(57) **ABSTRACT**

Techniques and systems for monitoring cardiac arrhythmias and delivering electrical stimulation therapy using a subcutaneous device (e.g. subcutaneous implantable (SD)) is described. In one or more other embodiments, SD is implanted into a patient's heart. Electrical signals are then sensed which includes moderately lengthened QRS duration data from the patient's heart. A determination is made as to whether cardiac resynchronization pacing therapy (CRT pacing) is appropriate based upon the moderately lengthened QRS duration in the sensed electrical signals. The CRT pacing pulses are delivered to the heart using electrodes. In one or more embodiments, the SD can switch between fusion pacing and biventricular pacing based upon data (e.g. moderately lengthened QRS, etc.) sensed from the heart.

SYSTEMS AND METHODS FOR LEADLESS CARDIAC RESYNCHRONIZATION THERAPY

Matter enclosed in heavy brackets [ ] appears in the original patent but forms no part of this reissue specification; matter printed in italics indicates the additions made by reissue; a claim printed with strikethrough indicates that the claim was canceled, disclaimed, or held invalid by a prior post-patent action or proceeding.

RELATED APPLICATION

The present application claims priority and other benefits from U.S. Provisional Patent Application Ser. No. 61/907, 040, filed Nov. 21, 2013, entitled "SYSTEMS AND METHODS FOR LEADLESS CARDIAC RESYNCHRONIZATION THERAPY", incorporated herein by reference in its entirety.

CROSS-REFERENCE TO RELATED APPLICATION

Cross-reference is hereby made to the commonly-assigned related U.S. applications, Ser. No. 14/173,288, entitled "SYSTEMS AND METHODS FOR LEADLESS CARDIAC RESYNCHRONIZATION THERAPY", to Sambelashvili, filed concurrently herewith and incorporated herein by reference in their entireties.

TECHNICAL FIELD

The invention relates to medical devices, and, more particularly, to implantable medical devices configured to detect and treat cardiac arrhythmias.

BACKGROUND

Some types of implantable medical devices (IMDs), such as cardiac pacemakers or implantable cardioverter defibrillators (ICDs), provide therapeutic electrical stimulation to a heart of a patient via electrodes on one or more implantable endocardial or epicardial leads that are positioned in or adjacent to the heart. The therapeutic electrical stimulation may be delivered to the heart in the form of pulses or shocks for pacing, cardioversion or defibrillation. In some cases, an IMD may sense intrinsic depolarizations of the heart, and control the delivery of therapeutic stimulation to the heart based on the sensing.

Other types of IMDs include a leadless pacemaker, which may be used to sense electrical activity and/or deliver therapeutic signals to the heart. The leadless pacemaker may include one or more electrodes on its outer housing to deliver therapeutic electrical signals and/or sense intrinsic depolarizations of the heart. The leadless pacemaker may be positioned within or outside of the heart and, in some examples, may be anchored to a wall of the heart via a fixation mechanism.

Delivery of therapeutic electrical stimulation to the heart can be useful in addressing cardiac conditions such as ventricular dyssynchrony that may occur in patients. Ventricular dyssynchrony is a lack of synchrony or a difference in the timing of contractions in different ventricles of the heart. Significant differences in timing of contractions can reduce cardiac efficiency. Cardiac resynchronization therapy (CRT), delivered by an IMD to the heart, may enhance cardiac output by resynchronizing the electromechanical activity of the ventricles of the heart.

It is generally known that a greater number of patients may benefit from CRT but choose to forgo the therapy for a variety of reasons. For example, implanting an IMD involves a long procedure (~1.5-2 hours) requiring skilled electrophysiologists (EPs), who are unavailable in some rural areas. Additionally, although post-implant complications are unlikely, issues can arise such as LV lead dislodgement, phrenic nerve stimulation, and pocket hematomas. Moreover, some patients are non-responsive to CRT which may be due to the location electrical stimulation is delivered. It is therefore desirable to develop new methods and systems for delivering CRT that reduces the likelihood of post-implant complications and may be able to deliver more effective CRT.

SUMMARY

Generally, this disclosure describes various techniques and systems for monitoring cardiac conditions and delivering cardiac resynchronization therapy (CRT) (e.g. fusion pacing etc.) by using a subcutaneous device (SD) (e.g. subcutaneous implantable cardioverter defibrillator (SICD), loop recorder (e.g. REVEAL®), etc.) and/or a leadless pacing device (LPD) such as a percutaneous leadless pacing system. In particular, a conventional left ventricular lead is eliminated through the LPD being placed into a chamber of the heart.

After the SD and the LPD have been implanted, a first electrical signal (also referred to as the baseline rhythm) is sensed from a heart of a patient through the SD. The baseline rhythm can be an intrinsic rhythm of the heart or the rhythm that occurs with right ventricular (RV) pacing only. The first electrical signal is sensed as a subcutaneous ECG. Data extracted from the first signal is stored into memory of the SD. Post-implant, a second signal is sensed from the heart through the SD. Data is extracted from the second signal, which is stored into memory of the SD. A cardiac condition (e.g. ventricular dyssynchrony, etc.) can be determined to be present. After data, extracted from the first electrical signal (i.e. baseline), is compared to data extracted from the second electrical signal (post-implant signal). A determination is made at the time of implant or post-implant as to whether CRT is appropriate to treat the detected cardiac condition. The timing of the pacing pulses can be determined either by the SD or LPD device. Preferably, the SD determines the timing of the pulses. A determination can then be made as to the timing of the delivery of electrical stimuli (e.g. pacing pulses etc.) that is synchronized with the activation of the atria and right ventricle (RV). Electrical stimuli is typically delivered to the left ventricle (LV) but depending upon the patient's condition, electrical stimuli can be optionally delivered to another chamber of the heart such as the right ventricle by another leadless pacing device (LPD) to cardiac tissue. The LPD then receives communication from the SD requesting the LPD to deliver CRT to the heart. The SD senses and extracts data from a third electrical signal from the heart of the patient to determine whether the pacing by LPD provided efficacious resynchronization or whether the delivery and timing of the LPD pulse should be modified.

