WO 2011/133653 A1

INHIBITORS OF ARGINASE AND THEIR THERAPEUTIC APPLICATIONS

[0001] The present application claims the benefit of priority of U.S. Provisional Applications No. 61/326,892, which was filed on April 22, 2010, and No. 61/413,202, which was filed on November 12, 2010, the entire disclosures which are incorporated by reference as if fully set forth herein.

BACKGROUND OF THE INVENTION

[0002] The present invention relates generally to inhibitors of arginase and their use for the treatment of pathological states. Two isoforms of arginase have been identified to date. arginase I (ARG I), that is expressed in the cytosole and arginase II (ARG II), that is expressed in mitochondria. The arginase enzymes together with the nitric oxide synthase (NOS) enzymes play an important role in regulating the levels of nitric oxide in cells and in the development of pathophysiological disease states.

[0003] The arginases are implicated in various pathological states. These include without limitation erectile dysfunction, pulmonary hypertension, hypertension, atherosclerosis, renal disease, asthma, T-cell dysfunction, ischemia reperfusion injury, neurodegenerative diseases, wound healing, and fibrotic diseases. Although the mechanism of action of arginase enzymes in these disease states is still a subject of ongoing research, several studies imply that the arginase enzymes are often upregulated during pathological disease states.

[0004] For example, it is postulated that upregulation of arginase activity results in reduced levels of arginine which in turn reduces the level of nitric oxide (NO) a physiologically important signaling molecule that is required for cell division, arterial vasodilation, regulation of blood flow and for controlling muscular and neurological signal transduction.

[0005] In addition to its role in regulating nitric oxide (NO) levels, arginase also affects production of critical polyamines such as putrescine, spermidine and spermine. As arginase catabolizes L-arginine it produces ornithine. Ornithine is subsequently converted to putrescine, spermidine and spermine via ornithine decarboxylase, spermidine synthase and spermine synthase respectively. Thus, the arginase enzymes control physiological signaling

events by controlling the intracellular levels of polyamine signal transducers. See Wang, J-Y; and Casero, Jr., R. A., Ed; Humana Press, Totowa, NJ, 2006. Ornithine also provides an alternative biosynthetic pathway to proline and thereby supports collagen production (Smith, R. J.; Phang, J. M., The importance of ornithine as a precursor for proline in mammalian cells. *J. Cell. Physiol.* 1979, 98, 475–482. Albina, J. E.; Abate, J. A.; Mastrofrancesco, B. Role of ornithine as a proline precursor in healing wounds. *J. Surg. Res.* 1993,55, 97–102.)

[0006] Given the role of arginase in various pathological states, the present invention provides Formula I and Formula II compounds as inhibitors of arginase activity, as well as methodologies for using the inventive compounds as therapeutics.

SUMMARY OF THE INVENTION

[0007] The present invention provides certain boron-containing compounds according to Formulae I and II as described herein that are inhibitors of arginase activity. The invention also provides methods for using the inventive compounds in treatment. In one embodiment, therefore, inventive compounds and their pharmaceutically acceptable formulations are provided as therapeutic agents capable of inhibiting arginase activity. Compounds and pharmaceutical formulations in accordance with this invention are useful for treating a number of diseases and conditions, including but not limited to pulmonary hypertension, erectile dysfunction (ED), hypertension, atherosclerosis, renal disease, asthma, T-cell dysfunction, ischemia reperfusion injury, neurodegenerative diseases, wound healing, and fibrotic diseases.

[0092] The compound of the invention can exist in various isomeric forms, including configurational, geometric, and conformational isomers, including, for example, *cis*- or *trans*-conformations. Compounds of the present invention may also exist in one or more tautomeric forms, including both single tautomers and mixtures of tautomers. The term “isomer” is intended to encompass all isomeric forms of a compound of this invention, including tautomeric forms of the compound.

[0093] The compounds of the present invention may also exist in open-chain or cyclized forms. In some cases one or more of the cyclized forms may result in loss of water. The

specific composition of the open-chain and cyclized forms may be dependent on how the compound is isolated, stored or administered. For example the compound may exist primarily in an open-chained form under acidic conditions but cyclize under neutral conditions. All forms are included in the invention.

[0094] Some compounds described here can have asymmetric centers and therefore exist in different enantiomeric and diastereomeric forms. A compound of the invention can be in the form of an optical isomer or a diastereomer. Accordingly, the invention encompasses compounds of the invention and their uses as described herein in the form of their optical isomers, diastereoisomers and mixtures thereof, including a racemic mixture. Optical isomers of the compounds of the invention can be obtained by known techniques such as asymmetric synthesis, chiral chromatography, simulated moving bed technology or via chemical separation of stereoisomers through the employment of optically active resolving agents.

[0095] Unless otherwise indicated, "stereoisomer" means one stereoisomer of a compound that is substantially free of other stereoisomers of that compound. A typical stereomerically pure compound comprises greater than about 80% by weight of one stereoisomer of the compound and less than about 20% by weight of other stereoisomers of the compound, for example greater than about 90% by weight of one stereoisomer of the compound and less than about 10% by weight of the other stereoisomers of the compound, or greater than about 95% by weight of one stereoisomer of the compound and less than about 5% by weight of the other stereoisomers of the compound, or greater than about 97% by weight of one stereoisomer of the compound and less than about 3% by weight of the other stereoisomers of the compound.

[0096] If there is a discrepancy between a depicted structure and a name given to that structure, then the depicted structure controls. Additionally, if the stereochemistry of a structure or a portion of a structure is not indicated with, for example, bold or dashed lines, the structure or portion of the structure is to be interpreted as encompassing all stereoisomers of it. In some cases, however, where more than one chiral center exists, the structures and names may be represented as single enantiomers to help describe the relative stereochemistry.

Those skilled in the art of organic synthesis will know if the compounds are prepared as single enantiomers from the methods used to prepare them.

Exemplary (C₃-C₆)heteroaryl groups without limitation include pyridiny, benzimidazolyl, benzothiazol, imidazole, 1,2,3-triazole, 1,2,4-triazole, tetrazole, pyrimidine, imidazo[1,2-a]pyridine, oxazole, isoxazole, and furan. In an embodiment of the invention, the -(C₁-C₆)alkylene- can be methylene, or ethylene.

[0113] In some embodiments, R³ and R⁴ together with the boron atom to which they are bound form a 5- or 6-membered ring that is fully or partially saturated, and that optionally contains 1-3 additional heteroatom ring members selected from O, S, and N. The ring is optionally substituted with one or more substituents as defined herein for R' and R''.

[0114] Cyclic structures of this type are useful as prodrug forms of the inventive compounds by virtue of R³ and R⁴ forming a cyclic ester from diols. A useful diol in this regard is pinacol, and another diol is pinanediol. Other diols include but are not limited to neopentylglycol, 1,2-ethanediol, 1,2-propoanediol, 1,3-propanediol, 2,3-butanediol, 1,2-diisopropylethanediol and 5,6-decanediol.

[0115] Also contemplated are compounds wherein the boronic acid moiety in Formula I is esterified with a sugar. Compounds of this class are also useful as prodrugs. Suitable sugars include without limitation monosaccharides and disaccharides, for example, sugars selected from the group consisting of glucose, mannitol and sorbitol.

[0116] In other embodiments, R² is a (C₃-C₁₄)-cycloalkyl, optionally substituted by 1-3 substituents as defined hereinabove. Exemplary cycloalkyl groups are cyclohexyl and

cyclopentyl. Alternatively, R² is a (C₃-C₁₄)heterocycloalkyl, such as five- or six-membered heterocycloalkyl. Examples of Formula I compounds of these embodiments include those in the following table, wherein R' is defined as above, R has the same meaning as R', and W is a heteroatom as defined above:

[0117] It should be understood that 2-amino-4-borono-2-methylbutanoic acid is excluded from Formula I.

[0118] Exemplary Formula I compounds include without limitation compounds mentioned in Table 1 below. While some exemplary compounds are depicted with stereochemistry, it should be understood that the invention includes all possible stereoisomers, such as diastereomers, of the compounds.

FORMULA II COMPOUNDS

[0120] The present invention also relates to compounds according to Formula II.

[0121] For compounds that conform to Formula II, D is selected from the group consisting of straight or branched (C₃-C₅)alkylene, straight or branched (C₂-C₈)alkenylene, straight or branched (C₂-C₈)alkynylene, (C₃-C₁₄)arylene, and (C₃-C₁₄)cycloalkylene. In one embodiment one or more -CH₂- groups in D are optionally and independently replaced with a moiety selected from the group consisting of O, NR', S, SO, SO₂, and CR'R". However, no two adjacent -CH₂- groups in D are simultaneously replaced by O, NR', S, SO, or SO₂.

[0122] According to one embodiment, D conforms to formula -L¹-L²-CH₂-CH₂-, -CH₂-L¹-L²-CH₂-, -CH₂-CH₂-L¹-L²-, -L¹-CH₂-CH₂-L²-, -L¹-CH₂-L²-CH₂-, or -CH₂-L¹-CH₂-L²-.

