(57) **ABSTRACT**

Systems and methods dynamically assess energy efficiency by obtaining a minimum energy consumption of a system, receiving in a substantially continuous way a measurement of actual energy consumption of the system, and comparing the minimum energy consumption to the measurement of actual energy consumption to calculate a substantially continuous energy performance assessment. The system further provides at least one of a theoretical minimum energy consumption based at least in part on theoretical performance limits of system components, an achievable minimum energy consumption based at least in part on specifications for high energy efficient equivalents of the system components, and the designed minimum energy consumption based at least in part on specifications for the system components.

**ENERGY SEARCH ENGINE METHODS AND SYSTEMS**

**INCORPORATION BY REFERENCE TO ANY PRIORITY APPLICATIONS**

**[0001]** Any and all applications for which a foreign or domestic priority claim is identified in the Application Data Sheet as filed with the present application are hereby incorporated by reference under 37 CFR 1.57.

**BACKGROUND**

**[0002]** This disclosure relates generally to evaluating energy performance of a building, a building system, and/or a collection of buildings locally or over a large geographic area.

**[0003]** Existing energy and greenhouse gas measurement and verification protocols rely on walk around and observe audits that are defined in, for example, International Standards Organization (ISO) 50001, American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) Level 1 audits, ASHRAE Level 2 audits, and the like. These rely on static analytics and do not produce accurate results.

**[0004]** Another example of existing energy protocols is the U.S. EPA's Energy Star® program. The Energy Star® program has developed energy performance rating systems for several commercial and institutional building types and manufacturing facilities. These ratings, on a scale of 1 to 100, provide a means for benchmarking the energy efficiency of specific buildings and industrial plants against the energy performance of similar facilities of the same space type, based on a national average. A rating can be generated for ratable space types based on building attributes, such as square footage, weekly operating hours, and monthly energy consumption data. The Energy Star® ratings rely on static analytics, estimates, and forecasting, and do not produce accurate results and can be difficult to verify.

**[0005]** As a result of the lack of accurate and consistently reliable measurement and verification standards, false claims of carbon credits, Negawatts (energy saved as a result of energy conservation or increased efficiency), and other energy reductions are being made. Further, the lack of accurate and consistent energy assessment makes it difficult to accurately determine the benefit of corrective actions to equipment and systems, to normalize energy conservation investments, to calculate paybacks from energy conservation investments and retrofits of buildings, and the like.

**SUMMARY**

**[0006]** There is a need to dynamically assess the energy sustainability of a facility, i.e., how well it is using its energy, and identify wasted energy that is consistent and accurate.

**[0007]** Embodiments relate to an energy search engine using dynamic analytic algorithms based at least in part on, but not limited to one or more of smart meter data, other sensor data, sub-metered energy measurement data, weather data, gas data, utility rate schedules, basic facility information, such as, for example, the direction (north, south, east or west) that the building faces, total facility square footage, occupant scheduling, facility use, and the like to dynamically assess the energy sustainability of a facility.

**[0008]** In accordance with various embodiments, a method to assess energy usage comprises receiving in a substantially continuous way a measurement of actual energy consumption,

receiving in a substantially continuous way a measurement of ambient conditions, and comparing the measurement of actual energy consumption with a target energy consumption to calculate a substantially continuous energy performance assessment, wherein the target energy consumption is based at least in part on the measurement of ambient conditions. The method further comprising receiving in a substantially continuous way a measurement of facility occupancy and usage, wherein the target energy consumption is based at least in part on the measurement of ambient conditions and facility usage. In one embodiment, receiving in the substantially continuous way the measurement of ambient conditions comprises receiving the measurement of ambient conditions at least every 15 minutes. In one embodiment, the substantially continuous energy performance assessment comprises comparisons occurring at least every 15 minutes of the measurement of actual energy consumption with the target energy consumption.

**[0009]** Certain embodiments relate to a method to dynamically assess energy efficiency. The method comprises obtaining a minimum energy consumption of a system, receiving in a substantially continuous way a measurement of actual energy consumption of the system, and comparing the minimum energy consumption to the measurement of actual energy consumption to calculate a substantially continuous energy performance assessment. The system can be at least one of a building envelope, a building, a zone within a building, an energy subsystem, a facility, a group of buildings in near proximity to each other, a geographically diverse group of buildings, and the like.

**[0010]** In an embodiment, comparing the minimum energy consumption to the measurement of actual energy consumption comprises at least one of comparing in a substantially continuous way a theoretical minimum energy consumption of the system to the measurement of actual energy consumption to determine a theoretical energy efficiency for the system, where the theoretical minimum energy consumption is based at least in part on the theoretical performance limit of system components, comparing in a substantially continuous way an achievable minimum energy consumption of the system to the measurement of actual energy consumption to determine an achievable energy efficiency for the system, where the achievable minimum energy consumption is based at least in part on specifications for high energy efficient equivalents of the system components, and comparing in a substantially continuous way a designed minimum energy consumption of the system to the measurement of actual energy consumption to determine a designed energy efficiency for the system, where the designed minimum energy consumption is based at least in part on specifications for the system components.

**[0011]** Certain other embodiments relate to a method to dynamically assess energy usage. The method comprises obtaining an expected energy usage for a building having installed building systems and a load profile, receiving in a substantially continuous way measurements of actual energy consumption after an installation of at least one energy improvement measure for the building, establishing an energy usage for the building with the load profile based at least in part on the measurements received after the installation of the at least one energy improvement measure, and determining an impact of the at least one energy improvement measure. The method further comprises quantifying the effectiveness of the at least one energy improvement measure

by determining at least one of a payback calculation, a payment of an incentive, a valuation of real property, and a carbon offset used in carbon trading. The installed building systems can comprise at least one of an HVAC system, a lighting system, at least one plug load, a data center system, a water heating system, and the like. Installed energy improvement measure can comprise installing a renewable energy system, retrofitting equipment, commissioning, load shifting, load shedding, installing energy storage, and the like.

**[0012]** According to a number of embodiments, an apparatus to dynamically assess energy usage of a system comprises computer hardware including at least one computer processor, and computer readable-storage comprising computer-readable instructions that, when executed by the computer processor, cause the computer hardware to perform operations defined by the computer-executable instructions comprising obtaining a minimum energy consumption of a system, receiving in a substantially continuous way a measurement of actual energy consumption of the system, and comparing the minimum energy consumption to the measurement of actual energy consumption to calculate a substantially continuous energy performance assessment.

**[0013]** The computer-executable instructions further comprise at least one of comparing in a substantially continuous way a theoretical minimum energy consumption of the system to the measurement of actual energy consumption to determine a theoretical energy efficiency for the system, where the theoretical minimum energy consumption is based at least in part on the theoretical performance limit of system components, comparing in a substantially continuous way an achievable minimum energy consumption of the system to the measurement of actual energy consumption to determine an achievable energy efficiency for the system, where the achievable minimum energy consumption is based at least in part on specifications for high energy efficient equivalents of the system components, and comparing in a substantially continuous way a designed minimum energy consumption of the system to the measurement of actual energy consumption to determine a designed energy efficiency for the system, where the designed minimum energy consumption is based at least in part on specifications for the system components.

**[0014]** The system can comprise at least one of a building, a building envelope, at least one building system, a zone within the building, a data center, and the like. Receiving in the substantially continuous way the measurement of actual energy consumption of the system can comprise receiving the measurement of actual energy consumption at least every 15 minutes. The substantially continuous energy performance assessment can comprise comparisons occurring at least every 15 minutes of the minimum energy consumption to the measurement of actual energy consumption and at least one of a gas energy carbon footprint, an electrical energy carbon footprint, an estimate of wasted energy, an energy rating, an energy efficiency, and a power index.

**[0015]** For purposes of summarizing the disclosure, certain aspects, advantages and novel features of the inventions have been described herein. It is to be understood that not necessarily all such advantages may be achieved in accordance with any particular embodiment of the invention. Thus, the invention may be embodied or carried out in a manner that achieves or optimizes one advantage or group of advantages as taught herein without necessarily achieving other advantages as may be taught or suggested herein.

#### BRIEF DESCRIPTION OF THE DRAWINGS

**[0016]** FIG. 1 illustrates a schematic diagram of a system to assess and optimize energy usage for a facility, according to certain embodiments.

**[0017]** FIG. 2 illustrates an exemplary schematic diagram of an energy management system, according to certain embodiments.

