THIENOPYRAZOLES

Field of the Invention

This invention is directed to thienopyrazoles of Formula I, their preparation, pharmaceutical compositions comprising these compounds, and their pharmaceutical use in the treatment of disease states capable of being modulated by the inhibition of the protein kinases, in particular interleukin-2 inducible tyrosine kinase (ITK).

Background of the Invention

Protein kinases are a family of enzymes that participate in the signalling events which control the activation, growth and differentiation of cells in response to extracellular mediators and to changes in the environment. In general, these kinases fall into several groups; those which preferentially catalyse the phosphorylation of hydroxy groups of serine and/or threonine residues and those which preferentially catalyse the phosphorylation of hydroxy groups of tyrosine residues [S.K.Hanks and T.Hunter, FASEB. J., 1995, 9, pages 576-596]. Such phosphorylations may greatly modify the function of the proteins; thus, protein kinases play an important role in regulating a wide variety of cell processes including, especially, metabolism, cell proliferation, cell differentiation or cell survival.

Inappropriately high protein kinase activity has been implicated in many diseases resulting from abnormal cellular function. This might arise either directly or indirectly, for example by failure of the proper control mechanisms for the kinase, related for example to mutation, over-expression or inappropriate activation of the enzyme; or by over- or underproduction of cytokines or growth factors also participating in the transduction of signals upstream or downstream of the kinase. In all of these instances, selective inhibition of the action of the kinase might be expected to have a beneficial effect.

ITK, is a T cell specific tyrosine kinase of the Tec family that is required for normal Th2 function. Asthma is a disease characterised by increased Th2 cytokine production including IL-4. An inhibitor of ITK should therefore have an impact on disease progression in asthma through inhibition of Th2 cytokine production.

We have now found a novel group of thienopyrazoles, which have valuable pharmaceutical properties, in particular, the ability to inhibit protein kinases, more particularly, the ability to inhibit the protein kinase ITK.

In certain instances the solvate will be capable of isolation, for example when one or more solvent molecules are incorporated in the crystal lattice of the crystalline solid. "Solvate" encompasses both solution-phase and isolable solvates. Representative solvates include hydrates, ethanolates, methanolates, and the like.

Suitable esters of compounds of Formula I containing a hydroxy group, are for example acetates, citrates, lactates, tartrates, malonates, oxalates, salicylates, propionates, succinates, fumarates, maleates, methylene-bis-β-hydroxynaphthoates, gentisates, isethionates, di-p-toluoyltartrates, methanesulfonates, ethanesulfonates, benzenesulfonates, p-toluenesulfonates, cyclohexylsulfamates and quinate.

Suitable esters of compounds of Formula I containing a carboxy group, are for example those described by F.J.Leinweber, *Drug Metab. Res.*, 1987, 18, page 379.

An especially useful class of esters of compounds of Formula I containing a hydroxy group, may be formed from acid moieties selected from those described by Bundgaard et. al., *J. Med. Chem.*, 1989, 32, page 2503-2507, and include substituted (aminomethyl)-benzoates, for example dialkylamino-methylbenzoates in which the two alkyl groups may be joined together and/or interrupted by an oxygen atom or by an optionally substituted nitrogen atom, e.g. an

- 27 -

alkylated nitrogen atom, more especially (morpholino-methyl)benzoates, e.g. 3- or 4-(morpholinomethyl)-benzoates, and (4-alkylpiperazin-1-yl)benzoates, e.g. 3- or 4-(4-alkylpiperazin-1-yl)benzoates.

Some of the compounds of the present invention are basic, and such compounds are useful in the form of the free base or in the form of a pharmaceutically acceptable acid addition salt thereof.

Acid addition salts are a more convenient form for use; and in practice, use of the salt form inherently amounts to use of the free base form. The acids which can be used to prepare the acid addition salts include preferably those which produce, when combined with the free base, pharmaceutically acceptable salts, that is, salts whose anions are non-toxic to the patient in pharmaceutical doses of the salts, so that the beneficial inhibitory effects inherent in the free base are not vitiated by side effects ascribable to the anions. Although pharmaceutically acceptable salts of said basic compounds are preferred, all acid addition salts are useful as sources of the free base form even if the particular salt, per se, is desired only as an intermediate product as, for example, when the salt is formed only for purposes of purification, and identification, or when it is used as intermediate in preparing a pharmaceutically acceptable salt by ion exchange procedures. Pharmaceutically acceptable salts within the scope of the invention include those derived from mineral acids and organic acids, and include hydrohalides, e.g. hydrochlorides and hydrobromides, sulfates, phosphates, nitrates, sulfamates, acetates, citrates, lactates, tartrates, malonates, oxalates, salicylates, propionates, succinates, fumarates, maleates, methylene-bis-b-hydroxynaphthoates, gentisates, isethionates, di-p-toluoyltartrates, methane-sulfonates, ethanesulfonates, benzenesulfonates, p-toluenesulfonates, cyclohexylsulfamates and quinate.

Where the compound of the invention is substituted with an acidic moiety, base addition salts may be formed and are simply a more convenient form for use; and in practice, use of the salt form inherently amounts to use of the free acid form. The bases which can be used to prepare the base addition salts include preferably those which produce, when combined with the free acid, pharmaceutically acceptable salts, that is, salts whose cations are non-toxic to the patient in pharmaceutical doses of the salts, so that the beneficial inhibitory effects inherent in the free base

- 28 -

are not vitiated by side effects ascribable to the cations. Pharmaceutically acceptable salts, including those derived from alkali and alkaline earth metal salts, within the scope of the invention include those derived from the following bases: sodium hydride, sodium hydroxide, potassium hydroxide, calcium hydroxide, aluminium hydroxide, lithium hydroxide, magnesium hydroxide, zinc hydroxide, ammonia, ethylenediamine, N-methyl-glucamine, lysine, arginine, ornithine, choline, N,N'-dibenzylethylenediamine, chlorprocaine, diethanolamine, procaine, N-benzylphenethylamine, diethylamine, piperazine, tris(hydroxymethyl)aminomethane, tetramethylammonium hydroxide, and the like.

As well as being useful in themselves as active compounds, salts of compounds of the invention are useful for the purposes of purification of the compounds, for example by exploitation of the solubility differences between the salts and the parent compounds, side products and/or starting materials by techniques well known to those skilled in the art.

The compounds of the invention are ITK inhibitors and therefore have useful pharmacological activity. Accordingly, they are incorporated into pharmaceutical compositions and used in the treatment of patients suffering from certain medical disorders. The present invention thus provides, according to a further aspect, compounds of the invention and compositions containing compounds of the invention for use in therapy.

