360; WO 92/05793; Tutt, et al., 1991, J. Immunol. 147:60 69; U. S. Pat. Nos. 4,474,893; 4,714,681 ; 4,925,648; 5,573,920; 5,601,819; or Kostelny et al., 1992, J. Immunol. 148: 1547 1553). An F(ab')2 or Fab molecule may be constructed such that the number of intermolecular disulphide interactions occurring between the Ch1 and the CL domains can be reduced or else completely prevented.

"Epitopes" refer to protein determinants capable of binding specifically to an immunoglobulin or T cell receptors. Epitopic determinants usually consist of chemically active surface groups of molecules such as amino acids or sugar side chains or combinations thereof, and usually have specific 3-dimensional structural properties and also specific charge properties.

"Functional fragments" or "antigen-binding antibody fragments" may be fused with another polypeptide or protein, not originating from an antibody, via the amino terminus or carboxyl terminus thereof, by means of a covalent bond (e.g. a peptide linkage). Furthermore, antibodies and antigen-binding fragments may be modified by introducing reactive cysteines at defined locations, in order to facilitate coupling to a toxophore (see Junutula et al. Nat Biotechnol. 2008 Aug; 26(8):925-32).

Polyclonal antibodies can be prepared by methods known to a person of ordinary skill in the art. Monoclonal antibodies may be prepared by methods known to a person of ordinary skill in the art (Köhler and Milstein, Nature, 256, 495-497, 1975). Human and humanized monoclonal antibodies may be prepared by methods known to a person of ordinary skill in the art (Olsson et al.,

Meth Enzymol. 92, 3-16 or Cabilly et al. US 4,816,567 or Boss et al. US 4,816,397).

A person of ordinary skill in the art is aware of diverse methods for preparing human antibodies and fragments thereof, such as, for example, by means of transgenic mice (N Lonberg and D Huszar, Int Rev Immunol. 1995; 13(1):65-93) or Phage Display Technologien (Clackson et al., Nature. 1991 Aug 15;352(6336):624-8). Antibodies of the invention may be obtained from recombinant antibody libraries consisting for example of the amino acid sequences of a multiplicity of antibodies compiled from a large number of healthy volunteers. Antibodies may also be produced by means of known recombinant DNA technologies. The nucleic acid sequence of an antibody can be obtained by routine sequencing or is available from publically accessible databases.

An “isolated” antibody or binder has been purified to remove other constituents of the cell. Contaminating constituents of a cell which may interfere with a diagnostic or therapeutic use are, for example, enzymes, hormones, or other peptidic or non-peptidic constituents of a cell. A preferred antibody or binder is one which has been purified to an extent of more than 95% by weight, relative to the antibody or binder (determined for example by Lowry method, UV-Vis spectroscopy or by SDS capillary gel electrophoresis). Moreover an antibody which has been purified to such an extent that it is possible to determine at least 15 amino acids of the amino terminus or of an internal amino acid sequence, or which has been purified to homogeneity, the homogeneity being determined by SDS-PAGE under reducing or non-reducing conditions (detection may be determined by means of Coomassie Blau staining or preferably by silver coloration). However, an antibody is normally prepared by one or more purification steps.

The term “specific binding” or “binds specifically” refers to an antibody or binder which binds to a predetermined antigen/target molecule. Specific binding of an antibody or

binder typically describes an antibody or binder having an affinity of at least 10^{-7} M (as Kd value; i.e. preferably those with smaller Kd values than 10^{-7} M), with the antibody or binder having an at least two times higher affinity for the predetermined antigen/target molecule than for a non-specific antigen/target molecule (e.g. bovine serum albumin, or casein) which is not the predetermined antigen/target molecule or a closely related antigen/target molecule. The antibodies preferably have an affinity of at least 10^{-7} M (as Kd value; in other words preferably those with smaller Kd values than 10^{-7} M), preferably of at least 10^{-8} M, more preferably in the range from 10^{-9} M to 10^{-11} M. The Kd values may be determined, for example, by means of surface plasmon resonance spectroscopy.

The antibody-drug conjugates of the invention likewise exhibit affinities in these ranges. The affinity is preferably not substantially affected by the conjugation of the drugs (in general, the affinity is reduced by less than one order of magnitude, in other words, for example, at most from 10^{-8} M to 10^{-7} M).

The antibodies used in accordance with the invention are also notable preferably for a high selectivity. A high selectivity exists when the antibody of the invention exhibits an affinity for the target protein which is better by a factor of at least 2, preferably by a factor of 5 or more preferably by a factor of 10, than for an independent other antigen, e.g. human serum albumin (the affinity may be determined, for example, by means of surface plasmon resonance spectroscopy).

Furthermore, the antibodies of the invention that are used are preferably cross-reactive. In order to be able to facilitate and better interpret preclinical studies, for example toxicological or activity studies (e.g. in xenograft mice), it is advantageous if the antibody used in accordance with the invention not only binds the human target protein but also binds the species target protein in the species used for the studies. In one embodiment the antibody used in accordance with the invention, in addition

to the human target protein, is cross-reactive to the target protein of at least one further species. For toxicological and activity studies it is preferred to use species of the families of rodents, dogs and non-human primates. Preferred rodent species are mouse and rat. Preferred non-human primates are rhesus monkeys, chimpanzees and long-tailed macaques.

In one embodiment the antibody used in accordance with the invention, in addition to the human target protein, is cross-reactive to the target protein of at least one further species selected from the group of species consisting of mouse, rat and long-tailed macaque (Macaca fascicularis). Especially preferred are antibodies used in accordance with the invention which in addition to the human target protein are at least cross-reactive to the mouse target protein. Preference is given to cross-reactive antibodies whose affinity for the target protein of the further non-human species differs by a factor of not more than 50, more particularly by a factor of not more than ten, from the affinity for the human target protein.

Antibodies directed against a cancer target molecule

The target molecule towards which the binder, for example an antibody or an antigen-binding fragment thereof, is directed is preferably a cancer target molecule. The term "cancer target molecule" describes a target molecule which is more abundantly present on one or more cancer cell species than on non-cancer cells of the same tissue type. Preferably, the cancer target molecule is selectively present on one or more cancer cell species compared with non-cancer cells of the same tissue type, where selectively describes an at least two-fold enrichment on cancer cells compared to non-cancer cells of the same tissue type (a "selective cancer target molecule"). The use of cancer target molecules allows the selective therapy of cancer cells using the conjugates according to the invention.

Antibodies which are specific against an antigen, for example cancer cell antigen, can be prepared by a person of ordinary

skill in the art by means of methods with which he or she is familiar (such as recombinant expression, for example) or may be acquired commercially (as for example from Merck KGaA, Germany). Examples of known commercially available antibodies in cancer therapy are Erbitux® (cetuximab, Merck KGaA), Avastin® (bevacizumab, Roche) and Herceptin® (trastuzumab, Genentech). Trastuzumab is a recombinant humanized monoclonal antibody of the IgG1kappa type which in a cell-based assay (Kd = 5 nM) binds the extracellular domains of the human epidermal growth receptor with high affinity. The antibody is produced recombinantly in CHO cells.

In a preferred embodiment, the target molecule is a selective cancer target molecule.

In a particularly preferred embodiment, the target molecule is a protein.

In one embodiment, the target molecule is an extracellular target molecule. In a preferred embodiment, the extracellular target molecule is a protein.

Cancer target molecules are known to those skilled in the art. Examples of these are listed below.

Examples of cancer target molecules are:

(1) EGF receptor (NCBI reference sequence NP_005219.2), SEQ ID NO: 213 (1210 amino acids):

In a preferred subject matter of the invention, the cancer target molecule is selected from the group consisting of the cancer target molecules (1) - (60), in particular (1), (6) and (52).

In a further particularly preferred subject matter of the invention, the binder binds to an extracellular cancer target molecule which is selected from the group consisting of the cancer target molecules (1) - (60), in particular (1), (6) and (52).

In a further particularly preferred subject matter of the invention, the binder binds specifically to an extracellular cancer target molecule which is selected from the group consisting of the cancer target molecules (1) - (60), in particular (1), (6) and (52). In a preferred embodiment the binder is, after binding to its extracellular target molecule on the target cell, internalized by the target cell as a result of the binding. This causes the binder/active compound conjugate, which may be an immunoconjugate or an ADC, to be taken up by the target cell. The binder is then processed, preferably intracellularly, with preference lysosomally.

In one embodiment the binder is a binding protein. In a preferred embodiment the binder is an antibody, an antigen-binding antibody fragment, a multispecific antibody or an antibody mimetic.

Preferred antibody mimetics are affibodies, adnectins,

anticalins, DARPins, avimers, or nanobodies. Preferred multispecific antibodies are bispecific and trispecific antibodies.

In a preferred embodiment the binder is an antibody or an antigen-binding antibody fragment, more preferably an isolated antibody or an isolated antigen-binding antibody fragment.

Preferred antigen-binding antibody fragments are Fab, Fab', F(ab')2 and Fv fragments, diabodies, DAbs, linear antibodies and scFv. Particularly preferred are Fab, diabodies and scFv.

In a particularly preferred embodiment the binder is an antibody. Particularly preferred are monoclonal antibodies or antigen-binding antibody fragments thereof. Further particularly preferred are human, humanized or chimeric antibodies or antigen-binding antibody fragments thereof.

Antibodies or antigen-binding antibody fragments which bind cancer target molecules may be prepared by a person of ordinary skill in the art using known processes, such as, for example, chemical synthesis or recombinant expression. Binders for cancer target molecules may be acquired commercially or may be prepared by a person of ordinary skill in the art using known processes, such as, for example, chemical synthesis or recombinant expression. Further processes for preparing antibodies or antigen-binding antibody fragments are described in WO 2007/070538 (see page 22 "Antibodies"). The person skilled in the art knows how processes such as phage display libraries (e.g. Morphosys HuCAL Gold) can be compiled and used for discovering antibodies or antigen-binding antibody fragments (see WO 2007/070538, page 24 ff and AK Example 1 on page 70, AK Example 2 on page 72). Further processes for preparing antibodies that use DNA libraries from B cells are described for example on page 26 (WO 2007/070538). Processes for humanizing antibodies are described on page 30-32 of WO2007070538 and in detail in Queen, et al., Pros. Natl. Acad. Sci. USA 86:10029-10033, 1989 or in WO 90/0786. Furthermore, processes for the

recombinant expression of proteins in general and of antibodies in particular are known to the person skilled in the art (see, for example, in Berger and Kimrnel (Guide to Molecular Cloning Techniques, Methods in Enzymology, Vo1. 152, Academic Press, Inc.); Sambrook, et al., (Molecular Cloning: A Laboratory Manual, (Second Edition, Cold Spring Harbor Laboratory Press; Cold Spring Harbor, N.Y.; 1989) Vol. 1-3); Current Protocols in Molecular Biology, (F. M. Ausabel et al. [Eds.], Current Protocols, Green Publishing Associates, Inc. / John Wiley & Sons, Inc.); Harlow et al., (Monoclonal Antibodies: A Laboratory Manual, Cold Spring Harbor Laboratory Press (1988, Paul [Ed.]); Fundamental Immunology, (Lippincott Williams & Wilkins (1998)); and Harlow, et al., (Using Antibodies: A Laboratory Manual, Cold Spring Harbor Laboratory Press (1998)). The person skilled in the art knows the corresponding vectors, promoters and signal peptides which are necessary for the expression of a protein/antibody. Commonplace processes are also described in WO 2007/070538 on pages 41-45. Processes for preparing an IgG1 antibody are described for example in WO 2007/070538 in Example 6 on page 74 ff. Processes which allow the determination of the internalization of an antibody after binding to its antigen are known to the skilled person and are described for example in WO 2007/070538 on page 80. The person skilled in the art is able to use the processes described in WO 2007/070538 that have been used for preparing carboanhydrase IX (Mn) antibodies in analogy for the preparation of antibodies with different target molecule specificity.

Panitumumab (INN number 8499) (Drug Bank Accession Number DB01269) is a recombinant monoclonal human IgG2 antibody which binds specifically to the human EGF receptor 1 and is sold by Abgenix/Amgen. Panitumumab originates from the immunization of transgenic mice (XenoMouse). These mice are capable of producing human immunoglobulin (light and heavy chains). A specific B-cell clone was selected which produces antibodies against EGFR, and this clone was immortalized with CHO cells (Chinese hamster ovary cells). These cells are now used for the production of a 100% human antibody. Panitumumab is indicated for the treatment of EGFR-expressing, metastasizing colorectal carcinoma, which is resistant to chemotherapeutic treatment with fluoropyrimidine, oxaliplatin and irinotecan. It has an affinity of 10^{-11}M.

In a further embodiment, the anti-FGFR2 antibodies or antigen-binding antibody fragments comprise at least one, two or three CDR amino acid sequences of an antibody listed in Table 9 or Table 10 of WO2013076186. Preferred embodiments of such antibodies are likewise listed in WO2013076186 and incorporated herein by reference.

Anti-TWEAKR antibodies

In a preferred embodiment, when an anti-TWEAKR antibody or an antigen-binding fragment thereof is used in the processes according to the present invention, this antibody or fragment is selected from those described below. In addition, antibodies which bind to TWEAKR are known to the person skilled in the art, see, for example, WO2009/020933(A2) or WO2009140177 (A2).

The invention relates in particular to conjugates with antibodies or antigen-binding antibody fragments thereof or variants thereof which lead to strong activation of the TWEAKR (SEQ ID NO:169 (protein); SEQ ID NO:170 (DNA)), resulting in a strong induction of apoptosis in various cancer cells overexpressing TWEAKR.

The agonistic activity of TWEAKR with regard to the induction of apoptosis and inhibition of the proliferation of the anti-TWEAKR antibodies already described (e.g. PDL-192) is limited and does not reach the efficacy of the endogenous ligand TWEAK. This lack of agonistic activity is not based on reduced affinity, since these antibodies bind at the TWEAKR with affinities which, compared to the endogenous ligand TWEAK, are in a similar range (Michaelson JS et al, MAbs. 2011 Jul-Aug;3(4):362-75; Culp PA

et al, Clin Cancer Res. 2010 Jan 15;16(2):497-508), and even antibodies having a higher binding affinity do not necessarily display a more effective signalling activity (Culp PA, et al, Clin Cancer Res. 2010 Jan 15;16(2):497-508). In addition, it has been shown that the antitumour activity of the antibodies already described depends on the Fc effector function, and it was shown that ADCC plays an important role for the in-vivo efficacy in mouse models.