**[0018]** FIG. 3 is a flow chart of an exemplary energy search engine process to assess the amount of energy used for cooling and the amount of excessive cooling affected, according to certain embodiments.

**[0019]** FIG. 4 is an exemplary substantially continuous excessive cooling performance assessment, according to certain embodiments.

**[0020]** FIG. 5 is a flow chart of an exemplary energy search engine process to assess energy usage, according to certain embodiments.

**[0021]** FIG. 6 is a flow chart of an exemplary energy search engine process to dynamically assess energy efficiency, according to certain embodiments.

**[0022]** FIG. 7 is a flow chart of an exemplary energy search engine process to quantify the effectiveness of energy improving measures, according to certain embodiments.

**[0023]** FIG. 8 is an exemplary substantially continuous energy performance assessment, according to certain embodiments.

**[0024]** FIG. 9 is an exemplary continuous yearly key performance indicator assessment, according to certain embodiments.

**[0025]** FIG. 10 is an exemplary continuous monthly key performance indicator assessment, according to certain embodiments.

#### DETAILED DESCRIPTION

**[0026]** The features of the systems and methods will now be described with reference to the drawings summarized above. Throughout the drawings, reference numbers are re-used to indicate correspondence between referenced elements. The drawings, associated descriptions, and specific implementations are provided to illustrate embodiments of the inventions and not to limit the scope of the disclosure.

**[0027]** Embodiments of an energy search engine use dynamic energy related data to determine how well a facility is using energy and to identify wasted energy. Further embodiments dynamically guide building system adjustments to reduce energy waste, and verify the results of such actions. For example, contemporary heating, ventilation, and air conditioning (HVAC) systems use a combination of chilled coolant or chilled water, evaporative coils, forced air ducting, and hot water intermixed to provide comfort and fresh air to occupants of buildings. To provide this comfort, many building HVAC systems waste energy by simultaneously heating and cooling building air by relying on static factors and no external information to dynamically adjust the various HVAC components.

**[0028]** In one embodiment, a combination of dynamically varying factors are evaluated to dynamically adjust HVAC or other building systems for optimum occupancy comfort, lowest energy use, lowest tariff cost, and lowest GHG emissions. These factors include, but are not limited to, natural and environmental factors, occupant factors, utility tariff factors, and GHG emission factors. For example, outside temperatures near a building vary hourly throughout the workday and

evening. Throughout the day, the sun heats different aspects of the building which creates a variable heating component. As occupants move in and out of rooms and in and out of the building during the workday, their heat load contribution, fresh air requirements, occupant comfort requirements, and energy use via lighting, computers, and other office equipment or industrial processes in the building vary.

[0029] The energy search engine incorporates at least one of these dynamic variables in energy modeling algorithms to provide, for example, one or more of benchmarking energy use, comparing required energy use and costs to wasted energy use and costs, dynamically guiding building system adjustments, verifying the results of such actions, and determining an optimum size of alternate electric energy systems, such as solar, wind, fuel cells, and the like to generate energy for the building.

[0030] FIG. 1 illustrates an exemplary schematic diagram of a system 100 to dynamically assess and optimize energy usage for an energy subsystem of a facility, the facility or a network of facilities 104. Facilities 104 can comprise one or more buildings, residences, factories, stores, commercial facilities, industrial facilities, data centers and the like, one or more rooms, one or more offices, one or more zoned areas in a facility, one or more floors in a building, parking structures, stadiums, theatres, and the like, one or more systems, subsystems, and/or components 104a, a zone within the building/facility 104, a building envelope, and the like, locally or geographically remote.

[0031] The network of facilities 104 can comprise, for example, a geographic area, facility owner, property manager, campus, weather pattern, climate zone, facility activity type, facility total square footage, facility occupied square footage, volume of facility free space, facility schedule, facility activity levels (e.g. production quantities, number of students, etc.), utility company, applicable utility rate schedule, source of energy, type and size of local generation systems, type and size of local alternative energy systems (e.g. thermal solar, thermal storage, energy storage, etc.), type of construction material used, type of energy systems used, model of energy systems used, facility design specifications, required air changes, measured air changes, type of energy management system installed, model of energy management system installed, performance of any existing energy management system, applicable energy codes, applicable energy regulations, applicable energy standards, applicable greenhouse gas emissions codes, applicable greenhouse gas emissions regulations, applicable greenhouse gas emissions standards, energy service company servicing the facility, energy consulting firm servicing the facility, and the like.

[0032] Examples of the systems, subsystems and/or components 104a include but are not limited to fans, pumps, motors, chillers, lights, heaters, heat exchangers, blowers, electric valves, air conditioning equipment, compressors, heat pumps, HVAC systems, lighting systems, motors, water heating systems, plug loads, data/Telco, variable air volume devices (VAV), gas systems, electrical systems, mechanical systems, electromechanical systems, electronic systems, chemical systems, and the like.

[0033] The facility 104 and/or building 104 in the following discussion refer to the facility, its systems, subsystems, components, and/or a network of facilities as described above.

[0034] Energy entering the facility 104 can be of many forms, such as, for example, thermal, mechanical, electrical, chemical, light, and the like. The most common forms are

typically electricity or power, gas, thermal mass (hot or cold air, people), and solar irradiance. The electrical energy can be generated from traditional fossil fuels, or alternate forms of power generation, such as solar cells, wind turbines, fuel cells, any type of electrical energy generator, and the like. Ambient weather conditions, such as cloudy days, or time of day, such as nighttime, may be responsible for radiant energy transfer (gains or losses).

[0035] The facility 104 comprises measurement devices 104b configured to measure actual energy usage in real time. For example, sensors, such as wired and/or wireless sensors and/or sensor systems, can measure kilowatt hours and energy spikes of electrical energy used to power the lighting system, to power the air compressor in the cooling system and to heat water for lavatories, cubic feet of gas consumed by a heating or HVAC system, amount of air flow from compressors in the cooling or HVAC system, and the like. The sensors can comprise current sensors, voltage sensors, EMF sensors, touch sensors, contact closures, capacitive sensors, trip sensors, mechanical switches, torque sensors, temperature sensors, air flow sensors, gas flow sensors, water flow sensors, water sensors, accelerometers, vibration sensors, GPS, wind sensors, sun sensors, pressure sensors, light sensors, tensionmeters, microphones, humidity sensors, occupancy sensors, motion sensors, laser sensors, gas sensors (CO<sub>2</sub>, CO), speed sensors (rotational, angular), pulse counters, and the like.

[0036] The facility 104 further comprises control systems, such as, for example, load shedding relays, load shifting relays, Energy Management Systems (EMS), Building Management Systems (BMS), and the like, to control energy consuming and energy saving components of the facility 104. For example, one or more controllers can raise or lower automatic blinds, shut off/reduce heating or cooling in an HVAC system in the entire or just one room of the facility 104, switch usage of electricity from conventional generation to electricity generated by alternate forms, such as wind or solar, and the like.

[0037] The system 100 comprises an energy search engine 102 and a user interface 108. In an embodiment, the energy search engine 102 is a cloud computing system based in a network 110, such as the Internet 110, as illustrated in FIG. 1.

[0038] In other embodiments, the energy search engine 102 is not a cloud computing system, but receives and transmits information through the network 110, such as the Internet 110, a wireless local network, or any other communication network. In an embodiment, the energy search engine 102 is hosted in a device located inside the facility 104. The device acquires sensor data and/or smart meter data directly from existing sensors and smart meters 104b. The device receives weather information, utility rate schedules, utility pricing information, grid usage information, BIM information, and other via RF broadcast signals. The device calculates locally the energy performance, actionable information and communicates control signals to local relays 104c, energy systems and other systems.

[0039] The user interface 108 allows a user to transmit information to the energy search engine 102 and receive information from the energy search engine 102. In an embodiment, the user interface 108 comprises a Web browser and/or an application to communicate with the energy search engine 102 within or through the Internet 110. In an embodiment, the user interface 108 is associated with a display and a user input device, such as a keyboard.

**[0040]** The energy search engine **102** receives energy usage information from the measurement devices **104b** measuring energy usage of the systems, subsystems, and components **104c** of the facility **104** in a substantially continuous way. The measurement devices **104b** deliver data output that can include but is not limited to electric energy consumption data, natural or renewable gas data, air temperature data, air flow data, air quality data, building occupancy data, building zone level occupancy data, water data, environmental data, and geographic data, and the like. This data can be derived from individual circuits, critical components within the building **104** or its zones, or those systems that externally serve a building or group/network of buildings. In another embodiment, additional measurements of vibration, temperature, sound from critical motor components, and the like within buildings **104** or wherever motors are used for industrial or manufacturing processes are used to gauge the health of motor and equipment functions within the facility **104**.

