UNITED STATES PATENT OFFICE.

CHARLES E. LUCKE, OF NEW YORK, N. Y., ASSIGNOR TO WORTHINGTON PUMP AND MACHINERY CORPORATION, OF NEW YORK, N. Y., A CORPORATION OF VIRGINIA.

INTERNAL-COMBUSTION ENGINE.

Application filed July 25, 1921. Serial No. 487,260.

vaporization of fuel in internal combustion engines, and is particularly applicable to that class of engines operating on the Diesel

5 or constant pressure system. The especial object of the invention is to provide an apparatus and method employing solid injection of the oil or other liquid or solid fuel, by which the proper feed of 10 the fuel to the cylinder for securing the maximum power and economy may be at-tained. The specific means used for this purpose falls within the class of precombustion fuel supply by which partial combustion 15 occurs in a precombustion chamber communicating with the cylinder, and the fuel is gradually fed to the cylinder by the relative pressures in the precombustion chamber and cylinder, and the particular object is to 20 control the time, rate and amount of combustion in the precombustion chamber and the time and rate of fuel feed to the cylinder independently of the character and rate of fuel feed to the chamber, so as to secure the 25 results desired.

The present invention includes especially two features which are important in secur-ing the results desired. One feature con-sists in the provision of means for assuring 30 a high pressure being attained in the pre-combustion chamber during compression, notwithstanding the restriction of the opening between the cylinder and precombustion chamber that is desirable for securing the proper fuel feed to the cylinder. this result 35 being secured by a pressure equalizing nonreturn connection between the cylinder and precombustion chamber which is open during compression but closed during the feed-40 ing of fuel to the cylinder. The air compressed into the precombustion chamber is thus at the high pressure of the cylinder. and prompt delivery of fuel to the cylinder upon stoppage or reversal of the piston is thus secured. Another feature consists in 45 providing for reserving a portion of the air first by the pressure in the portion of the in the precombustion chamber behind the fuel, so that this air by expansion secures the complete expulsion of the fuel from the chamber to the cylinder and scavenges the 50chamber, creates currents in the cylinder

55

This invention relates to the feeding and fuel opening to the cylinder, or a portion aporization of fuel in internal combustion thereof, combines with the fuel to secure vaporization or gasification of the fuel with the partial combustion and increase of pressure desired. The air in the precombustion 60 chamber is thus divided into a body of fuel-combining air near the fuel feed opening to the cylinder, and a body of fuel-dis-placing air in the outer part of the chamber, and means preferably are provided for ad- 65 justing the relative amounts of air in these bodies so as to secure the results desired under different engine conditions.

Fuel is injected into the precombustion chamber during or about the end of com- 70 pression, and preferably near the end of the compression stroke and after the air has been compressed to igniting temperature. The arrangement of the spray is such that the fuel is wholly or largely delivered to the ⁷⁵ fuel-combining air near the fuel feed opening to the cylinder and thus the fuel, wholly or partially vaporized or gasified, is positioned in the part of the chamber next to the cylinder opening, and prompt ignition ⁸⁰ and combustion thus secured at the time the reverse flow of air to the cylinder begins on the completion of the compression stroke and the stoppage or reversal of the piston. The chamber may be provided with fuel 85 guards or other devices against which the fuel is injected and which aid in vaporizing or gasifying the fuel and in restricting contact of the fuel and air. or the precombustion chamber may be an open space without such ⁹⁰ tubes or devices of any kind. The partial combustion in the precombustion chamber increases the pressure of the air and vapor in the chamber, or, on later injection, prevents undue falling of the pressure in the 95 precombustion chamber, and upon stoppage or reversal of the piston the fuel, in the form of vapor and possibly some liquid, is fed gradually to the cylinder combustion space 100 by the flow from the precombustion chamber, precombustion chamber next the cylinder opening, and then by the expanding air in the outer portion of the chamber, until all 105 the fuel is consumed.