Generation of the anti-TWEAKR antibodies

A complete human antibody phage library (Hoet RM et al, Nat Biotechnol 2005;23(3):344-8) was employed to isolate TWEAKR-specific human monoclonal antibodies of the present invention by protein panning (Hoogenboom H.R., Nat Biotechnol 2005;23(3):1105-16) using dimeric Fc-fused extracellular domains of human and mouse TWEAKR as immobilized target. 11 different Fab phages were identified, and the corresponding antibodies were cloned into a mammalian EgG expression vector which provides the CH2-CH3 domains missing in the soluble FAb. Following identification of preferred antibodies, these were expressed as full-length IgGs. These constructs were expressed, for example, transiently in mammalian cells as described by Tom et al., Chapter 12 in Methods Express: Expression Systems edited by Micheal R. Dyson and Yves Durocher, Scion Publishing Ltd, 2007 (see AK-Example 1). The antibodies were purified by protein-A chromatography and characterized further by their binding affinity to soluble monomeric TWEAKR using ELISA and BIAcore analysis, as described in AK-Example 2. To determine the cell binding characteristics of the anti-TWEAKR antibodies, binding was tested by flow cytometry on a number of cell lines (HT29, HS68, HS578). NFκB reporter gene assays were carried out to examine the agonistic activity of all 11 antibodies identified (human IgG1). The antibody having the highest in vitro activity (TPP-883) was selected for further activity and affinity maturation (see AK-Example 1 for details). A single substitution variant having improved agonistic activity was detected: G102T of CDR-H3. In the end, 7 variants were selected

based on increased affinity compared to the best single substitution variant G102T. The corresponding DNA thereof was cloned into a mammalian IgG expression vector and examined for functional activity in the NF-kappaB reporter gene assay mentioned above. Finally, the sequences obtained were compared with human germ line sequences, and deviations without any significant effect on the affinity and the efficacy were adapted. The following antibodies were obtained by antibody library screening and by affinity and/or activity maturation. "TPP-2090", "TPP-2149", "TPP-2093", "TPP-2148", "TPP-2084", "TPP-2077", "TPP-1538", "TPP-883", "TPP-1854", "TPP-1853", "TPP-1857" and "TPP-1858".

Antibodies of the invention can furthermore be obtained by methods known in the art such as antibody phage display screening (see, for example, Hoet RM et al., Nat Biotechnol 2005;23(3):344-8), the well-established hybridoma technology (see, for example, Köhler and Milstein Nature. 1975 Aug 7;256(5517):495-7) or immunization of mice, *inter alia* immunization of hMAb mice (e.g. VelocImmune mouse®).

Particular embodiments of anti-TWEAKR antibodies

One embodiment of the invention is the provision of antibodies or antigen-binding antibody fragments thereof or variants thereof showing strong induction of caspase 3/7 in one or more TWEAKR-expressing cell lines. In a preferred embodiment, the one or more TWEAKR-expressing cell line(s) is/are present in the group consisting of WiDr, A253, NCI-H322, HT29 and 786-O. "Induction of caspase 3/7" can be measured by customary methods known in the art, including those described herein. In one embodiment, the "induction of caspase 3/7" is determined in accordance with the present invention using the activity determination with capase 3/7 solution (Promega, #G8093) and reading the luminescence on a VICTOR V (Perkin Elmer). At the end of the incubation time, the caspase 3/7 activity was determined and the induction factor of caspase 3/7 was determined in comparison to untreated cells. An antibody is said

to show "strong induction" of caspase 3/7 when the induction factor is greater than 1.2, preferably greater than 1.5, even more preferably greater than 1.8, even more preferably greater than 2.1, even more preferably greater than 2.5. What is provided are anti-TWEAKR antibodies leading to stronger induction of caspase 3/7 in HT29 cells compared to agonistic antibodies already described [e.g. PDL-192(TPP-1104), P4A8(TPP-1324), 136.1(TPP-2194)] and also compared to 300 ng/ml recombinant human TWEAK. This strong activity of inducing caspase 3/7 in cancer cells was also observed in WiDr, A253, NIC-H322 and 786-O cells where in most experiments the antibodies of the invention examined induced higher factors of change compared to the reference antibodies [PDL-192(TPP-1104), P4A8(TPP-1324)] and to 300 ng/ml TWEAK. Some antibodies of the invention bind to the TWEAKR only with moderate affinity (>10 nM) which is clearly less than the affinity of the endogenous ligand TWEAK, and also less compared to other known agonistic antibodies. This property offers further possible advantages such as, for example, potentially deeper penetration into the tumour.

In this regard, one embodiment of the invention is the provision of antibodies or antigen-binding antibody fragments thereof binding specifically to a TWEAKR at a novel epitope characterized by selective binding to aspartate (D) at position 47 (D47) of TWEAKR (SEQ ID NO:169; see also Figure 1). The dependencies identified for certain TWEAKR amino acids for antibody interaction correlate with the agonistic activity determined for these antibodies. The native ligand TWEAK shows an effective activation of the TWEAKR and binds depending on leucine 46 in the cysteine-rich domain of TWEAKR (Pellegrini et al, FEBS 280:1818-1829). P4A8 displays a very low agonistic activity and interacts at least partially with domains outside of the cysteine-rich domain of TWEAKR. PDL-192 displays a moderate agonistic activity and binds depending on R56 to the cysteine-rich domain, but opposite the TWEAK ligand site. Antibodies of the present invention (e.g. TPP-2090) bind depending on D47, and TWEAK binds depending on L46. Thus, TWEAK binds to a similar but different binding site (Figure 7).

Accordingly, the antibodies of the present invention displaying strong agonistic activity bind to a novel epitope (D47-dependent) for antibodies associated with very high agonistic activity.

The amino acid at position 47 (D47) of TWEAKR (SEQ ID NO:169) is considered to be critical for binding of the antibodies according to the invention, which means that the antibody binds specifically to the D at position 47 (D47) of TWEAKR (SEQ ID NO:169) when the antibody loses more than 20%, alternatively more than 30%, alternatively more than 40%, alternatively more than 50%, alternatively more than 60%, alternatively more than 70%, alternatively more than 80%, alternatively more than 90%, alternatively 100% of its ELISA signal by modification of this residue into alanine, as described in AK-Example 2 and Figure 6. Alternatively, an antibody binds specifically to the D at position 47 (D47) of TWEAKR (SEQ ID NO:169) when the antibody loses more than 20%, alternatively more than 30%, alternatively more than 40%, alternatively more than 50%, alternatively more than 60%, alternatively more than 70%, alternatively more than 80%, alternatively more than 90%, alternatively 100% of its ELISA signal for TPP-2614 compared to TPP-2203. Preferably, an antibody binds specifically to the D at position 47 (D47) of TWEAKR (SEQ ID NO:169) when the antibody loses more than 80% of its ELISA signal for TPP-2614 compared to TPP-2203.

In the present application, reference is made to the following preferred antibodies of the invention, as shown in the table below: “TPP-2090”, “TPP-2149”, “TPP-2093”, “TPP-2148”, “TPP-2084”, “TPP-2077”, “TPP-1538”, “TPP-883”, “TPP-1854”, “TPP-1853”, “TPP-1857”, “TPP-1858”.

Isotopes, salts, solvates, isotopic variants

The present invention also encompasses all suitable isotopic variants of the compounds according to the invention. An isotopic variant of a compound according to the invention is understood here as meaning a compound in which at least one atom within the compound according to the invention has been exchanged for another atom of the same atomic number, but with a different atomic mass than the atomic mass which usually or predominantly occurs in nature. Examples of isotopes which can be incorporated into a compound according to the invention are those of hydrogen, carbon, nitrogen, oxygen, phosphorus, sulphur, fluorine, chlorine, bromine and iodine, such as ^{2}H (deuterium), ^{3}H (tritium), ^{13}C, ^{14}C, ^{15}N, ^{17}O, ^{18}O, ^{32}P, ^{33}P, ^{33}S, ^{34}S, ^{35}S, ^{36}S, ^{18}F, ^{36}Cl, ^{82}Br, ^{123}I, ^{124}I, ^{129}I and ^{131}I. Particular isotopic variants of a compound according to the invention, especially those in which one or more radioactive isotopes have been incorporated, may be beneficial, for example, for the examination of the mechanism of action or of the active compound distribution in the body; due to comparatively easy preparability and detectability, especially compounds labelled

with ^{3}H or ^{14}C isotopes are suitable for this purpose. In addition, the incorporation of isotopes, for example of deuterium, can lead to particular therapeutic benefits as a consequence of greater metabolic stability of the compound, for example an extension of the half-life in the body or a reduction in the active dose required; such modifications of the compounds according to the invention may therefore in some cases also constitute a preferred embodiment of the present invention. Isotopic variants of the compounds according to the invention can be prepared by the processes known to those skilled in the art, for example by the methods described below and the procedures described in the working examples, by using corresponding isotopic modifications of the respective reagents and/or starting compounds.

Preferred salts in the context of the present invention are physiologically acceptable salts of the compounds according to the invention. Also encompassed are salts which are not themselves suitable for pharmaceutical applications but can be used, for example, for isolation or purification of the compounds according to the invention.

Physiologically acceptable salts of the compounds according to the invention include acid addition salts of mineral acids, carboxylic acids and sulphonic acids, for example salts of hydrochloric acid, hydrobromic acid, sulphuric acid, phosphoric acid, methanesulphonic acid, ethanesulphonic acid, benzenesulphonic acid, toluenesulphonic acid, naphthalenedisulphonic acid, acetic acid, trifluoroacetic acid, propionic acid, lactic acid, tartaric acid, malic acid, citric acid, fumaric acid, maleic acid and benzoic acid.

Physiologically acceptable salts of the inventive compounds also include salts of conventional bases, by way of example and with preference alkali metal salts (e.g. sodium and potassium salts), alkaline earth metal salts (e.g. calcium and magnesium salts) and ammonium salts derived from ammonia or organic amines having 1 to 16 carbon atoms, by way of example and with preference

ethylamine, diethylamine, triethylamine, ethyldiisopropylamine, monoethanolamine, diethanolamine, triethanolamine, dicyclohexylamine, dimethylaminoethanol, procaine, dibenzylamine, *N*-methylpiperidine, *N*-methylmorpholine, arginine, lysine and 1,2-ethylenediamine.

Solvates in the context of the invention are described as those forms of the compounds according to the invention which form a complex in the solid or liquid state by coordination with solvent molecules. Hydrates are a specific form of the solvates in which the coordination is with water. Solvates preferred in the context of the present invention are hydrates.

In addition, the present invention also encompasses prodrugs of the compounds according to the invention. The term "prodrugs" here denotes compounds which may themselves be biologically active or inactive, but are converted (for example by metabolic or hydrolytic means) to inventive compounds during their residence time in the body.

These also include proliferative blood diseases of the blood, the lymph system and the spinal cord, in solid form and as circulating cells, such as leukaemias, lymphomas and myeloproliferative diseases, for example acute myeloid, acute lymphoblastic, chronic lymphocytic, chronic myelogenous and hairy cell leukaemia, and AIDS-correlated lymphomas, Hodgkin's lymphomas, non-Hodgkin's lymphomas, cutaneous T cell lymphomas, Burkitt's lymphomas and lymphomas in the central nervous system.

These well-characterized diseases in humans can also occur with a comparable aetiology in other mammals and can likewise be treated there with the compounds of the present invention.

The treatment of the cancer diseases mentioned above with the compounds according to the invention comprises both a treatment of the solid tumors and a treatment of metastasizing or circulating forms thereof.

In the context of this invention, the term "treatment" or "treat" is used in the conventional sense and means attending to, caring for and nursing a patient with the aim of combating, reducing, attenuating or alleviating a disease or health abnormality, and improving the living conditions impaired by this disease, as, for example, in the event of a cancer.

The present invention thus further provides for the use of the compounds according to the invention for the treatment and/or prevention of disorders, in particular the disorders mentioned above.

The present invention further provides for the use of the

compounds according to the invention for producing a medicament for the treatment and/or prevention of disorders, in particular the disorders mentioned above.

The present invention further provides for the compounds according to the invention for use in a method for treatment and/or prevention of disorders, in particular the disorders mentioned above.

The present invention further provides for compounds for the use in a method for treatment and/or prevention of disorders, in particular the disorders mentioned above, using an effective amount of at least one of the compounds according to the invention.

Generally, the following aims can be pursued with the combination of compounds of the present invention with other cytostatically or cytotoxically active agents:

- improved efficacy in slowing the growth of a tumour, in reducing its size or even in the complete elimination thereof,

compared with treatment with an individual active compound;

- the possibility of using the chemotherapeutics used in a lower dosage than in the case of monotherapy;

- the possibility of a more tolerable therapy with fewer side effects compared with individual administration;

- the possibility of treatment of a broader spectrum of tumour diseases;

- the achievement of a higher rate of response to the therapy;

- a longer survival time of the patient compared with present-day standard therapy.

In addition, the compounds according to the invention can also be used in combination with radiotherapy and/or surgical intervention.

The present invention further provides medicaments which comprise at least one compound according to the invention, typically together with one or more inert, nontoxic, pharmaceutically suitable excipients, and the use thereof for the aforementioned purposes.

The compounds according to the invention can act systemically and/or locally. For this purpose, they can be administered in a suitable manner, for example parenterally, possibly inhalatively or as implants or stents.

The compounds according to the invention can be administered in suitable administration forms for these administration routes.

Parenteral administration can bypass an absorption step (for example intravenously, intraarterially, intracardially, intraspinally or intralumbally) or include an absorption (for example intramuscularly, subcutaneously, intracutaneously,

percutaneously or intraperitoneally). Administration forms suitable for parenteral administration include preparations for injection and infusion in the form of solutions, suspensions, emulsions or lyophilizates. Preference is given to parenteral administration, especially intravenous administration.

In general, it has been found to be advantageous in the case of parenteral administration to administer amounts of from about 0.001 to 1 mg/kg, preferably about 0.01 to 0.5 mg/kg, of body weight to achieve effective results.

It may nevertheless be necessary where appropriate to deviate from the stated amounts, specifically as a function of body weight, route of administration, individual response to the active compound, nature of the preparation and time or interval over which administration takes place. Thus, in some cases less than the abovementioned minimum amount may be sufficient, while in other cases the upper limit mentioned must be exceeded. In the case of administration of greater amounts, it may be advisable to divide them into several individual doses over the day.

Examples

The examples which follow illustrate the invention. The invention is not restricted to the examples.

Unless stated otherwise, the percentages in the tests and examples which follow are percentages by weight; parts are parts by weight. Solvent ratios, dilution ratios and concentration data for the liquid/liquid solutions are in each case based on volume.

990.0 mg (2.79 mmol) of (1R)-1-[1-benzyl-4-(2,5-difluorophenyl)-1H-pyrrol-2-yl]-2,2-dimethylpropan-1-amine were initially charged in 15.0 ml of dichloromethane, and 828.8 mg (3.91 mmol) of sodium triacetoxyborohydride and 129.9 mg (3.21 mmol) of acetic acid were added, and the mixture was stirred at RT for 5 min. 698.1 mg (3.21 mmol) of 2-(trimethylsilyl)ethyl (3-oxopropyl)carbamate (Intermediate L58) dissolved in 15.0 ml of dichloromethane were added, and the reaction mixture was stirred at RT overnight. The reaction mixture was diluted with ethyl acetate and the organic phase was washed in each case twice with saturated sodium carbonate solution and saturated NaCl solution. The organic phase was dried over magnesium sulphate and the solvent was evaporated under reduced pressure. The residue was purified using silica gel (mobile phase: dichloromethane/methanol 100:2). The solvents were evaporated under reduced pressure and the residue was dried under high vacuum. This gave 1.25 g (73% of theory) of the compound 2-(trimethylsilyl)ethyl [3-({(1R)-1-[1-benzyl-4-(2,5-difluorophenyl)-1H-pyrrol-2-yl]-2,2-dimethylpropyl}amino)propyl]carbamate.