**[0041]** Further, the energy search engine **102** receives in a substantially continuous way dynamic data relating to energy usage from one or more of a Building Information Modeling (BIM) **106**, a power grid **112**, a utility company **114**, building management **116**, and an environmental service **118**. For example, the BIM **106** can provide, but is not limited to specifications for the systems, subsystem, and components **104a** installed in the facility **104**, specifications for the systems, subsystem, and components with a higher energy rating that could have been installed in the facility **104**, and the like. The power grid **112** can provide, but is not limited to a dynamic grid response to renewable energy sources, plug-ins, projected grid demand, grid load information, energy supply capacity, and the like. The utility company or other sellers of energy **114** can provide, but are not limited to utility rate tariffs, real-time energy pricing, price bids, and the like. The building management **116** can provide, but is not limited to facility and zone level scheduling of the facility **104**, occupancy information, system status information (e.g. open doors, open windows, open shutters, etc.), and the like. The environmental service, such as a weather service, can provide, but is not limited to dynamic weather data for the location of the facility **104**, projected weather for the location of the facility **104**, severe weather alerts, geographical factors, and the like.

**[0042]** The energy search engine **102** analyzes the static data and the dynamic data received in the substantially continuous way and provides a substantially continuous energy assessment. Examples of the substantially continuous energy assessment include but are not limited to reports, benchmark results, energy performance assessments for the facility **104**, network of facilities **104** or any of its systems, subsystems, and components **104a**, site energy carbon footprint, source energy carbon footprint, source energy assessment, building and systems commissioning strategies, lighting strategies, data center and Telco strategies, water performance assessment, gas performance assessment, energy retrofit assessment, renewable energy assessment, and the like.

**[0043]** In an embodiment, the energy search engine **102** transmits commands to the control systems **104c** to control the systems, subsystems, and components **104a** to reduce or optimize the energy usage of the facility **104**. In an embodiment, the energy search engine **102** controls the systems, subsystems, and components **104a** in a substantially continuous way.

**[0044]** In an embodiment, substantially continuous comprises within a length of time or not to exceed a length of time which occurs at regular intervals. In another embodiment, data received in a substantially continuous way comprises data that is received within a definite length of time marked off by two instances. In other words, data received in a substantially continuous way is data that is received at regular time intervals, where the time interval does not exceed a pre-defined time interval. In another embodiment, the time interval is approximately within a pre-defined time interval. In another embodiment, the time interval is based at least in part on the type of information received. For example, weather can be received substantially continuously every hour, smart meter information can be received substantially continuously every 15 minutes, and grid load can be received substantially continuously every time interval which does not exceed an hour.

**[0045]** Further, in an embodiment, providing substantially continuous energy assessment comprises providing the energy assessment within a pre-defined time interval, not to exceed a pre-defined time interval, or the like. Further yet, controlling in a substantially continuous way to optimize energy usage comprises sending commands to the control systems **104c** or the like within a pre-defined time interval. Again, the time interval is based at least in part on the specific system being controlled. For example, the energy search engine may direct the facility **104** to shed or redistribute power at an interval not to exceed 5 minutes, while directing the blinds to raise or lower at an interval not to exceed 2 hours.

**[0046]** In certain embodiments, substantially continuous time intervals comprise one of time intervals not to exceed 1 minute, time intervals not to exceed 5 minutes, time intervals not to exceed 15 minutes, time intervals not to exceed 1 hour, time intervals not to exceed 1 day, and time intervals not to exceed 1 week.

**[0047]** FIG. 2 illustrates an exemplary block diagram of an embodiment of the energy search engine **102**. The energy search engine **102** comprises one or more computers or processors **202** and memory **204**. The memory **204** comprises modules **206** including computer-executable instructions, that when executed by the computer **202** cause the energy search engine **102** to analyze the energy data and provide the substantially continuous energy assessment metrics. The memory **204** further comprises data storage **208** including one or more databases to store the dynamic and or static data by the modules **206** to analyze energy usage and provide energy usage assessments.

**[0048]** The computers **202** comprise, by way of example, processors, Field Programmable Gate Arrays (FPGAs), System on a Chip (SOC), program logic, or other substrate configurations representing data and instructions, which operate as described herein. In other embodiments, the processors **202** can comprise controller circuitry, processor circuitry, processors, general-purpose single-chip or multi-chip microprocessors, digital signal processors, embedded microprocessors, microcontrollers and the like. The memory **204** can comprise one or more logical and/or physical data storage systems for storing data and applications used by the processor **202**. The memory **204** can further comprise an interface module, such as a Graphic User Interface (GUI), or the like, to interface with the user interface **108**.

**[0049]** In one embodiment, the energy search engine **102** calculates a score reflecting the energy performance of the facility **104**. In an embodiment, the score is a weighted aver-

age of one or more metrics that are calculated based at least in part on one or more energy variables. Examples of energy variables include, but are not limited to the time history of the energy (power, water, gas) consumed by the facility, the carbon equivalent of energy used at the site, the carbon equivalent of the energy generated at the source, the time history of the ambient weather conditions, the facility activity type, the facility total square footage, the facility occupied square footage, the volume of free space in the facility, the facility schedule, the facility activity levels (e.g. production quantities, number of students, and the like), the location of the facility, the applicable utility rate schedule, the output of any existing local (or on site) generation systems, the output of any existing local alternative energy systems (e.g. thermal solar, thermal storage, energy storage, and the like), the potential for local renewable generation, the potential for local alternative energy systems, the type of construction material used, the type of energy systems used, the facility design specifications, required air change, measured air changes, the type of energy management system installed, the performance of any existing energy management system, data from any existing energy, environmental and security monitoring systems, and the like.

**[0050]** The facility **104** and/or building **104** and/or subsystems **104a** refer to one or more of the facility, its systems, subsystems, and components, multiple buildings comprising the facility located locally or remotely, and a network of facilities in the following discussion.

**[0051]** In an embodiment, the score or energy metrics are calculated based on historical energy data for the past week, month, quarter, year or longer time period.

**[0052]** In an embodiment, data from one time period is used to backfill data missing from another time period. For example, if the data for February of 2012 is missing, then it can be backfilled using the following:

$$Y_2 = X_2 / X_1 * Y_1$$

where  $X_1$  is the average workday energy consumption for January 2011,  $X_2$  is the average workday energy consumption for January 2012, and  $Y_1$  is the 15-minute, hourly, daily, or weekly energy consumption for workdays in February 2011, and  $Y_2$  is the 15-minute, hourly, daily, or weekly energy consumption for the corresponding workdays in February 2012. The above method can be used to backfill missing energy data for off days.

**[0053]** In another example, the same missing data for February 2012 can be backfilled using the following:

$$Y_2 = 2 * (X_1 Z_2 + Z_1 X_2) / (X_1 Z_1) * Y_1$$

where  $X_1$  is the average workday energy consumption for January 2011,  $X_2$  is the average workday energy consumption for January 2012,  $Z_1$  is the average workday energy consumption for March 2011,  $Z_2$  is the average workday energy consumption for March 2012, and  $Y_1$  is the 15-minute, hourly, daily, or weekly energy consumption for workdays in February 2011, and  $Y_2$  is the 15-minute, hourly, daily, or weekly energy consumption for the corresponding workdays in February 2012. The above method can be used to backfill missing energy data for off days.

**[0054]** In an embodiment, the energy used by the facility is calculated using the following equation:

$$\text{Energy Used} = \text{Energy Sourced by the Utility} + \text{Energy Generated on Site} - \text{Energy Stored on Site}$$

where energy sourced by the utility is energy that is purchased from the utility company. The energy generated on site (locally) is energy generated by local energy generation systems as solar PV, wind turbines, fuel cells, gas power plant, etc. The energy stored on site is energy that is purchased from the utility or generated locally but is stored at the time of purchase or generation for later use in energy storage systems such as batteries, compressed air, pumped water, thermal storage, etc. If the energy storage systems are discharging, then the sign of the stored energy in the equation above is negative. Each of the components in the equation above can be measured, calculated or estimated.