For a full understanding of the invention, that aid in securing fuel contact with the a detailed description of constructions em-air, and supplies air to support combustion bodying and for carrying out the invention later in the stroke than otherwise possible, in the best forms now known to me, will while the other portion of the air near the now be given in connection with the accom-110

invention then be specifically pointed out in the claims.

In the drawings-

Figure 1 is a central section through the cylinder head, precombustion chamber and oil injection nozzle, showing the piston in elevation, the engine being shown as of the the precombustion chamber, and the space

10 two-cycle type, and Figures 2, 3, 4 and 5 are partial sections corresponding to Fig. 1 and showing modifications.

Referring now particularly to Fig. 1, A 15 is the engine cylinder, B the piston, C the cooling or water jacket, D the precombustion chamber, and E the oil injection nozzle mounted on the cylinder head through which the oil is forced by a suitable pump. \mathbf{This} 20 oil injection nozzle is shown as of the wellknown type adapted to deliver the oil in a coned spray at a suitable angle, but it will be understood that any other suitable form

of nozzle securing similar results may be 25 used. The nozzle is jacketed as usual by

extension c of cylinder jacket C. The cylinder head is provided with an opening preferably opposite the nozzle E, as shown, which opening receives a plug e30 which carries the fuel feed opening, this opening being shown as consisting of small perforations 1 arranged to distribute the fuel through the cylinder space and approximately parallel to the piston face. The 35 openings 1 form a restricted opening between the cylinder and precombustion chamber through which air is forced during the compression stroke of the piston. With the small openings desired for gradual fuel feed 40 to the cylinder, however, the pressure in the precombustion chamber may lag behind the pressure in the cylinder, and to avoid this a pressure equalizing passage f controlled by value g is shown connecting the cylinder 45 with the precombustion chamber during the compression stroke, while excess pressure in the precombustion chamber will close the valve g for a restricted fuel feed from the precombustion chamber to the cylinder 50 through openings 1. The precombustion chamber is divided horizontally by a partition h, and the two bodies of air above and below the partition are connected by opening m into and through which the fuel is 55 sprayed from nozzle E, the wall of this opening m thus forming a tube, and the fuel may be sprayed against the hot wall of the tube to aid in vaporization or gasification. There are thus formed two bodies of air, one body of fuel-combining air below the partition which receives the fuel so as to form a cloud of vaporized or gasified fuel within and near the plug e, and a body of 65

panying drawings forming a part of this amounts of air in the two bodies may be specification, and the features forming the adjusted by piston 2 moving in cylinder 3 adjusted by piston 2 moving in cylinder 3 and adjustable by stem 4 operated by handle 5 outside the engine, so that adjustment may be made while the engine is running. 70

The construction shown in Fig. 2 is similar to that shown in Fig. 1, except that a separate tube n receives the fuel spray in within the chamber is divided by an adjust-75 able partition o surrounding the tube, so that the two bodies of air above and below the partition may be adjusted by shifting the partition along the tube. The tube is the partition along the tube. The tube is shown as having the usual open lower end 80 opposite the cartridge e and the series of openings 6 above the partition through which the expanding fuel-displacing air passes to the tube. In Fig. 2, adjustment of the amounts of air in the two bodies may 85 be secured while the engine is running, by piston 7 having screw stem 8 which acts as \hat{a} guide for the stem of value q.

The construction shown in Fig. 3 secures to a partial extent the air division, but not 90 so positively as the construction shown in Figs. 1 and 2. The fuel is largely segregated at and near the cartridge e, however, and the air above the tube o and in the portion of the chamber most removed from the 95 cartridge, will secure the advantages of the construction in Figs. 1 and 2 to an important extent.

In the construction shown in Fig. 4, the fuel is segregated near the cartridge, and the 100 air divided only by the elongated form of the chamber, the spray and cartridge being at one end, thus providing a considerable body of air which is not reached directly by the spray. The pressure equalizing con- 105nection f and valve g are preferably posi-tioned as far as conveniently possible from the spray and cartridge so as to protect the valve from heating.