Compounds within the scope of the present invention are inhibitors of ITK, according to tests described in the literature, and tests described hereinafter, and which tests results are believed to correlate to pharmacological activity in humans and other mammals. Thus, in a further embodiment, the present invention provides compounds of the invention and compositions containing compounds of the invention for use in the treatment of a patient suffering from, or subject to, conditions which can be ameliorated by the administration of an inhibitor of ITK. For example, compounds of the present invention are useful in the treatment of asthma.

References herein to treatment should be understood to include prophylactic therapy as well as treatment of established conditions.

- 29 -

The present invention also includes within its scope pharmaceutical compositions comprising at least one of the compounds of the invention in association with a pharmaceutically acceptable carrier or excipient.

Compounds of the invention may be administered by any suitable means. In practice compounds of the present invention may generally be administered parenterally, topically, rectally, orally or by inhalation, especially by the oral route.

Compositions according to the invention may be prepared according to the customary methods, using one or more pharmaceutically acceptable adjuvants or excipients. The adjuvants comprise, inter alia, diluents, sterile aqueous media and the various non-toxic organic solvents. The compositions may be presented in the form of tablets, pills, granules, powders, aqueous solutions or suspensions, injectable solutions, elixirs or syrups, and can contain one or more agents chosen from the group comprising sweeteners, flavorings, colorings, or stabilizers in order to obtain pharmaceutically acceptable preparations. The choice of vehicle and the content of active substance in the vehicle are generally determined in accordance with the solubility and chemical properties of the active compound, the particular mode of administration and the provisions to be observed in pharmaceutical practice. For example, excipients such as lactose, sodium citrate, calcium carbonate, dicalcium phosphate and disintegrating agents such as starch, alginic acids and certain complex silicates combined with lubricants such as magnesium stearate, sodium lauryl sulfate and talc may be used for preparing tablets. To prepare a capsule, it is advantageous to use lactose and high molecular weight polyethylene glycols. When aqueous suspensions are used they can contain emulsifying agents or agents which facilitate suspension. Diluents such as sucrose, ethanol, polyethylene glycol, propylene glycol, glycerol and chloroform or mixtures thereof may also be used.

For parenteral administration, emulsions, suspensions or solutions of the products according to the invention in vegetable oil, for example sesame oil, groundnut oil or olive oil, or aqueous-organic solutions such as water and propylene glycol, injectable organic esters such as ethyl oleate, as well as sterile aqueous solutions of the pharmaceutically acceptable salts, are used. The solutions of the salts of the products according to the invention are especially useful

- 30 -

for administration by intramuscular or subcutaneous injection. The aqueous solutions, also comprising solutions of the salts in pure distilled water, may be used for intravenous administration with the proviso that their pH is suitably adjusted, that they are judiciously buffered and rendered isotonic with a sufficient quantity of glucose or sodium chloride and that they are sterilized by heating, irradiation or microfiltration.

For topical administration, gels (water or alcohol based), creams or ointments containing compounds of the invention may be used. Compounds of the invention may also be incorporated in a gel or matrix base for application in a patch, which would allow a controlled release of compound through the transdermal barrier.

For administration by inhalation compounds of the invention may be dissolved or suspended in a suitable carrier for use in a nebulizer or a suspension or solution aerosol, or may be absorbed or adsorbed onto a suitable solid carrier for use in a dry powder inhaler.

Solid compositions for rectal administration include suppositories formulated in accordance with known methods and containing at least one compound of the invention.

The percentage of active ingredient in the compositions of the invention may be varied, it being necessary that it should constitute a proportion such that a suitable dosage shall be obtained. Obviously, several unit dosage forms may be administered at about the same time. The dose employed will be determined by the physician, and depends upon the desired therapeutic effect, the route of administration and the duration of the treatment, and the condition of the patient. In the adult, the doses are generally from about 0.001 to about 50, preferably about 0.001 to about 5, mg/kg body weight per day by inhalation, from about 0.01 to about 100, preferably 0.1 to 70, more especially 0.5 to 10, mg/kg body weight per day by oral administration, and from about 0.001 to about 10, preferably 0.01 to 1, mg/kg body weight per day by intravenous administration. In each particular case, the doses will be determined in accordance with the factors distinctive to the subject to be treated, such as age, weight, general state of health and other characteristics which can influence the efficacy of the medicinal product.

- 31 -

The compounds according to the invention may be administered as frequently as necessary in order to obtain the desired therapeutic effect. Some patients may respond rapidly to a higher or lower dose and may find much weaker maintenance doses adequate. For other patients, it may be necessary to have long-term treatments at the rate of 1 to 4 doses per day, in accordance with the physiological requirements of each particular patient. Generally, the active product may be administered orally 1 to 4 times per day. Of course, for some patients, it will be necessary to prescribe not more than one or two doses per day.

Compounds of the invention may be prepared by the application or adaptation of known methods, by which is meant methods used heretofore or described in the literature.

In the reactions described hereinafter it may be necessary to protect reactive functional groups, for example hydroxy, amino, imino, thio or carboxy groups, where these are desired in the final product, to avoid their unwanted participation in the reactions. Conventional protecting groups may be used in accordance with standard practice, for examples see T.W.Greene and P.G.M.Wuts in "Protective Groups in Organic Chemistry" John Wiley and Sons, 1991.

It will be appreciated that compounds of the present invention may contain asymmetric centers. These asymmetric centers may independently be in either the R or S configuration. It will be apparent to those skilled in the art that certain compounds of the invention may also exhibit geometrical isomerism. It is to be understood that the present invention includes individual geometrical isomers and stereoisomers and mixtures thereof, including racemic mixtures, of compounds of Formula I hereinabove. Such isomers can be separated from their mixtures, by the application or adaptation of known methods, for example chromatographic techniques and recrystallisation techniques, or they are separately prepared from the appropriate isomers of their intermediates. Additionally, in situations where tautomers of the compounds of Formula I are possible, the present invention is intended to include all tautomeric forms of the compounds.

According to a further feature of the invention, acid addition salts of the compounds of this invention may be prepared by reaction of the free base with the appropriate acid, by the

- 32 -

application or adaptation of known methods. For example, the acid addition salts of the compounds of this invention may be prepared either by dissolving the free base in water or an aqueous alcohol solution or other suitable solvents containing the appropriate acid and isolating the salt by evaporating the solution, or by reacting the free base and acid in an organic solvent, such as tetrahydrofuran, in which case the salt separates directly or can be obtained by concentration of the solution.

Compounds of this invention can be regenerated from their acid addition salts by the application or adaptation of known methods. For example, parent compounds of the invention can be regenerated from their acid addition salts by treatment with an alkali, e.g. aqueous sodium bicarbonate solution or aqueous ammonia solution.

According to a further feature of the invention, base addition salts of the compounds of this invention may be prepared by reaction of the free acid with the appropriate base, by the application or adaptation of known methods. For example, the base addition salts of the compounds of this invention may be prepared either by dissolving the free acid in water or aqueous alcohol solution or other suitable solvents containing the appropriate base and isolating the salt by evaporating the solution, or by reacting the free acid and base in an organic solvent, in which case the salt separates directly or can be obtained by concentration of the solution.