While variables L¹ and L² are each independently selected from the group consisting of O, NR', S, SO, SO₂, and CR'R", when -L¹ and -L² are adjacent to each other L¹ and L² are not simultaneously O, NR', S, SO or a SO₂ group.

[0123] For certain Formula II compounds, any two adjacent -CH₂- groups in D optionally represent two members of a (C₃-C₁₄)-cycloalkylenyl group. Thus, for instance, when D is propylene the C₂ and C₃ atom can each omit a hydrogen atom so as to couple a -CH₂- group to form a cyclopropyl ring as illustrated by the following moiety .

[0124] Variable D is advantageously a three to five atom linker. A particularly advantageous embodiment provides for D as a four atom linker as described herein.

[0125] For formula II compounds, substituent X is selected from the group consisting of (C₃-C₁₄)-cycloalkylene and a (C₃-C₁₄)heterocycloalkylene. Variable M is selected from the group consisting of a bond, (C₁-C₆)alkylene-, -O-, -C(O)-, -C(S)-, -C(O)NH-, -C(S)NH-, -S-, -S(O)-, -S(O)₂-, -NR'-, and -C=NR¹¹-.

[0126] Substituent Y in Formula II is selected from the group consisting of H, (C₁-C₁₄)alkyl, -NR'R'', hydroxy(C₁-C₆)alkylene, (C₃-C₁₄)-cycloalkyl, (C₃-C₁₄)-cycloalkyl-(C₁-C₆)alkylene, (C₃-C₁₄)aryl, (C₃-C₁₄)aryl-(C₁-C₆)alkylene, (C₃-C₁₄)heterocycloalkyl, (C₃-C₁₄)heterocycloalkyl-(C₁-C₆)alkylene, (C₃-C₁₄)heteroaryl, (C₃-C₁₄)heteroaryl-(C₁-C₆)alkylene, (C₃-C₁₄)heteroaryl-(C₃-C₆)heterocycloalkylene-, (C₃-C₁₄)aryl-(C₃-C₁₄)heterocycloalkylene-, (C₃-C₁₄)-aryl-(C₁-C₆)alkyl-(C₃-C₁₄)heterocycloalkylene-, (C₃-C₁₄)heteroaryl-(C₁-C₆)alkyl-(C₃-C₁₄)heterocycloalkylene-, and (C₃-C₁₄)heterocycloalkyl-(C₁-C₆)alkyl-(C₃-C₁₄) heterocycloalkylene-.

[0127] For certain Formula II compounds, D is butylene, X is a (C₃-C₁₄)heterocycloalkylene, M is selected from the group consisting of a bond, (C₁-C₆)alkylene-, -O-, -C(O)-, -C(S)-, -C(O)NH-, -C(S)NH-, -S-, -S(O)-, -S(O)₂-, -NR'-, and -C=NR¹¹- and Y is selected from the group consisting of (C₃-C₁₄)heteroaryl, (C₃-C₁₄)cycloalkyl, (C₃-C₁₄)aryl, (C₃-C₁₄)aryl-(C₁-C₆)alkylene and (C₃-C₁₄)heteroaryl-(C₁-C₆)alkylene. According to another embodiment, however, M is selected from the group consisting of -C(O)-, -C(S)-, -C(O)NH-, -C(S)NH-, -S(O)₂- and -NR'-.

[0128] For certain Formula II compounds when M is -NR'-, substituent R' can be a methylene group or an ethylene group. Alternatively, R' is -C(O)-(C₁-C₈)alkylene, such as -C(O)-methylene.

[0129] Exemplary Formula II compounds include without limitation those illustrated in Table 1-A below. While some exemplary compounds are depicted with stereochemistry, it should be understood that the invention includes all possible stereoisomers, such as diastereomers, of the compounds.

[0139] Inventive compositions suitable for oral use may be prepared according to any method known to the art for the manufacture of pharmaceutical compositions. For instance, liquid formulations of the inventive compounds can contain one or more agents selected from the group consisting of sweetening agents, flavoring agents, coloring agents and preserving agents in order to provide pharmaceutically elegant and palatable preparations of the arginase inhibitor.

[0140] For tablet compositions of Formula I or Formula II compounds, the active ingredient in admixture with non-toxic pharmaceutically acceptable excipients is used for the manufacture of tablets. Examples of such excipients include without limitation inert diluents, such as calcium carbonate, sodium carbonate, lactose, calcium phosphate or sodium phosphate; granulating and disintegrating agents, for example, corn starch, or alginic acid; binding agents, for example starch, gelatin or acacia, and lubricating agents, for example magnesium stearate, stearic acid or talc. The tablets may be uncoated or they may be coated by known coating techniques to delay disintegration and absorption in the gastrointestinal tract and thereby to provide a sustained therapeutic action over a desired time period. For example, a time delay material such as glyceryl monostearate or glyceryl distearate may be employed.

[0141] Formulations for oral use may also be presented as hard gelatin capsules wherein the active ingredient is mixed with an inert solid diluent, for example, calcium carbonate, calcium phosphate or kaolin, or as soft gelatin capsules wherein the active ingredient is mixed with water or an oil medium, for example peanut oil, liquid paraffin or olive oil.

[0142] For aqueous suspensions the inventive compound is admixed with excipients suitable for maintaining a stable suspension. Examples of such excipients include without

[0143] Oral suspensions can also contain dispersing or wetting agents, such as naturally-occurring phosphatide, for example, lecithin, or condensation products of an alkylene oxide with fatty acids, for example polyoxyethylene stearate, or condensation products of ethylene oxide with long chain aliphatic alcohols, for example heptadecaethyleneoxycetanol, or condensation products of ethylene oxide with partial esters derived from fatty acids and a hexitol such as polyoxyethylene sorbitol monooleate, or condensation products of ethylene oxide with partial esters derived from fatty acids and hexitol anhydrides, for example polyethylene sorbitan monooleate. The oily suspensions may contain a thickening agent, for example beeswax, hard paraffin or cetyl alcohol.

[0145] Sweetening agents such as those set forth above, and flavoring agents may be added to provide palatable oral preparations. These compositions may be preserved by the addition of an anti-oxidant such as ascorbic acid.

[0146] Dispersible powders and granules suitable for preparation of an aqueous suspension by the addition of water can provide the active ingredient in admixture with a dispersing or wetting agent, suspending agent and one or more preservatives. Suitable dispersing or wetting agents and suspending agents are exemplified by those already mentioned above. Additional excipients, for example sweetening, flavoring and coloring agents, may also be present.

[0147] Pharmaceutical compositions of the invention may also be in the form of oil-in-water emulsions. The oily phase may be a vegetable oil, for example olive oil or arachis oil, or a mineral oil, for example liquid paraffin or mixtures of these. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose any bland fixed oil may be employed including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid find use in the preparation of injectables.

[0149] Compounds that conform to Formula I or Formula II may also be administered in the form of suppositories for rectal administration of the drug. These compositions can be prepared by mixing the drug with a suitable non-irritating excipient which is solid at ordinary temperatures but liquid at the rectal temperature and will therefore melt in the rectum to release the drug. Examples of such materials are cocoa butter and polyethylene glycols.

SYNTHESIS OF COMPOUNDS

[0151] Compounds of the invention are prepared using any number of the general methodologies described hereinbelow and can be adapted to the synthesis of compounds not

specifically described. The choice of an appropriate synthetic methodology is guided by the choice of the Formula I or Formula II compound desired and the nature of functional groups present in the intermediate and final product. Thus, selective protection/deprotection protocols may be necessary during synthesis depending on the specific functional groups desired and protecting groups being used. A description of such protecting groups and how to introduce and remove them is found in: *Protective Groups in Organic Synthesis*, Third Edition, T. W. Green and P. G. M. Wuts, John Wiley and Sons, New York, **1999**. Illustrative of the general synthetic methodologies used to make Formula I or Formula II compounds are those set forth below.

I. SYNTHESIS OF FORMULA I COMPOUNDS

[0152] Formula I compounds where D-B(OR³)(OR⁴) is -CH₂-L₁-L₂-CH₂-B(OH)₂ and R₂ is a substituted alkyl group, can be conveniently prepared using a glycine benzophenone imine ester as illustrated in Scheme A set forth below. In this method the starting amino acid imine **A-1** can be purchased or prepared by reacting benzophenone imine with the desired amino acid ester (O'Donnell, M. J., *Aldrichimica Acta*, **2001**, 34, 3-15). Alkylation of **A-1** in Scheme A with electrophile **A-2** using typical alkylation conditions such as lithium bis(trimethylsilyl)amide, LDA or sodium hydride in a polar aprotic solvent such as THF provides the monoalkylated product **A-3**. Similar reaction conditions can be used to introduce the second substituent to provide intermediate **A-4**. Subsequent hydrolysis provides the target compound **A-5** (**Scheme A**).

[0153] In some instances it may be preferable or necessary to build one or both amino acid substituents in a multi-step process. An example of this is provided in Scheme A where allyl bromide is used in the second alkylation step giving intermediate **A-6** under alkylating conditions described above. Following removal of the benzophenone and subsequent protection of the amine, the terminal olefin is oxidized to give aldehyde intermediate **A-8**.