Another embodiment of the present disclosure is directed to a combination of a LPD and an intravenously implanted device (IID) to deliver CRT using the same or similar technique described above. In particular, the LPD delivers pacing pulses to cardiac tissue after receiving a command signal from the IID.

3

4

Yet other embodiments of the present disclosure is directed to an LPD used in combination with an ICD or a pacemaker. In particular, the LPD delivers pacing pulses to cardiac tissue after receiving a command signal from the ICD or pacemaker and terminates CRT when a termination condition is met.

In addition, the SD and the LPD may be configured to engage in one-way or two-way communication between the SD and the LPD. This one-way or two-way communication may be used to initiate therapy and/or confirm that therapy should be delivered. For example, one-way communication may allow the SD to transmit a communication message to the LPD instructing the LPD to deliver CRT. Left-Ventricular (LV) pacing can be achieved using a miniaturized percutaneous leadless pacing system (PLPS) placed on the endocardial wall of the LV or substernally/retrosternally. Such pacing resolves problems associated the conventional devices.

In another embodiment, the SD transmits a control signal to the LPD to initiate CRT. The LPD senses a cardiac signal (i.e. a second electrical signal) from the heart of the patient. Based on the cardiac signal, the LPD could determine whether to deliver CRT or the type of CRT to deliver to the heart from the LPD. In one or more embodiments, the LPD, based on the second electrical signal, could initially determine that CRT is not necessary. The initial determination by the LPD could use very simplified tests such as a threshold of one or more parameters. In one or more embodiments, the SD could perform a more detailed analysis as to whether CRT should be delivered. Using the sensed data from the LPD and/or SD, the SD could generate another signal to the LPD that either confirms or overrides the LPDs initial determination.

In another embodiment, the LPD could sense a cardiac signal that indicates a switch should occur between fusion pacing to biventricular pacing. Determining whether to switch between fusion pacing and biventricular pacing could be determined based upon one or more parameters (e.g. moderately lengthened QRS, etc.). The LPD could be configured to either automatically switch between fusion pacing and biventricular pacing or to wait until the SD confirms or denies switching between the CRT pacing mode (i.e. fusion pacing and biventricular pacing). The SD could be configured to send a confirmatory signal or a signal denying the LPD switching the pacing mode.

In yet another embodiment, the LPD could determine that biventricular pacing is required over fusion pacing in contravention to the SD communication. In one embodiment, the LPD would deliver biventricular pacing. In one or more other embodiments, the LPD could determine that fusion pacing is required over biventricular pacing in contravention to the SD communication. In this scenario, the LPD could deliver fusion pacing.

In one or more other embodiments, SD is implanted into a patient's heart. For example, the SD could be a conventional ICD or a SD described herein). Electrical signals are then sensed which includes moderately lengthened QRS duration data from the patient's heart. A determination is made as to whether cardiac resynchronization pacing therapy (CRT pacing) is appropriate based upon the moderately lengthened QRS duration in the sensed electrical signals. The CRT pacing pulses are delivered to the heart using electrodes. In one or more embodiments, the SD can switch between fusion pacing and biventricular pacing based upon data (e.g. moderately lengthened QRS, etc.) sensed from the heart.

The details of one or more examples are set forth in the accompanying drawings and the description below. Other features, objects, and advantages will be apparent from the description and drawings, and from the claims.

BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 is a conceptual drawing illustrating an example system that includes a subcutaneous implantable cardioverter defibrillator (SICD) implanted exterior to the rib cage of a patient and a leadless pacing device (LPD) implanted within a cardiac chamber of the patient.

FIGS. 2A and 2B are conceptual drawings illustrating different views of the example SICD of FIG. 1

FIG. 3 is a conceptual drawing illustrating the example LPD of FIG. 1.

FIG. 4 is a functional block diagram illustrating an example configuration of the SICD of FIG. 1.

FIG. 5 is a functional block diagram illustrating an example configuration of the LPD of FIG. 1.

FIG. 6 is a functional block diagram illustrating an example configuration of the programmer of FIG. 1.

FIG. 7 is a flow diagram of an exemplary process delivering cardiac resynchronization therapy through a LPD in communication with a SICD.

FIG. 8 is a diagram that compares QRS complexes during fusion pacing to QRS complexes that occur during intrinsic rhythm.

FIGS. 9A-C are conceptual diagrams of a patient implanted with an exemplary substernal/retrosternal implantable cardiac system.

DETAILED DESCRIPTION

In the following detailed description of illustrative embodiments, reference is made to the accompanying figures of the drawing which form a part hereof, and in which are shown, by way of illustration, specific embodiments which may be practiced. It is to be understood that other embodiments may be utilized and structural changes may be made without departing from (e.g., still falling within) the scope of the disclosure presented hereby.