Compounds of this invention can be regenerated from their base addition salts by the application or adaptation of known methods. For example, parent compounds of the invention can be regenerated from their base addition salts by treatment with an acid, e.g. hydrochloric acid.

Compounds of the present invention may be conveniently prepared, or formed during the process of the invention, as solvates (e.g. hydrates). Hydrates of compounds of the present invention may be conveniently prepared by recrystallisation from water.

- 33 -

The starting materials and intermediates which are not commercially available may be prepared by the application or adaptation of known methods, for example methods as described in the Examples or their obvious chemical equivalents.

Compounds of the invention may also be prepared by interconversion of other compounds of the invention.

Thus, for example, compounds of formula (I) containing a carboxy group may be prepared by hydrolysis of the corresponding esters. The hydrolysis may conveniently be carried out by alkaline hydrolysis using a base, such as an alkali metal hydroxide, e.g. lithium

- 41 -

hydroxide, or an alkali metal carbonate, e.g. potassium carbonate, in the presence of an aqueous/organic solvent mixture, using organic solvents such as dioxan, tetrahydrofuran or methanol, at a temperature from about ambient to about reflux. The hydrolysis of the esters may also be carried out by acid hydrolysis using an inorganic acid, such as hydrochloric acid, in the presence of an aqueous/inert organic solvent mixture, using organic solvents such as dioxan or tetrahydrofuran, at a temperature from about 50°C to about 80°C.

As another example compounds of formula (I) containing a carboxy group may be prepared by acid catalysed removal of the tert-butyl group of the corresponding tert-butyl esters using standard reaction conditions, for example reaction with trifluoroacetic acid at a temperature at about room temperature.

As another example compounds of formula (I) containing a carboxy group may be prepared by hydrogenation of the corresponding benzyl esters. The reaction may be carried out in the presence of ammonium formate and a suitable metal catalyst, e.g. palladium, supported on an inert carrier such as carbon, preferably in a solvent such as methanol or ethanol and at a temperature at about reflux temperature. The reaction may alternatively be carried out in the presence of a suitable metal catalyst, e.g. platinum or palladium optionally supported on an inert carrier such as carbon, preferably in a solvent such as methanol or ethanol.

As another example of the interconversion process, compounds of formula (I) containing a $Y^1Y^2N-C(=O)-$ group may be prepared by coupling compounds of formula (I) containing a carboxy group, with an amine of formula Y^1Y^2NH , to give an amide bond using standard peptide coupling procedures. Examples include (i) coupling in the presence of O-(7-azabenzotriazol-1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate and triethylamine (or diisopropylethylamine) in tetrahydrofuran (or dimethylformamide) at room temperature, (ii) coupling in the presence of a carbodiimide, for example dicyclohexylcarbodiimide in the presence of triethylamine, (iii) treatment with 1-hydroxybenzotriazole and a carbodiimide, such as 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide, in an inert solvent such as dimethylformamide and at a temperature at about room temperature. Thus, for example, 3-(5-hydroxymethyl-1H-indol-2-yl)-1H-thieno[3,2-c]pyrazole-5-carboxylic acid (Example 37) may be reacted with 1-(4-fluorophenyl)piperazine in the presence of 1-ethyl-3-(3-

- 42 -

dimethylaminopropyl)carbodiimide and 1-hydroxybenzotriazole to produce [4-(4-fluorophenyl)-piperazin-1-yl]-[3-(5-hydroxymethyl-1H-indol-2-yl)-1H-thieno[3,2-c]pyrazol-5-yl]-methanone (Example 38).

Soc., Perkin I, 1977, 2436-2441) to obtain 5-methyl-4-nitro-thiophene-2-carboxylic acid methyl ester [Intermediate (23)].

Step 2. 5-Methyl-4-nitro-thiophene-2-carboxylic acid methyl ester [15.09 g., 75.0 mM, Intermediate (23)] is dissolved in ethyl acetate (200 mL) to which 10% palladium on charcoal (1.03 g) is added and the mixture is shaken under 50 psi of hydrogen. The catalyst is removed by filtration and the solvent is removed leaving 4-amino-5-methyl-thiophene-2-carboxylic acid methyl ester [12.82 g., 99.8%, Intermediate (24)] as a yellow solid; MS 171.9 (100%, M + 1).

Step 3. A magnetically stirred mixture of potassium acetate (4.52 g, 46.1 mM) in toluene (100 mL) containing 4-amino-5-methyl-thiophene-2-carboxylic acid methyl ester [12.8 g, 74.7 mM, Intermediate (24)] is warmed to dissolve the amine. Acetic anhydride (13.8 mL, 124.9 mM) is added to this mixture and it is heated in an oil bath. Isoamyl nitrite (9.73 mL, 72.4 mM) is added over 30 minutes. Heating at 93°C is continued overnight. The cooled mixture is diluted with ethyl acetate (100 mL), filtered and the filtrate is concentrated to a black solid which is purified by chromatography, eluting with heptane-25% ethyl acetate, heptane-35% ethyl acetate, heptane-40% ethyl acetate, heptane-50% ethyl acetate, heptane-60% ethyl acetate. Fractions containing pure product are combined and concentrated to afford 1-acetyl-1H-thieno[3,2-c]pyrazole-5-carboxylic acid methyl ester [9.74 g, 49.3%, Intermediate (25)].

Step 4. To a suspension of 1-acetyl-1H-thieno[3,2-c]pyrazole-5-carboxylic acid methyl ester [1.3 g, 5.79 mmol, Intermediate (25)] in methanol (30 mL) is added sodium methoxide (25 wt% in methanol). The resulting solution mixture is stirred at 60°C oil bath for 20 minutes. The oil bath is removed and stirred for 5 minutes. To this is added a solution of iodine (1.76g, 6.93 mmol) in dimethyl formamide (2 mL). The reaction mixture then heated to 60°C for 1 hour. The solvent is removed in vacuo. The crude is partitioned between ethyl acetate (100 mL) and water (100 mL) and aqueous layer is further extracted with twice ethyl acetate (25 mL). The combined ethyl acetate phases are washed with brine, dried over sodium sulfate and filtered. The solvent is removed in vacuo to give 3-iodo-1H-thieno[3,2-c]pyrazole-5-carboxylic acid methyl ester [1.58g, 89%, Intermediate (26)] as light yellow solid; ¹H NMR [(CD₃)₂SO]: δ 13.80 (1H, brs, NH), 7.947 (1H, s), 3.870 (3H, s).