[0154] The highly versatile aldehyde group can be utilized to prepare a wide variety of target compounds. One convenient use is in reductive amination reactions as shown in Scheme A. Here, treatment with the desired amine and a reducing agent like sodium cyanoborohydride gives amine intermediate **A-9**, which after hydrolysis, provides the target

compounds **A-10**. Depending on the specific functional group desired, certain protecting groups may be required.

[0155] Scheme A

[0156] Alternatively, in the case where a protected boronic acid electrophile is not available or is incompatible with synthetic protocol, Formula I compounds can be synthesized by replacing electrophile **A-2** with a terminal olefin followed by the introduction of boron in a later step following alkylation using hydroboration chemistry.

[0157] For enantioselective synthesis of Formula I compounds, a variety of different synthetic approaches may be used. Accordingly, in one embodiment an optically pure ketone is used in place of the achiral benzophenone. See, for example, Tabcheh, et al. *Tetrahedron* **1991**, *47*, 4611-4618 and Belokon et al. *Angew Chem, Int Ed* **2001**, *40*, 1948-1951.

[0158] Alternatively, asymmetric induction can be achieved in the second alkylation reaction by using a chiral catalyst. See, for example, Ooi, et al. *Tet Lett.* **2004**, *45*, 1675-1678; Ohshima et al. *J. Am. Chem. Soc.* **2009**, *125*, 11206-11207; and, Belokon et al. *Tetrahedron* **2001**, *57*, 2491-2498.

[0159] In yet another embodiment, enantioselectivity can be introduced by the use of an optically pure oxazinone to synthesize Formula I compounds (Dastlik, K. A.; Sundermeier, U., Johns, D. M.; Chen, Y.; Williams, R. M. *Synlett* **2005**, *4*, 693-696). This approach is illustrated in Scheme B.

[0160] Scheme B

[0161] Here, the optically active oxazinone **B-4** is used to stereo-selectively direct sequential alkylations to form intermediate **B-7**. These alkylations can be carried out under reaction conditions that are specific for the electrophile being used (e.g. **B-2**, **B-3**, and **B-6**). Alternative approaches to synthesize **B-5** and **B-7** include the aldol reaction that involves the coupling of an aldehyde with the oxazinone followed by reduction of the resulting double bond. The inventive compounds are obtained by decomposition of the di-substituted

oxazinone followed by removal of the protecting groups. Thus, cleaving the oxazinone heterocycle via hydrogenation or using an alkali metal/ammonia reduction followed by treatment of intermediate **B-8** with aqueous acid provides the target disubstituted amino acid **B-9**.

[0162] If a butaneboronic acid is desired as one of the substituents in the final product electrophile, **B-2** or **B-3** can be used as an alkylating agent. **B-2** can be easily prepared from **B-1** by treatment with pinacol in THF. If iodo-intermediate **B-3** is desired, it can be prepared from the corresponding bromide via treatment with sodium iodide in acetone.

[0163] Alternatively, synthesis entails modification of one or both substituents after the alkylation steps. This may be required when the desired functionality in the final product is not compatible with the alkylation reaction conditions or if the desired substituent is not conveniently introduced as an electrophile due to limited reactivity. An example is illustrated in Scheme C, wherein allyl iodide is used as an efficient alkylating agent then further modified after cleavage of the oxazinone ring system. In this example, the allyl intermediate **C-1** is treated with lithium in ammonia to remove the oxazinone ring. The resulting acid can be protected as ester **C-3** and subsequently treated with ozone to give the corresponding aldehyde.

[0164] The aldehyde (**C-4**) is a very flexible functional group and can be used in many types of reactions to make a wide variety of different analogs. As an example, it can be used in reductive amination reactions to prepare compounds with amine substituents R1 and R2 as in intermediate **C-5**. The final target compounds (**C-6**) can be obtained after deprotection of the ester, amino and boronic acid moieties.

[0165] Scheme C

[0166] In another embodiment, syntheses of some Formula I compounds employ the Ugi reaction (Doemling, A., *Chem. Rev.* **2006**, *106*, 17-89. This method is illustrated in Scheme D. In the Ugi reaction a ketone or aldehyde (**D-3**) is treated with an isocyanate such as tert-butyl isocyanate and an amine source like ammonium acetate to give directly the amino acid derivative with the carboxylic acid and amine protected as a tert-butylamide and acetamide respectively. In this reaction different isocyanates and amine sources can be used depending on the desired amine and carboxylic acid protecting groups desired. If optically active products are desired chiral optically pure isocyanates and and/or amine sources can be used. The reactions using these reagents may be enantioselective, or at least provide diastereomeric mixtures of products that can be easily separated.

[0167] Scheme D

[0168] The synthesis of key intermediate **D-3** can be completed using a wide variety of methods. One very convenient method utilizes carboxylic acid **D-1**. In this method the carboxylic acid is activated and coupled with methoxymethylamine to form Weinreb amide **D-2**. This can be completed using a wide variety of coupling reagents such as EDC, DCC or PyBOP, or directly from the acid chloride of **D-1**. The Weinreb amide can be converted to the desired ketone by reacting it with the appropriate Grignard reagent to give intermediate **D-3**.

[0169] After the Ugi reaction is complete, the terminal olefin can be treated with a borane source such as pinacolborane to introduce the boronic acid moiety. Final deprotection of intermediate **D-5** gives target compound **D-6**.

[0170] Many examples with an aminomethylene substituent in the α -position can be conveniently prepared using the method illustrated in Scheme E. Here an aminomalonate starting material such as **E-1**, where the amine is protected as a benzyl carbamate (Cbz) and the acids are protected as esters, is used to generate disubstituted amino acid derivative **E-2** via alkylation with 4-bromobutene. Selective hydrolysis of the diester with potassium hydroxide in ethanol gives acid ester **E-3**. Selective reduction of the carboxylic acid using a chloroformate and sodium borohydride gives alcohol **E-4** which can be protected using dimethoxypropane and an organic acid such as toluenesulfonic acid. Hydroboration of **E-5**

with pinacolborane gives **E-6**, which after deprotection provides alcohol **E-7**. Oxidation of the alcohol provides the intermediate aldehyde **E-8**, which after reductive amination and final deprotection gives the target compound **E-11**.

[0171] Scheme E

[0172] As an alternative to the method in Scheme E where the benzyl carbamate is used as the amine protecting group, the corresponding *t*-butyl carbamate (Boc) protected amino malonate derivative can also be used. Here, as illustrated in Scheme F, diethyl 2-(*tert*-butoxycarbonylamino)malonate **F-1** is alkylated with 4-bromobutene to give the disubstituted malonate intermediate **F-2**. Selective hydrolysis of the diester using basic conditions such as potassium hydroxide in ethanol gives mono acid **F-3**. Reduction of the carboxylic acid using ethyl chloroformate and sodium borohydride gives the primary alcohol which can be conveniently protected as an acetate using standard conditions such as acetic anhydride and DMAP. If desired, many alternative protecting groups can be used. This group is simply introduced to facilitate the subsequent hydroboration reaction that provides intermediate **F-6**.

Once the hydroboration reaction is complete, the acetate can be removed and the resulting alcohol (**F-7**) can be oxidized to the corresponding aldehyde (**F-8**) and used in reductive amination reactions with amine **F-9** to give protected products **F-10**. Deprotection using aqueous acid then gives the desired products **F-11**. In addition to reductive amination reactions, intermediate aldehyde **F-8** can be used in a wide variety of reactions to produce desired substituents. The use of aldehydes to form heterocycles or other products is well known to those skilled in the art of organic synthesis.

[0371] While under an argon atmosphere, a solution of oxalyl chloride (1.46 g, 0.88 mL, 11.6 mmol) in dichloromethane (15 mL) was cooled to -78 °C and treated with dimethyl sulfoxide (1.8 g, 1.64 mL, 23.2 mmol) and stirred for 10 minutes. To this mixture ethyl 2-(tert-butoxycarbonylamino)-2-(hydroxymethyl)-6-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)hexanoate (2.4 g, 5.78 mmol) in anhydrous dichloromethane (15 mL) was added and the mixture was stirred for 30 minutes. The reaction mixture was quenched by adding triethylamine (3.5 g, 4.8 mL, 34.7 mmol) at -78 °C and slowly warming the reaction mixture to room temperature. The mixture was diluted with dichloromethane (25 mL) and washed successively with water (2 x 25 mL) and saturated aqueous sodium chloride (25 mL). Organic layer was dried over magnesium sulfate, filtered and evaporated to dryness. The resulting residue was purified using a combiflash system (40 g column, eluted with 20-40% ethyl acetate in heptanes) to give ethyl 2-(tert-butoxycarbonylamino)-2-formyl-6-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)hexanoate (1.35 g, 57%). ¹HNMR (CDCl₃) δ 9.58 (s, 1 H), 5.64 (bs, 1 H), 4.25 (m, 2 H), 2.13 (m, 2 H), 1.45 (m, 9 H), 1.28 (m, 4 H), 1.24 (s, 12 H), 0.88 (t, *J* = 6.4 Hz, 3 H), 0.77 (t, *J* = 7.9 Hz, 2 H). [0372] A slurry of ethyl 2-(tert-butoxycarbonylamino)-2-formyl-6-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)hexanoate (172 mg, 0.42 mmol) and propylamine (40 μL, 0.49

mmol, 1.3 equiv) in 1,2-dichloroethane (3 mL) was treated with sodium triacetoxyborohydride (352 mg, 1.66 mmol, 4 equiv). Acetic acid (2 drops, ca 3-5 equiv) was added and the mixture stirred at room temperature for 17 hours then 60 °C for 1 hour. Once the reaction was complete, saturated aqueous sodium bicarbonate was added and the solution was extracted with dichloromethane. II. SYNTHESIS OF FORMULA II COMPOUNDS