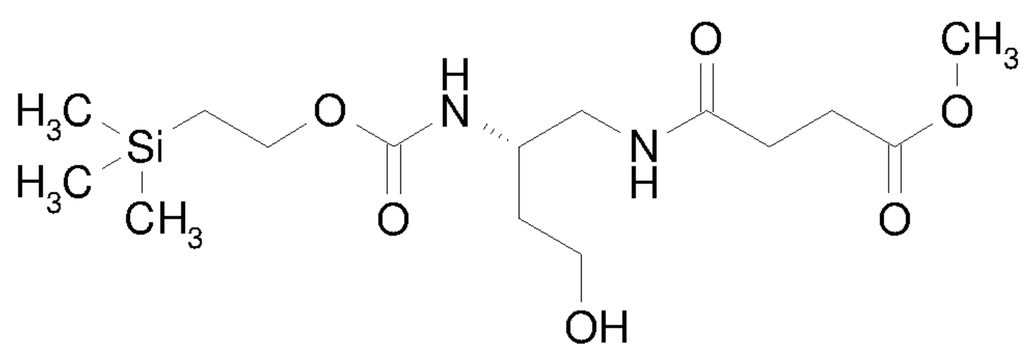
Ethyl acetate was added to the reaction mixture and the organic phase was washed three times with water and once with saturated NaCl solution. The organic phase was dried over magnesium sulphate and the solvent was evaporated under reduced pressure. The residue was purified using silica gel (mobile phase: cyclohexane/ethyl acetate 3:1). Methyl (8S)-8-(2-hydroxyethyl)-2,2-dimethyl-6,11-dioxo-5-oxa-7,10-diaza-2-silatetradecan-14-oate



1000 mg (2.84 mmol) of (3S)-3-{[(benzyloxy)carbonyl]amino}-4-[(tert-butoxycarbonyl)amino]butanoic acid were initially charged in 10.0 ml of 1,2-dimethoxyethane, and 344.4 mg (3.4 mmol) of 4-methylmorpholine and 504 mg (3.69 mmol) of isobutyl chloroformate were added. After 10 min of stirring at RT, the reaction was cooled to 5°C and 161 mg (4.26 mmol) of sodium

borohydride dissolved in 3 ml of water were added a little at a time with vigorous stirring. After 1 h, the same amount of sodium borohydride was added again and the reaction was then slowly warmed to RT. 170 ml of water were added and the reaction was then extracted four times with in each case 200 ml of ethyl acetate. The phases were separated and the organic phase was washed once with citric acid and then with saturated sodium bicarbonate solution. The organic phase was dried over magnesium sulphate, the solvent was evaporated under reduced pressure and the residue was dried under high vacuum. This gave 760 mg (78% of theory) of the compound benzyl tert-butyl [(2S)-4-hydroxybutane-1,2-diyl]biscarbamate.

LC-MS (Method 1): R_t = 0.84 min; MS (ESIpos): m/z = 339 $(M+H)^+$.

760 mg (2.16 mmol) of this intermediate dissolved in 13 ml of hydrogen chloride/dioxane were stirred at RT for 20 min. The reaction was then concentrated to 5 ml, and diethyl ether was added. The precipitate was filtered off and lyophilized from acetonitrile/water 1:1.

The product obtained in this manner was dissolved in 132 ml of DMF, and 345.5 mg (2.35 mmol) of 4-methoxy-4-oxobutanoic acid, 970 mg (2.55 mmol) of HATU and 1025 µl of *N*,*N*-diisopropylethylamine were added. The mixture was stirred at RT for 5 min. The solvent was removed under reduced pressure and the residue that remained was purified by preparative HPLC. The appropriate fractions were combined and the acetonitrile was evaporated under reduced pressure. The aqueous phase that remained was extracted twice with ethyl acetate and the organic phase was then concentrated and dried under high vacuum.

The intermediate obtained in this manner was taken up in methanol and hydrogenated over 10% palladium on activated carbon at RT under hydrogen standard pressure for 1 h. The catalyst was then filtered off and the solvent was removed under reduced pressure.

247 mg of this deprotected compound were taken up in 20 ml of

DMF, and 352 mg (1.36 mmol) of 1-({[2-(trimethylsilyl)ethoxy]carbonyl}oxy)pyrrolidine-2,5-dione and 592 µl of *N*,*N*-diisopropylethylamine were added. The reaction mixture was stirred at RT for 1 h and then concentrated, and the residue was purified by preparative HPLC. The solvents were then evaporated under reduced pressure and the residue was dried under high vacuum. This gave, over these 5 reaction steps, 218 mg of the title compound in a total yield of 21%.

B-2. General process for expressing anti-TWEAKR antibodies in mammalian cells

The antibodies, for example TPP-2090, were produced in transient mammalian cell cultures as described by Tom et al., Chapter 12 in Methods Express: Expression Systems edited by Micheal R. Dyson and Yves Durocher, Scion Publishing Ltd, 2007 (see AK-Example 1).

B-3. General process for purifying antibodies from cell supernatants

The antibodies, for example TPP-2090, were obtained from the cell culture supernatants. The cell supernatants were clarified by centrifugation of cells. The cell supernatant was then purified by affinity chromatography on a MabSelect Sure (GE Healthcare) chromatography column. To this end, the column was equilibrated in DPBS pH 7.4 (Sigma/Aldrich), the cell supernatant was applied and the column was washed with about 10 column volumes of DPBS pH 7.4 + 500 mM sodium chloride. The antibodies were eluted in 50 mM sodium acetate pH 3.5 + 500 mM sodium chloride and then purified further by gel filtration chromatography on a Superdex 200 column (GE Healthcare) in DPBS pH 7.4.

The commercially available antibody cetuximab (trade name Erbitux) was purified from the commercial product by standard chromatographic methods (protein A, preparative SEC).

The commercially available antibody trastuzumab (trade name

Herceptin) was purified from the commercial product by standard chromatographic methods (protein A, preparative SEC).

From the commercial product (trade name CIMAher), the antibody nimotuzumab was purified from the commercial product by standard chromatographic methods (protein A, preparative SEC).

From the commercial product (trade name Vectibix), the antibody panitumumab was purified from the commercial product by standard chromatographic methods (protein A, preparative SEC).

B-4. General process for coupling to cysteine side chains

The following antibodies were used for the coupling reactions:

cetuximab (anti EGFR AK)

anti-TWEAKR AK 1 (TPP-2090)

trastuzumab (anti-Her2 AK)

nimotuzumab (anti-EGFR AK)

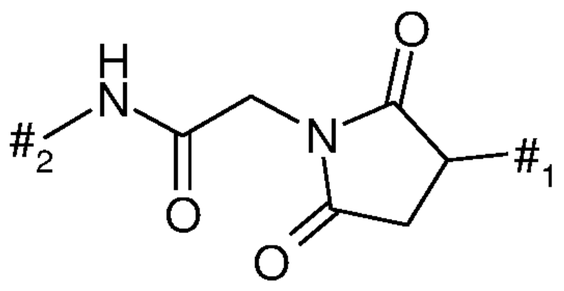
panitumumab (anti-EGFR AK)

Between 2 and 5 equivalents of tris(2-carboxyethyl)phosphine hydrochloride (TCEP), dissolved in PBS buffer, were added to a solution of the appropriate antibody in PBS buffer in the concentration range between 1 mg/ml and 20 mg/ml, preferably in the range of about 10 mg/ml to 15 mg/ml, and the mixture was stirred at RT for 1h. For this purpose, the solution of the respective antibody used can be employed at the concentrations stated in the working examples, or it may optionally also be diluted with PBS buffer to about half of the stated starting concentrations in order to get into the preferred concentration range. Subsequently, depending on the intended loading from 2 to 12 equivalents, preferably about 5-10 equivalents of the maleinimide precursor compound or halide precursor compound to

be coupled can be added as a solution in DMSO. Here, the amount of DMSO should not exceed 10% of the total volume. The reaction was stirred in the case of maleinimide precursors for 60-240 min at RT and in the case of halide precursors between 8 and 24 h at RT and then applied to PBS-equilibrated PD 10 columns (Sephadex® G-25, GE Healthcare) and eluted with PBS buffer. Generally, unless indicated otherwise, 5 mg of the antibody in question in PBS buffer were used for the reduction and the subsequent coupling. Purification on the PD10 column thus in each case afforded solutions of the respective ADCs in 3.5 ml PBS buffer. The sample was then concentrated by ultracentrifugation and optionally rediluted with PBS buffer. If required, for better removal of low-molecular weight components, concentration by ultrafiltration was repeated after redilution with PBS buffer. For biological tests, if required, the concentrations of the final ADC samples were optionally adjusted to the range of 0.5-15 mg/ml by redilution. The respective protein concentrations, stated in the working examples, of the ADC solutions were determined. Furthermore, antibody loading (drug/mAb ratio) was determined using the methods described under B-7.

Unless indicated otherwise, the immunoconjugates shown in the examples were prepared by this process. Depending on the linker, the ADCs shown in the examples may also be present to a lesser or higher degree in the form of the hydrolysed open-chain succinamides attached to the antibodies.

In particular the KSP-I-ADCs attached though the linker substructure



to thiol groups of the antibodies may optionally also be prepared in a targeted manner by rebuffering after the coupling and

stirring at pH 8 for about 20 h according to Scheme 26 via the ADCs attached via open-chain succinamides.

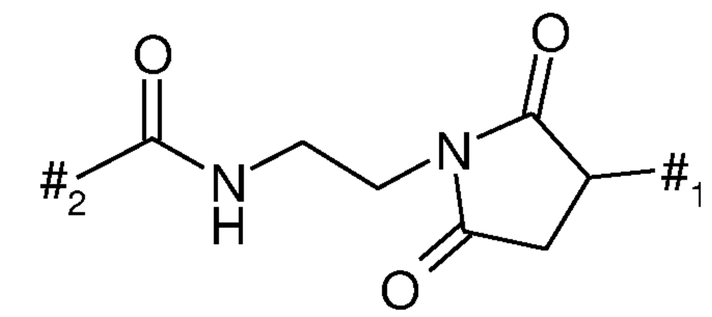
#1 represents the sulphur bridge to the antibody, and #2 the point of attachment to the modified KSP inhibitor

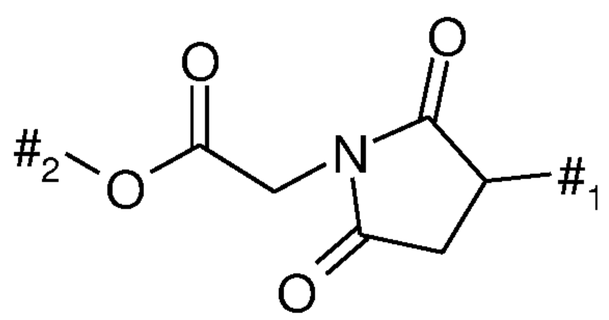
Such ADCs where the linker is attached to the antibodies through hydrolysed open-chain succinamides may optionally also be prepared in a targeted manner by an exemplary procedure as follows:

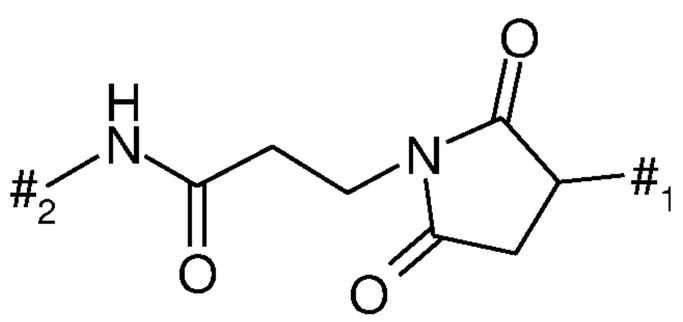
Under argon, a solution of 0.344 mg TCEP in 100 µl of PBS buffer was added to 60 mg of the antibody in question in 5 ml of PBS buffer (c~12 mg/ml). The reaction was stirred at RT for 30 min, and 0.003 mmol of a maleinimide precursor compound dissolved in 600 µl of DMSO was then added. After a further 1.5 h - 2 h of stirring at RT, the reaction was diluted with 1075 µl of PBS buffer which had been adjusted to pH 8 beforehand.

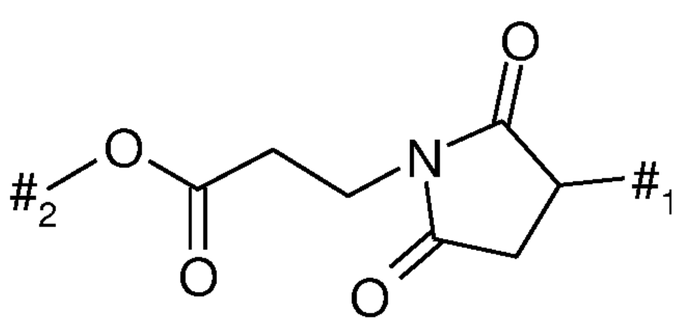
This solution was then applied to PD 10 columns (Sephadex® G-25, GE Healthcare) which had been equilibrated with PBS buffer pH 8 and was eluted with PBS buffer pH 8. The eluate was diluted with PBS buffer pH 8 to a total volume of 14 ml. This solution was stirred at RT under argon overnight. If required, the solution was then rebuffered to pH 7.2. The ADC solution was concentrated by ultracentrifugation, rediluted with PBS buffer (pH 7.2) and then optionally concentrated again to a concentration of about 10 mg/ml.

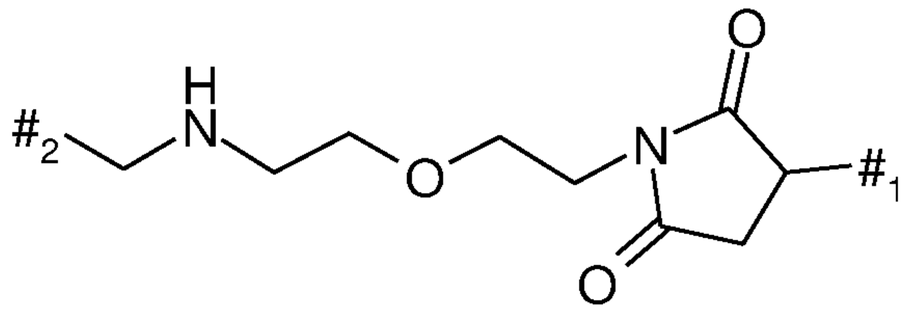
Other potentially hydrolysis-sensitive thianylsuccinimide bridges to the antibody in the working examples contain the following linker substructures, where #1 represents the thioether linkage to the antibody and #2 the point of attachment to the modified KSP inhibitor:

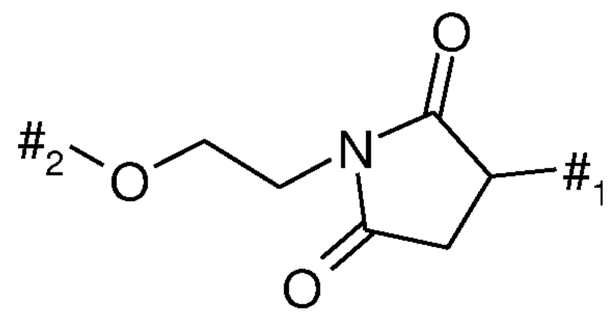


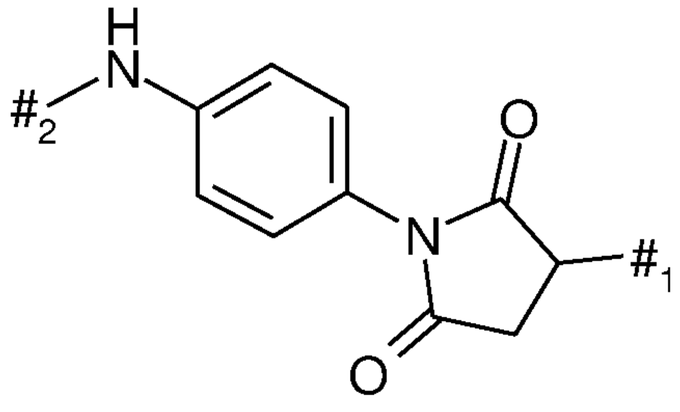












These linker substructures represent the linking unit to the antibody and have (in addition to the linker composition) a significant effect on the structure and the profile of the metabolites formed in the tumour cells.