After stirring for 30 minutes, the solvent is removed in vacuo. The solid is suspended in a mixture of ethyl acetate, heptane and methanol and stirred for a while. The solid is filtered and vacuum dried to give 3-iodo-thieno[3,2-c]pyrazole-1,5-dicarboxylic acid 1-tert-butyl ester 5-methyl ester [1.72 g, 87%, Intermediate (21)] as off-white solid; ^1H NMR $[(\text{CD}_3)_2\text{SO}]$: δ 6.880 (1H, s), 3.900 (3H, s), 1.633 (9H, s); LC/MS: 409 (M + H).

IN VITRO TEST PROCEDURES FOR ITK

Anti-CD3 stimulated IL-4 Assay from Murine splenocytes.

Introduction

The tyrosine kinase ITK is involved in intracellular signaling events induced by several lymphocyte surface receptors. Since ITK deficient mice show an impairment in IL-4 production from T cells, a cell based assay for IL-4 production is used to measure the cellular potency of the ITK inhibitors of the present invention. In this assay the level of IL-4 is measured from the media of anti-CD3-stimulated murine splenocytes, and the ability of compounds of the present invention to inhibit this response is determined.

Assay Conditions

Spleens from the mouse strain BALB/c are isolated and used to prepare a suspension of mixed splenocytes. The spleens are homogenized with cell strainer (Falcon Cat#352350 and 5ml syringe) in RPMI media. The mixture is spun down, and the pellets are suspended in 3ml of Red Blood Cell Lysing Buffer (Sigma Cat#7757) and left for 10 minutes at room temperature. Cells are spun down again, and resuspended in RPMI with 10% FBS and passed through cell strainer. Total cell numbers are determined with hemocytometer.

Splenocytes are adjusted to a cell density of 10 million per ml of RPMI medium supplemented with 10% Foetal Bovine Serum (FBS) and 100ul of the suspension plated out per well of a 96 round bottom plate. 50ul of RPMI medium containing 4x the final concentration of test

- 147 -

compound is added per well. For IC50 determination the following concentrations of compound are used. The starting concentration is 10uM and 7 series of 1:3 dilutions are followed, and each compound concentration is set up in triplicate wells. 50ul of 4x concentration are added. Cell cultures are then stimulated by addition of 50 ul of a 4ug/ml solution of anti-CD3 antibody, (BD Bioscience Cat# 553166) made up in RPMI plus 10% FBS media, and incubated in a 37°C CO2 incubator for 3 days. At the end of the 3 day incubation, culture medium is taken and 50 uls used to assay IL-4 production by ELISA (IL-4 ELISA kit from R&D Systems, city. Cat# M4000 kit) according to the standard conditions described by the manufacturer.

IL-4 levels are plotted as a function of compound concentration. The concentration of compound resulting in 50% inhibition of IL-4, termed IC50(IL-4), is determined from the resulting curve.

1. Add 100ul of 1X10E7/ml mouse splenocytes in RPMI plus 10% FBS media to 96 well round bottom plates.
2. Add 50ul of Itk compounds (4x final concentration) in RPMI plus 10% FBS media
3. Add 50ul of 4ug/ml anti-CD3 antibody in RPMI plus 10% FBS media
4. Incubate at 37c CO2 incubator for 3 days
5. Transfer 150ul culture media into fresh plate
6. 50ul of the media is subject to Elisa analysis (R & D Cat# M4000 kit)

FlashPlate ITK Protocol for ITK Inhibition Determination

ITK kinase is produced with an N-terminal Maltose Binding Protein tag (MW= ~114 kDa) using a Baculovirus expression system. The transfer of radioactive [γ -³³P] phosphate from [γ -³³P]ATP to ITK during the autophosphorylation of ITK is measured by scintillation counting. Streptavidin-coated FlashPlate Plus™ 384 well microplates (PerkinElmer Life Sciences) are designed for in-plate radiometric assays. The interior of