[0544] In addition to the foregoing methodologies that are generally applicable to all compounds described herein, the present invention also provides methodologies that are more specific to compounds of Formula II. Thus, in one embodiment, a Formula II compound synthesis is accomplished using the Ugi reaction (Doemling, A., *Chem. Rev.* **2006**, *106*, 17-89). This method is illustrated in Scheme A-I. Thus, treating a ketone or an aldehyde (**A-3**), with an isocyanate such as tert-butyl isocyanate and an amine source like ammonium acetate gives an amino acid derivative in which the carboxylic acid is protected as a tert-butylamide and the α-amine group is protected as an acetamide. By using different isocyanates and amines as starting materials, therefore, a series of amino acid precursors are obtained in which the amine and carboxylic acid groups are orthogonally protected. If optically active products are desired chiral optically pure isocyanates and and/or amine sources can be used. The reactions using these reagents may be enantioselective or, at least, provide diastereomeric mixtures of products that can be resolved using analytical separation techniques known in the chemical art.

[0545] Scheme A-I

[0546] The synthesis of key intermediate **A-3** shown in Scheme A-1 can be achieved using several methods. One such method utilizes an activated carboxylic acid **A-1** and methoxymethylamine to form a Weinreb amide **A-2**. Alternatively, the carboxylic acid is coupled to the amine using a variety of coupling reagents such as EDC, DCC or PyBOP, or directly using the acid chloride of **A-1**. The Weinreb amide is then converted to the desired ketone by reacting it with an appropriate Grignard reagent to give the desired intermediate **A-3** which is reacted with an appropriate isocyanate in the presence of an amine such as ammonium acetate to give **A-4**.

[0547] Reaction of the terminal olefin of **A-4** with a borane source such as pinacolborane gives the protected boronic acid derivative (**A-5**), which upon deprotection gives the target compound, an α -borono amino acid **A-6**.

[0548] Those skilled in the art of organic synthesis will recognize that several methods exist for the asymmetric synthesis of substituted amino acids. See, for example, Vogt, H. and Brase, S. *Organic & Biomolecular Chemistry* **2007**, *5*, 406-430.

[0549] In another embodiment, Formula II compounds are synthesized using the general protocol illustrated in Scheme B-I. Thus, reaction of the ketone intermediate **B-1** (prepared using methods outlines in Scheme A-I), with a chiral auxiliary such as (R) or (S)-*N-tert*-

butanesulfinamide (**B-2**) in the presence of a Lewis acid like $\text{Ti}(\text{OEt})_4$ results in the formation of the corresponding *tert*-butanesulfinyl imine **B-3**. See Ellman, J. A.; Owens, T. D. and Tang, T. P. *Acc. Chem. Res.* **2002**, *35*, 984-995.

[0550] The stereoselective introduction of cyanide is achieved by reacting *tert*-butanesulfinyl imine **B-3** with Et_2AlCN . If the corresponding aminonitrile product **B-4** is obtained as a mixture of two isomers, then the isomeric mixture is resolved using chromatography. Subsequent hydroboration of the terminal double bond using a wide variety of borane reagents, such as pinacol borane in the presence of an iridium catalyst gives the corresponding pinacol borane intermediate **B-6**. Hydrolysis of intermediate **B-6** using a strong acid like 6 N HCl converts the cyano group to a carboxylic acid group and deprotects the dioxaborane moiety to give the target compound **B-7**.

[0551] Scheme B-I

[0552] Those having skill in the art will recognize that the starting materials and reaction conditions may be varied, the sequence of the reactions altered, and additional steps can be employed to synthesize compounds according to Formula II, as demonstrated by the following examples. As stated above, in some cases, protection of certain reactive functionalities may be necessary to achieve some of the above transformations. In general, the need for such protecting groups as well as the conditions necessary to attach and remove such groups will be apparent to those skilled in the art of organic synthesis.

The preparation of compounds of the present invention is illustrated further by the following examples, which are not to be construed as limiting the invention in scope or spirit to the specific procedures and compounds described in them.

[0637] In a 500 mL round-bottomed flask under a positive pressure of nitrogen, was added a methylene chloride (125 mL) solution of (*R*)-*N*-Boc-pyrrolidine-3-carboxylic acid (7.00 g,

0.0325 mol). This solution was cooled to 0 °C using an ice/water bath and treated sequentially with, *N*-(3-dimethylaminopropyl)-*N'*-ethylcarbodiimide hydrochloride (7.48 g, 0.0390 mol) and 1-hydroxybenzotriazole (5.29 g, 0.0391 mol) in single portions. Following the addition of the coupling agents, the reaction mixture became cloudy, but upon further stirring a clear solution was obtained. The reaction mixture was stirred at 0 °C for 20 min then charged with *N,O*-dimethylhydroxylamine hydrochloride (4.78 g, 0.0490 mol) and triethylamine (13.5 mL, 0.0968 mol). The cooling bath was removed and the reaction mixture was allowed to warm to room temperature with stirring over a period of 1 h. The resulting solution was diluted with dichloromethane (600 mL) and 1 N HCl (1000 mL), mixed thoroughly and separated. The organic layer was washed with saturated aqueous sodium bicarbonate (300 mL) and saturated aqueous sodium chloride (300 mL), then dried over Na₂SO₄, filtered and concentrated to give *tert*-butyl (3*R*)-3-[methoxy(methyl)carbamoyl]pyrrolidine-1-carboxylate as a colorless oil (7.00 g; 83%). ¹H NMR (400 MHz, CDCl₃) δ 3.73 (s, 3 H), 3.60 - 3.37 (m, 4 H), 3.21 (s, 3 H), 2.35 - 2.09 (m, 3 H) 1.47 (s, 9 H); ESI MS found for C₁₂H₂₂N₂O₄ *m/z* [159.1 (M + 1-Boc)]

Step 2: tert-Butyl (3R)-3-hex-5-enoylpyrrolidine-1-carboxylate

[0638] In a 500 mL single necked round bottomed flask, a solution of *tert*-butyl (3*R*)-3-[methoxy(methyl)carbamoyl]pyrrolidine-1-carboxylate (7.00 g, 27.1 mmol) in tetrahydrofuran (100 mL) was cooled to 0 °C and treated with 0.5 M THF solution of 3-butenylmagnesium bromide (130 mL, 65 mmol) via a pressure equalizing addition funnel over a period of 20 minutes. Once the addition was complete, the cooling bath was removed and the mixture was allowed to warm to room temperature and stir for an additional 4 h. The reaction mixture was carefully quenched with 1 N HCl (300 mL) and stirred for an additional 20 min. The aqueous layer was extracted with ethyl acetate (3 x 200 mL) and the combined organic layers were dried over Na₂SO₄, filtered and concentrated to a yellow oil. Purification of the crude product by flash column chromatography (silica gel, 10% ethyl acetate in hexanes) afforded *tert*-butyl (3*R*)-3-hex-5-enoylpyrrolidine-1-carboxylate (6.62 g; 96%) as a

light yellow oil. $^1\text{H NMR}$ (400 MHz, CDCl_3) δ 5.73 - 5.69 (m, 1 H), 4.99 - 4.91 (m, 2 H), 3.61 - 3.42 (m, 2 H), 3.13 - 3.05 (m, 1 H), 2.50 (t, $J = 7.2$ Hz, 2 H), 2.26 (q, $J = 7.2$ Hz, 2 H), 2.11 - 1.90 (m, 3 H), 1.38 (s, 9 H); ESI MS found for $\text{C}_{14}\text{H}_{23}\text{NO}_3$ m/z [154.1 (M+1-Boc)].

Step 3: 2-Acetamido-N-tert-butyl-2-[(3R)-1-tert-butylcarboxylpyrrolidin-3-yl]hex-5-enamide

[0639] A solution of *tert*-butyl (3*R*)-3-hex-5-enoylpyrrolidine-1-carboxylate (1.00 g, 3.95 mmol), ammonium acetate (761 mg, 9.87 mmol) and *tert*-butyl isocyanide (2 mL, 30 mmol) in 2,2,2-trifluoroethanol (2 mL) was sealed in a 10 mL microwave vial. The reaction mixture was irradiated in a CEM microwave at 85 °C for 1.5 h. After cooling to room temperature, the solution was diluted with ethyl acetate (75 mL) and washed with saturated aqueous sodium bicarbonate (30 mL), water (30 mL) and saturated aqueous sodium chloride (30 mL). The organic layer was dried over Na_2SO_4 , filtered and concentrated. Purification by flash column chromatography (silica gel, eluting with 20% ethyl acetate in hexanes) afforded recovered starting material (0.265 g, 27%) and 2-acetamido-*N-tert*-butyl-2-[(3*R*)-1-*tert*-butylcarboxylpyrrolidin-3-yl]hex-5-enamide as a mixture of diastereomers (1.06 g, 68%); ESI MS found for $\text{C}_{21}\text{H}_{37}\text{N}_3\text{O}_4$ m/z .