As described herein, the present disclosure provides many benefits to physicians and patients who receive implantable medical devices for delivery of cardiac resynchronization therapy (CRT). For example, the present disclosure reduces the time spent and expertise needed by a physician to implant a subcutaneous device (e.g. subcutaneous implantable cardioverter defibrillator (SICD), loop recorder (e.g. REVEAL) etc.) and a leadless pacing device (LPD) such as a percutaneous leadless pacing system. Moreover, postimplant complications are reduced since LPDs do not require a lead in or near the left ventricle (LV); therefore, lead dislodgement is eliminated as a complication. Phrenic nerve stimulation is also unlikely because a LV lead is not employed for cardiac resynchronization therapy (CRT) delivery.

Exemplary methods, devices, and systems are described with reference to FIGS. 1-9. It is appreciated that elements or processes from one embodiment may be used in combination with elements or processes of the other embodiments, and that the possible embodiments of such methods, devices, and systems using combinations of features set forth herein is not limited to the specific embodiments shown in the Figures and/or described herein. Further, it will be recognized that the embodiments described herein may include many elements that are not necessarily shown to scale. Still

further, it will be recognized that timing of the processes and the size and shape of various elements herein may be modified but still fall within the scope of the present disclosure, although certain timings, one or more shapes and/or sizes, or types of elements, may be advantageous over others.

This disclosure describes various techniques and systems in which the presence of ventricular dyssynchrony is determined to exist; and, in response, cardiac resynchronization therapy (CRT) is delivered to cardiac tissue via a leadless pacing device (LPD) that is controlled by a subcutaneous device (e.g. subcutaneous implantable cardioverter defibrillator (SICD), loop recorder etc. The presence of ventricular dyssynchrony is determined at implant or optionally post-implantation of the devices. For example, post-implant, ventricular dyssnchrony can be inferred to be present depending upon measured atrioventricular (AV) delays and/or P waves. The SICD can then send a control signal to the LPD to deliver therapeutic electrical stimulation (e.g. pacing pulses etc.) to the heart. The LPD can be implanted within a chamber of the heart or substernally/retrosternally.

FIG. 1 is a conceptual drawing illustrating an example system 10 that includes a subcutaneous device (SD) 30 (e.g. SICD, loop recorder (i.e. REVEAL®) etc.) implanted exterior to a rib cage of patient 14 and a leadless pacing device (LPD) 16 implanted within right ventricle 18 of patient 14. The SD 30 can be implanted external to a rib cage and within the vasculature. Additionally or alternatively, an implantable medical device can be implanted substernally/retrosternally, as described in U.S. Patent Application 61/819,946, entitled "IMPLANTABLE MEDICAL DEVICE SYSTEM HAVING IMPLANTABLE CARDIAC DEFIBRILLATOR SYSTEM AND SUBSTERNAL LEADLESS PACING DEVICE" filed May 6, 2013, incorporated by reference in its entirety. In the example of FIG. 1, system 10 includes LPD 16 and SD 30. External programmer 20 may be configured to communicate with one or both of LPD 16 and SD 30. Generally, there are no wires or other direct electrical (e.g., hardwired) connections between SD 30 and LPD 16. In this manner, any communication between SD 30 and LPD 16 may be described as "wireless" communication. Patient 14 is ordinarily, but not necessarily, a human patient.

Exemplary SD 30 includes a housing 32 configured to be subcutaneously implanted outside the rib cage of patient 14. The subcutaneous implantation location may be anterior to the cardiac notch, for example. In addition, housing 32 may carry three subcutaneous electrodes 34A-34C (collectively "electrodes 34"). In other examples, housing 32 may carry fewer or greater than three electrodes. Lead 36 may be configured to couple to housing 32 and extend from housing 32 to a different subcutaneous location within patient 14. For example, lead 36 may be tunneled laterally and posteriorly to the back of patient 14 at a location adjacent to a portion of a latissimus dorsi muscle. Lead 36 may carry electrode coil 38 along a length of lead 36 and sensing electrode 40 at a distal end of lead 36. SD 30 may be configured such that heart 12 may be disposed at least partially between housing 30 and electrode coil 38 of lead 36. In some examples, lead 36 may carry two or more electrode coils 38 and/or two or more sensing electrodes 40.

SD 30 may contain, within housing 32, signal processing and therapy delivery circuitry to detect cardiac conditions (e.g., ventricular dyssnchrony, arrhythmias such as brady-cardia and tachycardia conditions etc.) and to communicate with LPD 16 to apply appropriate electrical stimuli (e.g. pacing and/or anti-tachyarrhythmia shock therapy (e.g., defibrillation or cardioversion shocking pulses)) to heart 12.

SD 30 also may be configured to apply pacing pulses via one or more electrodes 34. SD 30 may be configured to apply the anti-tachyarrhythmia shock pulses between coil electrode 38 and one or more of electrodes 34 and/or the electrically conductive housing 32 (e.g., an additional can electrode) of SD 30. SD 30 may be configured to communicate with programmer 20 via an RF communication link, inductive coupling, or some other wireless communication protocol.