From 2 to 8 equivalents of the precursor compound to be coupled were added as a solution in DMSO to a solution of the antibody in question in PBS buffer in a concentration range between 1 mg/ml and 20 mg/ml, preferably about 10 mg/ml, depending on the intended loading. After 30 min to 6 h of stirring at RT, the same amount of precursor compound in DMSO was added again. Here, the amount of DMSO should not exceed 10% of the total volume. After a further 30 min to 6 h of stirring at RT, the reaction was applied to PD 10 columns (Sephadex® G-25, GE Healthcare) equilibrated with PBS and eluted with PBS buffer. Generally, unless indicated otherwise, 5 mg of the antibody in question in PBS buffer were used for the reduction and the subsequent coupling. where

§^{2} represents the linkage to the carbonyl group

and

<u>B-6a. General process for preparing closed succinimide-cysteine adducts:</u>

In an exemplary embodiment, 10 µmol of the maleinimide precursor compounds described above were taken up in 3-5 ml of DMF, and 2.1 mg (20 µmol) of L-cysteine were added. The reaction mixture was stirred at RT for 2 h to 24 h, then dried under reduced pressure and then purified by preparative HPLC.

B-6aa. General process for preparing isomeric open succinamide-cysteine adducts:

In an exemplary embodiment, 68 µmol of the maleinimide precursor compounds described above were taken up in 15 ml of DMF, and with 36 mg (136 µmol) of N-{[2-(trimethylsilyl)ethoxy]carbonyl}-L-cysteine were added. The reaction mixture was stirred at RT for ~20 h, then dried under reduced pressure and then purified by preparative HPLC. The appropriate fractions were combined and the solvents were evaporated under reduced pressure, and the residue was then dissolved in 15 ml of THF/water 1:1. 131 µl of a 2M aqueous lithium hydroxide solution were added, and the reaction was stirred at RT for 1 h. The reaction was then neutralized with a 1M hydrochloric acid, the solvent was evaporated under reduced pressure and the residue was purified by preparative HPLC. This gave ~50% of theory of the regioisomeric protected intermediates as a colourless foam.

In the last step, 0.023 mmol of these regioisomeric hydrolysis products were dissolved in 3 ml of 2,2,2-trifluoroethanol. 12.5 mg (0.092 mmol) of zinc chloride were added, and the reaction was stirred at 50°C for 4 h. 27 mg (0.092 mmol) of ethylenediamine-N,N,N',N'-tetraacetic acid were then added, and the solvent was evaporated under reduced pressure. The residue was purified by preparative HPLC. Concentration of the appropriate fractions and lyophilization of the residue from acetonitrile/water gave the hydrolysed open sulphanylsuccinamides as a regioisomer mixture.

B-6b. General process for preparing lysine adducts:

In an exemplary embodiment, 10 µmol of the activated ester

precursor compounds described above were taken up in 3-5 ml of DMF, and □-amino-protected L-lysine was added in the presence of 30 µmol of *N*,*N*-diisopropylethylamine. The reaction mixture was stirred at RT for 2 h to 24 h, then dried under reduced pressure and then purified by preparative HPLC. The protective group was then removed by known methods.

Further purification and characterization of the conjugates according to the invention

After the reaction, in some instances the reaction mixture was concentrated, for example by ultrafiltration, and then desalted and purified by chromatography, for example using a Sephadex® G-25 column. Elution was carried out, for example, with phosphate-buffered saline (PBS). The solution was then sterile filtered and frozen. Alternatively, the conjugate can be lyophylized.

B-7. Determination of the antibody, the toxophor loading and the proportion of open cysteine adducts

For protein identification in addition to molecular weight determination after deglycosylation and/or denaturing, a tryptic digestion was carried out which, after denaturing, reduction and derivatization, confirms the identity of the protein via the tryptic peptides found.

The toxophor loading of the PBS buffer solutions obtained of the conjugates described in the working example was determined as follows:

Determination of toxophor loading of lysine-linked ADCs was carried out by mass spectrometric determination of the molecular weights of the individual conjugate species. Here, the antibody conjugates were first deglycosylated with PNGaseF, and the sample was acidified and, after HPLC separation/desalting, analysed by mass spectrometry using ESI-MicroTofQ (Bruker Daltonik). All spectra over the signal in the TIC (Total Ion

Chromatogram) were added and the molecular weight of the different conjugate species was calculated based on MaxEnt deconvolution. The DAR (= drug/antibody ratio) was then calculated after signal integration of the different species.

The toxophor loading of cysteine-linked conjugates was determined by reversed-phase chromatography of the reduced and denatured ADCs. Guanidinium hydrochloride (GuHCl) (28.6 mg) and a solution of DL-dithiothreitol (DTT) (500 mM, 3 µl) were added to the ADC solution (1 mg/ml, 50 µl). The mixture was incubated at 55°C for one hour and analysed by HPLC.

HPLC analysis was carried out on an Agilent 1260 HPLC system with detection at 220 nm. A Polymer Laboratories PLRP-S polymeric reversed-phase column (catalogue number PL1912-3802) (2.1 x150 mm, 8 µm particle size, 1000 Å) was used at a flow rate of 1 ml/min with the following gradient: 0 min, 25%B; 3 min, 25%B; 28 min, 50%B. Mobile phase A consisted of 0.05% trifluoroacetic acid (TFA) in water, mobile phase B of 0.05% trifluoroacetic acid in acetonitrile.

The detected peaks were assigned by retention time comparison with the light chain (L0) and the heavy chain (H0) of the non-conjugated antibody. Peaks detected exclusively in the conjugated sample were assigned to the light chain with one toxophor (L1) and the heavy chains with one, two and three toxophors (H1, H2, H3).

Average loading of the antibody with toxophors was calculated from the peak areas determined by integration as double the sum of the toxophor number weighed integration results of all peaks divided by the sum of the singly weighed integration results of all peaks. In individual cases, it may be possible that, owing to co-elution of some peaks, it is not possible to determine toxophor loading accurately.

In the cases where light and heavy chains could not be separated sufficiently by HPLC, determination of toxophor loading of

cysteine-linked conjugates was carried out by mass spectrometric determination of the molecular weights of the individual conjugate species at light and heavy chain.

Guanidinium hydrochloride (GuHCl) (28.6 mg) and a solution of DL-dithiothreitol (DTT) (500 mM, 3 µl) were added to the ADC solution (1 mg/ml, 50 µl). The mixture was incubated for one hour at 55°C and analysed by mass spectrometry after online desalting using ESI-MicroTof$_Q$ (Bruker Daltonik).

For the DAR determination, all spectra were added over the signal in the TIC (Total Ion Chromatogram), and the molecular weight of the different conjugate species at light and heavy chain was calculated based on MaxEnt deconvolution. The average loading of the antibody with toxophores was calculated by integration of certain molecular weight areas as double the sum of the toxophor number weighed integration results of all peaks divided by the sum of the singly weighed integration results of all peaks.

To determine the proportion of the open cysteine adduct, the molecular weight area ratio of closed to open cysteine adduct (molecular weight delta 18 Dalton) of all singly conjugated light and heavy chains was determined. The mean of all variants yielded the proportion of the open cysteine adduct.

B-8. Checking the antigen-binding of the ADCs

The capability of the binder of binding to the target molecule was checked after coupling had taken place. The person skilled in the art is familiar with multifarious methods which can be used for this purpose; for example, the affinity of the conjugate can be checked using ELISA technology or surface plasmon resonance analysis (BIAcore™ measurement). The conjugate concentration can be measured by the person skilled in the art using customary methods, for example for antibody conjugates by protein determination. After drying over magnesium sulphate, the solvent was evaporated under reduced pressure and the residue was purified using silica gel (mobile phase: dichloromethane/methanol 100:1). The solvents were evaporated under reduced pressure and the residue was dried under high vacuum. This gave 188.6 mg (74%) of the compound 2-[3-({(1R)-1-[1-benzyl-4-(2,5-difluorophenyl)-1H-pyrrol-2-yl]-2,2-dimethylpropyl}amino)propyl]-1H-isoindole-1,3(2H)-dione.

LC-MS (Method 1): R_t = 1.00 min; MS (ESIpos): m/z = 541 $[M+H]^+$.

171.2 mg (0.32 mmol) of 2-[3-({(1R)-1-[1-benzyl-4-(2,5-difluorophenyl)-1H-pyrrol-2-yl]-2,2-dimethylpropyl}amino)propyl]-1H-isoindole-1,3(2H)-dione were initially charged in 5.0 ml of dichloromethane, and 73.6 mg (0.73 mmol) of triethylamine were added. At 0°C, 94.9 mg (0.70 mmol) of acetoxyacetyl chloride were added, and the reaction mixture was stirred at RT overnight. The reaction mixture was diluted with ethyl acetate and the organic phase was washed twice with saturated sodium bicarbonate solution and once with sat. NaCl solution. After drying over magnesium sulphate, the solvent was evaporated under reduced pressure and the residue was purified using Biotage Isolera (silica gel, column 10 g SNAP, flow rate 12 ml/min, ethyl acetate/cyclohexane 1:3). The solvents were evaporated under reduced pressure and the residue was dried under high vacuum. This gave 159.0 mg (77%) of the compound 2-({(1R)-1-[1-benzyl-4-(2,5-difluorophenyl)-1H-pyrrol-2-yl]-2,2-dimethylpropyl}[3-(1,3-dioxo-1,3-dihydro-2H-isoindol-2-yl)propyl]amino)-2-oxoethyl acetate.

LC-MS (Method 1): R_t = 1.35 min; MS (ESIpos): m/z = 642 $[M+H]^+$.

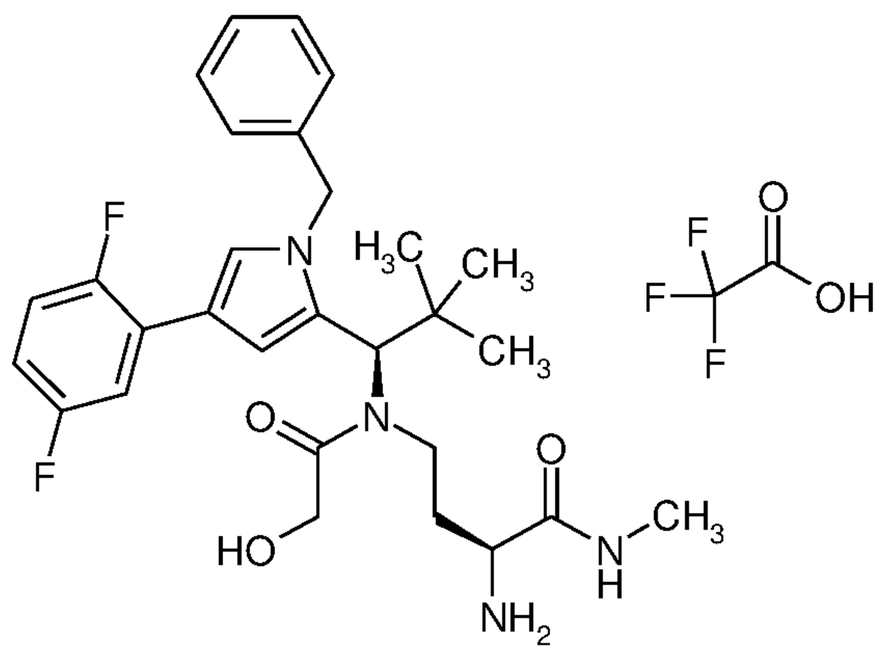
147.2 mg (0.23 mmol) of 2-({(1R)-1-[1-benzyl-4-(2,5-difluorophenyl)-1H-pyrrol-2-yl]-2,2-dimethylpropyl}[3-(1,3-dioxo-1,3-dihydro-2H-isoindol-2-yl)propyl]amino)-2-oxoethyl acetate were initially charged in 4.0 ml of ethanol, and 356.2 mg (4.59 mmol) of methanamine (40% in water) were added. The

reaction mixture was stirred at 50°C overnight. The solvent was evaporated under reduced pressure and the residue was co-distilled with toluene three times. The residue was purified using silica gel (mobile phase: dichloromethane/methanol 10:1). The solvents were evaporated under reduced pressure and the residue was dried under high vacuum. This gave 67.4 mg (63%) of the title compound.

LC-MS (Method 1): R_t = 0.91 min; MS (ESIpos): m/z = 470 $[M+H]^+$.

Example 99

Trifluoroacetic acid / (2S)-2-amino-4-[{(1R)-1-[1-benzyl-4-(2,5-difluorophenyl)-1H-pyrrol-2-yl]-2,2-dimethylpropyl}(glycoloyl)amino]-N-methylbutanamide (1:1)



First, Intermediate C52 was reductively alkylated with benzyl (2S)-2-{[(benzyloxy)carbonyl]amino}-4-oxobutanoate analogously to C2. The secondary amino group was then acylated with 2-chloro-2-oxoethyl acetate as described in Intermediate C27.

190 mg (0.244 mmol) of this intermediate were taken up in 7.5 ml of ethanol, and 0.35 ml of a 40% strength solution of methanamine in water was added. The reaction was stirred at 50°C for 3 h, and the same amount of methanamine was then added again. After a further 5 h of stirring at 50°C, the reaction was concentrated and the residue was purified by preparative HPLC. This gave 78 mg (48% of theory) of this title compound.

LC-MS (Method 1): R_t = 1.32 min; MS (EIpos): m/z = 661 $[M+H]^+$.

78 mg (0.118 mmol) of this intermediate were dissolved in 8 ml of ethanol and, after addition of 15 mg of 10% palladium on activated carbon, hydrogenated under standard hydrogen pressure at RT for 3 min. The catalyst was then filtered off, the solvent was removed under reduced pressure and the product was purified by preparative HPLC. After lyophilization from acetonitrile/water, 33 mg (44% of theory) of the title compound were obtained.

LC-MS (Method 1): R_t = 0.88 min; MS (ESIpos): m/z = 527 $(M+H)^+$.

^{1}H NMR (500 MHz, DMSO-d_6): δ = 8.1 (m, 1H), 8.0 (m, 3H), 7.9 (m, 1H), 7.65 (m, 1H), 7.5 (s, 1H), 7.15-7.35 (m, 5H) 7.0 (m, 1H), 6.85 (m, 1H), 5.6 (s, 1H), 4.9 and 5.2 (2d, 2H), 4.02 and 4.22 (2d, 2H), 3.2-3.5 (m, 6H), 0.7 and 1.46 (2m, 2H), 0.8 (s, 9H).