After 15 min, 4,4,5,5-tetramethyl-1,3,2-dioxaborolane (600 μL , 4 mmol) was added in a

single portion via syringe. After an additional 5 min at 0 °C the solution was warmed to room temperature and stirred for an additional 15 min. The reaction was then cooled once more in an ice/water bath and stirred for 10 min. From a separate flask, a THF solution (4 mL) of 2-acetamido-*N*-*tert*-butyl-2-[(3*R*)-1-*tert*-butylcarboxylpyrrolidin-3-yl]hex-5-enamide (1.06 g, 2.68 mmol) in tetrahydrofuran (4 mL) was transferred via syringe into the reaction mixture while it continued to stir at 0 °C for 10 minutes. The cold reaction mixture is then allowed to warm to room temperature and stirred for an additional 4 hours, prior to quenching the reaction by pouring it into a solution of saturated aqueous sodium bicarbonate (20 mL) and ethyl acetate (20 mL). After extraction, the organic layer was separated and the aqueous layer was further extracted using ethyl acetate (2 x 20 mL). The combined organic extracts were dried over Na₂SO₄, filtered and concentrated to afford *tert*-butyl (3*R*)-3-[1-acetamido-1-(*tert*-butylcarbamoyl)-5-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)pentyl]pyrrolidine-1-carboxylate (1.46 g) as an oil, which was used without additional purification. To this solution was added a 6M aqueous solution of hydrogen chloride (10 mL) in a single portion and the reaction was heated under refluxing conditions for 18 h. At the end of 18 hours the reaction mixture was cooled to room temperature prior to dilution with water (10 mL). The aqueous layer was washed with ethyl acetate (20 mL) and concentrated *in vacuo* prior to lyophilization to afford (R)-2-amino-6-borono-2-((R)-pyrrolidin-3-yl)hexanoic acid dihydrochloride (0.657 g) as a mixture of diastereomers. After continued bubbling for 10 min the argon was replaced with a slow stream of hydrogen. After 1.5 h the reaction was complete (reaction monitored by TLC for the disappearance of starting material (50% ethyl acetate in heptane, R_f 0.3) and solution was purged with argon, filtered through the Celite 545 and the filter cake washed with methanol. The methanol solution was concentrated and collected solvents evaporated to give crude 2-acetamido-N-tert-butyl-2-(piperidin-4-yl)-6-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)hexanamide (2.20 g 96%) which was used without further purification (contained approximately 10% product with loss of boronic acid protecting group). ^1H NMR (CDCl_3 , 300 MHz) δ 6.95 (s, 1 H), 5.53 (s, 1 H), 3.09 (bt, $J = 11.1$ Hz, 2 H), 2.80 (ddd, $J_1 = 14.1$ Hz, $J_2 = 13.5$ Hz, $J_3 = 4.5$ Hz, 1 H), 2.65 - 2.48 (m, 2 H), 2.26 (dddd, $J_1 = 12.0$ Hz, $J_2 = 12.0$ Hz, $J_3 = 3.0$ Hz, $J_4 = 2.7$ Hz, 1 H), 2.00 - 1.90 (m, 1 H), 1.98 (s, 3 H), 1.78 - 1.63 (m, 2 H), 1.45 - 1.00 (m, 5 H), 1.36 (s, 9 H), 1.21 (s, 8 H), 0.73 (t, $J = 7.5$ Hz, 2 H).

Step 6: 2-acetamido-2-(1-benzylpiperidin-4-yl)-N-tert-butyl-6-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)hexanamide

[0776] A solution of 2-acetamido-N-tert-butyl-2-(piperidin-4-yl)-6-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)hexanamide (480 mg, 1.10 mmol) and benzaldehyde (138 mg, 131 μ L, 1.30 mmol) in 1,2-dichloroethane (1 mL) was stirred for 20 minutes then treated with sodium triacetoxyborohydride (420 mg, 2.20 mmol). After 5 hours, the reaction mixture was quenched with saturated aqueous sodium bicarbonate (10 mL), diluted with saturated aqueous sodium chloride (50 mL) and extracted with dichloromethane (3 x 40 mL). Organic layers were collected, dried over $MgSO_4$, filtered and concentrated. MPLC purification (25g column, 1-10% methanol in dichloromethane) gave 2-acetamido-2-(1-benzylpiperidin-4-yl)-N-tert-butyl-6-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)hexanamide as a colorless oil (538 mg, 93%), which was used immediately in the subsequent step (approximately 10% of the product had the boronic acid deprotected).

Step 7: 2-amino-2-(1-benzylpiperidin-4-yl)-6-borohexanoic acid

[0777] A solution of 2-acetamido-2-(1-benzylpiperidin-4-yl)-N-tert-butyl-6-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)hexanamide (510 mg, 0.97 mmol) in 6 N HCl (15 mL) was heated to a gentle reflux for 16 h. After cooling to room temperature, the reaction mixture was transferred to a separatory funnel, diluted with deionized water (15 mL) and washed with dichloromethane (3 x 25 mL). The aqueous layer was concentrated to give an off-white solid that was purified by HPLC (5-95% acetonitrile in water). The fractions containing product were concentrated, redissolved in deionized water (15 mL), frozen in liquid nitrogen and lyophilized to give 2-amino-2-(1-benzylpiperidin-4-yl)-6-borohexanoic

[0830] More specific descriptions of diseases and conditions follow below.

Erectile Dysfunction

[0831] The observation that there are differences in the activity of arginase in the penis of young mice versus older mice led to the conclusion that arginase may play a role in erectile

dysfunction (ED). In this context, Champion *et. al.*, (Am. J. Physiol. Heart Circ. Physiol. 292:340-351, (2006) and Biochem. and Biophys. Research Communications, 283:923-27, (2001)), observed an increase of mRNA expression levels and arginase protein in aged mice along with a reduction in the activity of constitutively active NOS.

[0832] Nitric oxide is implicated in nonadrenergic, noncholinergic neurotransmission that leads to smooth-muscle relaxation in the corpus cavernosum enabling penile erection (New England Journal of Medicine, 326, (1992)), Hence, erectile dysfunction can often be treated by elevating penile tissue nitric oxide (NO) levels. Such an elevation in tissue nitric oxide (NO) levels can be achieved by inhibiting arginase activity in penile tissue of aged subjects. Stated differently, arginase has been postulated to deplete the pool of free L-arginine available to NOS in cells which results in lower levels of nitric oxide (NO) and erectile dysfunction. See, Christianson *et. al.*, (Acc. Chem. Res., 38:191-201, (2005)), and (Nature Structural Biol., 6(11):1043-1047, (1999)). Inhibitors of arginase, therefore, can play a role in the treatment of erectile dysfunction.

Pulmonary Hypertension

[0833] It has been proposed that alterations in arginine metabolism are involved in the pathogenesis of pulmonary hypertension (Xu *et al.*, FASEB J., 18:1746-48, 2004). The proposition is based in part on the finding that arginase II expression and arginase activity are significantly elevated in pulmonary artery endothelial cells derived from lung explants of patients with class I pulmonary hypertension.

[0834] Additionally, secondary pulmonary hypertension is emerging as one of the leading causes of mortality and morbidity in patients suffering from hemolytic anemias, such as thalassemia and sickle cell disease. The underlying cause for secondary pulmonary hypertension is impaired nitric oxide bioavailability due to release of arginase following hemolysis which decreases the pool of free arginine that is required for nitric oxide (NO) synthesis. Accordingly, inhibition of arginase activity can provide a potential therapeutic avenue for treating pulmonary hypertension.

Hypertension

[0835] Xu, W. *et al.*, FASEB 2004, 14, 1746-8 proposed a fundamental role of arginase II in blood pressure regulation. In this context, high levels of vascular arginase are correlated to

concomitant reduction of vascular nitric oxide (NO) in hypertensive animals. For instance, up-regulation of arginase activity precedes a rise in blood pressure in rats that were genetically predisposed to hypertension (i.e., spontaneously hypertensive rats), but administration of the anti-hypertensive agent hydralazine lowered blood pressure with a decrease in the expression levels of vascular arginase, thereby indicating a strong correlation between the arginase activity and blood pressure (Berthelot *et al.* Life Sciences, 80:1128-34, (2008). Similar administration of the known arginase inhibitor N^ω-hydroxy-nor-L-arginine (nor-NOHA) lowered blood pressure and improved the vascular response of resistance vessels to blood flow and pressure in spontaneously hypertensive animals, thereby highlighting inhibitors of arginase as candidate therapeutics for treating hypertension (Demougeot *et al.*, (J. Hypertension, 26:1110-18, (2008).