**[0055]** In an embodiment, the energy score and metrics can be proportional to the energy performance of a facility relative in a specific time period compared to its performance in a base period. In an embodiment, the base period is one year.

**[0056]** In an embodiment, the metric can be proportional to the composition of source energy (solar PV, utility power, fuel cell, solar thermal, gas generator, energy storage, etc.) relative to an optimum composition of source energy for a facility, given the measured, calculated or estimated energy usage of the facility, the type of systems in the facility, the facility schedule, the facility location, the ambient weather conditions, and the like.

**[0057]** In an embodiment, the metrics include but are not limited to the facility electric energy use index (kWhr/ft<sup>2</sup>), the facility gas use index (therms/ft<sup>2</sup>), and the facility electric demand index (kw/ft<sup>2</sup>).

**[0058]** In an embodiment, the metric can be proportional to the equivalent greenhouse gas emissions of the energy used at the facility **104**, proportional to the energy generated using local renewable energy systems, proportional to the energy generated using alternative fuel systems (e.g. hydrogen fuel cells, or the like), proportional to the use of alternative energy systems, proportional to the ratio of energy used during off hours to the energy used during work hours, proportional to the ratio of energy used during work days to the energy used during off days, proportional to the minimum rate of energy consumption during a period of time (day, month, year, etc.), proportional to the simultaneous heating and cooling that may be occurring in the facility **104**, or the like.

**[0059]** In another embodiment, the metric can be proportional to the correlation between energy used for heating energy and heating requirements, proportional to the correlation between the energy used for cooling and the cooling requirements, proportional to the estimated, calculated, or measured energy used for heating divided by the amount of heating affected, proportional to the estimated, calculated or measured energy used for cooling divided by the amount of cooling affected, and the like. Heating requirements, cooling requirements, amount of heating affected, or the amount of cooling affected can be calculated using, but not limited to one or more of the following: ambient weather, ambient environmental conditions, desired internal temperature, ventilation rates, outside air circulation, recirculation rates, recirculated air, energy consumed by loads inside the facility **104**, heat generated by other sources inside the facility **104**, heat entering or leaving the facility **104** through mass or thermal transfer, and the like. In one embodiment, the heating degree hours, a difference between ambient temperature and supply air temperature inside the facility for each hour, can be used as a measure of affected heating (heating kWhr/degree heated). In another embodiment, the cooling degree hours, a difference between the ambient temperature and the supply air

temperature inside the facility **104** for each hour, can be used as a measure of affected cooling (cooling kWhr/degree cooled).

[0060] In another embodiment, the required heating enthalpy hours, a difference between ambient enthalpy and a target temperature and humidity inside the facility, can be used as a measure of required heating. In another embodiment, the required cooling enthalpy hours, a difference between ambient enthalpy and a target temperature and humidity inside the facility, can be used as a measure of required cooling.

[0061] In another embodiment, the affected heating enthalpy hours, a difference between ambient enthalpy and supply air enthalpy inside the facility for each hour, can be used as a measure of affected heating (heating energy kWhr/kJ heated). In another embodiment, the cooling enthalpy hours, a difference between the ambient enthalpy and the supply air temperature inside the facility **104** for each hour, can be used as a measure of affected cooling (cooling kWhr/KJ cooled).

[0062] FIG. 3 is a flow chart of an exemplary energy search engine process **300** to assess the amount of energy used for cooling and the amount of excessive cooling affected. For example, the amount of energy used for cooling during workdays during a year can be estimated from the profile of total energy used during the year. The interval energy (energy consumed at regular intervals, typically 15 or 30 minutes, or any other regular interval) for a 12 month period is used. At blocks **310** and **312**, the average energy and average cooling degree requirement, respectively, for each time interval during work days is calculated for each month.

[0063] At block **314**, the minimum energy profile for workdays is calculated and at block **316**, the average energy used for cooling is calculated as the difference between the energy profile and the minimum energy used during workdays.

[0064] At block **318** to block **324**, the minimum energy required to cool the facility by one degree is estimated for each time interval during workdays. At block **326**, the minimum energy needed for cooling during the year is calculated from the results of blocks **322** and **324**.

[0065] At block **328**, the amount of energy used for excessive energy, i.e. the amount of energy wasted due to excessive cooling is estimated. At block **330**, the energy profile for the year is calculated assuming the cooling and heating systems are at their peak efficiency all year long. The process can be repeated for time intervals during off-days.

[0066] FIG. 4 is an exemplary substantially continuous excessive cooling performance assessment **400**. The performance assessment **400** is a topographical map of the facility **104** showing estimated excessive cooling energy for an average hour throughout the day in each month for a year. The excessive cooling is estimated by considering the load inside the building and the cooling requirement from the ambient weather, as described in FIG. 3. For example, the performance assessment **400** indicates total cooling costs being estimated at \$117,000, with \$75,000 in overcooling between 10 AM and 3 AM, and \$19,000 in overcooling between 3 AM and 10 AM. Overcooling is estimated at \$96,000, being up to 76% of the cooling costs. In an embodiment of the performance assessment **400**, color can be used to indicate energy intensity, where brighter shades of a color indicate greater energy intensity and darker shades of the color represent lighter energy intensity (or vice versa).

[0067] In an embodiment, the metric can be proportional to the time history of the number of air changes, proportional to the fraction of outside air introduced to the facility, proportional to the fraction of return air recirculated, where return air is air that is exhausted from the facility using exhaust fans, proportional to the air quality inside the facility, proportional to facility peak demand and the load duration curve, which represents the time spent at each power level from the lowest demand to the peak demand, proportional to the level of compliance of the facility **104** or any of its subsystems **104a** with one or more of existing and/or future energy regulations, standards, codes, specifications and guidelines, and the like.

[0068] In another embodiment, the metric can be proportional to the level of energy demand reduction or load shedding initiated in response to a request from the grid or utility. The energy demand reduction can be calculated relative to a baseline that is adjusted for one or more of the following factors: ambient weather conditions, ambient environment conditions, changes in facility schedule, changes in facility activity, changes in facility occupancy, and the like. In an embodiment, the projected energy demand reduction for the facility **104** can be calculated by estimating the amount of energy that will be used for cooling as described above and assuming that a certain percentage of the cooling energy will be reduced.

[0069] In a yet further embodiment, the metric can be proportional to the change in energy consumption of the facility **104** or any of its energy subsystems **104a** compared to an energy baseline, an energy benchmark, a computed energy usage, an estimated energy usage or a projected energy usage.

[0070] In an embodiment, an energy baseline can be calculated for any measured or calculated metric, and correlated with ambient weather conditions, facility usage, and facility schedule. The calculated baseline can be used to project the value of the metric given projections of ambient weather conditions, facility usage, facility schedule, or changes in energy systems.

[0071] In an embodiment, the metric can be proportional to the cost of total energy used at the facility **104**, proportional to the cost of gas energy used at the facility, proportional to the cost of energy used at the facility **104** from renewable energy sources, proportional to the cost of energy used at the facility **104** from alternative energy sources, proportional to the total cost to generate the energy at the source, proportional to the cost of delivering the energy from the source to the facility **104**, proportional to the total cost of electric energy used at the facility **104**, proportional to the peak electric energy demand costs at the facility **104**, proportional to the electric energy consumption costs at the facility **104**, proportional to the avoided energy consumption costs, proportional to the avoided peak demand costs, or the like.

[0072] In another embodiment, the metric can be proportional to the energy consumed in the facility **104**, proportional to the total energy that can be delivered to the facility **104**, proportional to the total energy that can be generated in the facility **104**, proportional to the total energy that can be reduced in the facility **104**, proportional to the reliability of the sources of energy to the facility **104** and the total uptime of one or more of the facility's energy sources, proportional to the power quality (e.g. power factor, total harmonic distortion, energy in harmonic frequencies, voltage spikes, voltage drops, power surges, etc.) of the power in the facility **104** or any of its energy subsystems **104a**, proportional to number of megawatts (MW) or megawatt-hours (MWhr) avoided as a

response to an energy emergency, or the like. An example of such avoided energy is the load shed as part of a utility's Demand Response program.

[0073] In another embodiment, any of the metrics can be calculated every year, month, week, day, hour, or in a substantially continuous manner.

[0074] In a further embodiment, any of the metrics can be calculated in the cloud-based server 102 and can be offered as a subscription-based service.