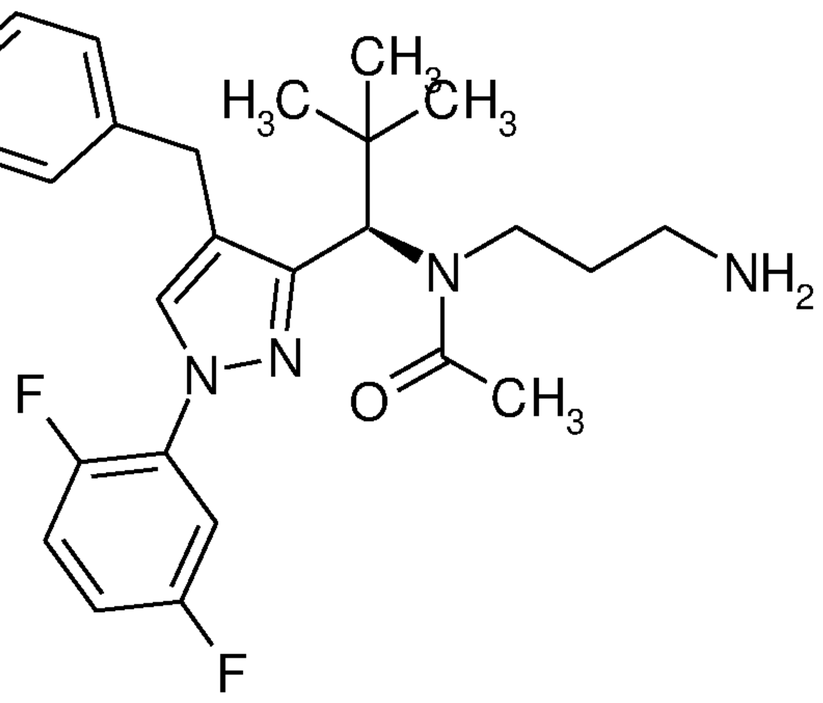
Example 181

N-(3-Aminopropyl)-N-{(1R)-1-[4-benzyl-1-(2,5-difluorophenyl)-1H-pyrazol-3-yl]-2,2-dimethylpropyl}acetamide



1.01 g (2.84 mmol) of (1R)-1-[4-benzyl-1-(2,5-difluorophenyl)-1H-pyrazol-3-yl]-2,2-dimethylpropan-1-amine were initially charged in 20 ml of 1,2-dichloroethane, and 0.84 g (3.98 mmol) of sodium triacetoxyborohydride and 2.56 g (42.65 mmol) of acetic acid were added, and the mixture was stirred at RT for 5 min. A solution of 0.54 g (3.13 mmol) of tert-butyl (3-oxopropyl)carbamate in 5 ml of 1,2-dichloroethane was then added, and the reaction mixture was stirred overnight. The mixture was then evaporated to dryness, the residue was taken up in ethyl acetate and filtered and the product-containing filtrate was evaporated to dryness.

51.26 mg of the residue were dissolved in 0.8 ml of 1,2-

dichloromethane and added to 7.85 mg (0.1 mmol) of acetyl chloride on a deep 96-well multititre plate 25.8 mg (0.2 mmol) of *N*,*N*-diisopropylethylamine were then added and the mixture was shaken at RT overnight. The solvent was then removed completely using a centrifugal drier, 0.4 ml of 1,2-dichlorethane and 0.4 ml of trifluoroacetic acid were added and the mixture was shaken overnight. The solvent was then removed completely using a centrifugal drier, and 0.8 ml of DMF were added to the residue. The mixture was then filtered and the target compound was isolated from the filtrate by preparative LC-MS (Method 9). The product-containing fractions were concentrated under reduced pressure using a centrifugal dryer. The residue of each product fraction was dissolved in 0.6 ml of DMSO. These were combined and finally freed of the solvent in a centrifugal dryer. This gave 12.2 mg (27% of theory; purity 100%) of the title compound.

Isomer 2

LC-MS (Method 1): R_t = 0.80 min; MS (EIpos): m/z = 814 $[M+H]^+$.

First, L-cysteine was converted with 1-({[2-(trimethylsilyl)ethoxy]carbonyl}oxy)pyrrolidine-2,5-dione in DMF in the presence of *N*,*N*-diisopropylethylamine into N-{[2-(trimethylsilyl)ethoxy]carbonyl}-L-cysteine.

The mixture was then concentrated under reduced pressure, and the residue was purified by preparative HPLC. The solvent was evaporated under reduced pressure and the residue was dried under high vacuum. This gave 10 mg (89%) of the protected intermediate; it was not possible to separate the regioisomers neither by HPLC nor by LC-MS.

LC-MS (Method 1): R_t = 1.38 min; MS (EIpos): m/z = 1120 $[M+H]^+$.

The residue was purified by preparative HPLC. Concentration of the appropriate fractions and lyophilization of the residue from acetonitrile/water gave 8.3 mg (99% of theory) of the title compound as a regioisomer mixture in a ratio of 87:13.

LC-MS (Method 5): R_t = 2.3 min and 2.43 min; MS (ESIpos): m/z = 832 $(M+H)^+$.

Alternatively, the regioisomeric title compounds were prepared as follows:

To this end, first L-cysteine was converted with 1-({[2-(trimethylsilyl)ethoxy]carbonyl}oxy)pyrrolidine-2,5-dione in DMF in the presence of *N,N*-diisopropylethylamine into N-{[2-(trimethylsilyl)ethoxy]carbonyl}-L-cysteine.

55 mg (0.068 mmol) of Intermediate F104 and 36 mg (0.136 mmol) of N-{[2-(trimethylsilyl) ethoxy]carbonyl}-L-cysteine were dissolved in 15 ml of DMF, and the mixture was stirred at RT for 20 h. The mixture was then concentrated and the residue was purified by preparative HPLC. The appropriate fractions were combined and the solvents were evaporated under reduced pressure, and the residue was then dissolved in 15 ml of THF/water 1:1. 131 µl of a 2M aqueous lithium hydroxide solution were added and the reaction was stirred at RT for 1 h. The reaction was then neutralized with a 1M hydrochloric acid, the

solvent was evaporated under reduced pressure and the residue was purified by preparative HPLC. This gave 37 mg (50% of theory) of the regioisomeric protected intermediates as a colourless foam.

LC-MS (Method 5): R_t = 3.33 min and 3.36 min; MS (ESIpos): m/z = 976 $(M+H)^+$.

In the last step, 25 mg of this intermediate were dissolved in 3 ml of 2,2,2-trifluoroethanol. 12.5 ml (0.092 mmol) of zinc chloride were added, and the reaction was stirred at 50°C for 4 h. 27 mg (0.092 mmol) of ethylenediamine-N,N,N',N'-tetraacetic acid were then added, and the solvent was evaporated under reduced pressure. The residue was purified by preparative HPLC. Concentration of the appropriate fractions and lyophilization of the residue from acetonitrile/water gave 18.5 mg (85% of theory) of the title compound as a regioisomer mixture in a ratio of 21:79.

LC-MS (Method 5): R_t = 2.37 min and 3.44 min; MS (ESIpos): m/z = 832 $(M+H)^+$.

The targeted preparation of the individual regioisomers of the title compounds was carried out as follows:

Example 199-2

4-[(2-{[2-({(2S)-2-Amino-4-[{(1R)-1-[1-benzyl-4-(2,5-difluorophenyl)-1H-pyrrol-2-yl]-2,2-dimethylpropyl}(glycoloyl)amino]butanoyl}amino)ethyl]amino}-2-oxoethyl)amino]-2-{[(2R)-2-amino-2-carboxyethyl]sulphanyl}-4-oxobutanoic acid / trifluoroacetic acid (1:1)

First, methyl L-cysteinate was converted with 1-({[2-(trimethylsilyl)ethoxy]carbonyl}oxy)pyrrolidine-2,5-dione in DMF in the presence of *N*,*N*-diisopropylethylamine into methyl N-{[2-(trimethylsilyl)ethoxy]carbonyl}-L-cysteinate.

53 mg (0.251 mmol) of commercially available 3-bromo-4-methoxy-4-oxobutanoic acid and 70 mg (0.251 mmol) of methyl N-{[2-(trimethylsilyl)ethoxy]carbonyl}-L-cysteinate were dissolved in 5 ml of DMF, and aqueous sodium bicarbonate solution was added while monitoring the pH. After stirring 15 min of stirring at RT, the mixture was adjusted to pH=4.3 with acetic acid and the reaction was concentrated. The residue was purified by preparative HPLC. Combination of the appropriate fractions and evaporation of the solvents under reduced pressure gave 72 mg (70% of theory) of 4-methoxy-3-{[(2R)-3-methoxy-3-oxo-2-({[2-(trimethylsilyl)ethoxy]carbonyl}amino)propyl] sulphanyl}-4-oxobutanoic acid.

LC-MS (Method 1): R_t = 0.93 min; MS (ESIpos): m/z = 410 $(M+H)^+$.

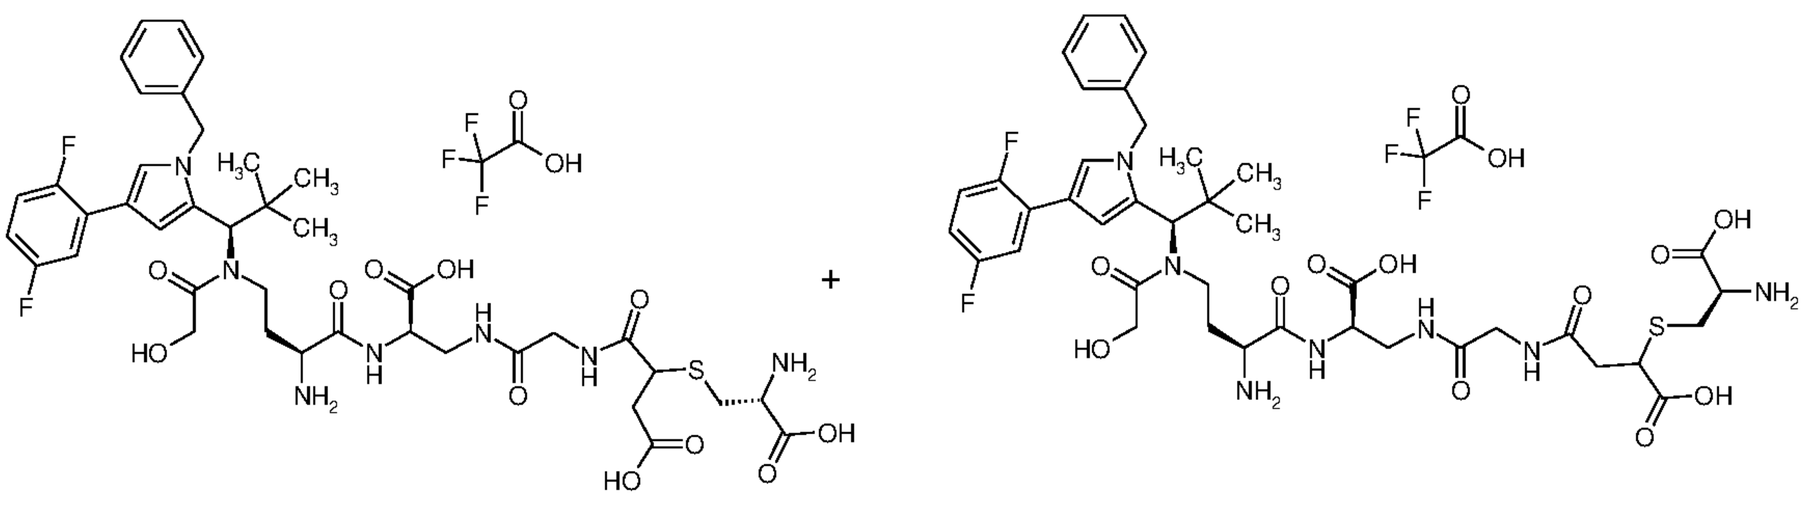
and

4-[(2-{[(2R)-2-({(2S)-2-amino-4-[{(1R)-1-[1-benzyl-4-(2,5-difluorophenyl)-1H-pyrrol-2-yl]-2,2-dimethylpropyl}(glycoloyl)amino]butanoyl}amino)-2-carboxyethyl]amino}-2-oxoethyl)amino]-2-{[(2R)-2-amino-2-carboxyethyl]sulphanyl}-4-oxobutanoic acid / trifluoroacetic acid (1:1)



First, L-cysteine was converted with 1-({[2-(trimethylsilyl)ethoxy]carbonyl}oxy)pyrrolidine-2,5-dione in DMF in the presence of *N*,*N*-diisopropylethylamine into N-{[2-(trimethylsilyl)ethoxy]carbonyl}-L-cysteine.

11 mg (0.013 mmol) of Intermediate F193 and 8 mg (0.016 mmol) of N-{[2-(trimethylsilyl) ethoxy]carbonyl}-L-cysteine were dissolved in 3 ml of DMF, and the mixture was stirred at RT for 20 h. The mixture was then concentrated and the residue was purified by preparative HPLC.

The appropriate fractions were combined and the solvents were evaporated under reduced pressure, and the residue was then dissolved in 2 ml of THF/water 1:1. 19 µl of a 2M aqueous lithium hydroxide solution were added and the reaction was stirred at RT for 1 h. Another 19 µl of the 2M aqueous lithium hydroxide solution were then added and the reaction was stirred at RT overnight. The mixture was then neutralized with a 1M hydrochloric acid, the solvent was evaporated under reduced pressure and the residue was purified by preparative HPLC. This gave 4.1 mg (38% of theory) of the regioisomeric protected

intermediates as a colourless foam.

LC-MS (Method 1): R_t = 1.03 min (broad); MS (ESIpos): m/z = 1020 $(M+H)^+$.

The residue was purified by preparative HPLC. Concentration of the appropriate fractions and lyophilization of the residue from acetonitrile/water gave 5 mg (quant.) of the title compound as a regioisomer mixture in a ratio of 20:80.

LC-MS (Method 1): R_t = 0.78 min (broad); MS (ESIpos): m/z = 876 $(M+H)^+$.

The mixture was then concentrated and the residue was purified by preparative HPLC. The appropriate fractions were combined and the solvents were evaporated under reduced pressure, and the residue was then dissolved in 2 ml of THF/water 1:1. 15 µl of a 2M aqueous lithium hydroxide solution were added and the reaction was stirred at RT for 15 min. The reaction was then adjusted to a pH of ~3 with a 1M hydrochloric acid, diluted with 20 ml of sodium chloride solution and extracted twice with 20 ml of ethyl acetate. The organic phase was dried over magnesium sulphate and concentrated, and the residue was lyophilized from acetonitrile/water. This gave 8.4

mg (78% of theory over 2 steps) of the regioisomeric protected intermediates as a colourless foam.

LC-MS (Method 1): R_t = 1.44 min and 3.43 min; MS (ESIpos): m/z = 1107 $(M+H)^+$.

In the last step, 8 mg (0.007 mmol) of this intermediate were dissolved in 5 ml of 2,2,2-trifluoroethanol. 9.8 ml (0.072 mmol) of zinc chloride were added, and the reaction was stirred at 50°C for 1.5 h. Ethylenediamine-N,N,N',N'-tetraacetic acid were then added, and the solvent was evaporated under reduced pressure. The residue was purified by preparative HPLC. Concentration of the appropriate fractions and lyophilization of the residue from acetonitrile/water gave 4 mg (59% of theory) of the title compound as a regioisomer mixture in a ratio of 31:67.

LC-MS (Method 1): R_t = 0.79 min and 0.81 min; MS (ESIpos): m/z = 819 $(M+H)^+$.