[0836] Arginase also plays a role in reflex cutaneous hypertension by lowering the cellular levels of nitric oxide (NO). Nitric oxide causes vasodilation and levels of nitric oxide (NO) are normally elevated or lowered to maintain blood pressure at physiologically acceptable levels. Kenny *et al.*, (J. of Physiology 581 (2007) 863-872), hypothesized that reflex vasodilation in hypertensive subjects can attenuate arginase inhibition, thereby implicating a role for arginase inhibitors for the treatment of hypertension.

Asthma

[0837] Arginase activity is also associated with airway hyperresponsiveness in asthma. For example, arginase I is upregulated in human asthmatics and in mice suffering from acute and chronic asthma, whilst levels of arginase II and NOS isoforms remain unchanged (Scott *et al.*, Am. J. Physiol. Lung Cell Mol. Physiol. 296:911-920 (2009)). Furthermore, methacholine induced responsiveness of the central airways in the murine chronic model attenuated upon the administration of the arginase inhibitor S-(2-boronoethyl)-L-cysteine. The similarity between expression profiles of ARG I in humans and in mice having chronic asthma indicates that compounds capable of inhibiting arginase activity are candidate therapeutics for treating asthma.

[0838] Other lines of evidence reveal further correlations between increased activity of arginase in asthmatic lung tissue and disease progression, such as an upregulation for genes related to the metabolism of cationic amino acids, including arginase I and II in mice having

asthma (Rothenberg *et al.*, (J. Clin. Invest., 111:1863-74 (2003), and Meurs *et. al.*, (Expert Opin. Investig Drugs, 14(10):12211231, (2005)).

[0839] Further, levels of all amino acids are lower in the plasma of asthmatics, but the levels of arginine are significantly lower in plasma compared to that of a normal subject (Morris *et al.*, (Am. J. Respir. Crit Care Med., 170:148-154, (2004)). Thus, arginase activity is significantly increased in the plasma from an asthmatic, in which elevated levels of arginase activity may contribute to the lower bioavailability of plasma arginine that creates an nitric oxide (NO) deficiency, which is responsible for promoting hyperreactive airways in asthmatics.

Inflammation

[0840] Arginase activity also is associated with autoimmune inflammation (Chen *et al.*, Immunology, 110:141-148, (2003)). The authors identified upregulation in the expression levels of the ARG I gene in murine spinal cells from animals undergoing experimental autoimmune encephalomyelitis (EAE). Administration of the arginase inhibitor amino-6-boronoheptanoic acid (ABH), however, resulted in the animals developing a much milder form of EAE than in control animals. These results implicate inhibitors of arginase in a therapeutic role for treating autoimmune encephalomyelitis.

[0841] Moreover, Horowitz *et al.*, (American J. Physiol Gastrointestinal Liver Physiol., 292:G1323-36, (2007)), suggest a role for arginase enzymes in vascular pathophysiology. For example, these authors indicate a loss of nitric oxide (NO) production in chronically inflamed gut blood vessels in patients suffering from irritable bowel disease (IBD), Crohn's disease and ulcerative colitis. The loss in nitric oxide (NO) production correlated with an upregulation of arginase expression and activity that reduced levels of arginine preventing nitric oxide synthase (NOS), from synthesizing nitric oxide (NO). Inhibitors of arginase activity, therefore, may be candidate therapeutics for treating vascular pathophysiology.

Ischaemia Reperfusion

[0842] Arginase inhibition is also suggested to play a cardioprotective role during ischaemia reperfusion. More specifically, inhibition of arginase protects against myocardial infarction by a mechanism that may be dependent on NOS activity and the consequent

bioavailability of nitric oxide (NO) (Pernow *et al.*, (Cardiovascular Research, 85:147-154 (2010))).

Myocardial Infarction and Artherosclerosis

[0843] Arginase I polymorphism is associated with myocardial infarction along with an increased risk of developing carotid artery intima media thickness that is considered to be a reliable indicator of artherosclerosis as well as of other coronary arterial diseases (Brousseau *et al.*, (J. Med Genetics, 44:526-531, (2007))). Increased arginase activity elevates levels of ornithine that is biochemically involved in promoting the formation of the matrix and cellular components of artherosclerotic plaque. *Id.* Thus, arginase inhibitors may serve as candidate therapeutics for treating artherosclerosis. Berkowitz *et al.*, (Circulation Res. 102, (2008)), implicated a role for ARGII in the formation of plaque and artherosclerosis. Oxidation of LDLP that accompanies plaque formation increases arginase activity and lower nitric oxide (NO) levels in endothelial cells. In particular, levels of ARGII are elevated in artherosclerotic mice, indicating a role for inhibitors of arginase as candidate therapeutics for treating artherosclerosis.

[0844] Additionally, studies by Ming *et al.*, (Current Hypertension Reports., 54:54-59, (2006)), indicate that an upregulation of arginase rather than endothelial nitric oxide (NO) dysfunction plays an important role in cardiovascular disorders, including artherosclerosis. That arginase is involved in cardiovascular diseases is further supported by the observation ARG1 and ARGII activity is upregulated in cardiac myocytes which in turn negatively impacts NOS activity and myocardial contractility. (See, Margulies *et al.*, Am. J. Physiol. Heart Circ. Physiol., 290:1756-62, (2006)).

Immune Response

[0845] The arginine/nitric oxide (NO) pathway may also play a role in immune response, such as after organ transplants. For instance, it was postulated that reperfusion of an orthotopic liver transplant graft caused a significant increase in ornithine levels due to upregulation of arginase activity in the graft (Tsikas *et al.*, (Nitric oxide, 20:61-67, (2009))). The elevated levels of hydrolytic and proteolytic enzymes in the graft may result in a less favorable outcome for the grafted organ. Thus, inhibiting the arginase enzymes may present an alternate therapeutic avenue for improving the outcome of a transplant.

Psoriasis

[0846] Arginase has been implicated to play a role in the pathogenesis of psoriasis. For example, ARG I is highly expressed in hyperproliferative psoriasis, and in fact, it is responsible for down regulation of nitric oxide (NO) an inhibitor of cell proliferation, by competing for the common substrate L-arginine as postulated by D. Bruch-Gerharz *et al.* *American Journal of Pathology* 162(1) (2003) 203-211. More recent work by Abeyakirithi *et al.* (*British J. Dermatology*, (2010)), and Berkowitz *et al.*, (WO/2007/005620) support the finding of low nitric oxide (NO) levels in psoriatic keratinocytes. Abeyakirithi *et al.*, found that psoriatic keratinocytes were poorly differentiated and hyperproliferative. The poor differentiation was postulated to result from low levels of nitric oxide (NO), not because of poor expression of NOS, but rather the over expression of arginase that competes with NOS for substrate L-arginine. Thus, inhibition of arginase may provide therapeutic relief from psoriasis.

Wound Healing

[0847] Under normal physiological conditions, nitric oxide (NO) plays an important role in promoting wound healing. For example, Hulst *et al.*, (*Nitric Oxide*, 21:175-183, (2009)), studied the role of ARG I and ARG II in wound healing. Immediately following injury, it is desirable to elevate tissue levels of nitric oxide (NO) so as to promote angiogenesis and cell proliferation that are important for healing. Inhibitors of arginase may therefore find use as therapeutics to treat wounds because such compounds would elevate tissue levels of nitric oxide (NO). Further support for the use of arginase inhibitors as candidate therapeutics for treating wounds was provided by South *et al.* (*Experimental Dermatology*, 29:664-668 (2004)), who found a 5-fold increase in arginase I in chronic wounds such as skin erosions and blisters.

Cystic Fibrosis

[0848] Cystic fibrosis (CF) is a multisystem disorder caused by mutations of the cystic fibrosis transmembrane conductance regulator (CFTR) gene. The common symptoms of CF are persistent pulmonary infection, difficulty in breathing, pancreatic insufficiency, and elevated sweat chloride levels. CF can be fatal if untreated, with pulmonary diseases,

resulting from mucus build-up and decreased mucociliary clearance, being the leading cause of morbidity and mortality.

[0849] It has been asserted that patients with cystic fibrosis (CF) have increased plasma and sputum arginase activity, with an accompanying decrease in the levels of plasma l-arginine (H. Grasemann *et al.*, *Am. J. Respir. Crit. Care Med.* 172(12) (2005) 1523-1528. The increased arginase activity, however, results in lower physiological levels of nitric oxide (NO) that can cause airway obstruction decreased pulmonary function in patients suffering from cystic fibrosis (CF).

[0850] Impaired electrical field induced-stimulation of smooth muscle relaxation in the airway of a mouse model of CF and the administration of l-arginine and NO reversed this effect as proposed by M. Mhanna *et al.* *Am. J. Respir. Cell Mol. Biol.* 24(5) (2001) 621-626. Graesmann *et al.*, found a positive correlation exists between pulmonary function and exhaled NO and NO metabolite concentrations in the sputum of CF patients (Grasemann, H; Michler, E; Wallot, M; Ratjen, F., *Pediatr Pulmonol.* **1997**, 24, 173-7).