SD 30 differs from traditionally used ICDs in that housing 32 may be larger in size than the housing of a traditional ICD to accommodate larger capacity batteries, for example. In addition, SD 30 may be implanted subcutaneously whereas a traditional ICD may be implanted under muscle or deeper within patient 14. In other examples, housing 32 may be shaped or sized differently to be implanted subcutaneously instead of under a muscle or within deep tissue. Moreover, SD 30 does not include leads configured to be placed in the bloodstream (e.g., endocardial or epicardial leads). Instead, SD 30 may be configured to carry one or more electrodes (e.g., electrodes 34) on housing 32 together with one or more subcutaneous leads (e.g., lead 36) that carry defibrillation coil electrode 38 and sensing electrode 40. In other examples, lead 36 may include additional electrodes. These subcutaneously implanted electrodes of SD 30 may be used to provide therapies similar to that of traditional ICDs without invasive vascular leads. In other examples, the exact configuration, shape, and size of SD 30 may be varied for different applications or patients. Although SD 30 is generally described as including one or more electrodes, SD 30 may typically include at least two electrodes to deliver an electrical signal (e.g., therapy) and/or provide at least one sensing vector. Other exemplary SDs 30 can be used in combination with LPD 16. For example, SD 30 includes intravenously implanted device (IID), an ICD or a pace-maker or any other suitable device.

System 10 also includes one or more LPDs, such as LPD 16. LPD 16 may be, for example, an implantable leadless pacing device (e.g., a pacemaker, cardioverter, and/or defi-brillator) that provides electrical signals to heart 12 via electrodes carried on the housing of LPD 16. In the example of FIG. 1, LPD 16 is implanted within left ventricle 16 of heart 12 to sense electrical activity of heart 12 and/or deliver electrical stimulation, e.g., CRT such as fusion pacing, to heart 12. Fusion pacing involves left ventricle (LV) 24 only pacing with an electrode on the LPD 16 in coordination with the intrinsic right ventricle (RV) activation. Alternatively, fusion pacing can involve pacing the RV with an electrode on the LPD 16 in coordination with the intrinsic LV acti-vation. In this scenario, the LPD 16 is placed within the right ventricle 18.

LPD 16 is schematically shown in FIG. 1 attached to a wall of the left ventricle 24 via one or more fixation elements (e.g. tines, helix etc.) that penetrate the tissue. These fixation elements may secure LPD 16 to the cardiac tissue and retain an electrode (e.g., a cathode or an anode) in contact with the cardiac tissue. LPD 16 may also include one or more motion sensors (e.g., accelerometers) configured to detect and/or confirm cardiac conditions (e.g. ventricular dyssynchrony, tachyarrhythmias etc.) from these mechanical motions of heart 12. Since LPD 16 includes two or more electrodes carried on the exterior housing of LPD 16, no other leads or structures need to reside in other chambers of heart 12. However, in other examples, system 10 may include addi-tional LPDs within respective chambers of heart 12 (e.g., left atrium 26, right atrium 22).

Using the electrodes carried on the housing of LPD 16, LPD 16 may be capable sensing intrinsic electrical signals,

e.g., an electrocardiogram (ECG). SD **30** may similarly sense intrinsic electrical signals from the sensing vectors of electrodes **34**, **38**, and **40**. These intrinsic signals may be electrical signals generated by cardiac muscle and indicative of depolarizations and repolarizations of heart **12** at various times during the cardiac cycle. LPD **16** may generate an electrogram from these cardiac signals that may be used by LPD **16** to detect cardiac conditions (e.g. ventricular dys-synchrony, arrhythmias, such as tachyarrhythmias), or iden-tify other cardiac events, e.g., ventricle depolarizations or atrium depolarizations. LPD **16** may also measure imped-ances of the carried electrodes and/or determine capture thresholds of those electrodes intended to be in contact with cardiac tissue. In addition, LPD **16** may be configured to communicate with external programmer **20**. The configura-tions of electrodes used by LPD **16** for sensing and pacing may be typically considered bipolar but unipolar may also be used.

External programmer **20** may be configured to commu-nicate with one or both of SD **30** and LPD **16**. In examples where external programmer **20** only communicates with one of SD **30** and LPD **16**, the non-communicative device may receive instructions from or transmit data to the device in communication with programmer **20**. In some examples, programmer **20** comprises a handheld computing device, computer workstation, or networked computing device. Pro-grammer **20** may include a user interface that receives input from a user. In other examples, the user may also interact with programmer **20** remotely via a networked computing device. The user may interact with programmer **20** to communicate with LPD **16** and/or SD **30**. For example, the user may interact with programmer **20** to send an interro-gation request and retrieve therapy delivery data, update therapy parameters that define therapy, manage communi-cation between LPD **16** and/or SD **30**, or perform any other activities with respect to LPD **16** and/or SD **30**. Although the user is a physician, technician, surgeon, electrophysiologist, or other healthcare professional, the user may be patient **14** in some examples.

Programmer **20** may also allow the user to define how LPD **16** and/or SD **30** senses electrical signals (e.g., ECGs), detects cardiac conditions (e.g. ventricular dyssynchrony, arrhythmias etc.), delivers therapy, and communicates with other devices of system **10**. For example, programmer **20** may be used to change detection parameters. In another example, programmer **20** may be used to manage therapy parameters that define therapies such as CRT. Moreover, programmer **20** may be used to alter communication proto-cols between LPD **16** and SD **30**. For example, programmer **20** may instruct LPD **16** and/or SD **30** to switch between one-way and two-way communication and/or change which of LPD **16** and/or SD **30** are tasked with initial detection of a cardiac condition.

Programmer **20** may communicate with LPD **16** and/or SD **30** via wireless communication using any techniques known in the art. Examples of communication techniques may include, for example, radiofrequency (RF) telemetry, but other techniques are also contemplated. In some examples, programmer **20** may include a programming head that may be placed proximate to the patient's body near the LPD **16** and/or SD **30** implant site in order to improve the quality or security of communication between LPD **16** and/or SD **30** and programmer **20**.

