(54) Title: METHOD OF AND APPARATUS FOR PROCESSING DATA AT A REMOTE WORKSTATION

## (57) Abstract

A method and apparatus for processing at a remote workstation (14), data files that are compressed and collected into groups on a local area network (10) at a central location. The files of a group are transferred to the workstation over an ISDN switched telephone network (22) in response to automatic requests from the workstations. The workstation requests depend on unprocessed files at the workstation as well as the time and date, in order to reduce the connection time. When files are received at the workstation the first is immediately decompressed and presented to the operator. In the meantime the next file which the operator is expected to need is decompressed in the background and is ready for processing as soon as the operator finishes with the first. When the operator switches to the next file the processing results are automatically saved and a further file is decompressed and held in a queue for the operator.

5                                   **METHOD OF AND APPARATUS FOR PROCESSING  
DATA AT A REMOTE WORKSTATION**

**BACKGROUND OF THE INVENTION**

The invention relates to high performance remote data processing and,  
10 more particularly, to a method of and apparatus for the effective remote  
assignment, transmission, processing, collection, and management of documents  
which can be represented as digital data.

Many industries require the processing and management of a large  
number of documents. These documents are typically paper, but can also include  
15 other physical media, such as photographs, audio or video recordings, art works,  
physical evidence, etc. Much of the information in these documents may be  
converted into a digital format and stored into a computer system via a variety of  
techniques, such as digital scanning for paper and photographs and digital recording  
for audio and video. In addition, there are many source documents which are  
20 native to a computer environment, such as word processing and spreadsheet files  
or a record from a computer database. Documents which are composed of one or  
more of these different data types can be referred to as electronic or digital  
documents.

While the concept of electronic or digital documents is not new, the  
25 increasing use of digital imaging techniques to acquire and store business records,  
as well as the prevalence of personal computing data at the office, presents a

series of technical opportunities and challenges for the efficient distribution and comprehensive management of such documents.

For instance, it is often desirable to grant remote access to electronic documents so that employees may work at home or some other remote location.

5 Having employees work at home is becoming increasingly popular because it provides benefits to both the employer and the stay-at-home employee. So called, "telecommuting" employees can save a firm a great deal of overhead expense in terms of office space. Telecommuting also allows a firm to hire talented workers who could not otherwise work in the office setting. For example, employees with  
10 a long-term illness or physical handicap, or parents with small children may enthusiastically work at home because of the flexible work schedule, but could not conveniently work in an office.

Giving a remote employee access to the digital electronic documents upon which they must work presents several technical problems. These documents  
15 can be very large in size in terms of the number of digital bits they represent. The size of a typical bi-level 8.5" x 11" page scanned at 200 dots per inch can range from 5K bytes to 200K bytes depending upon the amount of information contained on the scanned page. An average compressed image size could be 50K bytes. Color and gray scale images can be an order of magnitude larger, and audio/video  
20 recordings an order of magnitude larger again. This contrasts sharply with typical ASCII data transmissions which are less than 2K per terminal screen in size.

Secondly, in many occupations, a remote employee will be rated or compensated based on productivity, such as the number of forms processed per

hour. Because the document is delivered to the remote employee via the transmission and display of digital data, the workstations through which the remote employees work must be capable of a sufficiently high level of performance that they do not impede the employee's productivity. Assuming that the performance of a workstation in the central office is adequate for the requisite productivity, the remote workstations have the problem of maintaining performance levels while coping with the additional task of receiving and transmitting the data over a considerable distance.

These issues of electronic document data size and high workstation performance are typically solved by the use of higher bandwidth telecommunications facilities. While very high bandwidth facilities are available from a local phone company, they can also be prohibitively expensive. A practical economic alternative for a small remote site is a medium bandwidth "switched line" digital service. The "switched line" offered by the telephone company has one transmission wire installed between the remote site and the phone company and another wire installed between the phone company and the central office. As with typical voice telephone service, the phone company connects the two sites on an "on-demand" basis and charges for the connection based on a series of call factors, including the time of day and the duration of the connection. Thus, like any other business expense, it becomes highly desirable to minimize the ongoing cost of the telephone service required to support the transmission of these electronic documents.