[0851] Taken together, these results indicate that increased Arginase activity in CF contributes to the NO deficiency and pulmonary obstruction in CF by limiting the availability of l-arginine to NOS. Thus, inhibitors of arginase activity are candidate therapeutics for treating cystic fibrosis (CF)

Organ Protection

[0852] Another therapeutic avenue for compounds in accordance with the present invention is protecting organs during transport from donor to a site where they will be transplanted into a recipient. Ischemic reperfusion injury (IR) due to exposure of the transplant organs to a period of warm ischemia (time from donor until flushed with preservation media), and cold ischemia (hypothermic preservation) is frequently observed in patients undergoing transplant surgery. Ischemic reperfusion injury (IR) and accompanying primary graft dysfunction and/or acute or chronic rejection results due to alteration in the cellular activity of the L-Arginine/NO pathway.

[0853] It was proposed that Arginase 1 and arginase 2 are released from apoptotic endothelial cells and kidney cells within the first 24 hours of organ removal from the body. To counteract the released arginase, L-Arginine is added to preservation media. Results with

canine kidney transplants indicate that addition of L-arginine reduced the incidence and severity of ischemia, resulted in post-transplant with lower MDA levels at 1 hour, and lowered BUN & Serum creatinine levels during the first 72hrs. See Erkasap, S; Ates, E., *Nephrol Dial Transplant*. **2000**, *15*, 1224-7.

[0854] Similar results were observed for canine lung grafts over a 24 hour period when lungs were preserved in the University of Wisconsin solution supplemented with L-Arginine. Yen et al., observed that the addition of L-arginine to the preservation medium increased pulmonary endothelial protection and lowered the incidence of ischemia when compared to a control that is preserved in medium that does not contain L-arginine (Chu, Y; Wu, Y.C.; Chou, Y.C.; Chueh, H.Y, Liu HP, Chu JJ, Lin PJ., *J Heart Lung Transplant*. **2004**, *23*, 592-8).

[0855] Koch et al. stated that improved myocardial contractility and relaxation in heart muscle of rats following transplantation when hearts were preserved in HTK solution having L-Arginine and N-alpha-acetyl-histidine (Koch A, Radovits T, Loganathan S, Sack FU, Karck M, Szabó GB., *Transplant Proc*. **2009**, *41*, 2592-4).

[0856] Addition of an arginase inhibitor, therefore, can be a candidate therapeutic for preventing and/or reducing the incidence and risk of ischemic reperfusion injury by a synergistically increasing the organ protective effect of the preservation media. Given the low number of available organs that are suitable for transplant and the loss and injury of organs due to the onset of ischemia, arginase inhibitors in accordance with the present invention can find use as therapeutics for preserving organs, increasing organ availability by reducing the amount of ischemic reperfusion injury during organ transport.

Leishmaniasis

[0857] Leishmaniasis is caused by a protozoan and manifests as cutaneous leishmaniasis (i.e., skin infection causing hypo-pigmented nodules) and visceral leishmaniasis (more severe affecting internal organs). Arginase is postulated to play a role in disease progression since the parasite relies on arginase for the synthesis of cellular polyamines that are essential for pathogenesis. Inhibition of arginase, therefore, would reduce cellular parasitic burden and promote increased nitric oxide (NO) levels enhancing parasitic clearance. See Liew FY *et al.* *Eur J Immunol* 21 (1991) 2489, Iniesta V *et al.* *Parasite Immunol*. 24 (2002) 113–118, and

Kane MM *et al. J. Immunol.* 166 (2001) 1141-1147. Compounds according to Formula I or Formula II, therefore can be used as therapeutics for treating leishmaniasis.

Myeloid Derived Suppressor Cells (MDSC)

[0858] MDSC's are potent immune modulators that limit immune responses through several pathways, such as, L-arginine depletion via arginase 1 release into the microenvironment (Rodriguez 2009 *Cancer Res*), MHC restricted suppression (Nagaraj S, Gupta K, Pisarev V, Kinarsky L, Sherman S, Kang L, Herber DL, Schneck J, Gabrilovich DI., *Nat Med.* **2007**, *13*, 828-35), induction of T regulatory cells (Serafini P, Mgebroff S, Noonan K, Borrello I., *Cancer Res.* **2008**, *68*, 5439-49), and production of IL10 (Rodrigues JC, Gonzalez GC, Zhang L, Ibrahim G, Kelly JJ, Gustafson MP, Lin Y, Dietz AB, Forsyth PA, Yong VW, Parney IF., *Neuro Oncol.* **2010**, *12*, 351-65) (Sinha P, Clements VK, Bunt SK, Albelda SM, Ostrand-Rosenberg S., *J Immunol.* **2007**, *179*, 977-83), for instance.

[0859] It is postulated that tumor development is accompanied by an increase in the number of MDSC's both peripherally and infiltrated within tumors. See Almand B, Clark JI, Nikitina E, van Beynen J, English NR, Knight SC, Carbone DP, Gabrilovich DI., *J Immunol.* **2001**, *166*, 678-89 and Gabrilovich D., *Nat Rev Immunol.* **2004**, *4*, 941-52. Treatment of tumor bearing mice with established chemotherapeutics such as gemcitabine and 5-Fluorouracil eliminates MDSC immunosuppression and results in delayed tumor growth. See Le HK, Graham L, Cha E, Morales JK, Manjili MH, Bear HD., *Int Immunopharmacol.* **2009**, *9*, 900-9 and Vincent J, Mignot G, Chalmin F, Ladoire S, Bruchard M, Chevriaux A, Martin F, Apetoh L, Rébé C, Ghiringhelli F., *Cancer Res.* **2010**, *70*, 3052-61, respectively. Moreover, inhibition of arginase 1 enhanced antitumor immunity by reducing MDSC function. Thus, inhibitors of arginase, such as compounds in accordance with the present invention reduce or delay tumor growth and can be used in combination with established anti-cancer agents in the treatment of cancer.

Helicobacter pylori (*H. pylori*)

[0860] *Helicobacter pylori* (*H. pylori*) is a Gram-negative bacterium that colonizes the human gastric mucosa. Bacterial colonization can lead to acute or chronic gastritis and is highly associated with peptic ulcer disease and stomach cancer. The observation that the addition of L-arginine to co-culture of *H. pylori* and macrophages increased nitric oxide (NO)

mediated killing of the *H. pylori* (Chaturvedi R, Asim M, Lewis ND, Algood HM, Cover TL, Kim PY, Wilson KT., *Infect Immun.* **2007**, *75*, 4305-15), supports the hypothesis that bacterial arginase competes with macrophage arginase for free arginine that is required for nitric oxide (NO) synthesis. See Gobert AP, McGee DJ, Akhtar M, Mendz GL, Newton JC, Cheng Y, Mobley HL, Wilson KT., *Proc Natl Acad Sci U S A.* **2001**, *98*, 13844-9. L-arginine is required for T-cell activation and for the rapid clearance of bacteria from infected cells. By depleting the pools of free L-arginine in vivo, *H. pylori* reduces arginine-induced CD3zeta expression on T-cells and prevents T-cell activation and proliferation. See Zabaleta J, McGee DJ, Zea AH, Hernández CP, Rodríguez PC, Sierra RA, Correa P, Ochoa AC., *J Immunol.* **2004**, *173*, 586-93.

[0861] The inhibition of bacterial arginase using the known inhibitor NOHA, however, reestablished CD3 expression on T-cells and (Zabaleta J 2004), and enhanced production of NO by macrophages, thus, promoting macrophage mediated clearance of bacteria from infected cells. See Chaturvedi R, Asim M, Lewis ND, Algood HM, Cover TL, Kim PY, Wilson KT., *Infect Immun.* **2007**, *75*, 4305-15.

[0862] Furthermore, Lewis et al., have suggested a role for arginase II in *H. pylori* infection. For example, these authors indicate that argII^{-/-} primary macrophages incubated with *H. pylori* extracts showed enhanced NO production and correspondingly an increased (~15%) NO-mediated killing of bacterial cells (Lewis ND, Asim M, Barry DP, Singh K, de Sablet T, Boucher JL, Gobert AP, Chaturvedi R, Wilson KT., *J Immunol.* **2010**, *184*, 2572-82). Inhibitors of arginase activity, therefore, may be candidate therapeutics for treating vascular pathophysiology. Inhibitors of arginase activity, therefore, may be candidate therapeutics for treating *H. pylori* infections and for treating gastric ulcers, peptic ulcers and cancer.

Sickle Cell Disease (SCD)

[0863] Sickle-cell disease (SCD), or sickle-cell anaemia, or drepanocytosis, is a genetic blood disorder, characterized by red blood cells that assume an abnormal, rigid, sickle shape. Sickling decreases the cells' flexibility and increases the risk of complications. An increase in the concentration of reactive oxygen species (ROS) in circulation causes adherence of blood cells and consumption of NO that results in poor vasodilation or the inability of blood

vessels to vasodilate. The inability to vasodilate along with the increased adherence of blood cells in SCD results in vaso occlusive crisis and pain.