[0075] FIGS. 5, 6, and 7 are flow charts of exemplary search engine processes to actively process energy consumption data, environmental data, and building use data, examples of which are described above, in a plurality of time frames, including real time, to provide one or more of the metrics related to the minimum energy required by the facility 104 and its critical subsystems 104a for a unique geographic location, use, environment, and occupancy associated with the facility 104, examples of which are described above.

[0076] In other embodiments, the energy search engine algorithms provide energy and sustainability ratings for commercial, municipal, campus, state, and federal buildings. Another embodiment provides carbon footprinting of buildings and facilities. Yet another embodiment evaluates the value of real property by evaluating its energy consumption and effectiveness and efficiency of installed systems and components. A further embodiment evaluates the instant demand response, load shedding, load shifting, and additional local generating potential of buildings, facilities, campuses and their systems. A yet further embodiment guides and evaluates actionable energy efficiency and demand response improvement measures, equipment retrofits, and commissioning strategies. In an embodiment, the technology enables compliance with legislated energy efficiency mandates and goals.

[0077] FIG. 5 is a flow chart of an exemplary energy search engine process 500 to assess energy usage for the facility 104. The facility 104 and/or building 104 and/or subsystem 104 refer to one or more of the facility, its systems, subsystems, and components, multiple buildings comprising the facility located locally or remotely, and a network of facilities in the following discussion. Beginning at block 510, the process 500 receives substantially continuous measurements of actual energy consumption of the facility 104. In an embodiment, the process 500 receives measurements related to the actual energy consumption of the facility 104 from the measurement devices 104b. Examples of the measurements of actual energy consumption are smart meter readings, electric meter readings, gas meter readings, current measurements, facility energy variables as described above, and the like.

[0078] In another embodiment, receiving substantially continuous measurements comprises receiving measurements at least every 15 minutes. In another embodiment, receiving substantially continuous measurements comprises receiving measurements at least every 5 minutes. In a further embodiment, receiving substantially continuous measurements comprises receiving measurements at least every 1 hour.

[0079] At block 512, the process 500 receives substantially continuous measurements of ambient conditions. For example, the energy search engine 102 can receive weather reports including the outside air temperature, outside air humidity, cloud coverage, UV index, precipitation level, evaporative transpiration (ET) number, weather forecast, and the like. In another example, the status of doors, windows, and

shutters associated with the facility 104 can change with time and can be received in a substantially continuous manner.

[0080] At block 514, the process 500 obtains a target energy consumption of the facility 104 based at least in part on the ambient conditions. Target energy consumption can be a calculated energy consumption based on baseline performance, desired environmental conditions inside the facility (temperature, humidity, air quality, etc.) projected facility schedule, projected facility usage, and projected weather conditions. Average facility energy consumption at a given ambient condition and facility usage level can be calculated based on historic data. This average can be set as a target for the facility when similar weather and facility usage are anticipated.

[0081] At block 516, the process 500 compares the measurement of the actual energy consumption with the target energy consumption for the facility 104, and at block 518, the process 500 calculates a substantially continuous energy performance assessment based at least in part on the comparison of the measurement of the actual energy consumption with the target energy consumption.

[0082] Metrics found on the performance assessment can include but are not limited to one or more of total gas and electric current energy costs per square foot of the facility 104, baseline electric energy rating, peak electrical energy rating, gas energy rating, efficiency of heating gas use, simultaneous heating and cooling, nighttime power index, weekend power index, EMS scheduling, full time loading, an overall performance assessment, energy wasted annually, range of estimated energy wasted annually, cost to produce energy at the source, cost to deliver energy to the facility 104, waste as a percent of total energy used, cost of annual gas and electric energy wasted annually, electrical energy carbon footprint, gas energy carbon footprint, total energy carbon footprint, target energy usage in cost per square foot of the facility 104, annual energy savings target, historical electricity and gas usage, historical monthly peak demand for electricity, historical energy map showing annual energy usage versus the time of the day the usage occurred, wasted heating based on a comparison of heating requirements and the actual energy used for heating, simultaneous heating and cooling based on an estimated energy used for cooling during business hours and an estimated energy used for heating during business hours, wasted cooling during business hours based on a comparison of relative cooling required during business hours and an estimated energy used for cooling during business hours, wasted cooling during non-business hours based on a comparison of relative cooling required during non-business hours and an estimated energy used for cooling during non-business hours, cooling degree hours, heating degree hours, peak reduction, energy savings recommendations, energy source planning, energy source investment payback including but not limited to fuel call, grid tied solar, thermal storage, battery-based peak shedding, and utility based on electric utility data, gas utility data, National Oceanic and Atmospheric Administration (NOAA) weather data for the facility 104, and the like.

[0083] In another embodiment, the metric can be proportional to the level of compliance with one or more energy standards, such as, for example, ISO 50001, LEED Silver, LEED Gold, LEED Platinum, and the like.

[0084] In another embodiment, the metric can be proportional to the cost of bringing the facility to compliance with one or more energy standard.

[0085] In another embodiment, the metric can be proportional to the energy savings (in consumption kWhr, demand kW or energy costs \$) that can be realized by bringing the facility to compliance with one or more energy standard.

[0086] In another embodiment, the metric can be proportional to the absolute efficiency of the energy subsystem or facility 104. The absolute efficiency of the energy subsystem 104 can be the ratio between the measured, calculated or estimated energy consumed by the subsystem 104 and the energy the subsystem 104 would have consumed if it operated at the theoretical limits of the subsystem 104.

[0087] In another embodiment, the metric can be proportional to the achievable efficiency of the energy subsystem or facility 104. The achievable efficiency of the energy subsystem 104 can be the ratio between the measured, calculated or estimated energy consumed by the subsystem 104 and the energy the subsystem 104 would have consumed if it operated at the highest efficiency achievable by such subsystems 104.

[0088] In an embodiment, the metric can be proportional to the design efficiency of the energy subsystem or facility 104. The design efficiency of the energy subsystem or facility 104 can be the ratio between the measured, calculated or estimated energy consumed by the subsystem 104 and the energy the subsystem 104 would have consumed if it operated per the manufacturer's design specification.

[0089] In an embodiment, the metric can be proportional to the savings realized (consumption kWhr, demand kW, energy costs in \$) if one or more energy subsystems is operating at its theoretical, absolute, or design efficiency.

[0090] FIG. 6 is a flow chart of an exemplary energy search engine process 600 to dynamically assess energy efficiency for the facility 104. Energy search engine algorithms analyze measured energy data versus computed minimum required energy to provide, for example, energy efficiency ratings, energy consumption profiles, energy load factors, critical component assessment, and life cycle analysis of critical components.

[0091] Beginning at block 610, the process 600 obtains a minimum energy consumption for the facility 104.

[0092] Obtaining the minimum energy consumption at block 610 comprises obtaining the theoretical energy consumption based at least in part on models of the installed building systems, subsystems, and components 104a at block 612. In an embodiment, obtaining the minimum energy consumption comprises obtaining a theoretical energy consumption based at least in part on ideal models or the theoretical limits of the installed building systems, subsystems, and components 104a.

[0093] Obtaining the minimum energy consumption at block 610 further comprises obtaining an achievable minimum energy consumption based at least in part on specifications for high energy efficiency equivalents of the installed building systems, subsystems, and components 104a at block 614 and obtaining a designed minimum energy consumption based at least in part on specifications and cumulative loads for the installed building systems, subsystems, and components 104a at block 616.

[0094] At block 620, the process 600 receives substantially continuous measurements of the facility energy consumption. In an embodiment, the measurements are provided by the measurement devices 104b. In another embodiment, measurements are calculated. In a further embodiment, the measurements are estimated.

[0095] At block 630, the process 600 compares the minimum energy consumption to the measurement of the facility energy consumption in a substantially continuous way. Comparing at block 630 comprises comparing the theoretical minimum energy consumption to the measurement of the facility energy consumption at block 632, comparing the achievable minimum energy consumption to the measurement of the facility energy consumption at block 634, and comparing the designed minimum energy consumption to the measurement of the facility energy consumption at block 636.

[0096] At block 640, the process 600 calculates a substantially continuous energy performance assessment for the facility 104. Calculating the substantially continuous energy performance at block 640 comprises determining a theoretical energy efficiency at block 642, determining an achievable energy efficiency at block 644, and determining a designed energy efficiency at block 646.