One type of medium bandwidth switched line is the Integrated Services Digital Network ("ISDN") which has three transmission channels, two of which transfer data at a 64K band rate (the so called "B channels") and one of which transfers data at 16K band, for a total 144K baud bandwidth. U.S. Patents  
5 Nos. 4,930,123 of Shimzu and 5,200,993 of Wheeler et al. describe the communication of data to remote workstations using ISDN lines.

Further problems are presented to the employer of a team of remote employees. In order to manage, control, and compensate the activity of the remote employees, the employer must have the capability of efficiently making work  
10 assignments of the digital documents, and monitoring and managing the progress of the assignments. This gives the employer the ability to make sure that the work is completed in a timely and cost effective manner and that an individual worker's activity is assessed and compensated accurately. The accomplishment of this work management in a distributed remote environment can be greatly enhanced by the  
15 use of automated processes for work assignment, monitoring, accounting, and compensation.

#### **SUMMARY OF THE INVENTION**

The present invention is directed to solving the foregoing and other  
20 problems involved in remote workstations by improving the efficiency with which document data is assigned, transmitted, and collected to and from these workstations, as well as ensuring that optimal workstation performance is maintained while work is being processed.

Thus, it is an object of the present invention to provide high performance remote access to digital electronic documents on a network.

It is another object of the invention to reduce the overall cost of transmission over a switched communications medium when accessing a series of  
5 digital documents.

It is still a further object of the invention to minimize the amount of idle time for a worker at a remote workstation such that worker productivity can be maximized.

It is an object of the invention to simplify management of remote  
10 workstations by automatically assigning, distributing, tracking, and collecting digital documents.

In an illustrative embodiment of the invention, a method of and apparatus for, utilizing a remote high-performance workstation system involves processing a series of digital documents that are accessed at a central location.  
15 The method and apparatus also automatically assign and manage such documents for transmission of the documents to the remote sites from the central office.

Digital documents are stored on a computer or network of computers as document files at the central location. The document files are compressed to save storage space and reduce transmission time. The computer system examines  
20 the digital documents available on the system and then, based on a set of predetermined criteria, assigns some or all of the documents to a remote employee or a group of remote employees. In addition, the system identifies the particular digital pages of each document which are required by the employee or group of

employees to accomplish the assigned business processing. For digital scanned images the system can also identify particular areas of an image, called "clippings", which are required for processing, and only transmit those instead of the entire digital page. These methods help to minimize the transmitted data, which in turn  
5 increases performance of, and minimizes transmission costs for, the remote workstation.

Compressed data files of the digital documents may be sent to the remote workstation automatically, where they are made into an inventory of work. A central processor on the network keeps track of the documents sent to the  
10 remote location. The remote user decompresses the files in inventory one at a time and processes them.

A remote employee's workstation computer may be programmed to maintain a certain level of work in inventory. As the remote employee processes documents, the amount of work in inventory decreases. When the amount of work  
15 falls below a particular threshold level, the remote computer automatically requests an additional volume of work by placing a call, i.e., establishing a telecommunications link, to the central office. By default, this call will be placed at a time scheduled to minimize the cost of the data transfer or to coordinate access to a limited amount of computing or telecommunications facilities at the  
20 central office. Only those pages of the digital documents which have been assigned to the remote employee or the group to which he or she belongs, and which are required for the business data processing, will be automatically transmitted to the remote workstation. Information is recorded in the central

computer to indicate the status of these documents for the purposes of management reporting. In addition, any data that had been modified in the course of processing the inventory at the workstation, as well as the status for documents previously transmitted to the workstation, will be sent back to the central office  
5 during this data call.

Because the data call is deferred until a minimum volume of work is required, and because updates to the central office data base are deferred until the next data call is placed, the bandwidth utilization of any given data call is nearly 100 percent, assuring minimal connection time. Stated differently, there is never  
10 any idle connect time during a call between the remote site and the central site when using this method, thus minimizing the associated cost of the call.