Figure 5 illustrates another form of fuel 110 feed opening and equalizing connection without the air division. In this construction the fuel feed opening 9 is formed in a thin partition so that the walls of the opening are short and thus the action of a flow 115 passage in a comparatively thin plate is se-cured. From this thin partition the walls taper outwardly for increased thickness, thus securing the desired strength and thermal conductivity, and the form pref- 120 erably is of a nozzle coned on one or both sides of the opening so as to provide a nozzle producing a smooth uniform jet. The equalizing connection s in this case is formed by a series of ports arranged an- 125 nularly about the plug p and closed by a light plate valve t.

The general operation of the construction fuel-displacing air behind the fuel or in the shown in Figs. 1 and 2 is the same and as outer part of the chamber. The relative follows: The fuel is injected through the ¹³⁰

5

gasified by contact with the hot compressed gine, apart from the air division, is the same air, the action being aided by contact with the inner wall of the tube, and partial comportion of the chamber next the plug e, the air in the precombustion chamber forced into the cylinder being then at high compression, the connection f with its open value g assur-10 ing free passage of the air from the cylinder to the precombustion chamber during compression. Prompt ignition and combustion is thus started when or before the reverse flow from the cylinder begins on reversal of 15 the piston and the increased pressure in the precombustion chamber closes the value g. Upon reversal, therefore, there will be a flow of vapor and possibly liquid from the inner portion of the precombustion chamber through the openings 1 into the cylinder and 20 the combustion in the precombustion chamber and expansion of the air above the partition h or o will sustain the pressure in the precombustion chamber during this outflow fuel to the cylinder by the relative pressures 25 to maintain a vigorous flow until all the fuel has been fed to the cylinder and consumed. Thus, instead of a violent explosion or

sudden pressure rise in the precombustion chamber, there will be a slow rise of pres-30 sure if the injection occurs sufficiently before dead center, producing and maintaining a flow of fuel and expanding air from the precombustion chamber into the cylinder, thus securing the graduated fuel feed 35 to the cylinder and air supply from the

chamber that is desired for producing and maintaining combustion for a considerable time, in spite of the fact that the fuel pump may have injected all of the fuel into the 40 chamber instantaneously. If the injection

- takes place later, there may be no rise of pressure in the precombustion chamber, but the required relative pressures between the precombustion chamber and the cylinder
- will be secured by the outward movement of the piston coacting with the combustion in the precombustion chamber acting to sustain the relative pressures therein and thus substantially the same results be secured as with
- 50 a rise of pressure in the precombustion chamber on earlier injection. The construction will operate well with a timed pump. and inaccuracies in the timing of the latter will be compensated for to such an extent
- 55 that the use of a less delicate and troublesome pump apparatus is permitted than with many other forms of fuel feed, and at the same time suitable control of internal pressures of the engine is secured.

60 The general operation of the constructions shown in Figs. 3 and 4 is the same as above described, except that the air division is not so complete and positive in the construction shown in Figs. 3 and 4 and the fuel displac-65 ing and scavenging action of the air is less fuel feed opening and a body of fuel-displac-

nozzle E in a fine spray and is vaporized or secured. The general operation of the enin connection with Fig. 5 as above described.

While the invention has been described bustion follows within the tube and in that in connection with solid injection of fuel 70 and an especial object of the invention is to provide a satisfactory engine of this character, it will be understood that the invention is applicable also with compressed air spraying of fuel to the precombustion cham- 75 ber and is thus claimed.

> The invention is not to be limited to the specific form and construction of devices shown, but many modifications may be made therein by those skilled in the art while re- 80 taining the invention defined by the claims. What is claimed is:

> 1. In an internal combustion engine, the combination with a precombustion chamber having a fuel feed opening to the cylinder ⁸⁵ and means for injecting fuel into the chamber during or about the end of compression to secure limited combustion and feed of in the chamber and cylinder, of a pressure 90. equalizing connection between the chamber and cylinder open during compression, means for closing said connection during the feeding of fuel to the cylinder, and means for dividing the air compressed in the chamber ⁹⁵ into a body of fuel-combining air near the fuel feed opening and a body of fuel-displacing air behind the fuel.