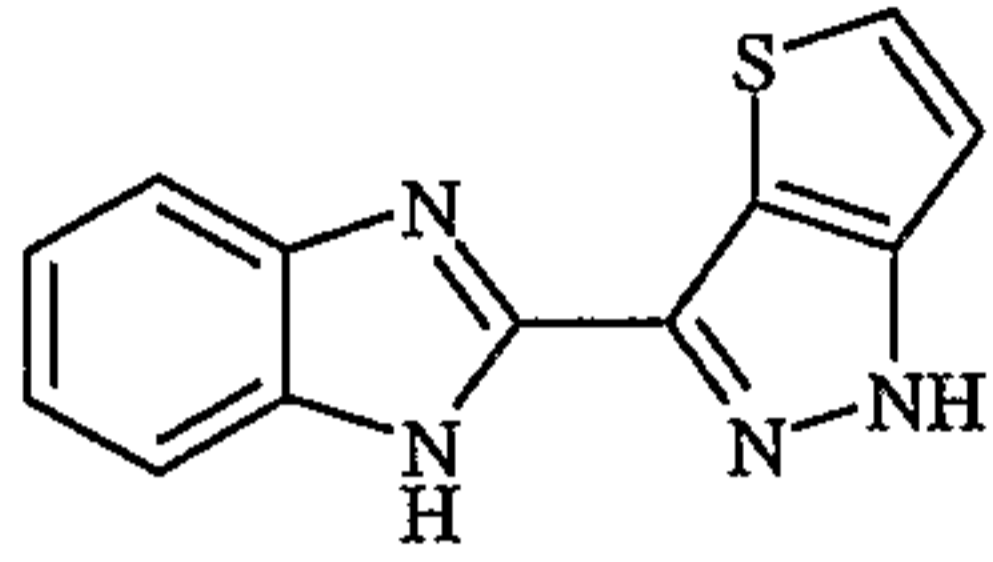

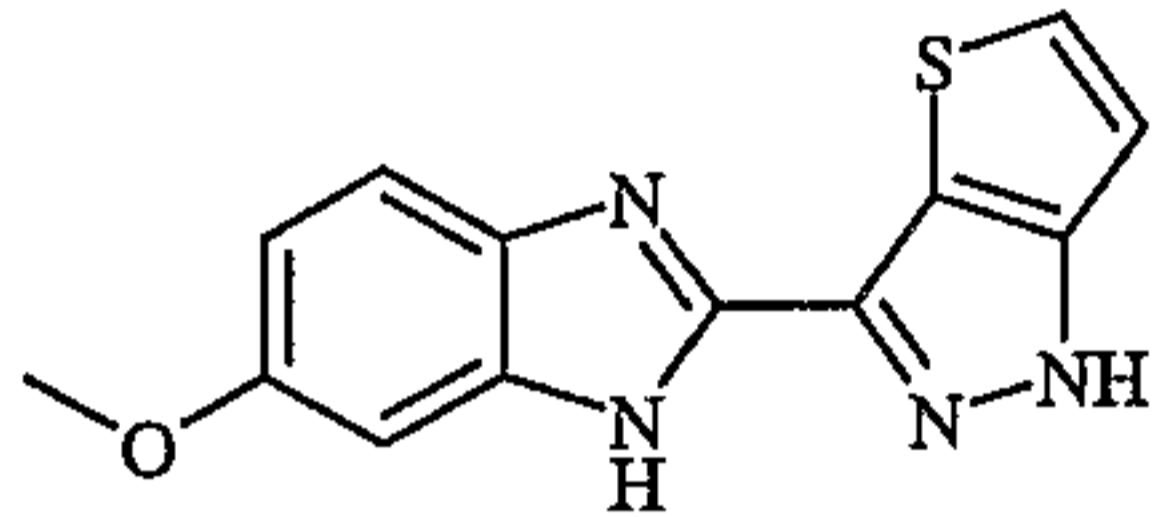

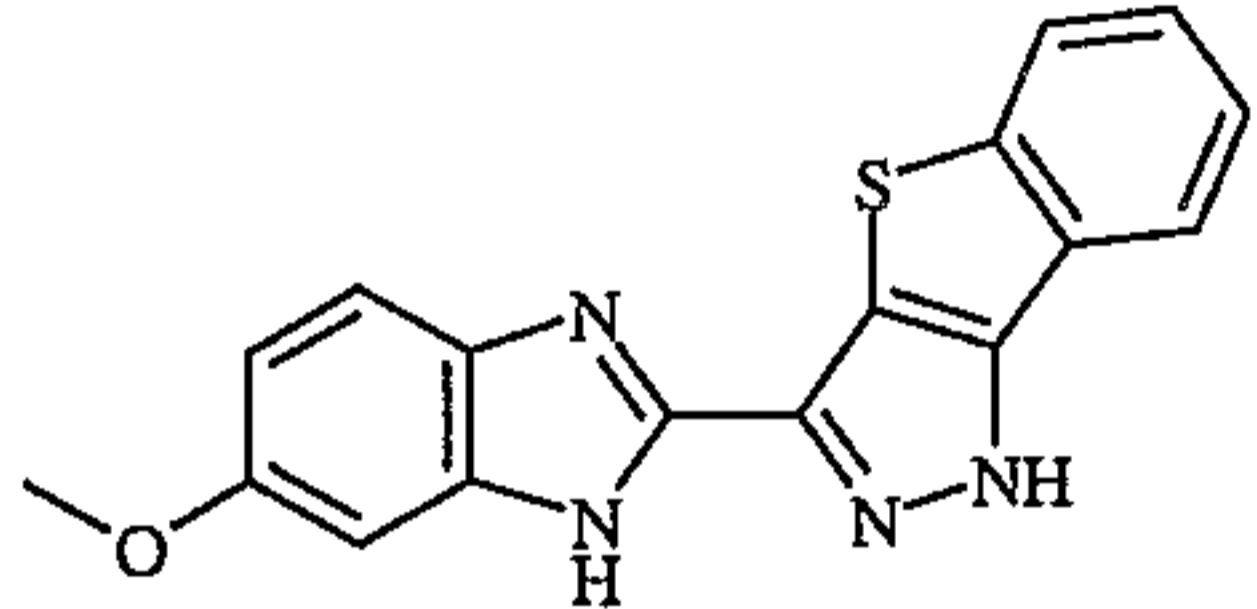

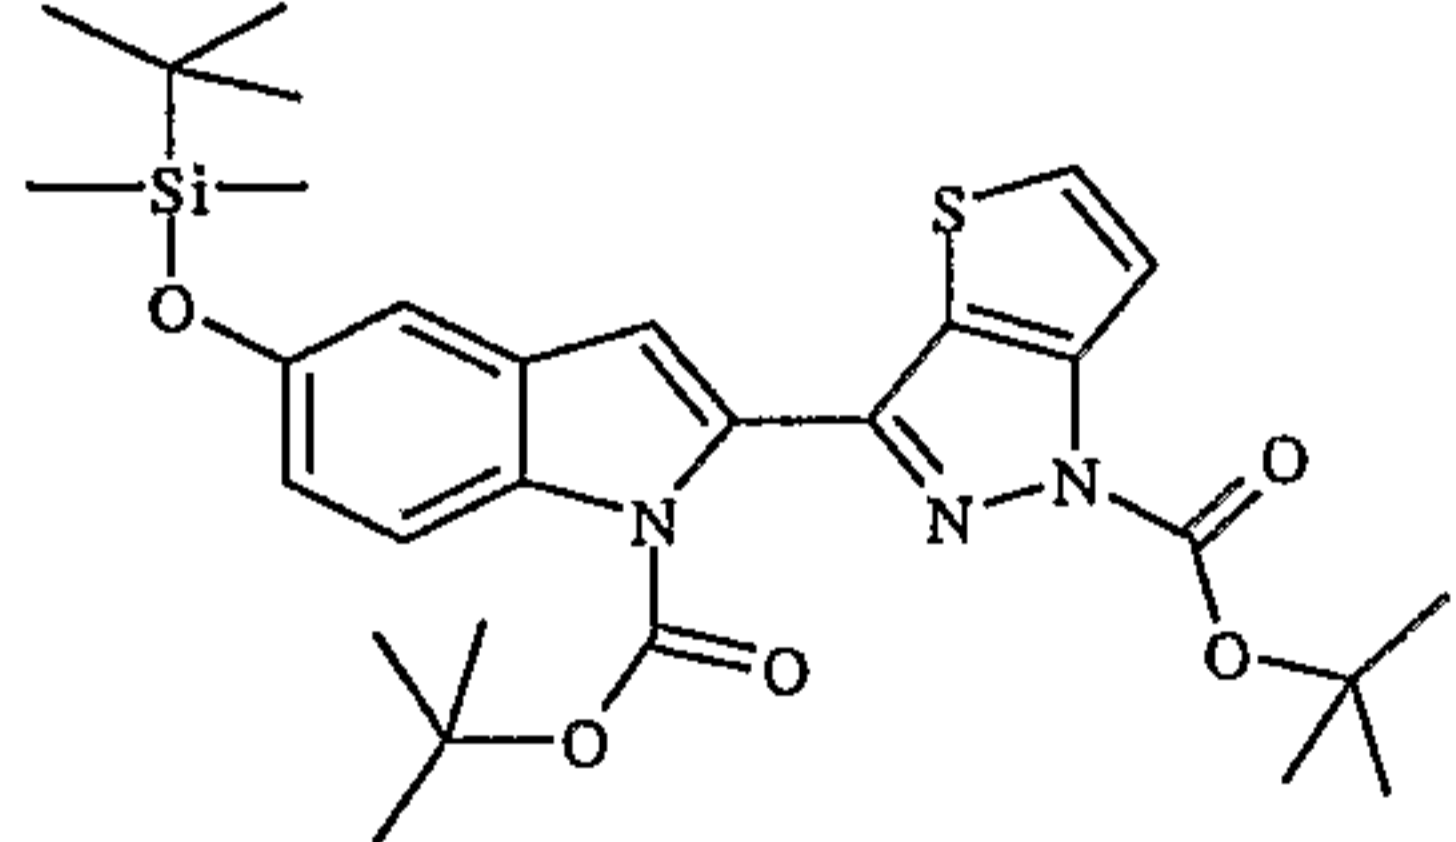

- 148 -

each well is permanently coated with a thin layer of scintillant and a covalently bound layer of Streptavidin. ITK is incubated with [γ - ^{33}P]ATP, biotinylated anti-MBP antibody (Cell Signaling TechnologyTM) and test compounds in a 384-well Streptavidin-coated FlashPlate. The biotinylated anti-MBP binds tightly to the MBP-tagged ITK and cross-links it to Streptavidin on the plate surface. Unreacted ^{33}P -ATP is washed away and ^{33}P -phosphorylated ITK is measured when the [γ - ^{33}P] incorporated into ITK stimulates the scintillant on the well to emit light. Radioactivity is assessed in a Packard TopCount scintillation counter. Reagents are pipetted and dispensed using Beckman Biomek robotic equipment. Test compounds (2 μl per well) are pre-diluted from 1mM 100% dimethyl sulfoxide solutions into water containing 30% dimethyl sulfoxide to produce dose response curves (10 point curves from (final) 30 μM to ~ 1 nM); all tests are performed in duplicate. Background binding is assessed by substituting the enzyme inhibitor EDTA (25mM final concentration) for test compound and maximal binding is assessed by inclusion of assay buffer instead of compound. Test compounds are added to the wells first (2 μl) followed by 10 μl enzyme solution in assay buffer. After 30 minutes pre-incubation, all other reagents are added in a 10 μl volume. The final reagent concentrations/well are as follows: 20 nM enzyme, 0.25 μCi [γ - ^{33}P]ATP, assay buffer: 20 mM HEPES (pH 7.5), 0.15 M NaCl, 3mM MgCl_2 , 3mM MnCl_2 , 0.01% Triton X-100, 1 mM DTT, 5% glycerol and 0.01% γ -globulin. The plate is incubated at room temperature (RT) for 60 minutes for the kinase reaction. The reaction is stopped with 20 μl of 50mM EDTA and the biotinylated anti-MBP is allowed to bind to the ITK and the Streptavidin for a further 60 minutes at RT. The unbound reagents are washed away with 2 x 100 μl phosphate-buffered saline (PBS). Radioactivity is measured for 45 sec/well.