[0864] Low levels of plasma L-arginine are normally detected in patients with SCD (Morris CR, Kato GJ, Poljakovic M, Wang X, Blackwelder WC, Sachdev V, Hazen SL, Vichinsky EP, Morris SM Jr, Gladwin MT., *JAMA*. **2005**, *294*, 81-90) According to these authors, lysis of red blood cells (RBC's) in patients suffering from SCD causes the release of arginase and a subsequent lowering of physiological L-Arginine levels. This sequence of biological events lowers physiological concentrations of nitric oxide (NO), a signaling molecule that plays a role in vasodilation. Other biological events also limit NO bioavailability. These include, for example, the uncoupling of nitric oxide synthase (NOS), and the subsequent decrease in physiological NO levels, as well as the reaction of superoxide (O_2^-) reactive oxygen species with NO to sequester the latter as ONOO⁻.

[0865] Based on these observations, inhibitors of arginase, especially arginase I inhibitors are being proposed by the present inventors as candidate therapeutics for patients with sickle cell disease. As stated above, SCD causes the uncoupling of eNOS due to low physiological levels L-arginine. Inhibition of arginase present in the blood circulation, however, may address this problem by increasing the physiological levels L-arginine, the substrate of endothelial nitric oxide synthase (eNOS). This sequence of events, importantly, are proposed by the present inventors to enhance endothelial function and relieve vasoconstriction associated with SCD.

Human Immunodeficiency Virus (HIV)

[0866] HIV is caused by virus that infects CD4+ helper T cells and causes severe lymphopaenia that predisposes the infected individuals to opportunistic infection. Although, anti-retroviral therapy (ART) is extensively used to combat HIV infection, the wide spread use of anti-retroviral drugs has resulted in the generation of resistant strains of HIV.

[0867] A correlation exists between the activity of arginase in patients suffering from HIV and the severity of HIV disease. That is increased arginase activity has been correlated to increased viral titres in HIV patients. These patients also show decrease serum arginine levels as well as decreased levels of CD4+/CD8+ cells.

[0868] Taken together, these observations suggest a role for arginase inhibitors, such as compounds according to Formulae I or II as candidate therapeutics in the treatment of HIV infection.

Chronic Hepatitis B Virus (HBV)

[0869] Chronic hepatitis B infection is a viral disease that is transmitted by contact with infected body fluids. Chronic HBV infections are characterized by inflammation of the liver and jaundice and if left untreated can cause cirrhosis of the liver that can progress to form hepatocellular carcinomas. Anti-viral drugs currently used, however, have low efficacy against chronic HBV infections. Serum and liver homogenates of patients with chronic HBV infections show reduced levels of arginine and increased arginase activity. For infected patients moreover, the increased arginase activity is correlated to an impaired cytotoxic T-lymphocytes (CTL) response with reduced IL-2 production and CD3z expression.

[0870] Replenishing serum arginine to physiologically acceptable levels, however, reconstituted CD3z and IL-2 expression, implicating a role for arginase inhibitors as potential therapeutics in the treatment of chronic HBV infections.

[0871] Routes of Administration and Dosing Regimen

[0872] Despite ample evidence associating arginase inhibition with therapies of various diseases and conditions, only a limited number of compounds are known that are capable of inhibiting arginase activity. The present invention therefore provides compounds and their pharmaceutical compositions that are useful in treating a subject suffering from such a disease or condition, as more generally set forth above.

[0873] The compound or composition of the invention can be formulated as described hereinabove and is suitable for administration in a therapeutically effective amount to the subject in any number of ways. The therapeutically effective amount of a Formula I or Formula II compound can depend upon the amounts and types of excipients used, the amounts and specific types of active ingredients in a dosage form, and the route by which the compound is to be administered to patients. However, typical dosage forms of the invention comprise a compound, or a pharmaceutically acceptable salt, solvate, hydrate, isomer, or prodrug thereof.

[0874] Typical dosage levels for Formula I or Formula II compounds generally range from about 0.001 to about 100 mg per kg of the patient's body weight per day which can be administered in single or multiple doses. An exemplary dosage is about 0.01 to about 25 mg/kg per day or about 0.05 to about 10 mg/kg per day. In other embodiments, the dosage level is from about 0.01 to about 25 mg/kg per day, about 0.05 to about 10 mg/kg per day, or about 0.1 to about 5 mg/kg per day.

[0875] A dose typically ranges from about 0.1 mg to about 2000 mg per day, given as a single once-a-day dose or, alternatively, as divided doses throughout the day, optionally taken with food. In one embodiment, the daily dose is administered twice daily in equally divided doses. A daily dose range can be from about 5 mg to about 500 mg per day, such as, for example, between about 10 mg and about 300 mg per day. In managing the patient, the therapy can be initiated at a lower dose, perhaps from about 1 mg to about 25 mg, and increased if necessary up to from about 200 mg to about 2000 mg per day as either a single dose or divided doses, depending on the patient's global response.

[0876] Depending on the disease to be treated and the subject's condition, the compounds according to Formula I or Formula II may be administered by oral, parenteral (*e.g.*, intramuscular, intraperitoneal, intravenous, ICV, intracisternal injection or infusion, subcutaneous injection or implant), inhalation, nasal, vaginal, rectal, sublingual, or topical (*e.g.*, transdermal, local) routes of administration. The compounds can be formulated, alone or together, in suitable dosage unit formulations containing conventional non-toxic pharmaceutically acceptable carriers, adjuvants and vehicles, as described above, that are appropriate for each route of administration. The invention also contemplates administration of the compounds of the invention in a depot formulation, in which the active ingredient is released over a defined time period.

INHIBITION OF ARGINASE

[0877] The inventive compounds inhibit human arginase I (ARG I) and arginase II (ARG II) as evidenced by an *ex vivo* assay set forth by a published protocol (Baggio et al. *J. Pharmacol. Exp. Ther.* **1999**, 290, 1409-1416). The assay established the concentration of inhibitor that is required to reduce arginase activity by 50% (IC₅₀).

ASSAY PROTOCOL

[0878] Inhibition of arginase I (ARG I) and arginase II (ARG II) by Formula I and Formula II compounds is followed spectrophotometrically at 530 nm. The compound to be tested is dissolved in DMSO at an initial concentration 50-fold greater than its final concentration in the cuvette. 10 μ l of the stock solution is diluted in 90 μ l of the assay buffer that comprises 0.1M sodium phosphate buffer containing 130 mM NaCl, pH 7.4, to which is added ovalbumin (OVA) at a concentration of 1 mg/ml. Solutions of arginase I and II are prepared in 100 mM sodium phosphate buffer, pH 7.4 containing 1 mg/ml of OVA to give an arginase stock solution at a final concentration of 100 ng/ml.

[0879] To each well of a 96-well microtiter plate is add 40 μ l of enzyme, 10 μ l of an inventive compound and 10 μ l of enzyme substrate (L-arginine + manganese sulfate). For wells that are used as positive controls, only the enzyme and its substrate are added, while wells used as negative controls contain only manganese sulfate.

[0880] After incubating the microtiter plate at 37 °C for 60 minutes, 150 μ l of a urea reagent obtained by combining equal proportions (1:1) of reagents A and B is added to each well of the microtiter plate to stop the reaction. The urea reagent is made just before use by combining Reagent A (10 mM o-phthaldialdehyde, and 0.4% polyoxyethylene (23) lauryl ether (w/v) in 1.8 M sulfuric acid) with Reagent B (1.3 mM primaquine diphosphate, 0.4% polyoxyethylene (23) lauryl ether (w/v), 130 mM boric acid in 3.6 M sulfuric acid). After quenching the reaction mixture, the microtiter plate is allowed to stand for an additional 10 minutes at room temperature to allow color development. The inhibition of arginase is computed by measuring the optical density (OD) of the reaction mixture at 530 nm and normalizing the OD value to percent inhibition observed in the control. The normalized OD is then used to generate a dose-response curve by plotting the the normalized OD values against log [concentration] and using regression analysis to compute the IC₅₀ values.

[0881] Table 2 below ranks the potency of Formula I compounds on a scale from **1** through **5**, that is, the most potent compounds are designated as **1** and the least potent compounds being designated as **5**. A similar potency analysis for Formula II compounds is illustrated in Table 2-A. Thus, a potency value of **1** refers to inventive compounds with IC₅₀ values in the range from 0.1 nM to 250 nM; a potency value of **2** refers to inventive compounds with IC₅₀

values in the range from 251 nM to 1000 nM; compounds having a potency value of **3** exhibit IC_{50} values in the range from 1001 nM to 2000 nM; inventive compounds with IC_{50} values in the range from 2001 nM to 5000 nM are assigned a potency value of **4**, and compounds with IC_{50} values above 5001 nM are assigned a potency value of **5**.

EFFICACY MODEL

[0885] As described hereinabove, the compounds according to the invention are useful in the treatment and prevention of a variety of disorders and conditions that are affected by levels of nitric oxide (NO) regulated, in part, by arginase enzymes. The compounds are assessed for efficacy in such treatment and prevention by their performances in standardized *in vivo* tests. *In vivo* models to assess efficacy are developed for this purpose as described below.