[0097] For example, the absolute or theoretical efficiency metric for a fan can be calculated from a measurement, estimation or calculation of one or all of the following: fan upstream pressure, fan downstream pressure, flow temperature, fan speed, mass flow rate through the fan, volumetric flow rate through the fan, and/or energy consumed by the fan. The fan's absolute efficiency is then calculated by dividing the energy consumed by the energy that should have been consumed by the fan if it operated at its theoretical efficiency under the same conditions of upstream pressure, downstream pressure, fan speed, flow temperature, volumetric flow rate, or mass flow rate through the fan.

[0098] In another example, the achievable efficiency metric for a fan can be calculated from a measurement, estimation or calculation of one or all of the following: fan upstream pressure, fan downstream pressure, flow temperature, fan speed, mass flow rate through the fan, volumetric flow rate through the fan, and/or energy consumed by the fan. The fan's achievable efficiency is then calculated by dividing the energy consumed by the energy that should have been consumed by the highest performing fan available operating under the same conditions of upstream pressure, downstream pressure, fan speed, flow temperature, volumetric flow rate, or mass flow rate through the fan.

[0099] In a further example, the design efficiency metric for a fan can be calculated from a measurement, estimation or calculation of one or all of the following: fan upstream pressure, fan downstream pressure, flow temperature, fan speed, mass flow rate through the fan, volumetric flow rate through the fan, and/or energy consumed by the fan. The fan's design efficiency is then calculated by dividing the energy consumed by the energy that should have been consumed by the fan operating per the manufacturer's design specifications under the same conditions of upstream pressure, downstream pressure, fan speed, flow temperature, volumetric flow rate, or mass flow rate through the fan.

[0100] In another example, the theoretical efficiency of a facility envelope on hot days can be calculated assuming a perfectly insulated facility envelope that blocks all radiant heat transfer into the facility 104, all convective heat transfer into the facility 104, and all infiltration of mass in and out of the facility 104. The heat generated in the facility 104 is calculated from a measurement, estimate, or calculation of the energy consumed in the facility 104, such as indoor lighting, plug load, heating gas, etc., and the heat generated by occupants and processes in the facility 104. The heat removed from the facility 104 can be calculated from a measurement,

estimate, or calculation of the difference between enthalpy of the ventilation and cooling air leaving the envelope and the enthalpy of the ventilation and cooling air entering the envelope. The facility **104** can be assumed to be at constant operating temperature. For a perfectly insulated envelope at a constant internal temperature, the heat removed from the facility **104** is equal to the heat generated in the facility **104**. The envelope efficiency on a hot day can be calculated as the ratio of the heat generated in the facility **104** divided by the heat removed from the facility **104**.

**[0101]** In a further example, the design efficiency of a roof top packaged HVAC unit can be calculated by measuring the enthalpy (temperature, humidity and flow rate) of the air entering the HVAC system (fraction of return air+fraction of outside air), the enthalpy of the air leaving the HVAC system (supplied to the facility **104**) and the energy consumed by the HVAC system. The energy consumed by the HVAC is divided by the [enthalpy of air entering the HVAC–enthalpy of air leaving the HVAC] to yield a measured coefficient of performance (COP). The measured COP is then divided by the design COP specified by the HVAC manufacturer at the given HVAC load and the resulting ratio comprises the design efficiency of the HVAC system.

**[0102]** FIG. 7 is a flow chart of an exemplary energy search engine process **700** for demand side analysis. In one embodiment, the energy search engine **102** matches varying demand side load requirements to supply side generating and grid capability to establish relative value energy pricing.

**[0103]** The exemplary process **700** quantifies the effectiveness of energy improving measures, such as rating the energy efficiency and carbon footprint of the facility **104** and/or any or all of its systems **104a** (individually or collectively) to determine opportunities to introduce energy efficiency, install retrofits, commission facilities for monitoring based commissioning (MBCx), retrocommissioning (RCx), continuous commissioning, and the like, and provide peak reduction and demand response strategies and actions.

**[0104]** Beginning at block **710**, the process **700** obtains an energy usage benchmark for the facility **104**. In an embodiment, the energy usage benchmark is an energy usage point of reference across a network of facilities that share something in common against which the energy usage of the facility **104** may be compared. For example, the benchmark could be one of an Energy Star® rating, historical energy use of the facility **104**, energy performance of buildings in a specific geographic area, energy performance of buildings of a certain size, energy performance of buildings of a certain activity, energy performance of buildings with a certain type of cooling technology, energy performance of buildings with a certain type of heating technology, energy performance of buildings with a certain type of construction material, energy performance of buildings with a certain brand and model of EMS, energy performance of buildings with a certain energy certification, energy performance of buildings with a certain energy rating, energy performance of buildings with a certain local energy source (e.g. solar PV), or the like.

**[0105]** At block **712**, the process **700** receives substantially continuous measurements of actual energy consumption for the facility **104** before installation of energy improvement measures. In an embodiment, the measurements are obtained from the measurement devices **104b**.

**[0106]** At block **714**, the process **700** establishes a first baseline of energy usage for the facility **104** based at least in part on the measurements of actual energy consumption

received before the installation of the energy improvement measures. In an embodiment, establishing the baseline before installation comprises obtaining an expected energy usage for the facility which has installed systems, subsystems, and components **104c**, and a load profile. The baseline is established by recording the energy performance of the facility over a period of time, e.g. 3 months or 1 year. Multiple baselines can be calculated, such as for night hours on work days, morning hours on work days, afternoon hours on work days, night hours on off days, morning hours on off days, afternoon hours on off days.

**[0107]** Different types of baselines can be calculated, including, but not limited to total energy consumption (kWhr), electrical energy consumption (kWhr), electrical demand (kW), gas consumption (therms), energy used for lighting (kWhr), demand due to lighting (kW), energy used for cooling (kWhr), demand due to cooling (kW), and the like. Baselines can also be normalized with ambient weather conditions, cooling degree hours, heating degree hours, facility usage levels, facility occupancy, etc. For example, the baseline of energy consumed (kWhr) during morning hours on work days, could be the average consumption during morning hours for all workdays of a certain segment or entire segment of the baseline calculation period. The consumption baseline can be normalized to cooling degree hours by dividing the average consumption for each of the morning hours on work days with the average cooling degree hour for each of those hours.

**[0108]** At block **716**, the process **700** compares the benchmark with the baseline established before the installation of the at least one energy improvement measure.

**[0109]** At block **718**, the process **700** receives substantially continuous measurements of actual energy consumption for the facility **104** after installation of at least one energy improvement measure. In an embodiment, the measurements are obtained from the measurement devices **104b**.

**[0110]** Examples of energy improvement measures are, but not limited to, installing a renewable energy system, retrofitting equipment, commissioning, load shifting, load shedding, installing energy storage, installing LED lighting systems, installing variable frequency drive (VFD) systems, installing new windows, installing new wall insulation, replacing inefficient boilers, upgrading the insulation of hot and cold water pipes, installing economizer systems, installing evaporative cooling systems, adding circulation fans, changing the location of supply and return ventilation air ducts, installing pool covers, installing thermal storage systems, installing shades and awnings, and the like.

**[0111]** At block **720**, the process **700** establishes a second baseline based at least in part on the measurements of actual energy consumption received after the installation of the energy improvement measures. In an embodiment, establishing the baseline after installation comprises obtaining an energy usage for the facility which has installed systems, subsystems, and components **104c**, and a load profile.

**[0112]** At block **722**, the process **700** compares the first baseline established before installation of the at least one energy improvement measure with the baseline established after installation of the at least one energy improvement measure.

**[0113]** At block **724**, the process **700** compares the benchmark with the baseline established after installation of the at least one energy improvement measure.

**[0114]** At block 726, the process 700 quantifies the effectiveness of the at least one energy improvement measure. In an embodiment, the process 700 determines the impact of the at least one energy improvement measure against the first baseline of energy usage for the facility 104. In another embodiment, the process 700 determines the impact of the at least one energy improvement measure against the benchmark for the facility 104. In an embodiment, quantifying the effectiveness of the at least one energy improvement comprises determining one or more of a payback calculation, a payment of an incentive, a valuation of real property for purposes that include projecting the value of operational strategies and behaviors or equipment replacements that result in altered real property valuations, a carbon offset used in carbon trading, and the like.