To make more efficient use of the computing hardware at the remote site, the user may be processing data documents from the inventory at the workstation, while a data call is in progress. Also, as soon as the first page of the  
15 first document is received by the workstation, it can be made available to the user for processing, assuming there is no remaining inventory or this document is needed immediately for some other reason, e.g., it is a priority matter. As the user works, the workstation continues to receive new pages and documents from the central office. When the last document transmission is completed and the status  
20 and change data has been sent back to the central office, the data call is automatically terminated. Because the transmission task is completed in the background, the performance which the remote employee experiences is identical

to that of a workstation connected to a local area network ("LAN") at the central office.

In addition, further performance enhancements are obtained through the use of anticipatory processing when work flow is reasonably predictable. As  
5 an example, while the remote employee views and processes a given document, the software at the workstation automatically selects the next document file available and decompresses it in the background. When the user has completed work on the current document, the user can switch to the next document with minimal delay.

10 At the central office, the computer stores information regarding the state of every document in the system, i.e. at the central office LAN and at all of the remote workstations. It also stores information on the processing history of the documents. As documents complete each processing step, the system can automatically update a payroll system to indicate that a particular remote worker  
15 should receive compensation for the processing work completed. In addition, other statistics are automatically retained on worker productivity and can be transferred to a human resources system for use in evaluating local and remote worker output and quality.

#### **BRIEF DESCRIPTION OF THE DRAWINGS**

20 The foregoing and other features of the present invention will be more readily understood from the following detailed description taken together with the accompanying drawings, in which:

FIG. 1 is a block diagram illustrating a hardware arrangement for practicing the method of the present invention;

FIG. 2 is a flow chart illustrating a portion of a method according to the invention, for sending work to a remote workstation;

5 FIG. 3 is a flow chart illustrating a portion of a method carried out at a remote site, according to the invention, for routing documents in the system;

FIG. 4 is a flow chart illustrating anticipatory processing of data files; and

10 FIG. 5 is a flow chart that illustrates inventory management processing at a remote site.

#### **DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT**

The system of the present invention involves two major components, as shown in FIG. 1: a local area network, i.e. LAN, 10 located at a central office 12, and remote workstations 14 located at remote sites 16. At the central office 15 12 a document server 15 and local workstations 18 are connected on the LAN 10. Also present on the LAN 10 are a high-speed scanner 24 and an archive storage unit 26. The archive storage unit 26 can be a "jukebox" type optical storage unit, which can store millions of electronic documents on a series of optical disks that are selected using a jukebox type disk changer mechanism.

20 On the network is a remote gateway server 20, which may be an ISDN gateway server. Server 20 connects the LAN to the remote workstations, e.g. over ISDN lines 22.

FIG. 2 illustrates the program controlled procedure for sending work to an employee at a workstation 14 at remote a site 16. This procedure is under the control of a program stored on the document server 15 at the central office. According to this procedure, the documents are digitally scanned (step 100) using the high-speed scanner 24. The scanned images are compressed and stored as image files (step 102), in order to drastically reduce their size. The uncompressed image file for a scanned image of a document that has considerable "white space", such as a form, can occupy more than 10 times the storage space of the image file when in compressed form.

The compressed image files are loaded onto a network device, such as the document server 15. If a large number of images are scanned at once, or if they are to be stored for an extended period of time, they may be stored in another network device, such as the archive storage unit 26.

As new documents are received by the document server 15, a program executing on the document server, known as a document router, evaluates the characteristics of each document and compares them against a set of predetermined criteria called "routing rules", which have been established and represented in a database (step 104). These rules could consist of any information that would allow the selection of certain documents which are suitable for a particular remote user (employee) or group of workers to process. For example, the files may be selected according to type, such as a Medicaid form, location of the client, date of the form, or any other criteria. Associated with each rule is a named

"destination" which describes a user or group of users or a computer program assigned to perform business data processing for a given document.