C: Assessment of biological efficacy

The biological activity of the compounds according to the invention can be shown in the assays described below:

m. C-1a Determination of the cytotoxic effects of the ADCs directed against TWEAKR

The analysis of the cytotoxic effects of the anti-TWEAKR-ADCs was carried out with various cell lines:

NCI-H292: human mucoepidermoid lung carcinoma cells, ATCC-CRL-1848, standard medium: RPMI 1640 (Biochrom; #FG1215, stab. glutamine) + 10% FCS (Biochrom; #S0415), TWEAKR-positive, EGFR-positive.

BxPC3: human pancreas carcinoma cells, ATCC-CRL-1687, standard medium: RPMI 1640 (Biochrom; #FG1215, stab. glutamine) + 10% FCS (Biochrom; #S0415), TWEAKR-positive.

KPL4: human breast carcinoma cells, standard medium: RPMI 1640 + GlutaMAX I + 10% FBS, cell bank, Bayer Pharma AG (identity checked and confirmed on 19.7.2012 at DSMZ), Berlin, ERBB2-positive.

The cells are cultivated by a standard method, as indicated in the American Tissue Type Collection (ATCC) for the respective cell lines.

MTT assay

The test is carried out by detaching the cells with a solution of Accutase in PBS (Biochrom AG #L2143), pelleting, resuspending in culture medium, counting and sowing into a 96-well culture plate with white bottom (Costar #3610) (1000-2000 cells in 100 µl/well depending on the cell used) and incubating in an incubator at 37°C and 5% carbon dioxide. After 48 h, the antibody drug conjugates are added in 10 µl of culture medium in concentrations of from 10^{-5}M to 10^{-13}M to the cells (triplicates) and incubated in an incubator at 37°C and 5% carbon dioxide. After 72 h, the proliferation is detected using the MTT assay (ATCC, Manassas, Virginia, USA, catalogue No. 30-1010K). At the end of the selected incubation time, the MTT reagent is incubated with the cells for 4 h, followed by lysis of the cells overnight by addition of the detergent. The dye formed was detected at 570 nm. The proliferation of cells which were not treated with test substance but were otherwise identically treated was defined as the 100% figure.

CTG assay

The cells were cultivated according to the standard method using the growth media listed under C-1. The test was carried out by detaching the cells with a solution of trypsin (0.05%) and EDTA (0.02%) in PBS (Biochrom AG #L2143), pelleting, resuspending in culture medium, counting and sowing into a 96-well culture plate with white bottom (Costar #3610) (at 75 µl/well, the following cell numbers are per well: NCI-H292: 2500 cells/well, BxPC3 2500 cells/well) and incubating in an incubator at 37°C and 5% carbon dioxide. After 24 h, the antibody drug conjugates were added in 25 µl of culture medium (concentrated four-fold) to the cells to give final antibody drug conjugate concentrations of 3 x 10^{-7} M to 3 x 10^{-11} M on the cells (triplicates). The cells were then incubated in an incubator at 37°C and 5% carbon dioxide. On a parallel plate, the cell activity at the start of the active compound treatment (day 0) was determined using the Cell Titer Glow (CTG) luminescent cell viability assay (Promega #G7573 and

#G7571). To this end, per cell batch 100 µl of the substrate were added, the plates were then covered with aluminium foil, shaken on the plate shaker at 180 rpm for 2 minutes, allowed to stand on the laboratory bench for 8 minutes and then measured using a luminometer (Victor X2, Perkin Elmer). The substrate detects the ATP content of the living cells generating a luminescence signal whose intensity is directly proportional to the viability of the cells. After 72 h of incubation with the antibody drug conjugates, the viability of these cells was then also determined using the Cell Titer Glow luminescent cell viability assay as described above. From the data measured, the IC_{50} of the growth inhibition was calculated in comparison to day 0 using the DRC (Dose Response Curve) analysis spreadsheets and a 4-parameter fit. The DRC analysis spreadsheet is a biobook spreadsheet developed by Bayer Pharma AG and Bayer Business Services on the IDBS E-WorkBook Suite platform (IDBS: ID Business Solutions Ltd., Guildford, UK).

C-1b Determination of the inhibition of the kinesin spindle protein KSP/ Eg5 by selected examples

The motor domain of the human kinesin spindle protein KSP /Eg5 (from tebu-bio/ Cytoskeleton Inc, No. 027EG01-XL) is incubated at a concentration of 10 nM with 50 µg/ml taxol- (from Sigma No. T7191-5MG) stabilized microtubuli (bovine or porcine, from tebu-bio/ Cytoskeleton Inc) for 5 min at RT in 15 mM PIPES, pH 6.8 (5 mM $MgCl_2$ and 10mM DTT, from Sigma). The freshly prepared mixture is aliquoted into a 384-well MTP. The inhibitors to be examined at concentrations of 1.0×10^{-6} M to 1.0×10^{-13} M and ATP (final concentration 500 µM, from Sigma) are then added.

Incubation is at RT for 2 h. ATPase activity is detected by detecting the inorganic phosphate formed using malachite green (from Biomol). After additon of the reagent, the assay was incubated at RT for 50 minutes prior to detection of the absorption at a wavelength of 620 nm. Monastrol and Ispinesib (from Adooq A10486) are used as positive control. The individual data of the dose-activity curve are eight-fold determinations. The IC50 values are means of three independent experiments. The 100% control was the sample which had not been treated with inhibitors.

Table 4 below summarizes the IC50 values of representative working examples from the assay described: In an exemplary manner, they confirm the high potency at the target of the toxophors and ADC methods described.

C-2 Internalisation assay

Internalisation is a key process which enables specific and efficient provision of the cytotoxic payload in antigen-expressing cancer cells via antibody drug conjugates (ADC). This process is monitored via fluorescent labelling of specific TWEAKR antibodies and an isotype control antibody (M014). First, the fluorescent dye is conjugated to lysines of the antibody. Conjugation is carried out using a two-fold molar excess of CypHer 5E mono NHS ester (Batch 357392, GE Healthcare) at pH 8.3. After the coupling, the reaction mixture is dialysed at 4°C (sSlide-A-Lyser Dialysis Cassettes MWCD 10kD, from Pierce) overnight to remove excess dye and to adjust the pH, and the protein solution is then concentrated (VIVASPIN 500, from Sartorius stedim biotec). Determination of the dye load of the antibody is by spectrophotometric analysis (NanoDrop) and subsequent calculation (D: $P = A_{dye}\,\varepsilon_{protein} : (A_{280} - 0.16A_{dye})\,\varepsilon_{dye}$). The dye load of the TWEAKR antibody examined here and the isotype control were of a comparable order. In cell binding assays, it is confirmed that the conjugation did not lead to a change in the affinity of the antibody.

The labelled antibodies are used for the internalisation assay. Prior to the start of the treatment, the cells (2 x 10^4/well) are sown in 100 µl medium in a 96-well MTP (fat, black, clear bottom No 4308776, from Applied Biosystems). After 18 h of incubation at 37°C/5%CO_2, the medium is replaced and labelled anti-TWEAKR antibodies are added in different concentrations (10, 5, 2.5, 1, 0.1 µg/ml). The same treatment protocol is applied to the labelled isotype control (negative control). The

chosen incubation times are 0, 0.25 h, 0.5 h, 1 h, 1.5 h, 2 h, 3 h, 6 h and 24 h. The fluorescence measurement is carried out using the InCellanalyser 1000 (from GE Healthcare). This was followed by kinetic evaluation via measurement of the parameters granule counts/cell and totale granule intensity/cell.

Following binding to the TWEAKR, TWEAKR antibodies were examined for the internalisation ability. For this purpose, cells with different TWEAKR expression levels were chosen. A target-mediated specific internalisation was observed with the TWEAKR antibodies, whereas the isotype control showed no internalisation.

C-3 *In vitro* tests for determining cell permeability

The cell permeability of a substance can be investigated by means of in vitro testing in a flux assay using Caco-2 cells [M.D. Troutman and D.R. Thakker, *Pharm. Res.* 20 *(8)*, 1210-1224 (2003)]. For this purpose, the cells were cultured for 15-16 days on 24-well filter plates. For the determination of permeation, the respective working example was applied in a HEPES buffer to the cells either apically (A) or basally (B) and incubated for 2 hours. After 0 hours and after 2 hours, samples were taken from the cis and trans compartments. The samples were separated by HPLC (Agilent 1200, Böblingen, Germany) using reverse phase columns. The HPLC system was coupled via a Turbo Ion Spray Interface to a Triple Quadropol mass spectrometer API 4000 (Applied Biosystems Applera, Darmstadt, Germany). The permeability was evaluated on the basis of a Papp value, which was calculated using the formula published by Schwab et al. [D. Schwab *et al.*, *J. Med. Chem.* 46, 1716-1725 (2003)]. A substance was classified as actively transported when the ratio of P_{app} (B-A) to P_{app} (A-B) (efflux ratio) was >2 or <0.5.

Of critical importance for toxophores which are released intracellularly is the permeability from B to A [P_{app} (B-A)] and the ratio of P_{app} (B-A) to P_{app} (A-B) (efflux ratio): the lower this permeability, the slower the active and passive transport

processes of the substance through the monolayer of Caco-2 cells. If additionally the efflux ratio does not indicate any active transport, the substance may, following intracellular release, remain longer in the cell. Hence, there is also more time available for interaction with the biochemical target (in this case: kinesin spindle protein, KSP / Eg5).

Table 5 below sets out permeability data for representative working examples from this assay:

C-4 *In vitro* tests for determining the substrate properties for P-glycoprotein (P-gp)

Many tumour cells express transporter proteins for drugs, and this frequently accompanies the development of resistance towards cytostatics. Substances which are not substrates of such transporter proteins, such as P-glycoprotein (P-gp) or BCRP, for example, could therefore exhibit an improved activity profile.

The substrate properties of a substance for P-gp (ABCB1) were determined by means of a flux assay using LLC-PK1 cells which overexpress P-gp (L-MDR1 cells) [A.H. Schinkel *et al.*, *J. Clin. Invest.* 96, 1698-1705 (1995)]. For this purpose, the LLC-PK1 cells or L MDR1 cells were cultured on 96-well filter plates for 3-4 days. For determination of the permeation, the respective test substance, alone or in the presence of an inhibitor (such as ivermectin or verapamil, for example), was applied in a HEPES buffer to the cells either apically (A) or basally (B) and incubated for 2 hours. After 0 hours and after 2 hours, samples were taken from the cis and trans compartments. The samples were separated by HPLC using reverse phase columns. The HPLC system was coupled via a Turbo Ion Spray Interface to a Triple Quadropol mass spectrometer API 3000 (Applied Biosystems Applera, Darmstadt, Germany). The permeability was evaluated on the basis of a Papp value, which was calculated using the formula published by Schwab et al. [D. Schwab *et al.*, *J. Med. Chem.* 46, 1716-1725 (2003)]. A substance was classified as P=gp substrate when the efflux ratio of P_{app} (B-A) to P_{app} (A-B) was >2.

As further criteria for the evaluation of the P-gp substrate properties, the efflux ratios in L-MDR1 and LLC-PK1 cells or the efflux ratio in the presence or absence of an inhibitor may be compared. If these values differ by a factor of more than 2, the substance in question is a P-gp substrate.

C-5 Pharmakokinetics

C5a: Identification of the ADC metabolites after internalisation *in vitro*

Description of the method:

Internalisation studies with immunoconjugates are carried out to analyse metabolites formed intracellularly. To this end, human lung tumour cells NCI H292 ($3x10^5$/well) are sown in 6-well plates and incubated overnight (37°C, 5% CO_2). The cells are treated with 10 µg/ml of the ADC to be examined. Internalisation is carried out at 37°C and 5% CO_2. At various time points (0, 4, 24, 48, 72 h), cell samples are taken for further analysis. First, the supernatants (about 5 ml) are harvested and, after centrifugation (2 min, RT, 1000 rpm Heraeus Variofuge 3.0R), stored at -80°C. The cells are washed with PBS and detached with Accutase, and the cell number is determined. After another washing, a defined number of cells (2 x 10^5) is treated with 100 µl of lysis buffer (Mammalian Cell Lysis Kit (Sigma MCL1) and incubated with continuous shaking (Thermomixer, 15 min, 4°C, 650 rpm) in Protein LoBind tubes (eppendorf Cat. No. 0030 108.116). After the incubation, the lysate is centrifuged (10 min, 4°C, 12000 g, eppendorf 5415R) and the supernatant is harvested. The supernatant obtained is stored at -80°C. All samples are then analysed as follows.

Measurement of the compounds in the culture supernatant or cell lysate is carried out after precipitation of the proteins with methanol or acetonitrile by high-pressure liquid chromatography (HPLC) coupled to a triple-quadrupole mass spectrometer (MS).

For work-up of 50 µl of culture supernatant/cell lysate, 150 µl of precipitation reagent (generally acetonitrile) are added and the mixture is shaken for 10 seconds. The precipitation reagent contains an internal standard (ISTD) in a suitable concentration (generally in the range of 20-100 ng/ml). After 3 minutes of

centrifugation at 16000 g, the supernatant is transferred into an autosampler vial, made up with 500 µl of a buffer suitable for the mobile phase and shaken again.

The two matrix samples are then measured using the HPLC-coupled triple-quadrupol mass spectrometer API6500 from AB SCIEX Deutschland GmbH.

For calibration, concentrations of 0.5-2000 µg/l are added to plasma samples. The detection limit (LOQ) is about 2 µg/l. The linear range extends from 2 to 1000 µg/l.

For calibration of the tumour samples, concentrations of 0.5-200 µg/l are added to the supernatant of untreated tumours. The detection limit is 4 µg/l. The linear range extends from 4 to 200 µg/l.

Quality controls for testing validity contain 5 and 50 µg/l.

NCI-H292 cells were incubated with in each case 10 µg/ml of the ADCs from Examples 104b, 119b, 155b, 165b and 173b. After 72 h, the cells were washed with PBS, lysed and deep-frozen (-80°C). Using the method described above, the cell lysates and cell culture supernatants were worked up, and after extraction the following metabolites were identified and quantified:

155b	162	10	< 0.2

165b	162	8.8	< 0.2

NCI-H292 cells were incubated with in each case 10 µg/ml of the ADCs from Examples 179a, 226a, 85b and 208b. After 72 h, the cells were washed with PBS, lysed and deep-frozen (-80°C). Using the method described above, the cell lysates and cell culture supernatants were worked up, and after extraction the following metabolites were identified and quantified:

C5b: Identification of the ADC metabolites *in vivo*

After i.v. administration of 3-30 mg/kg of different ADCs, the plasma and tumour concentrations of the ADCs and any metabolites occuring can be measured, and the pharmacokinetic parameters such as clearance (CL), area under the curve (AUC) and half-times ($t_{1/2}$) can be calculated.

Analysis for quantification of any metabolites occurring

Measurement of the compounds in plasma and tumour is carried out after precipitation of the proteins with methanol or acetonitrile by high-pressure liquid chromatography (HPLC) coupled to a triple-quadrupole mass spectrometer (MS).

For work-up of 50 µl of plasma, 250 µl of precipitation reagent (generally acetonitrile) are added and the mixture is shaken for 10 seconds. The precipitation reagent contains an internal standard (ISTD) in a suitable concentration (generally in the range of 20-100 ng/ml). After 3 minutes of centrifugation at 16000 g, the supernatant is transferred into an autosampler vial, made up with 500 µl of a buffer suitable for the mobile phase and shaken again.