LPD **16** and SD **30** may engage in communication to facilitate the appropriate detection of ventricular dyssyn-chrony and/or delivery of CRT. The communication may include one-way communication in which one device is

configured to transmit communication messages and the other device is configured to receive those messages. The communication may instead include two-way communica-tion in which each device is configured to transmit and receive communication messages. LPD **16** and SD **30** may be configured to communicate with each other provide alternative electrical stimulation therapies.

Although LPD **16** may at least partially determine whether or not LPD **16** delivers CRT or another therapy to patient **14**, LPD **16** may perform one or more functions in response to receiving a request from SD **30** and without any further analysis by LPD **16**. In this manner, SD **30** may act as a master device and LPD **16** may act as a slave device. In this configuration, LPD **16** passively senses. Specifically, a WT mode is employed as a trigger mode to pace in syn-chrony. In one or more embodiments, the LPD **16** can be configured to actively sense.

FIGS. 2A and 2B are conceptual drawings illustrating different views of SD **30** of FIG. **1**. FIG. **2A** is a top view of SD **30**, and FIG. **2B** is a front view of SD **30**. In the example of FIGS. **2A** and **2B**, housing **32** may be constructed as an ovoid with a substantially kidney-shaped profile. The ovoid shape of housing **32** may promote ease of subcutaneous implantation and may minimize patient discomfort during normal body movement and flexing of the thoracic muscu-lature. In other examples, housing **32** may be constructed with different shapes intended for different implant locations and/or to house different components, subcutaneous leads, or configurations for electrodes **34** FIG. **2B**.

Housing **32** may contain the electronic circuitry of SD **30**. Header **48** and connector **46** may provide an electrical connection between distal electrode coil **38** and distal sens-ing electrode **40** of lead **36** and the circuitry within housing **32**. Subcutaneous lead **36** may include distal defibrillation coil electrode **38**, distal sensing electrode **40**, insulated flexible lead body **42** and proximal connector pin **44**. Distal sensing electrode **40** may be sized appropriately to match the sensing impedance of electrodes **34A-34C** to be used in combination.

In some examples, electrodes **34** are each welded into place on a flattened periphery of housing **32** and are con-nected to electronic circuitry inside housing **32**. Electrodes **34** may be constructed of flat plates, or alternatively, spiral electrodes (as described in U.S. Pat. No. 6,512,940, incor-porated herein in its entirety) and mounted in a non-con-ductive surround shroud (as described in U.S. Pat. Nos. 6,522,915 and 6,622,046, both incorporated herein in their entirety). Electrodes **34** shown in FIG. **2B** may be positioned on housing **32** to form orthogonal signal vectors. However, electrodes **34** may be positioned to form any non-orthogonal signal vectors in other examples. In addition, housing **32** may include fewer or greater than three electrodes. More-over, housing **32** may be configured as an electrically conductive surface and operate as an electrode. Housing **32** may be referred to as a "can electrode" or used as an indifferent electrode. In some examples, housing **32** may be used as an electrode with coil electrode **38** during delivery of (electrical stimuli e.g. pacing pulses, anti-tachyarrhyth-mia shock).

FIG. **3** is a conceptual drawing illustrating example LPD **16** of FIG. **1**. As shown in FIG. **3**, LPD **16** includes case **50**, cap **58**, electrode **60**, electrode **52**, fixation mechanisms **62**, flange **54**, and opening **56**. Together, case **50** and cap **58** may be considered the housing of LPD **16**. In this manner, case **50** and cap **58** may enclose and protect the various electrical components within LPD **16**. Case **50** may enclose substan-tially all of the electrical components, and cap **58** may seal

case **50** and create the hermetically sealed housing of LPD **16**. Although LPD **16** is generally described as including one or more electrodes, LPD **16** may typically include at least two electrodes (e.g., electrodes **52** and **60**) to deliver an electrical signal (e.g., therapy such as CRT) and/or provide at least one sensing vector. Electrodes **52** and **60** are carried on the housing created by case **50** and cap **58**. In this manner, electrodes **52** and **60** may be considered leadless electrodes. In the example of FIG. **3**, electrode **60** is disposed on the exterior surface of cap **58**. Electrode **60** may be a circular electrode positioned to contact cardiac tissue upon implantation. Electrode **52** may be a ring or cylindrical electrode disposed on the exterior surface of case **50**. Both case **50** and cap **58** may be electrically insulating. Electrode **60** may be used as a cathode and electrode **52** may be used as an anode, or vice versa, for delivering CRT or other appropriate cardiac therapy (ATP, shock etc.). However, electrodes **52** and **60** may be used in any stimulation configuration. In addition, electrodes **52** and **60** may be used to detect intrinsic electrical signals from cardiac muscle. In other examples, LPD **16** may include three or more electrodes, where each electrode may deliver therapy and/or detect intrinsic signals. CRT delivered by LPD **16** may be considered to be "painless" to patient **14** or even undetectable by patient **14** since the electrical stimulation occurs very close to or at cardiac muscle and at relatively low energy levels compared with alternative devices.