FIG. 3 illustrates the document router program of step 104 in FIG. 2 in further detail. For the first document received by the document router (Step 200), a first rule and its associated destination is obtained from the rules database (Step 202). The rule is compared with the data characteristics of the document (Step 204). For instance, a sample rule might be: "DOCUMENT TYPE is a Medical Claims Form and the TOTAL CLAIM AMOUNT field is greater than \$1,000" with an associated destination of SUPERVISOR. If the rule condition was evaluated to be TRUE (Step 205) for a given document, then the document would be assigned a destination of "SUPERVISOR" (Step 206) and the program would exit (Step 210) back to the routine of Fig. 2. If the rule condition is not true, the next rule in the rules database would be obtained (Step 208). It would then be compared to the document characteristics (Step 204). This loop would continue until a destination was determined, based on finding a match between the rule and the document characteristics. If after the last rule in the rules database has been compared (Step 207), there is no rule in the database that is a match, a default destination is assigned (Step 209) and the program exits.

Returning to FIG. 2, associated with each possible destination are a set of page selection and clipping extraction definitions for each possible type of document. The particular pages and clippings associated with the destination are extracted from the document (Step 105). The clipped document files are then held on the document server until remote users, who are associated with the various

destinations, sign on and request documents to work on (step 106). When the remote user login is complete, the files assigned to a destination associated with a particular user are then transferred from the document server to the remote workstation for processing (Step 108). When this transfer is complete, the user  
5 connection to the document server is terminated (Step 110).

Another portion of the program that operates the system according to the invention is stored at the remote workstation 14. This program is illustrated by FIG. 4. According to the program, the image files are first received over an ISDN line (step 300). Since the image files received at the remote workstation 14  
10 are in compressed form, each image file is decompressed automatically in order for the remote user to view the image and perform work relevant to the image (Step 302). Once the first image file is decompressed, the remote user can begin work on that file.

While working on each image file (Step 304), the remote user occupies  
15 very little of the workstation processor time. For example, while the user is typing data that is relevant to the first image into the workstation, the majority of the processor time is spent waiting for the next character to be typed. This time can be utilized, in part, for decompressing the next image file (Step 306) so that the next image will be available for viewing when the remote user finishes working on  
20 the first image.

When the user finishes work relevant to the first image, the user switches to the second image which has already been decompressed and can thus appear on the screen almost instantaneously (Step 308). Since the second image

is stored in RAM after its decompression, the speed with which the user can switch to the second image is limited only by the monitor refresh time. By anticipating the need for the second image while the user is working on the first image, the user can continue work from the first image to the second without interruption. The idle  
5 time of the user is thereby greatly reduced.

After the user switches to the second image, the user can be working related to the second image (Step 310). While the user performs work related to the second image, the third image file is decompressed (Step 312) and the data created during the processing of the first image is stored (Step 214). Therefore,  
10 the delay time is reduced when switching images by eliminating at least two sources of delay: (1) delay in decompression of the next image, and (2) delay in saving the data related to the previous image.

When the user finishes work on the second image, he switches to the third image (Step 316). This process continues while the worker goes through the  
15 files in the inventory at his workstation. For a group of N images, as the user works on the next-to-the-last image (N-1) (Step 318), the last image (N) is decompressed (Step 320), and the data related to second to the last image (N-2) is stored (Step 322).

After work is performed relating to all images, an ISDN connection can  
20 be established between the remote workstation and the ISDN gateway to communicate to the central office the data developed by the remote user related to the images using the automatic transfer program described previously. The images themselves will not need to be transmitted back to the network unless they

have been changed in some way at the remote workstation, because the central office network retains copies of the images.

It should be noted that the present invention is effective in part because of the anticipation of workflow. This is most possible, and the benefits of the invention are greatest, where work may progress in a predictable fashion. As an example, a clerk who processes credit card applications for a particular region of the country by entering the data written on the application into a mainframe application can be assigned a continuous stream of new applications by the document router. The system can anticipate that when one application is processed, the operator will ask for the next one assigned. Because of this, the system can prepare the next document by ensuring that it has been transferred from the server, decompressed, and is ready for viewing by the time the remote workstation operator actually needs it. It may also be a requirement of the program to prioritize documents, e.g., to present first the most important or critical documents or the oldest documents. Thus, the program anticipates which document and which portion of the document will be needed next. The anticipated document is decompressed in RAM at the workstation before it is needed and while the user is working on a previously requested or anticipated document.

Naturally there may still be occasions where the user wishes to view a document out of the anticipated sequence. In such a case the document is available, but the user must wait for the images of the documents in the file to be transferred and decompressed, perhaps in the anticipated order.