During the work-up of a tumour, the latter is treated with 3 times the amount of extraction buffer. The extraction buffer contains 50 ml of Tissue Protein Extraction Reagent (Pierce, Rockford, IL), two pellets of Complete-Protease-Inhibitor-Cocktail (Roche Diagnostics GmbH, Mannheim, Germany) and phenylmethylsulphonyl fluoride (Sigma, St. Louis, MO) in a final concentration of 1 mM. The sample is homogenized twice for 20 minutes in a Tissuelyser II (Qiagen), at maximum stroke number. 50 µl of the homogenate are transferred into an autosampler vial and made up with 150 µl of methanol including ISTD. After 3 minutes of centrifugation at 16000 g, 10 µl of the supernatant are made up with 180 µl of a buffer suitable for the mobile phase and shaken again. The tumour sample is then ready for measuring.

The two matrix samples are then measured using the HPLC-coupled triple-quadrupol mass spectrometer API6500 from AB SCIEX Deutschland GmbH.

For calibration, concentrations of 0.5 - 2000 µg/l are added to plasma samples. The detection limit (LOQ) is about 2 µg/l. The linear range extends from 2 to 1000 µg/l.

For calibration of the tumour samples, concentrations of 0.5 - 2000 µg/l are added to the supernatant of untreated tumours. The detection limit is 5 µg/l. The linear range extends from 5 to 200 µg/l.

Quality controls for testing validity contain 5 and 50 µg/l, in

plasma additionally 500 µg/l.

Following administration of 10 mg/kg of the ADCs from Examples 119b and 104b in the control groups from the xenograft models with NCI-H292, the mice were sacrificed after 24 h, blood was removed and the tumours were isolated. Using the method described above, the plasma and tumour samples were worked up, and after extraction the following metabolites were identified and quantified:

ADC administered (Example Number)	Isolated metabolite (Example Number)	Metabolite concentration in the tumour [µg/l]	Metabolite concentration in the plasma [µg/l]
119b	158	155	< 5
104b	199	147	< 5
104b	198	27.4	< 5
104b	135	5.23	< 5
104b	197	7.75	< 5

Analysis for quantification of the antibodies used

The antibody part of the ADCs was determined using a ligand binding assay (ELISA) as total IgG concentration in plasma samples and tumour lysates. Here, the sandwich ELISA format was used. This ELISA had been qualified and validated for the determination in plasma and tumour samples. The ELISA plates were coated with anti-human goat IgG Fc antibodies. After incubation with the sample, the plates were washed and incubated with a detector conjugate of simian anti-human IgG(H+L) antibody and horseradish peroxidase (HRP). After a further washing step, the HRP substrate was added to OPD and the colour development was monitored via absorption at 490 nm. Standard samples having a known IgG concentration were fitted using a 4-parameter equation. Within the lower (LLOQ) and upper (ULOQ) quantification limits, the unknown concentrations were determined by interpolation.

C-6 Activity test *in vivo*

The activity of the conjugates according to the invention was tested, for example, using xenograft models. The person skilled in the art is familiar with methods in the prior art which allow the activity of the compounds according to the invention to be tested (see, for example, WO 2005/081711; Polson et al., Cancer Res. 2009 Mar 15;69(6):2358-64). To this end, a tumour cell line expressing the target molecule of the binder was implanted into rodents (for example mice). A conjugate according to the invention, an isotype control conjugate, a control antibody or isotonic saline was then administered to the implant animals. The administration took place once or more than once. Following an incubation time of several days, the size of the tumour was determined by comparing conjugate-treated animals and the control group. The conjugate-treated animals displayed a smaller tumour size.

C-6a. Growth inhibition / regression of experimental tumours in the mouse

Human tumour cells expressing the antigen for the antibody drug conjugate are inoculated subcutaneously into the flank of immunosuppressed mice, for example NMRi nude or SCID mice. 1-10 million cells are detached from the cell culture, centrifuged and resuspended in medium or medium / matrigel. The cell suspension is injected under the skin of the mouse.

Within a few days, a tumour grows. Treatment is commenced after the tumour is established, at a tumour size of approximately 40 mm^2. To examine the effect on larger tumours, treatment may be initiated only at a tumour size of 50-100 mm^2.

Treatment with ADCs is carried out via the intravenouse route into the tail vein of the mouse. The ADC is administered in a volume of 5 ml/kg.

The treatment protocol depends on the pharmacokinetics of the antibody. As standard, treatment takes place three times in succession every fourth day. For a quick assessment, a protocol with a single treatment may be employed. However, the treatment may also be continued, or a second cycle of three treatment days may follow at a later time.

As standard, 8 animals are used per treatment group. In addition to the groups to which the active substances are administered, one group is treated as control group only with the buffer, according to the same protocol.

During the experiment, the tumour area is measured regularly in two dimensions (length / width) using a caliper. The tumour area is determined as length x width. The ratio of the mean tumour area of the treatment group to that of the control group is stated as T/C area.

When after the end of the treatment all groups of the experiment are terminated at the same time, the tumours can be removed and weighed. The ratio of the mean tumour weights of the treatment group to that of the control group is stated as T/C weight.

C-6c. Efficacy of the anti-EGFR antibody drug conjugates in the NCI-H292 tumour model on single treatment

1 million NCI-H292 cells are inoculated subcutaneously into the flank of female NMRI-nude mice (Janvier). At a tumour size of ~37 mm^2 on day 9, the animals are treated once with a dose of 3 mg/kg of ADC or 2.5 mg/kg toxophor A (N-(3-aminopropyl)-N-{(1R)-1-[1-benzyl-4-(2,5-difluorophenyl)-1H-imidazol-2-yl]-2,2-dimethylpropyl}-2-hydroxyacetamide) or toxophor B (N-[(3R)-3-amino-4-fluorobutyl]-N-{(1R)-1-[1-benzyl-4-(2,5-difluorophenyl)-1H-imidazol-2-yl]-2,2-dimethylpropyl}-2-hydroxyacetamide). After the treatment, the tumour growth is monitored up to day 25.

Treatment with the antibody drug conjugates according to

Examples 35A and 02A results in a marked inhibition of the growth of the tumours compared to the control group. During the treatment with 3 mg/kg, there is a regression of most tumours. Table 7 shows the T/C values determined for tumour weights and tumour area on day 25. Here, the antibody drug conjugate 35A shows better efficacy than cetuximab and than toxophor A or toxophor B.

Table 7:

Example	**Dosage**	**T/C weight**	**T/C area**
Toxophor A	2.5 mg/kg	0.82	0.87
Toxophor B	2.5 mg/kg	0.40	0.57
cetuximab	3 mg/kg	0.47	0.54

C-6d. Efficacy of anti-EGFR and anti-TWEAKR antibody drug conjugates in the NCI-H292 tumour model on single treatment

C-6f. Efficacy of the anti-TWEAKR antibody drug conjugates in the NCI-H292 tumour model on single treatment (2 independent experiments)

In both experiments, 1 million NCI-H292 cells are inoculated subcutaneously into the flank of female NMRI-nude mice (Janvier). At a tumour size of 45 mm^2 on day 10 (experiment 1) or day 8 (experiment 2), treatment is carried out once intravenously at a dose of 3 mg/kg of antibody drug conjugate. After the treatment, the tumour growth is monitored up to day 18 (Experiment 1) or day 24 (Experiment 2).

Single treatment with the anti-TWEAKR antibody drug conjugates 02B, 07B and 08B in Experiment 1 results in a marked inhibition of growth of the tumours compared to the control group and the unconjugated anti-TWEAKR antibody. C-6g. Efficacy of the anti-TWEAKR antibody drug conjugates in the A375 tumour model on repeat treatment

5 million A375 (human melanoma) cells are inoculated subcutaneously into the flank of female NMRI-nude mice (Janvier). At a tumour size of 41 mm^2 on day 10, treatment is initiated intravenously at a dosage of 10 mg/kg (day 10, 14, 18). After the treatment, the tumour growth is monitored up to day 22.

Treatment with the antibody drug conjugates according to Examples 38B and 104B results in a marked inhibition of the growth of the tumours compared to the control group. Table 10 shows the T/C values determined for tumour weights and tumour area on day 22. Treatment with the respective control conjugate (isotype antibody against an irrelevant antigen) results in a markedly weaker tumour growth-inhibiting action. Treatment with the unconjugated antibodies likewise results in an in some cases weaker inhibition of the growth of the tumours.

Table 10:

Example	Dosage	T/C weight	T/C area
anti-TWEAKR antibody	10 mg/kg	0.32	0.52

D. Working examples of pharmaceutical compositions

The compounds according to the invention can be converted to pharmaceutical formulations as follows:

i.v. solution:

The compound according to the invention is dissolved in a concentration below the saturation solubility in a physiologically acceptable solvent (e.g. isotonic saline solution, D-PBS, or a formulation with glycine and sodium chloride in citrate buffer with addition of polysorbate 80). The solution is subjected to sterile filtration and dispensed into sterile and pyrogen-free injection vessels.

i.v. solution:

The compounds according to the invention can be converted to the administration forms mentioned. This can be accomplished in a manner known per se by "mixing with" or "dissolving in" inert, non-toxic, pharmaceutically suitable excipients (e.g. buffer substances, stabilizers, solubilizers, preservatives). The following, for example, may be present: amino acids (glycine, histidine, methionine, arginine, lysine, leucine, isoleucine, threonine, glutamic acid, phenylalanine and others), sugars and related compounds (glucose, saccharose, mannitol, trehalose, sucrose, mannose, lactose, sorbitol), glycerol, sodium salts, potassium, ammonium salts and calcium salts (e.g. sodium chloride, potassium chloride or disodiumhydrogenphosphate and many others), acetate/acetic acid buffer systems, phosphate buffer systems, citric acid and citrate buffer systems, trometamol (TRIS and TRIS salts), Polysorbates (e.g. Polysorbate 80 and Polysorbate 20), Poloxamers (e.g. Poloxamer 188 and Poloxamer 171), Macrogols (PEG derivatives, e.g. 3350), Triton X-100, EDTA salts, glutathione, albumins (e.g. human), urea, benzyl alcohol, phenol, chlorocresol, metacresol, benzalkonium chloride and many others.

Lyophilizate for subsequent conversion into an i.v., s.c. or i.m. solution:

Alternatively the compounds of the invention may be converted into a stable lyophilizate (possibly with the aid of abovementioned excipients) and, before being administered, reconstituted with a suitable solvent (e.g. injection-grade water, isotonic saline solution) and administered.

Working examples of anti-TWEAKR antibodies

All examples were carried out using standard methods known to the person skilled in the art, unless described here in detail. Routine methods of molecular biology of the examples that follow

can be carried out as described in standard laboratory textbooks such as Sambrook et al., Molecular Cloning: a Laboratory Manual, 2. Edition; Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y., 1989.

AK EXAMPLE 1: Antibody preparation using an antibody library

A complete human phage display library (Hoet RM et al, Nat Biotechnol 2005;23(3):344-8) was employed to isolate TWEAKR-specific human monoclonal antibodies of the present invention by protein panning (Hoogenboom H.R., Nat Biotechnol 2005;23(3):1105-16), where dimeric Fc-fused extracellular domains of human and murine TWEAKR were immobilized as target.

Table AK-1: List of recombinant antigens used for antibody selection

Nomenclature	Description	SEQ ID NO

The antigens were biotinylated using an about 2-fold molar excess of biotin-LC-NHS (Pierce; Cat. No. 21347) according to the instructions of the manufacturer and desalted using Zeba desalting columns (Pierce; Cat. No. 89889). Washed magnetic beads (DynaBeads) were incubated overnight with 200 nM biotinylated antigen at 4°C and blocked for 1 h at 4°C with blocking buffer (PBS with 3% BSA, 0.05% Tween-20). The blocked Fab phage library was added to the blocked TWEAKR beads (DynaBeads Streptavidin-M280 - Invitrogen 112-06D) and incubated at room temperature for 30 min. After stringent washing (3 x with blocking buffer and 9 x with PBS (150 mM NaCl; 8 mM Na2HPO4; 1.5 mM KH2PO4; adjusted to pH = 7.4-7.6) with 0.05% Tween-20), Fab phages binding specifically to biotinylated TWEAKR beads (DynaBeads Streptavidin- M280 - Invitrogen 112-06D) were resuspended in PBS and, for amplification, used directly for

infecting *Escherichia coli* strain TG1. In the second selection round, two murine TWEAKR (200 nM) were used to select for cross-reactive binders, and in the third selection round the concentration of human TWEAKR was reduced (100 nM) to increase the selection pressure for high-affinity binders.

11 different Fab phages were identified and the corresponding antibodies were cloned into a mammalian IgG expression vector which provided the missing CH2-CH3 domains not present in the soluble Fab. The resulting IgGs were expressed transiently in mammalian cells as described in Tom et al., Chapter 12 in Methods Express: Expression Systems edited by Micheal R. Dyson and Yves Durocher, Scion Publishing Ltd, 2007. Briefly, a CMV promoter-based expression plasmid was transfected into HEK293-6E cells and incubated in Fernbach bottles or Wave bags. Expression took place at 37°C for 5 to 6 days in F17 medium (Invitrogen). 1% Ultra-Low IgG FCS (Invitrogen) and 0.5 mM valproic acid (Sigma) were added as supplements 24 h after the transfection. The antibodies were purified by protein-A chromatography and characterized further by their binding affinity to soluble monomeric TWEAKR using ELISA and BIAcore analysis, as described in AK-Example 2.

To determine the cell binding characteristics of the anti-TWEAKR antibodies, binding to a number of cell lines (HT29, HS68, HS578) was examined by flow cytometry. The cells were suspended in dilutions of the antibodies (5 µg/ml) in FACS buffer and

incubated on ice for 1 h. A second antibody (PE goat-anti-human IgG, Dianova #109-115-098) was then added. After 1 h of incubation on ice, the cells were analysed by flow cytometry using an FACS array (BD Biosciences).

NF-kappaB reporter gene assays were carried out to assess the agonistic activity of all 11 antibodies identified (human IgG1). HEK293 cells were transiently transfected with an NF-kappaB reporter construct (BioCat, Cat. No. LR-0051-PA) using 293fectin according to the instructions of the manufacturer. Transfected cells were sown in F17 media (serum-free; Invitrogen) at 37C, 5% CO2 into white polylysine-coated 384-well plates (BD). The next day, the cells were stimulated with various concentrations of purified antibodies for 6 h, and a luciferase assay was then carried out using standard methods.

Internalisation was monitored via fluorescence labelling of anti-TWEAKR antibodies (CypHer 5E mono NHS ester; GE Healthcare). Prior to the treatment, HT29 cells were sown (2 x 10^4/well) in 100 µl of medium in 96-well MTP plates (thick, black, transparent botton, No. 4308776, Applied Biosystems). After 18 h of incubation at 37°C/5%CO_2, the medium was replaced and labelled anti-TWEAKR antibodies were added in different concentrations (10, 5, 2.5, 1, 0.1 µg/ml). The chosen incubation time was 0, 0.25, 0.5, 1, 1,5, 2, 3, 6 and 24h. Fluorescence measurement was carried out in an InCell-analyser 1000 (GE Healthcare).

The antibody having the highest in vitro activity (TPP-883) was selected for further activity and affinity maturation.

Amino acid sequences of the light (SEQ ID NO.71) and heavy (SEQ ID NO.72) chains of TPP-883; CDRs both of the heavy and the light chain are underlined.