Fixation mechanisms **62** may attach LPD **16** to cardiac tissue. Fixation mechanisms **62** may be active fixation tines, screws, clamps, adhesive members, or any other types of attaching a device to tissue. As shown in the example of FIG. **3**, fixation mechanisms **62** may be constructed of a memory material that retains a preformed shape. During implantation, fixation mechanisms **62** may be flexed forward to pierce tissue and allowed to flex back towards case **50**. In this manner, fixation mechanisms **62** may be embedded within the target tissue.

Flange **54** may be provided on one end of case **50** to enable tethering or extraction of LPD **16**. For example, a suture or other device may be inserted around flange **54** and/or through opening **56** and attached to tissue. In this manner, flange **54** may provide a secondary attachment structure to tether or retain LPD **16** within heart **12** if fixation mechanisms **62** fail. Flange **54** and/or opening **56** may also be used to extract LPD **16** once the LPD needs to be explanted (or removed) from patient **14** if such action is deemed necessary.

In another example, LPD **16** may be configured to be implanted external to heart **12**, e.g., near or attached to the epicardium of heart **12**. An electrode carried by the housing of the fusion pacing LPD **16** may be placed in contact with the epicardium and/or one or more electrodes placed in contact with the epicardium at locations sufficient to provide therapy (e.g., on external surfaces of the left and/or right ventricles). In any example, SD **30** may communicate with one or more leadless or leaded devices implanted internal or external to heart **12**.

FIG. **4** is a functional block diagram illustrating an example configuration of SD **30** of FIG. **1**. In the illustrated example, SD **30** includes a processor **70**, memory **72**, shock module **75**, signal generator **76**, sensing module **78**, telemetry module **74**, communication module **80**, activity sensor **82**, and power source **84**. Memory **72** includes computer-readable instructions that, when executed by processor **70**, cause SD **30** and processor **70** to perform various functions attributed to SD **30** and processor **70** herein (e.g., detection of ventricular dyssynchrony, communication with LPD **16**,

and/or delivery of anti-tachyarrhythmia shock therapy, if needed). Memory **72** may include any volatile, non-volatile, magnetic, optical, or electrical media, such as a random access memory (RAM), read-only memory (ROM), non-volatile RAM (NVRAM), electrically-erasable programmable ROM (EEPROM), flash memory, or any other digital or analog media.

Processor **70** may include any one or more of a microprocessor, a controller, a digital signal processor (DSP), an application specific integrated circuit (ASIC), a field-programmable gate array (FPGA), or equivalent discrete or analog logic circuitry. In some examples, processor **70** may include multiple components, such as any combination of one or more microprocessors, one or more controllers, one or more DSPs, one or more ASICs, or one or more FPGAs, as well as other discrete or integrated logic circuitry. The functions attributed to processor **70** herein may be embodied as software, firmware, hardware or any combination thereof.

Processor **70** controls signal generator **76** to deliver stimulation therapy to heart **12** according to a therapy parameters, which may be stored in memory **72**. For example, processor **70** may control signal generator **76** to deliver electrical pulses (e.g., shock pulses) with the amplitudes, pulse widths, frequency, or electrode polarities specified by the therapy parameters. In this manner, signal generator **76** may deliver electrical pulses to heart **12** via electrodes **34**, **38**, and/or **40**. In addition, housing **30** may be configured as an electrode and coupled to signal generator **76** and/or sensing module **78**. SD **30** may use any combination of electrodes to deliver anti-tachycardia therapy and/or detect electrical signals from patient **14**. However, in general, coil electrode **38** may be used to deliver an anti-tachyarrhythmia shock, if necessary.

Signal generator **76** may also include shock module **75**. Shock module **75** may include circuitry and/or capacitors required to deliver an anti-tachyarrhythmia shock. For example, signal generator **76** may charge shock module **75** to prepare for delivering a shock. Shock module **75** may then discharge to enable signal generator **76** to deliver the shock to patient **14** via one or more electrodes. In other examples, shock module **75** may be located within SD **30** but outside of signal generator **76**.

Signal generator **76** is electrically coupled to electrodes **34**, **38**, and **40**. In the illustrated example, signal generator **76** is configured to generate and deliver electrical stimuli (e.g. anti-tachyarrhythmia shock therapy) to heart **12**. For example, signal generator **76** may, using shock module **75**, deliver shocks to heart **12** via a subset of electrodes **34**, **38**, and **40**. In some examples, signal generator **76** may deliver pacing stimulation, and cardioversion or defibrillation shocks in the form of electrical pulses. In other examples, signal generator may deliver one or more of these types of stimulation or shocks in the form of other signals, such as sine waves, square waves, or other substantially continuous time signals.

Signal generator **76** may include a switch module and processor **70** may use the switch module to select, e.g., via a data/address bus, which of the available electrodes are used to deliver shock and/or pacing pulses. The switch module may include a switch array, switch matrix, multiplexer, or any other type of switching device suitable to selectively couple stimulation energy to selected electrodes.

Electrical sensing module **78** may be configured to monitor signals from at least one of electrodes **34**, **38**, and **40** in order to monitor electrical activity of heart **12**, impedance, or other electrical phenomenon. Sensing may be done to determine heart rates or heart rate variability, or to detect

arrhythmias (e.g., tachyarrhythmia) or other electrical signals. Sensing module 78 may also include a switch module to select which of the available electrodes are used to sense the heart activity, depending upon which electrode combination, or electrode vector, is used in the current sensing configuration. In examples with several electrodes, processor 70 may select the electrodes that function as sense electrodes, i.e., select the sensing configuration, via the switch module within sensing module 78. Sensing module 78 may include one or more detection channels, each of which may be coupled to a selected electrode configuration for detection of cardiac signals via that electrode configuration. Some detection channels may be configured to detect cardiac events, such as P- or R-waves, and provide indications of the occurrences of such events to processor 70, e.g., as described in U.S. Pat. No. 5,117,824 to Keimel et al., which issued on Jun. 2, 1992 and is entitled, "APPARATUS FOR MONITORING ELECTRICAL PHYSIOLOGIC SIGNALS," and is incorporated herein by reference in its entirety. Processor 70 may control the functionality of sensing module 78 by providing signals via a data/address bus.