The process of transferring documents to a remote user workstation is largely hidden from the remote workstation operator by a program stored on the remote workstation which executes in the background while the user is processing documents in the foreground. The logic for this program is depicted in FIG 5. This program maintains a count of the current inventory of documents to process on the remote workstation. Associated with this inventory are three user-configurable threshold values used to determine if an automatic call to the central office is required. In ascending value, they are termed the "empty", "low", and "high" thresholds. In addition, there is a user-configurable table called the "call schedule table" which has the following format, as an example:

Row No.	Day	Time	State	Comment
1	2-6	9:00-18:00	Empty	Peak rate only when empty
2	2-6	18:00-9:00	Low	Off-peak if low
3	2-6	10:00-11:00	None	Block weekday peak even hours
4	2-6	12:00-13:00	None	Block weekday peak even hours
5	2-6	14:00-15:00	None	Block weekday peak even hours
6	2-6	16:00-17:00	None	Block weekday peak even hours
7	7-1	0:00-0:00	Low	Anytime weekend if low

The first column, called "Day", of this table is a numeric range code for the day of the week with Sunday coded as day "1". For example, "2-6" in the table stands for Monday through Friday. The second column, called "Time", is a time of day range indicated with military time format. The third column, call "State", is one of the values None, Empty, or Low. The value "None" is used to indicate that

automatic calling is not permitted for the given period. The value "Empty" is used to indicate that automatic calling is only permitted if the Current Inventory is below the Empty Threshold value. Finally, the value "Low" is used to indicate that automatic calling is permitted if the Current Inventory is below the Low Threshold value. The comment field is used to describe the purpose of that row in the table.

The call management program works by periodically checking to see how many unprocessed documents are in its current inventory (Step 400). This period is user-configurable and would typically be set for 5 minute intervals. It then evaluates the state of the inventory by comparing it against the empty threshold (Step 402). If the current inventory is below this threshold, then the state of the inventory is set as "Empty" (Step 404). If the inventory is not below this threshold, then it's level is compared against the low threshold (Step 406). If the current inventory is below this threshold, then the state of the inventory is considered "Low" (Step 408). If the inventory is not below this level, then the program exits to wait until the next period begins. (Step 410).

If the inventory state is either Empty or Low, the program will proceed to scan each row of the call schedule table (Step 412). The processing for each row can be described as follows: if the current day is not within the day range of the row, proceed to the next row (Step 414). If the current time is not within the time range of the row, proceed to the next row (Step 416). If the current day is within the day range (yes at Step 414) and the current time is within the time range for a row (yes at Step 416), then if the current inventory state is less than or equal to the state level of the row (Step 418), proceed to the next row. If the current

inventory state is greater than the state level of the row (Step 418), then the program will exit and wait (Step 410) until the next period to repeat this procedure. If all the rows of the table have been processed successfully (Step 420), then proceed with automatic calling of the LAN gateway (Step 422).

5           In the example call schedule table, row nos. 1 through 6 are configured to control call scheduling from Monday through Friday as follows:

          Calls may be placed from 9am-10am, 11am-12pm, 1pm-2pm, 3pm-4pm, 5pm-6pm from Monday through Friday if the remote workstation is Empty. Calls may be placed 6pm-9am from Monday through Friday if the remote  
10 workstation is Low on work. The effect of rows 1 and 2 is to defer calling during peak rate hours until it is absolutely required. For instance, if the remote workstation becomes Low on work at 5:30pm, the call schedule table will defer calling until either the workstation is Empty or until 6:00pm. The effect of rows nos. 3 through 6 is to block calling during office hours which start with an even  
15 number. Presumably, other remote workstations are configured for the converse situation, i.e., to block calling during office hours which begin with an odd number. The last row no. 7 indicates that calls may be placed anytime on Saturday or Sunday if the remote workstation becomes Low on work. This kind of configuration permits scheduled, efficient sharing of a limited number of host phone  
20 lines.