Maturation was carried out in a first mutations collection round, followed by recombination of those amino acid modifications which increased affinity and activity most. For collecting mutations NNK (N = AGCT, K = G or T), randomization was carried out at the following individual amino acid positions by site-directed mutagenesis using synthetic oligonucleotides including NNK codon diversification (continuous amino acid nomenclature): S35, S36, Y37 and N39 in CDR-L1; A51, S53, S54, Q56 and S57 in CDR-L2; S92, Y93, S94, S95, G97 and I98 in CDR-L3; P31, Y32, P33, M34 and M35 in CDR-H1; Y50, S52, P53, S54, G56, K57 and H59 in CDR-H2; G99, G100, D101, G102, Y103, F104,

D105 and Y106 in CDR-H3. The DNA of all individual NNK saturation mutagenesis libraries was cloned into a mammalian IgG expression vector for activity maturation or into a phagemid vector for affinity maturation. Affinity maturation was carried out by phage panning. Washed magnetic beads (DynaBeads) were incubated overnight with 10 nM, 1 nM, 100 pM or 10 pM biotinylated antigen at 4°C and blocked for 1 h at 4°C with blocking buffer (PBS with 3% BSA, 0.05% Tween-20). The blocked Fab phage library was added in 10000-fold, 1000-fold or 100-fold excess, compared to the theoretical library complexity, to the blocked TWEAKR-DynaBeads and incubated at room temperature for 30 min. That means that 12 strategies were followed in total (4 antigen concentrations x 3 Fab phage titres). After stringent washing (3 x with blocking buffer and 9 x with PBS with 0.05% Tween-20), Fab phages binding specifically to biotinylated TWEAKR DynaBeads (DynaBeads Streptavidin- M280 - Invitrogen 112-06D) were resuspended in PBS and, for amplification, used directly for infecting *Escherichia coli* strain TG1. In selection round two, the concentration of human TWEAKR-Fc was reduced (1 nM, 100 pM, 10 pM and 1 pM), and the same Fab phage titre was used for all 12 strategies (4.4×10^{11}). For the expression of soluble Fab, the phagemid vector was digested with MluI to remove the gene-III membrane anchor sequence required for the Fab display on the phage, and the vector was re-ligated. 96 variants of each of the 12 selection pools were expressed as soluble Fabs and examined in an ELISA format. To this end, 2.5 nM biotinylated TWEAKR-Fc were antigen-coated, and binding of soluble Fabs was demonstrated using anti-c-Myc antibodies (Abcam ab62928). 7 single substitution variants (consecutive amino acid nomenclature) with improved binding to TWEAKR-Fc (Seq ID No 138) were demonstrated: S36G of CDR-L1, A51Q and S57K of CDR-L2, S94T and G97F of CDR-L3, M35I of CDR-H1 and G102T of CDR-H3. For the activity maturation, HEK293 cells were transfected with an NF-kappaB reporter (BioCat, Cat. No. LR-0051-PA). Transfected cells were sown in F17 media (serum-free; Invitrogen) in white, polylysine-coated 384-well plates (BD), and individual variants of the NNK-diversified position antibodies (human IgG1) libraries were expressed transiently in mammalian cells. The next day, NF-kappaB reporter

cells were stimulated with the individual NNK antibody variants expressed for 6 h, and a luciferase assay was then carried out using standard methods. 1 single substitution variant having improved agonistic activity was detected: G102T of CDR-H3. This variant was also obtained by affinity maturation, and there, too, it showed the highest enhancement of affinity. After mutation collection by affinity and activity screening, all 7 favourable individual substitutions (library complexity: 128 variants) were recombined into a recombination library. To this end, oligonucleotides were synthesized to introduce selected mutations or the corresponding wild type amino acid at each selected position. The library was established using successive rounds of overlap extension PCR. The final PCR product was ligated into a bacterial soluble Fab expression vector, and 528 variants were selected at random (~ 4-fold excess of the sample taken) for an equilibrium ELISA screen with soluble Fabs, as described above. In the end, 7 variants were selected based on increased affinity compared to the best single substitution variant G102T. The corresponding DNA of these was cloned into a mammalian IgG expression vector and examined for functional activity in the above-mentioned NF-kappaB reporter cell assay. Finally, the sequences obtained were compared with human germ line sequences, and deviations without any significant effect on the affinity and the efficacy were adapted. Antibodies having the sequences below were obtained by antibody library screening and by affinity and/or activity maturation:

EXAMPLE 2: Biochemical characteristics of the antibodies

Determination of binding affinities by Biacore analysis:

Binding affinities of anti-TWEAKR antibodies were examined using surface plasmon resonance analysis on a Biacore T100 instrument (GE Healthcare Biacore, Inc.). The antibodies were immobilized on a CM5 sensor chip using an indirect capture reagent, anti-human IgG(Fc). Reagents of the "Human Antibody Capture Kit" (BR-1008-39, GE Healthcare Biacore, Inc.) were used as described by the manufacturer. Anti-TWEAKR antibodies were injected at a concentration of 10 µg/ml at 10 µl/min for 10 sec.

Various concentrations (200 nM, 100 nM, 50 nM, 25 nM, 12.5 nM, 6.25 nM, 3.12 nM, 1.56 nM) of purified recombinant human TWEAKR protein (TPP-2305, SEQ ID NO:168) in HEPES-EP buffer (GE Healthcare Biacore, Inc.) were injected over immobilised anti-TWEAKR antibodies at a flow rate of 60 µl/min for 3 minutes, the dissociation time being 5 minutes. Sensorgrams were generated after in-line reference cell correction, followed by subtraction of the buffer sample. The dissociation constant (K_D) was calculated based on the ratio of association (k_{on}) and dissociation (k_{off}) constants, obtained by fitting sensorgrams using a 1:1 first order binding model.

It was determined that the antibodies of the invention bind TWEAKR with moderate affinity (K_D 10 - 200 nM), whereas some

comparative antibodies (e.g. PDL-192(TPP-1104), 136.1(TPP-2194), 18.3.3(TPP-2193), P4A8(TPP-1324), P3G5(TPP-2195), P2D3(TPP-2196), ITEM-1, ITEM-4) show high-affinity binding (0.7 – 3.7 nM). The sequences of the variable domains of the antibodies PDL-192, 136.1, 18.3.3, P4A8, P3G5 snd P2D3 were obtained from the patent literature WO2009/020933 and WO2009/140177, and the sequences coding for the constant region of human IgG1 and murine IgG2 were added, resulting in full-length IgGs PDL-192(TPP-1104), 136.1(TPP-2194), 18.3.3(TPP-2193), P4A8(TPP-1324), P3G5(TPP-2195), P2D3(TPP-2196). The range of the affinities measured in this study agrees well with published data: for PDL-192, 18.3.3 and 136.1, KD values of 5.5, 0.2 and 0.7 nM have been published (WO2009/020933); for P4A8 2.6 nM (WO2009/140177). For comparison: the native ligand TWEAK binds TWEAKR with a K_D value of 0.8 – 2.4 nM (Immunity. 2001 Nov;15(5):837-46; Biochem J. 2006 Jul 15;397(2):297-304; Arterioscler Thromb Vasc Biol. 2003 Apr 1;23(4):594-600).

As a result, it can be recorded that the antibodies of the invention (TPP-883, TPP-1538, TPP-2077, TPP-2084, TPP-2148, TPP-2093, TPP-2149 and TPP-2090) bind TWEAKR with moderate affinity (K_D 10 – 200 nM).

Characterization of the binding epitope of TPP-2090 using N- and C-terminally truncated variants of the TWEAKR ectodomain:

The alignment of the cysteine-rich domain of TWEAKR (amino acids 34-68) of different species (Figure 1-Alignment) shows that it is well conserved in all 6 species analysed. PDL-192 binds depending on R56 (WO2009/020933: Figure 2B) and does therefore not bind to rat, pig and mouse TWEAKR. TPP-2090 binds depending on the conserved amino acid D47, and therefore binds to all species shown.

In a first approach to characterizing the binding epitope of the antibodies mentioned above, a N- and C-terminally truncated mutant of the TWEAKR ectodomain was generated and examined for its ability to bind the various anti-TWEAKR antibodies. Amino

acids 28 to 33 were deleted N-terminally and amino acids 69 to 80 were deleted C-terminally, such that the cysteine-rich domains with disulphide bridges between Cys36-Cys49, Cys52-Cys67 and Cys55-Cys64 remained intact (compare Figure 2). Both constructs, the full ectodomain 28-80 including N- and C-terminus and the truncated ectodomain 34-68, were expressed and purified as Fc fusion proteins TPP-2202 and TPP-2203, respectively.

To analyse the binding, 1 µg/ml of the corresponding dimeric TWEAKR Fc construct was coated, and 0.3 µg/ml and 0.08 µg/ml of biotinylated IgG were used as soluble binding partner. Detection was carried out using streptavidin-HRP and Amplex Red substrate. IgGs were biotinylated using an about 2-fold molar excess of biotin-LC-NHS (Pierce; Cat. No. 21347) according to the instructions of the manufacturer and desalted using Zeba desalting columns (Pierce; Cat. No. 89889). At all concentrations used of the soluble ligand, the antibodies of the present invention displayed saturated binding to both constructs, whereas the antibodies P4A8(TPP-1324), P3G5(TPP-2195) and Item-4 showed saturated binding only to the full-length ectodomain, but worsened binding to the N- and C-terminally truncated constructs (Figure 3 & Figure 4). This shows that the binding epitope of the antibodies of the present invention is located in the cysteine-rich domain between amino acids 34-68. To analyse whether the N-terminus or the C-terminus of the TWEAKR ectodomain is required for P4A8(TPP-1324) and P3G5(TPP-2195) binding, a monomeric ectodomain having the C-terminal deletion of amino acids 69 to 80 was generated. Binding of P4A8(TPP-1324) and P3G5(TPP-2195) to the C-terminally truncated TWEAKR ectodomain is likewise worsened, whereas the antibodies of the present invention show saturated binding (Figure 5).

Effect of TWEAKR-Fc muteins on the antibody affinity

To examine the binding characteristics of the antibodies of the invention in more detail, certain muteins of TWEAKR suggested to be of relevance for the activity of known agonistic antibodies (WO2009/140177) were investigated. To this end, the full-length ectodomain (amino acids 28-80) having the individual amino acid substitutions below were expressed and purified as Fc fusion proteins: T33Q; S40R; W42A; M50A; R56P; H60K; L65Q.

To obtain dose-reaction data, the different TWEAKR-Fc muteins were coated at a low concentration (62 ng/ml) onto a 384-well Maxisorb ELISA plate, and a serial 2-fold dilution of biotinylated IgG beginning with a concentration of 100 nM was used as a soluble binding partner. As already published, ITEM-4 shows worsened binding to the H60K mutein [WO2009/140177: Figure 23F] and PDL-192 to the R56P mutein [WO2009/020933: Figure 22B]. In contrast to published data, ITEM-1 shows worsened binding to R56P, and all antibodies to W42A [WO2009/140177: Figure 23E, Figure 23F]. These differences can be explained by the methods chosen.

In contrast to ITEM-1, ITEM-4, PDL-192, 136.1 and 18.3.3, the antibodies of the present invention bind independently of all substitutions except for W42A.

Alanine scan of the cysteine-rich domain:

An alanine scan of the cysteine-rich domain (amino acids 34-68) was carried out in order to locate the binding site of the antibodies of the invention. Figure 6 shows that N- and C-terminally truncated variants of the full-length ectodomain of TWEAKR do not worsen binding of the antibodies of the invention. Accordingly, the binding epitope is located in the cysteine-rich domain. The substitutions below were introduced into the TWEAKR(34-68) Fc construct: S37A, R38A, S40A, S41A, W42A, S43A, D45A, D47A, K48A, D51A, S54A, R56A, R58A, P59A, H60A, S61A, D62A, F63A und L65A.

These TWEAKR(34-68) Fc muteins were expressed in HEK293 cells.

To obtain dose-reaction data, IgGs were coated at a concentration of 1 µg/ml onto a 384-well Maxisorp ELISA plate, and a serial 2-fold dilution of the supernatant comprising the TWEAKR mutein was used as soluble binding partner. Detection was carried out using anti-HIS-HRP and Amplex Red. The IgGs examined were TPP-2090 of the present invention, PDL-192 of WO2009/020933 and P4A8 of WO2009/140177.

Table AK-16: List of antibodies used for the alanine scan of the cysteine-rich domain

Nomenclature	Description	SEQ ID NO	
		Light chain	Heavy chain
P4A8(TPP-1324)	human IgG1	125	126
PDL-192(TPP-1104)	human IgG1	127	128
TPP 2090	human IgG1	1	2

To assess the relevance of the TWEAKR mutein for binding to various IgGs, a correlation blot at a certain mutein concentration was prepared. By way of example, Figure 6 shows the correlation blots for the 8-fold diluted supernatants of the TWEAKR expression broth, with PDL-192(TPP-1104) on the X axis and TPP-2090 on the Y axis. The blot shows that binding of TPP-2090 was worsened by substitution D47A, and binding of PDL-192(TPP-1104) was worsened by substitution R56A. Binding to P4A8(TPP-1324) was demonstrated for none of the constructs, which agrees with the results obtained above (Figure 6). Thus, the P4A8 epitope is localized at least partially outside of the cysteine-rich domain. The dependencies identified for certain TWEAKR amino acids for antibody interaction correlates with the agonistic activity determined for these antibodies. The native ligand TWEAK shows an effective activation of the TWEAKR and binds depending on leucine 46 in the cysteine-rich domain of TWEAKR (Pellegrini et al, FEBS 280:1818-1829). P4A8 displays a very low agonistic activity and interacts at least partially

with domains outside of the cysteine-rich domain of TWEAKR. PDL-192 displays a moderate agonistic activity and binds depending on R56 to the cysteine-rich domain, but opposite the TWEAK ligand site. TPP-2090 and TWEAK binding depends on D47 and L46, respectively, and they therefore bind to a similar binding site (Figure 7).

It can be concluded the the antibodies of the invention (e.g. TPP-2090) bind to TWEAKR in a manner depending on D47.

The dependencies identified for certain TWEAKR amino acids for antibody interaction correlates with the agonistic activity determined for these antibodies. The native ligand TWEAK shows an effective activation of the TWEAKR and binds depending on leucine 46 in the cysteine-rich domain of TWEAKR (Pellegrini et al, FEBS 280:1818-1829). P4A8 displays a very low agonistic activity and interacts at least partially with domains outside of the cysteine-rich domain of TWEAKR. PDL-192 displays a moderate agonistic activity and binds depending on R56 to the cysteine-rich domain, but opposite the TWEAK ligand site. Antibodies of the present invention (Example TPP-2090) bind in a manner depending on D47, and TWEAK binds in a manner depending on L46, and binds to a similar, but distinct, binding site (Figure 7). Accordingly, the antibodies of the present invention displaying strong agonistic activity bind to a novel epitope (D47-dependent) for antibodies associated with very high agonistic activity. It is interesting to note that Michaelson et al. (see page 369, left column in Michaelson JS et al, MAbs. 2011 Jul-Aug;3(4):362-75) gave an explanation for the fact that all agonistic antibodies examined by them have weaker agonistic activity than the natural ligand TWEAK. They conclude that reduced efficacy could be a function of the dimeric binding interaction of the antibodies with TWEAKR, with TWEAK probably entering into a trimeric interaction. It is therefore a surprising result that an antibody of the invention, in spite of its dimeric interaction with TWEAKR, has an even higher agonistic activity. This surprising activity is linked to the specific binding properties of the antibodies of the invention,

i.e. the specific binding to D47 of TWEAKR.