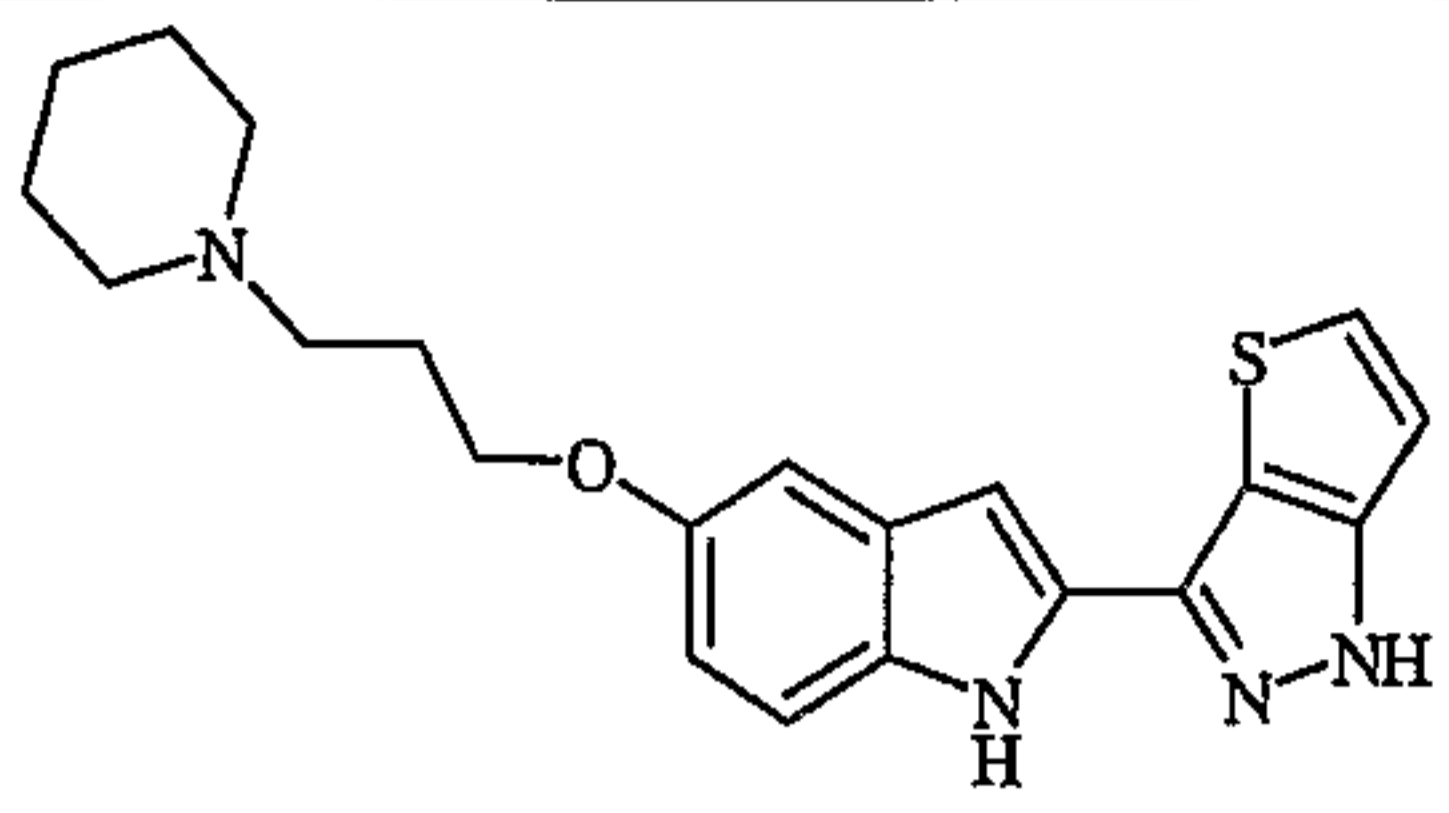

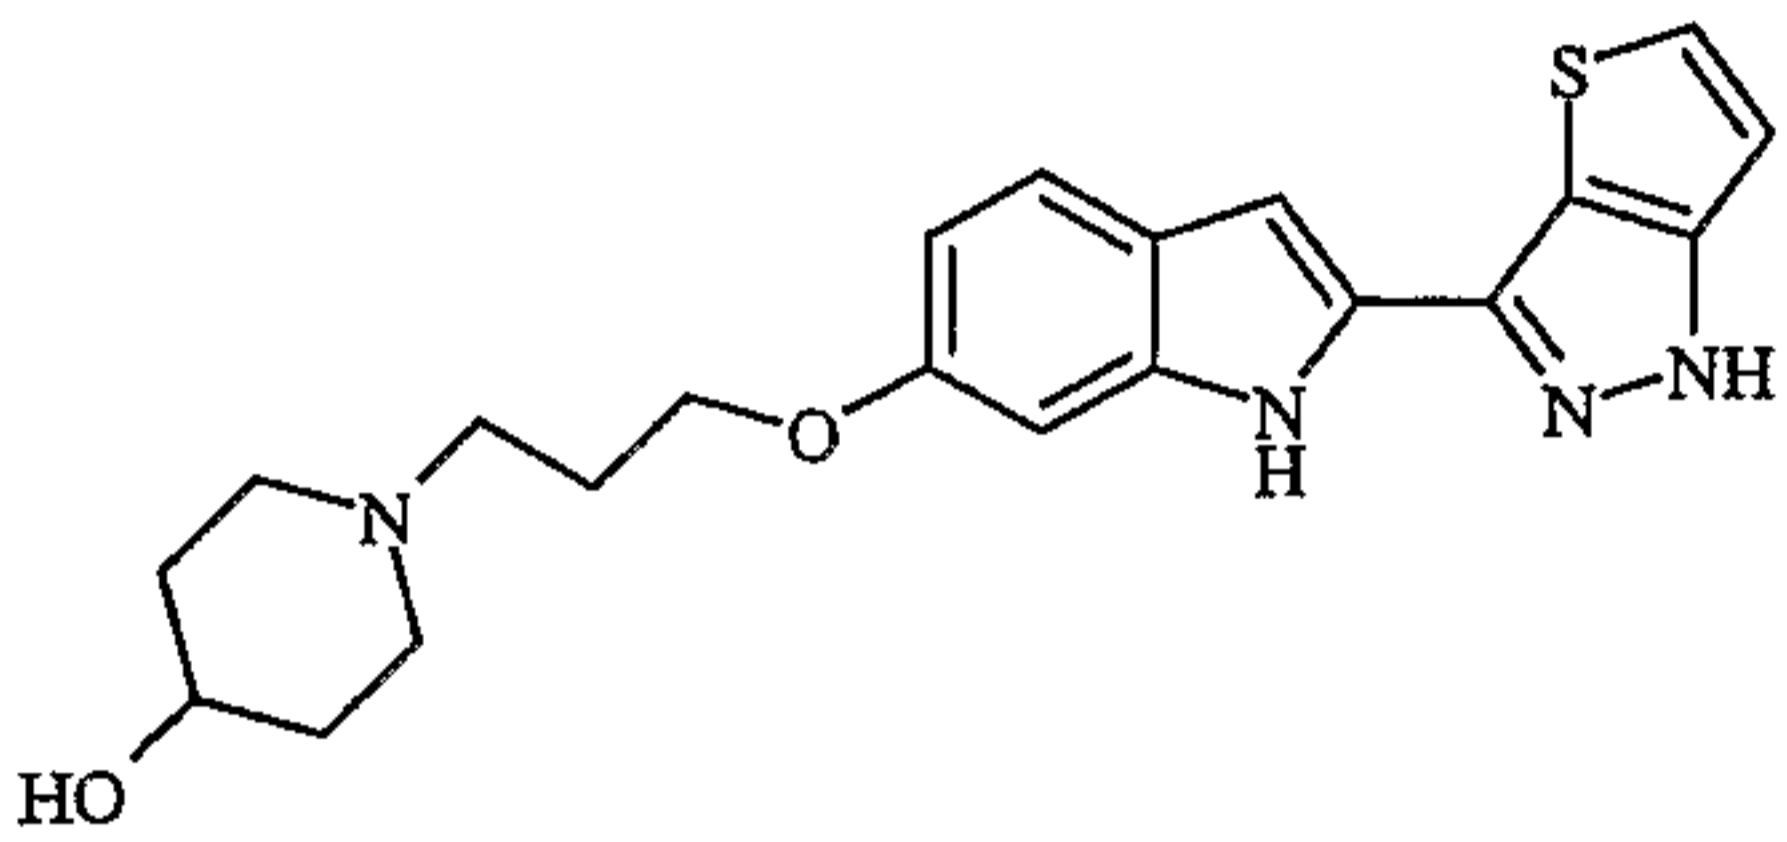

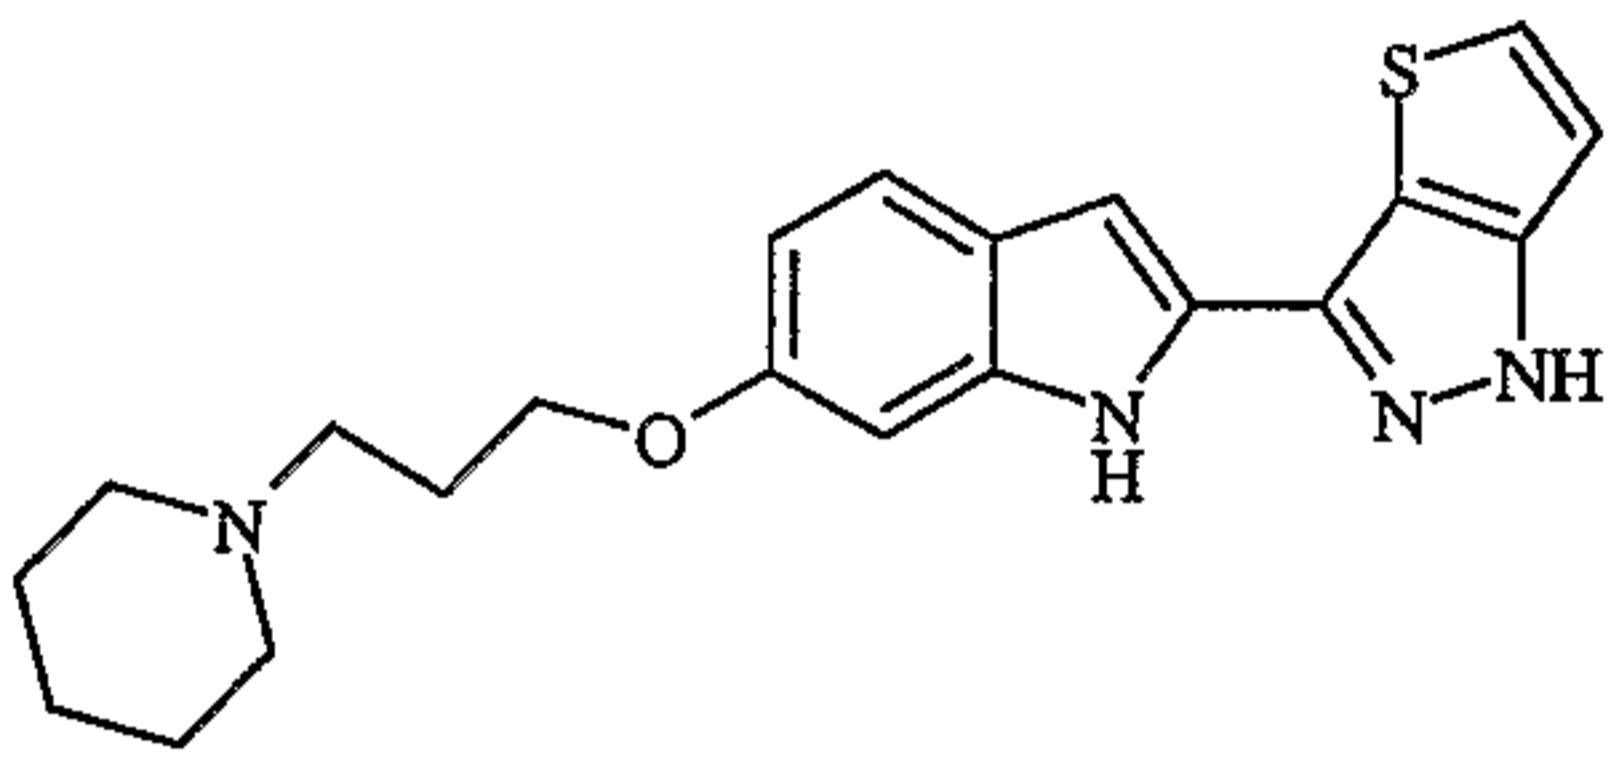