Processor 70 may include a timing and control module, which may be embodied as hardware, firmware, software, or any combination thereof. The timing and control module may comprise a dedicated hardware circuit, such as an ASIC, separate from other processor 70 components, such as a microprocessor, or a software module executed by a component of processor 70, which may be a microprocessor or ASIC. The timing and control module may implement programmable counters. If SD 30 is configured to generate and deliver pacing pulses to heart 12, such counters may control the basic time intervals associated with DDD, VVI, DVI, VDD, AAI, DDI, DDDR, VVIR, DVIR, VDDR, AAIR, DDIR and other modes of pacing.

Intervals defined by the timing and control module within processor 70 may include atrial and ventricular pacing escape intervals, refractory periods during which sensed P-waves and R-waves are ineffective to restart timing of the escape intervals, and the pulse widths of the pacing pulses. As another example, the timing and control module may withhold sensing from one or more channels of sensing module 78 for a time interval during and after delivery of electrical stimulation to heart 12. The durations of these intervals may be determined by processor 70 in response to stored data in memory 72. The timing and control module of processor 70 may also determine the amplitude of the cardiac pacing pulses.

Interval counters implemented by the timing and control module of processor 70 may be reset upon sensing of R-waves and P-waves with detection channels of sensing module 78. The value of the count present in the interval counters when reset by sensed R-waves and P-waves may be used by processor 70 to measure the durations of R-R intervals, P-P intervals, P-R intervals and R-P intervals, which are measurements that may be stored in memory 72. In some examples, processor 70 may determine that ventricular dyssynchrony has occurred based on AV interval and P-wave width measurements. Ventricular dyssynchrony is automatically addressed by updating AV delays every minute based on AV interval and Pwave width measurements.

In some examples, communication module 80 may be used to detect communication signals from LPD 16. LPD 16 may not include telemetry circuitry. Instead, LPD 16 may generate electrical signals via one or more electrodes with amplitudes and/or patterns representative of information to be sent to SD 30. The electrical signals may be carried by

pacing pulses or separate communication signals configured to be detected by SD 30. In this manner, communication module 80 may be configured to monitor signals sensed by sensing module 78 and determine when a communication message is received from LPD 16.

In other examples, SD 30 may also transmit communication messages to LPD 16 using electrical signals from one or more of electrodes 34, 38, and 40. In this case, communication module 80 may be coupled to signal generator 76 to control the parameters of generated electrical signals or pulses. Alternatively, processor 70 may detect communications via sensing module 78 and/or generate communications for deliver via signal generator 76. Although communication module 80 may be used to communicate using electrical signals via electrodes 34, 38 and 40, communication module 80 may alternatively or in addition use wireless protocols such as RF telemetry to communicate with LPD 16 or other medical devices. In some examples, telemetry module 74 may include this wireless communication functionality.

Memory 72 may be configured to store a variety of operational parameters, therapy parameters, sensed and detected data, and any other information related to the monitoring, therapy and treatment of patient 14. Memory 72 may store, for example, thresholds and parameters indicative of cardiac conditions such as ventricular dyssynchrony and/or therapy parameter values that at least partially define delivered CRT such as fusion pacing. In some examples, memory 72 may also store communications transmitted to and/or received from LPD 16.

Activity sensor 82 may be contained within the housing of SD 30 and include one or more accelerometers or other devices capable of detecting motion and/or position of SD 30. For example, activity sensor 82 may include a 3-axis accelerometer that is configured to detect accelerations in any direction in space. Accelerations detected by activity sensor 82 may be used by processor 70 to identify potential noise in signals detected by sensing module 78 and/or confirm the detection of arrhythmias or other patient conditions.

Telemetry module 74 includes any suitable hardware, firmware, software or any combination thereof for communicating with another device, such as programmer 20 (FIG. 1). As described herein, telemetry module 74 may transmit generated or received arrhythmia data, therapy parameter values, communications between SD 30 and LPD 16, or any other information. For example, telemetry module 74 may transmit information representative of sensed physiological data such as R-R intervals or any other data that may be used by LPD 16 to determine a condition of patient 14. Telemetry module 74 may also be used to receive updated therapy parameters from programmer 20. Under the control of processor 70, telemetry module 74 may receive downlink telemetry from and send uplink telemetry to programmer 20 with the aid of an antenna, which may be internal and/or external. Processor 70 may provide the data to be uplinked to programmer 20 and the control signals for the telemetry circuit within telemetry module 74, e.g., via an address/data bus. In some examples, telemetry module 74 may provide received data to processor 70 via a multiplexer. In some examples, SD 30 may signal programmer 20 to further communicate with and pass the alert through a network such as the Medtronic CareLink® Network developed by Medtronic, Inc., of Minneapolis, Minn., or some other network linking patient 14 to a clinician. SD 30 may

spontaneously transmit the diagnostic information to the network or in response to an interrogation request from a user.