          The workstation will then automatically call the LAN gateway using a pre-stored phone number, user id, and security password to establish a data connection. It will then receive files which have been assigned to the remote

workstation operator (Step 424) until the inventory level equals the "high threshold" (Step 426). It will also transmit any modified data from processed documents back to the document server (Step 428) for access by other users and for re-assignment by the document routing program. When this data transfer has  
5 been completed, the call is automatically terminated (Step 430) and waits for the next inventory check (Step 432).

The procedures described above provide many advantages over a manual calling process. First, the call schedule table can be configured to automatically call when the phone rates are lowest. This obviously reduces the  
10 overall cost of operating a remote workstation. Second, utilization of the lines into a LAN gateway can be maximized by scheduling remote workstation access. For instance, given one (1) incoming line for the LAN gateway and four (4) remote workstations, it is beneficial for the remote workstations to coordinate their calling to minimize retries and possible work starvation situations by configuring the call  
15 schedule table such that each workstation is permitted to call the LAN gateway in a different 15 minute interval. This increased utilization of the LAN gateway permits fewer LAN gateway phone lines to be configured for a given number of remote workstation users, again reducing the costs of operation. Third, the whole process of connection to the central site is hidden from the remote workstation operator,  
20 simplifying workstation operation and increasing productivity.

While the invention has been particularly shown and described with reference to preferred embodiments thereof, it will be understood by those skilled

in the art that various changes in form and details may be made therein without departing from the spirit and scope of the invention.

**WHAT IS CLAIMED IS:**

- 1                   1.     A method of remotely processing data arranged into digital  
2 data files at a remote workstation over telephone lines, comprising the steps  
3 of:  
4                             digitally compressing the data into compressed data files at  
5 a central location;  
6                             selecting, according to first predetermined criteria, a group  
7 of said compressed data files;  
8                             transferring said group of compressed data files from said  
9 central location to the remote workstation;  
10                            receiving the group of compressed data files in digital form  
11 at the remote workstation and storing at least some of said compressed data  
12 files at the remote workstation;  
13                            decompressing a first of said compressed data files in the  
14 group at the remote workstation, based on second predetermined criteria, while  
15 receiving and storing other compressed data files; and  
16                            decompressing a second of said compressed data files in the  
17 group at the remote workstation, based on the second predetermined criteria,  
18 while the first uncompressed file is available for a user at the remote  
19 workstation to perform work related to it.

1                   2.     The method of claim 1, further comprising the Steps of:  
2                                 decompressing a third data file at the remote workstation,  
3     and storing data created from work related to the first data file, both while the  
4     second data file is available to the user at the remote workstation to perform  
5     work related thereto.

1                   3.     The method of claim 2 further comprising the step of  
2     decompressing additional data files as data from previously processed files is  
3     received and stored.

1                   4.     The method of claims 1 or 2 wherein the data files are  
2     digital image files.

1                   5.     The method of claim 1 wherein the step of transferring is  
2     by means of ISDN telephone lines.

1                   6.     The method of claim 1 wherein the first predetermined  
2     criteria includes the type of data file which a user at the remote workstation is  
3     expected to process.

1                   7.     The method of claim 1 wherein the steps of selecting and  
2     transferring include:  
3                             receiving compressed data files;  
4                             forming compressed data file characteristics for each file  
5     based on the type of file;  
6                             comparing the characteristics of a data file to stored routing  
7     rules;  
8                             assigning the files to various groups based on the  
9     comparison; and  
10                            transferring a group of files to the remote workstation when  
11     a request is received from the workstation for files of that group.

1                   8.     The method of claim 1 wherein the second predetermined  
2     criteria includes the order in which the data file is received.

1                   9.     The method of claim 1 wherein the second predetermined  
2     criteria includes a priority assigned to the data file.

1                   10.    The method of claim 1, wherein the step of decompressing  
2     takes place during the step of transferring.

1                   11.    The method of claim 1, wherein the work to be performed  
2     by the user related to the data files includes entering data into the workstation.