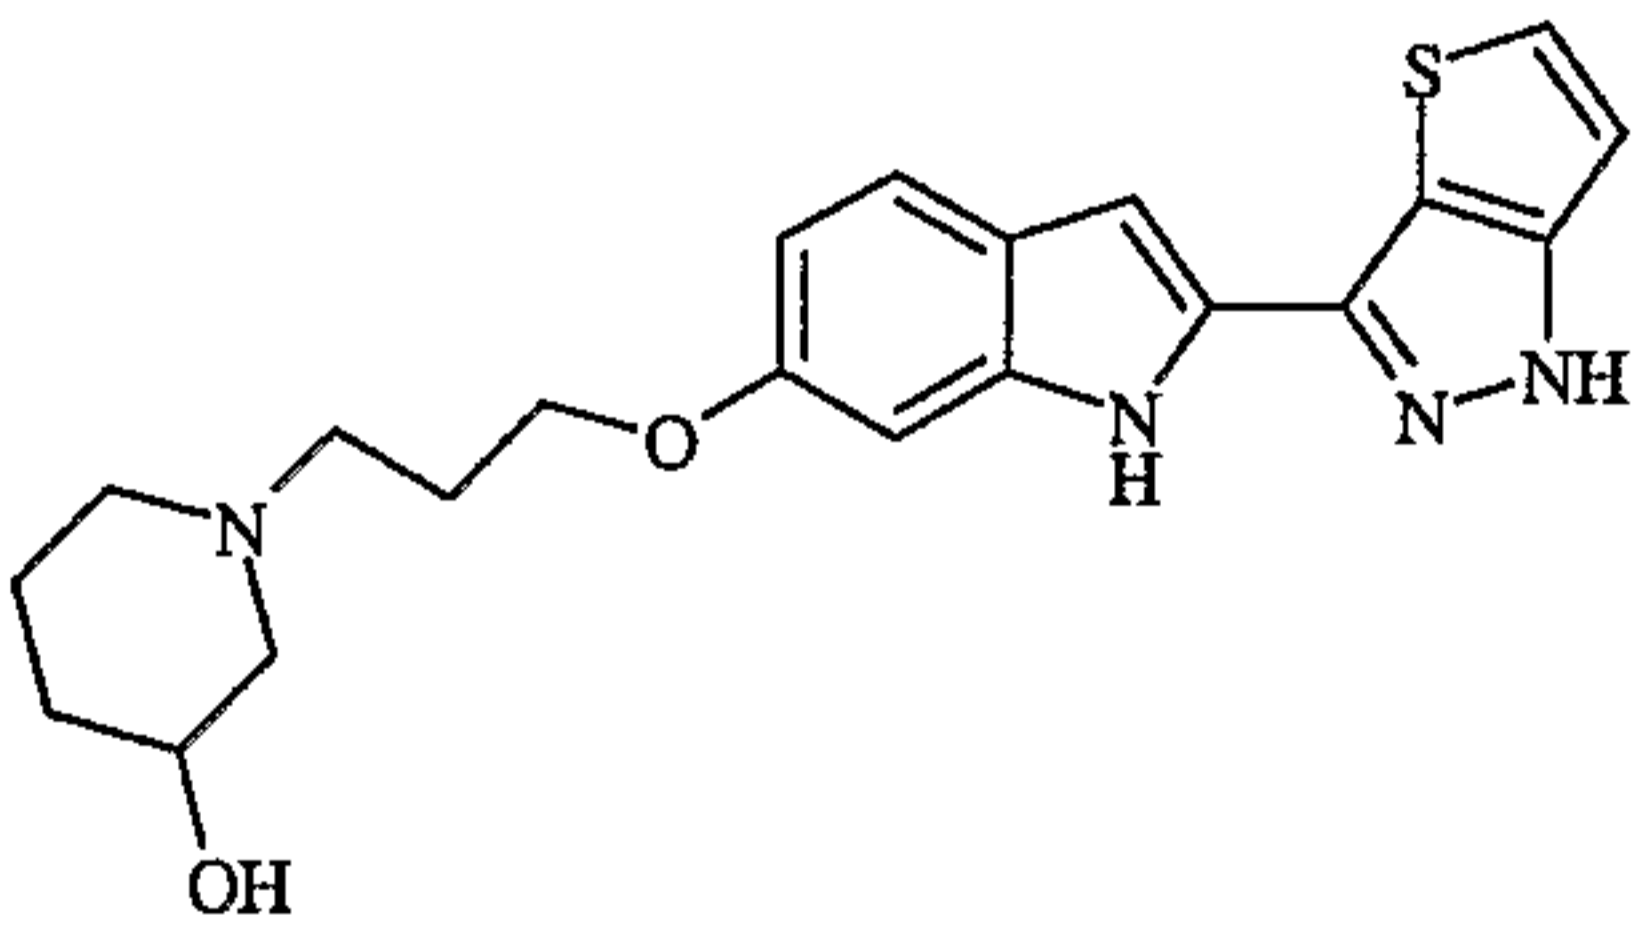

Results for compounds of the present invention in these tests are shown in Table I.