**[0115]** FIG. 8 is an exemplary substantially continuous energy performance assessment 800. The assessment 800 includes information about the current energy usage of the facility 104, rating of energy metrics, and targeted energy usage. For example, the metrics for current energy usage include the total gas and electric energy cost per square foot of the facility 104; low and high ranges for the annual estimated energy wasted, the percent of wasted energy out of the total energy used, the cost of the annual energy wasted; and carbon footprint metrics, such as the carbon footprint of the electrical energy used, the carbon footprint of the gas energy used, and total carbon footprint for the facility 104. Energy metrics, such as the baseline energy rating, the peak electrical energy rating, the gas energy rating, the efficiency of the gas used for heating, the occurrence of simultaneous heating and cooling, the nighttime power index, the weekend power index, the energy management system scheduling, and the full time loading levels, are rated on a poor, average or good scale. Finally, the assessment 800 includes a comparison of energy usage, energy savings, and carbon reductions for the current energy implementation of the facility with at least two suggested energy reduction implementations to provide a better target and a best target.

**[0116]** In an embodiment, the energy search engine 102 provides the energy performance of a network of facilities 104 on a multi-dimensional map. The multi-dimensional map plots one or more metrics on a geographical map with colors, coordinates and shapes. For example, a metric proportional to the fraction of a facility's energy demand that can be shed (reduced) at any given time can be plotted on a geographical map of the area. Every facility 104 can be indicated by a circle, with the size of the circle proportional to the levels of demand (in kW) that can be shed at each facility 104 and the color of the circle indicating the percent facility demand that can be shed. Similar maps can be used to animate the effect of a cloud passing on the potential for demand reduction across a network of facilities 104 based on demand projections calculated using the energy search engine 102.

**[0117]** In another example, several metrics can be plotted on a single map with every metric represented by a layer of a unique color, with the shades of each color proportional to the level of the metric (e.g. light shades of a color indicating smaller values of the metric and darker shades of the same color indicating larger values of the same metric).

**[0118]** FIG. 9 is an exemplary continuous yearly key performance indicator chart 900 and FIG. 10 is an exemplary continuous monthly key performance indicator chart 1000. Both charts 900 and 1000 track key performance indicators, including but not limited to baseline electric use index, peak

electrical energy use index, gas energy use index, heating gas efficiency consistency, simultaneous heating and cooling, nighttime power index, weekend power index, EMS scheduling, and full-time loading, as described above. Chart 900 indicates the year to date energy performance, while chart 1000 indicates the energy performance for a month. In an embodiment, the indicator bars are in color to represent score quality/level where red indicates a poor score, green indicates a good score, and yellow indicates a mediocre score that could be improved.

**[0119]** In an embodiment, one or more alerts are associated with one or more of the metrics. Exceeding, or dropping below a specified metric value and for a specified amount of time will signal an alert and cause an action to be taken. The action may include the closure of relays, a command to be sent via wired or wireless Ethernet®, RF module, machine interface, wired connection, or the like. The action may also include a message to be sent to a computer desktop, a mobile device, a mobile application, a Facebook® page, a Twitter® account, a message board, a broadcast system, or the like.

**[0120]** In an embodiment, one or more alerts are associated with one or more of the metrics. The alerts can be initiated when a metric exceeds or drops below a certain value for a specified amount of time if one or more other metrics, measured variables, such as, for example, temperature, pressure, humidity, flow, current, or the like, estimated variables, calculated variables, and/or any mathematical combination of the metrics and/or variables are at, above, or below a specific value for a specified amount of time, where the specific value can be a function of one or more metrics, measured variables, estimated variables, calculated variables, any mathematical combination of the variables, and/or any mathematical combination of the metrics.

**[0121]** Other embodiments of the energy search engine 102 can report a daily maintenance task list, where the energy search engine 102 generates a list of required maintenance tasks sorted by criticality, energy performance impact, cost performance impact, impact on carbon footprint, cost to fix, and the like. Further, an embodiment of the energy search engine 102 can report equipment diagnostics such that the energy search engine will continuously diagnose and rate the performance of each of the building's equipment 104a.

**[0122]** Further embodiments of the energy search engine 102 determines and reports on when and where a building or its energy consuming or energy generating subsystems are operating properly or are in need of maintenance, tuning, load shifting, load shedding, or equipment replacement based at least in part on data level flags that correspond with incremental level changes in energy consumed or generated.

**[0123]** In an embodiment, the energy search engine 102 uses day ahead projected hourly weather data and projected facility schedule and usage to predict energy performance (e.g. kWhr consumption, kW demand, efficiency metrics, etc.) based on a calculated baseline for the facility 104, and correlations of energy baseline with ambient weather, facility schedule and facility usage.

**[0124]** In another embodiment, the energy search engine 102 uses day ahead projected hourly weather data, projected facility schedule, projected facility usage, utility rate information, day ahead utility pricing information, day ahead grid information, day ahead energy cost information, to predict energy cost (kW demand cost, kWhr consumption cost, gas therm cost, water gallons cost, etc.) based on a calculated

baseline for the facility **104**, and correlations of energy baseline with ambient weather, facility schedule and facility usage.

**[0125]** In yet another embodiment, the energy search engine **102** provides data output that are useful to benchmark and evaluate real property energy consumption and carbon emissions/footprint for purposes that include projecting the value of operational strategies and behaviors or equipment replacements that result in altered real property valuations, and the like.

**[0126]** In yet further embodiments, the energy search engine **102** provides data output that are useful for auditing compliance with existing and emerging legislation on energy use, carbon emissions, and for achieving energy reduction and carbon emission reduction goals at facilities.

**[0127]** In other embodiments, the energy search engine **102** provides preplanned or instant actionable energy optimization strategies through activation of systems and circuits that shed and/or shift energy consumption and/or provide supplemental energy resources. The energy search engine **102** can provide data output to Energy Management Systems (EMS) and/or Building Management Systems (BMS) and/or load control relays to respond with either instant or preprogrammed load shedding strategies, load shifting strategies, and supplemental energy supply strategies, according to certain embodiments.

**[0128]** Depending on the embodiment, certain acts, events, or functions of any of the algorithms described herein can be performed in a different sequence, can be added, merged, or left out all together (e.g., not all described acts or events are necessary for the practice of the algorithm). Moreover, in certain embodiments, acts or events can be performed concurrently, e.g., through multi-threaded processing, interrupt processing, or multiple processors or processor cores or on other parallel architectures, rather than sequentially.

**[0129]** The various illustrative logical blocks, modules, and algorithm steps described in connection with the embodiments disclosed herein can be implemented as electronic hardware, computer software, or combinations of both. To clearly illustrate this interchangeability of hardware and software, various illustrative components, blocks, modules, and steps have been described above generally in terms of their functionality. Whether such functionality is implemented as hardware or software depends upon the particular application and design constraints imposed on the overall system. The described functionality can be implemented in varying ways for each particular application, but such implementation decisions should not be interpreted as causing a departure from the scope of the disclosure.

**[0130]** The various illustrative logical blocks and modules described in connection with the embodiments disclosed herein can be implemented or performed by a machine, such as a general purpose processor, a digital signal processor (DSP), an ASIC, a FPGA or other programmable logic device, discrete gate or transistor logic, discrete hardware components, or any combination thereof designed to perform the functions described herein. A general purpose processor can be a microprocessor, but in the alternative, the processor can be a controller, microcontroller, or state machine, combinations of the same, or the like. A processor can also be implemented as a combination of computing devices, e.g., a combination of a DSP and a microprocessor, a plurality of microprocessors, one or more microprocessors in conjunction with a DSP core, or any other such configuration.

**[0131]** The steps of a method, process, or algorithm described in connection with the embodiments disclosed herein can be embodied directly in hardware, in a software module executed by a processor, or in a combination of the two. A software module can reside in RAM memory, flash memory, ROM memory, EPROM memory, EEPROM memory, registers, hard disk, a removable disk, a CD-ROM, or any other form of computer-readable storage medium known in the art. An exemplary storage medium can be coupled to the processor such that the processor can read information from, and write information to, the storage medium. In the alternative, the storage medium can be integral to the processor. The processor and the storage medium can reside in an ASIC.

**[0132]** The above detailed description of certain embodiments is not intended to be exhaustive or to limit the invention to the precise form disclosed above. While specific embodiments of, and examples for, the invention are described above for illustrative purposes, various equivalent modifications are possible within the scope of the invention, as those ordinary skilled in the relevant art will recognize. For example, while processes or blocks are presented in a given order, alternative embodiments may perform routines having steps, or employ systems having blocks, in a different order, and some processes or blocks may be deleted, moved, added, subdivided, combined, and/or modified. Each of these processes or blocks may be implemented in a variety of different ways. Also, while processes or blocks are at times shown as being performed in series, these processes or blocks may instead be performed in parallel, or may be performed at different times.