1                   12. The method of claim 1, wherein the data files at the central  
2 location are on a network with a document server, and the step of transferring  
3 the group of data files to the remote workstation further comprises the steps  
4 of:  
5                   initiating a connection over ISDN telephone lines from the  
6 remote workstation to an ISDN gateway server on the network depending on  
7 an inventory of files at the remote workstation and without user intervention;  
8                   transmitting the group of compressed data files from the  
9 document server through the ISDN gateway over the ISDN lines to the remote  
10 workstation; and  
11                  terminating the ISDN connection from the ISDN gateway  
12 server to the remote workstation after the transfer is complete and without  
13 user intervention.

1                   13. The method of claim 1, further including the step of storing  
2 the compressed data files on the network in a network device selected from the  
3 group consisting of an image server and a jukebox archive storage unit.

1                   14. A method of business data processing at a remote  
2 workstation, a group of compressed image files located on a computer network  
3 at a central location, comprising the steps of:  
4                   establishing an ISDN telephone connection between the  
5 network and the remote workstation;

6                                   transferring at least a portion of the group of image files to  
7 the remote workstation over the ISDN lines;  
8                                   storing at least part of the portion of compressed image files  
9 at the remote workstation as compressed files;  
10                                  terminating the ISDN telephone connection when the  
11 transfer has been completed;  
12                                  decompressing at the remote workstation, a first image in  
13 the portion of image files based on predetermined criteria without user  
14 intervention;  
15                                  decompressing at the remote workstation without user  
16 intervention, a second image file in the group based on the predetermined  
17 criteria, while the uncompressed first image file is available for the user at the  
18 workstation to perform work related thereto;  
19                                  decompressing, at the remote workstation, a third image  
20 file;  
21                                  automatically storing data without user intervention created  
22 from the work related to the first image file when the user has stopped working  
23 on it and while the second image file is available for the user to perform work  
24 related thereto; and  
25                                  storing at least part of the compressed data files at the  
26 remote workstation.

1           15. The method of claim 14, further comprising the steps of:  
2                           creating image files from paper documents;  
3                           compressing the image files to form compressed images  
4 files;  
5                           storing the compressed image files at one of a network of  
6 servers or network archives; and  
7                           moving the group of image files through an ISDN gateway  
8 server on the network to the remote workstation over ISDN lines.

1           16. The method of claim 14, wherein:  
2                           the step of establishing an ISDN connection involves  
3 automatically initiating a connection from the remote workstation to an ISDN  
4 gateway server on the network over ISDN lines depending on an inventory of  
5 files at the remote workstation;  
6                           the step of transferring involves sending the group of image  
7 files from an ISDN gateway server on the network to the remote workstation  
8 over the ISDN lines; and  
9                           the step of automatically terminating the ISDN telephone  
10 connection involves ending the ISDN gateway server connection to the remote  
11 workstation when the files have been transferred.

1                   17. The method of claim 14, wherein the steps of automatically  
2 decompressing occur during the step of transferring.

1                   18. The method of claim 14, wherein the step of transferring  
2 involves transferring only the minimum number of pages which are required for  
3 the business data processing.

1                   19. The method of claim 14, wherein the step of transferring  
2 involves transferring only clipped image pages that are required for the business  
3 data processing in lieu of the entire image page.

1                   20. A method of processing compressed data files at a remote  
2 workstation, comprising the steps of:  
3                   receiving the compressed data files at the remote  
4 workstation;  
5                   automatically decompressing the first and second  
6 compressed data files in order as received;  
7                   presenting the first decompressed file in a format to be  
8 processed while second files are being decompressed;  
9                   subsequently decompressing and processing files according  
10 to a predefined criteria.

1                   21. A method of processing at a remote workstation, data at a  
2 central location arranged into digital data files, comprising the steps of:  
3                   initiating, according to predetermined criteria, a connection  
4 over the telephone lines from the remote workstation to the central location  
5 without user intervention;  
6                   indicating to the central location a group of data files  
7 needed;  
8                   transmitting the group of data files to the remote  
9 workstation; and  
10                  terminating the telephone connection after the transfer is  
11 complete.

1                   22. The method of claim 21 wherein the criteria involves the  
2 size of an inventory of unprocessed data files at the remote workstation.

1                   23. The method of claims 21 or 22 wherein the criteria involves  
2 the time of day.

1                   24. The method of claim 23 wherein the criteria involves the  
2 day of the week.