2. In an internal combustion engine, the combination with a precombustion chamber 100 having a fuel feed opening to the cylinder and means for injecting fuel into the chamber during or about the end of compression to secure limited combustion and feed of fuel to the cylinder by the relative pressures 105in the chamber and cylinder, of a pressure equalizing connection between the chamber and cylinder open during compression, means for closing said connection during the feeding of fuel to the cylinder, means for divid- 110 ing the air compressed in the chamber into a body of fuel-combining air near the fuel feed opening and a body of fuel-displacing air behind the fuel, and means for adjusting 115 the amounts of air in the bodies.

3. In an internal combustion engine, the combination with a precombustion chamber having a fuel feed opening to the cylinder and means for injecting fuel into the chamber during or about the end of compression 120 to secure limited combustion and feed of fuel to the cylinder by the relative pressures in the chamber and cylinder, of a pressure equalizing connection between the chamber 125 and cylinder open during compression, means for closing said connection during the feeding of fuel to the cylinder, means for dividing the air compressed in the chamber into a body of fuel-combining air near the

1,619,825

4. In an internal combustion engine, the **5** combination with a precombustion chamber having a restricted fuel feed opening to the cylinder, of a fuel tube in the chamber, means for injecting fuel into the tube, and a partition surrounding the tube and dividing 10 the air in the chamber into two bodies, one ber during or about the end of compression near the fuel feed opening and the other in

the outer part of the chamber.

5. In an internal combustion engine, the combination with a precombustion chamber 15 having a restricted fuel feed opening to the cylinder, of a fuel tube in the cylinder, means for injecting fuel into the tube, and a partition surrounding the tube and di viding the air in the chamber into two 20 bodies, one near the fuel feed opening and the other in the outer part of the chamber. said partition being adjustable to vary the amounts of air in the two bodies.

6. In an internal combustion engine, the combination with a precombustion chamber having a restricted fuel feed opening to the cylinder, of a fuel tube in the cylinder, means for injecting fuel into the tube. a partition surrounding the tube and dividing the air in the chamber into two bodies, one near 30 the fuel feed opening and the other in the outer part of the chamber, a pressure equalizing connection between the chamber and cylinder, and a valve acting to close said con-nection during the feed of fuel to the cylin-35 der.

7. In an internal combustion engine, the combination with a precombustion chamber having a fuel feed opening to the cylinder and means for injecting fuel into the chamber during or about the end of compression to secure limited combustion and feed of fuel to the cylinder by the relative pressures in the chamber and cylinder, of means for di-

ing air behind the fuel, and means for ad-justing the amounts of air in the bodies into a body of fuel-combining air near the while the engine is running. fuel feed opening and a body of fuel-displacing air behind the fuel, and means for adjusting the amounts of air in the bodies.

8. In an internal combustion engine, the 50 combination with a precombustion chamber having a fuel feed opening to the cylinder and means for injecting fuel into the chamto secure limited combustion and feed of fuel 55 to the cylinder by the relative pressures in the chamber and cylinder, of means for dividing the air compressed in the chamber into a body of fuel-combining air near the fuel feed opening and a body of fuel-displac. 60 ing air behind the fuel, and means for adjusting the amounts of air in the bodies while the engine is running.

9. In an internal combustion engine of that class having a precombustion chamber 65 in communication with the cylinder and from which the fuel is fed to the cylinder by the relative pressures in the chamber and cylinder, the combination with the chamber, of fuel-injecting devices co-acting with the 70 chamber to spray a charge of fuel into the compressed air near the cylinder opening, during or about the end of compression in such a manner as to secure partial combustion of the fuel in that part of the chamber 75 near the opening with a body of fuel-dis placing air in that part of the chamber remote from the opening, whereby the expan sion of the fuel-displacing air behind the fuel secures the feed of all the fuel to the 80 cylinder on the working stroke, a pressure equalizing connection between the chamber and cylinder open during compression, and means for closing said connection during the 85 feeding of fuel to the cylinder.

In testimony whereof, I have hereunto set my hand.

CHARLES E. LUCKE.