**[0133]** Unless the context clearly requires otherwise, throughout the description and the claims, the words “comprise,” “comprising,” and the like are to be construed in an inclusive sense, as opposed to an exclusive or exhaustive sense; that is to say, in the sense of “including, but not limited to.” The words “proportional to”, as generally used herein, refer to being based at least in part on. The words “coupled” or “connected”, as generally used herein, refer to two or more elements that may be either directly connected, or connected by way of one or more intermediate elements. Additionally, the words “herein,” “above,” “below,” and words of similar import, when used in this application, shall refer to this application as a whole and not to any particular portions of this application. Where the context permits, words in the above Detailed Description using the singular or plural number may also include the plural or singular number respectively. The word “or” in reference to a list of two or more items, that word covers all of the following interpretations of the word: any of the items in the list, all of the items in the list, and any combination of the items in the list.

**[0134]** Moreover, conditional language used herein, such as, among others, “can,” “could,” “might,” “may,” “e.g.,” “for example,” “such as” and the like, unless specifically stated otherwise, or otherwise understood within the context as used, is generally intended to convey that certain embodiments include, while other embodiments do not include, certain features, elements and/or states. Thus, such conditional language is not generally intended to imply that features, elements and/or states are in any way required for one or more embodiments or that one or more embodiments necessarily include logic for deciding, with or without author input or prompting, whether these features, elements and/or states are included or are to be performed in any particular embodiment.

[0135] The teachings of the invention provided herein can be applied to other systems, not necessarily the systems described above. The elements and acts of the various embodiments described above can be combined to provide further embodiments.

[0136] While certain embodiments of the inventions have been described, these embodiments have been presented by way of example only, and are not intended to limit the scope of the disclosure. Indeed, the novel methods and systems described herein may be embodied in a variety of other forms; furthermore, various omissions, substitutions and changes in the form of the methods and systems described herein may be made without departing from the spirit of the disclosure. The accompanying claims and their equivalents are intended to cover such forms or modifications as would fall within the scope and spirit of the disclosure.

What is claimed is:

1. A method to manage an energy event, the method comprising:

automatically receiving in a continuous way with computer hardware a measurement of actual energy consumption;

receiving energy information;

automatically calculating with the computer hardware a continuous energy performance assessment based at least in part on the measurement of actual energy consumption and the energy information;

automatically generating with the computer hardware energy management data based at least in part on the continuous energy performance assessment, the energy management data configured to provide an energy alert; and

based at least in part on the received continuous measurement of actual energy consumption, automatically determining with the computer hardware an impact of the energy management data.

2. The method of claim 1 wherein automatically receiving in a continuous way the measurement of actual energy consumption comprises receiving the measurement of actual energy consumption at least every 15 minutes.

3. The method of claim 1 wherein the energy information comprises at least one of demand management information, demand response information, price management information, and price response information.

4. The method of claim 1 wherein the energy information comprises at least one of a request to manage energy, a demand response request, a utility tariff, a schedule of energy costs based on time of day, a schedule of energy costs based on amount of energy used, real-time energy pricing, a price at which energy was purchased, market price for energy, an energy cost budget, an energy usage budget, a request to manage energy based on cost per time period, a request to manage energy based on cost per unit of energy, and a request to manage energy based on power per time period.

5. The method of claim 4 wherein the request to manage energy based on the cost per time period comprises a request to manage energy based on a threshold for one or more of cost/hour and cost/month.

6. The method of claim 4 wherein the request to manage energy based on cost per unit of energy comprises a request to manage energy based on a threshold for one or more of cost/kWh and cost/kW at one or more times.

7. The method of claim 4 wherein the request to manage energy based on power per time period comprises a request to manage energy based on a threshold for one or more of kW/hour and kW/month.

8. The method of claim 4 wherein the request to manage energy is based at least in part on at least one of environmental factors, weather, varying demand side load requirements, grid imbalance, variable energy generating resources, loss of electrical energy generating capacity, varying loads, availability of solar generated electrical energy, availability of wind generated electrical energy, and market price for energy.

9. The method of claim 1 wherein the energy alert comprises at least one of energy savings recommendations and energy source planning, wherein the energy savings recommendations comprise at least one of load shedding and load shifting, and wherein the energy source planning comprises switching to an alternative energy source.

10. The method of claim 1 further comprising sending a message to a broadcast system based at least in part on the energy alert.

11. The method of claim 1 further comprising initiating at least one of a purchase and a sale of energy based at least in part on the energy alert.

12. The method of claim 1 further comprising sending a command to close at least one relay associated with at least one energy consuming device based at least in part on the energy alert.

13. The method of claim 1 wherein the measurement of actual energy consumption comprises the measurement of actual energy consumption of a network of facilities.

14. The method of claim 13 wherein the network of facilities comprises one or more of buildings, residences, campuses, nanogrids, and microgrids associated with at least one of geographic area, facility owner, weather pattern, climate, utility, carbon market, energy market, power grid, power purchase agreement, and utility rate schedule.

15. An apparatus to manage an energy event, the apparatus comprising:

an energy search engine comprising computer hardware and configured to automatically receive in a continuous way a measurement of actual energy consumption;

the energy search engine further configured to receive energy information;

the energy search engine further configured to automatically calculate a continuous energy performance assessment based at least in part on the measurement of actual energy consumption and the energy information;

the energy search engine further configured to automatically generate energy management data based at least in part on the continuous energy performance assessment, the energy management data configured to provide an energy alert; and

the energy search engine further configured to automatically determine, based at least in part on the received continuous measurement of actual energy consumption, an impact of the energy management data.

16. The apparatus of claim 15 wherein automatically receiving in a continuous way the measurement of actual energy consumption comprises receiving the measurement of actual energy consumption at least every 15 minutes.

17. The apparatus of claim 15 wherein the energy information comprises at least one of demand management information, demand response information, price management information, and price response information.

18. The apparatus of claim 15 wherein the energy information comprises at least one of a request to manage energy, a demand response request, a utility tariff, a schedule of energy costs based on time of day, a schedule of energy costs based on amount of energy used, real-time energy pricing, a price at which energy was purchased, market price for energy, an energy cost budget, an energy usage budget, a request to manage energy based on cost per time period, a request to manage energy based on cost per unit of energy, and a request to manage energy based on power per time period.

19. The apparatus of claim 18 wherein the request to manage energy based on the cost per time period comprises a request to manage energy based on a threshold for one or more of cost/hour and cost/month.

20. The apparatus of claim 18 wherein the request to manage energy based on cost per unit of energy comprises a request to manage energy based on a threshold for one or more of cost/kWh and cost/kW at one or more times.

21. The apparatus of claim 18 wherein the request to manage energy based on power per time period comprises a request to manage energy based on a threshold for one or more of kW/hour and kW/month.

22. The apparatus of claim 18 wherein the request to manage energy is based at least in part on at least one of environmental factors, weather, varying demand side load requirements, grid imbalance, variable energy generating resources, loss of electrical energy generating capacity, varying loads,

availability of solar generated electrical energy, availability of wind generated electrical energy, and market price for energy.

23. The apparatus of claim 18 wherein the energy alert comprises at least one of energy savings recommendations and energy source planning, wherein the energy savings recommendations comprise at least one of load shedding and load shifting, and wherein the energy source planning comprises switching to an alternative energy source.

24. The apparatus of claim 15 wherein the energy search engine is further configured to send a message to a broadcast system based at least in part on the energy alert.

25. The apparatus of claim 15 wherein at least one of a purchase and a sale of energy is initiated based at least in part on the energy alert.

26. The apparatus of claim 15 wherein the energy search engine is further configured to send a command to close at least one relay associated with at least one energy consuming device based at least in part on the energy alert.

27. The apparatus of claim 15 wherein the measurement of actual energy consumption comprises the measurement of actual energy consumption of a network of facilities.

28. The apparatus of claim 27 wherein the network of facilities comprises one or more of buildings, residences, campuses, nanogrids, and microgrids associated with at least one of geographic area, facility owner, weather pattern, climate, utility, carbon market, energy market, power grid, power purchase agreement, and utility rate schedule.