1                   25. A system for processing at a remote workstation, data  
2 arranged into digital files at a central location, comprising:

3                               means at the central location for digitally compressing the  
4 data into compressed data files;

5                               selecting means at the central location for grouping the data  
6 files according to first predetermined criteria into a plurality of groups;

7                               transfer means for transferring at least one of said groups  
8 of data files to the remote workstation in response to a request from the  
9 remote workstation;

10                              first storing means for storing the compressed data files at  
11 the remote workstation; and

12                              decompression means at the remote workstation for  
13 decompressing the compressed data files in the group transferred to the remote  
14 workstation in a sequence based on a second predetermined criteria, said  
15 decompression means causing a first decompressed file to be available for  
16 processing at the remote workstation while at least one other data file is being  
17 decompressed and data files are being transferred.

1                   26. The system of claim 25 further including second storing  
2 means for storing data created by processing a file while another file is  
3 decompressed and available for processing, and still another file is being  
4 decompressed.

1                   27. The system of claim 25 wherein said transferring means  
2 includes an ISDN telephone system.

1                   28. The system of claim 27 further including a local area  
2 network at the central location and a storage means on the local area network  
3 for storing the groups of compressed data files; and wherein said transferring  
4 means includes an ISDN gateway on the local area network.

1                   29. A workstation remote from a central location at which  
2 compressed data files are located, comprising:

3                               means for requesting at least one group of compressed data  
4 files from the central location;

5                               means for receiving a group of data files transferred in  
6 response to the request;

7                               means for storing the compressed data files at the remote  
8 workstation; and

9                               means for automatically decompressing data files without  
10 user intervention in the group of transferred files in a sequence based on  
11 predetermined criteria, said decompressing means causing a first decompressed  
12 file to be available for processing while at least one other data file is being  
13 decompressed and other files are being transferred.

1                   30. The workstation of claim 29 wherein the predetermined  
2 criteria is the order in which files in the group are received.

1                   31. The workstation of claim 29 further comprising:  
2                               means for monitoring a volume of unprocessed data files at  
3 the workstation; and  
4                               wherein said means for requesting files from the central  
5 location operates in response to an indication from said monitoring means that  
6 the volume is below a particular level.

1                   32. The workstation of claim 31 further comprising  
2                               means for monitoring time and date; and  
3                               wherein said means for requesting also operates in response  
4 to an indication of the time and date.

1                   33. The workstation of claim 31 further comprising means for  
2 requesting that the transfer of files cease when the volume is above a certain  
3 level.

1                   34. A workstation remote from a central location at which data  
2 files are located, comprising:  
3                               means for requesting at least one group of data files from  
4 the central location;  
5                               means for receiving a group of data files transferred in  
6 response to the request;  
7                               means for causing a received file to be available for  
8 processing;  
9                               means for monitoring a volume of unprocessed data files at  
10 the workstation; and  
11                              means for controlling said means for requesting files so that  
12 a request is made in response to an indication from said monitoring means that  
13 the volume is below a particular level.

1                   35. The workstation of claim 34 further comprising  
2                               means for monitoring time and date; and  
3                               wherein said means for controlling also operates in response  
4 to an indication of the time and date.

1                   36. The system of claim 26 wherein the first and second storing  
2 means are a single memory.

# INTERNATIONAL SEARCH REPORT

International Application No  
**PCT/US 94/14785**

**A. CLASSIFICATION OF SUBJECT MATTER**  
IPC 6 H04L29/06

According to International Patent Classification (IPC) or to both national classification and IPC

**B. FIELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols)  
IPC 6 H04L

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

**C. DOCUMENTS CONSIDERED TO BE RELEVANT**

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

\* Special categories of cited documents :

- \*A\* document defining the general state of the art which is not considered to be of particular relevance
- \*E\* earlier document but published on or after the international filing date
- \*L\* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- \*O\* document referring to an oral disclosure, use, exhibition or other means
- \*P\* document published prior to the international filing date but later than the priority date claimed

- \*T\* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- \*X\* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- \*Y\* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- \*&\* document member of the same patent family

Date of the actual completion of the international search

2 May 1995

Date of mailing of the international search report