Power source **84** may be any type of device that is configured to hold a charge to operate the circuitry of SICD. Power source **84** may be provided as a rechargeable or non-rechargeable battery. In other examples, power source **84** may also incorporate an energy scavenging system that stores electrical energy from movement of SD **30** within patient **14**.

There may be numerous variations to the configuration of SD **30**, as described herein. In the examples of FIGS. 2A, 2B, and **4**, SD **30** may include housing **32** configured to be implanted in patient **14** external to a rib cage of patient **14**, one or more electrodes (e.g., electrodes **34**, **38**, and **40**) configured to be disposed external to the rib cage, and shock module **75** configured to at least partially deliver anti-tachyarrhythmia shock therapy to patient **14** via the one or more electrodes.

SD **30** may also include communication module **80** configured to transmit and/or receive communication messages between LPD **16** configured to be implanted within heart **12** of patient **14** and a sensing module **78** configured to sense an electrical signal from heart **12** of patient **14** via the one or more electrodes. Further, SD **30** may include one or more processors **70** configured to detect a ventricular dyssynchrony within the sensed electrical signal and determine, based on the detected ventricular dyssynchrony, to deliver CRT to patient **14** to treat the detected ventricular dyssynchrony. Processor **70** may also be configured to transmit, via communication module **80** and prior to delivering CRT, a communication message to LPD **16** requesting LPD **16** deliver fusion pacing to heart **12** of patient **14**.

FIG. **5** is a functional block diagram illustrating an example configuration of LPD **16** of FIG. 1. In the illustrated example, LPD **16** includes a processor **90**, memory **92**, signal generator **96**, sensing module **98**, shock detector **99**, activity sensor **100**, telemetry module **94**, and power source **102**. Memory **92** includes computer-readable instructions that, when executed by processor **90**, cause LPD **16** and processor **90** to perform various functions attributed to LPD **16** and processor **90** herein (e.g., detecting ventricular dyssnchrony, arrhythmias, communicating with SD **30**, and delivering anti-tachycardia pacing and post-shock pacing). Memory **92** may include any volatile, non-volatile, magnetic, optical, or electrical media, such as a random access memory (RAM), read-only memory (ROM), non-volatile RAM (NVRAM), electrically-erasable programmable ROM (EEPROM), flash memory, or any other digital or analog media.

Processor **90** may include any one or more of a microprocessor, a controller, a digital signal processor (DSP), an application specific integrated circuit (ASIC), a field-programmable gate array (FPGA), or equivalent discrete or analog logic circuitry. In some examples, processor **90** may include multiple components, such as any combination of one or more microprocessors, one or more controllers, one or more DSPs, one or more ASICs, or one or more FPGAs, as well as other discrete or integrated logic circuitry. The functions attributed to processor **90** herein may be embodied as software, firmware, hardware or any combination thereof.

Processor **90** controls signal generator **96** to deliver stimulation therapy to heart **12** according to a therapy parameters, which may be stored in memory **92**. For example, processor **90** may control signal generator **96** to deliver electrical pulses with the amplitudes, pulse widths, frequency, or electrode polarities specified by the therapy

parameters. In this manner, signal generator **96** may deliver pacing pulses (e.g., fusion pacing) to heart **12** via electrodes **52** and **60**. Although LPD **16** may only include two electrodes, e.g., electrodes **52** and **60**, LPD **16** may utilize three or more electrodes in other examples. LPD **16** may use any combination of electrodes to deliver therapy and/or detect electrical signals from patient **14**.

Signal generator **96** is electrically coupled to electrodes **52** and **60** carried on the housing of LPD **16**. In the illustrated example, signal generator **96** is configured to generate and deliver electrical stimulation therapy to heart **12**. For example, signal generator **96** may deliver pulses to a portion of cardiac muscle within heart **12** via electrodes **52** and **60**. In some examples, signal generator **96** may deliver pacing stimulation in the form of electrical pulses. In other examples, signal generator may deliver one or more of these types of stimulation in the form of other signals, such as sine waves, square waves, or other substantially continuous time signals. Although LPD **16** is generally described has delivering pacing pulses, LPD **16** may deliver cardioversion or defibrillation pulses in other examples.

Fusion pacing may be delivered to patient **14** as defined by a set of parameters. These parameters may include pulse intervals, pulse width, current and/or voltage amplitudes, and durations for each pacing mode.

Signal generator **96** may also include circuitry for measuring the capture threshold of one or both electrodes **52** and **60**. The capture threshold may indicate the voltage necessary to induce depolarization of the surrounding cardiac muscle. For example, signal generator **96** may measure the voltage of pacing signals needed to induce synchronized ventricular contractions. In examples in which LPD **16** includes more than two electrodes, signal generator **96** may include a switch module and processor **90** may use the switch module to select, e.g., via a data/address bus, which of the available electrodes are used to deliver pacing pulses. The switch module may include a switch array, switch matrix, multiplexer, or any other type of switching device suitable to selectively couple stimulation energy to selected electrodes. In the instance that the capture threshold exceeds useable limits, processor **90** may withhold delivery of therapeutic pacing. In addition, processor **90** may transmit communication to SD **30** if pacing cannot be delivered.

Electrical sensing module **98** monitors signals from at least one of electrodes **52** and **60** in order to monitor electrical activity of heart **12**, impedance, or other electrical phenomenon. Sensing may be done to determine heart rates or heart rate variability, or to detect ventricular dyssynchrony, arrhythmias (e.g., tachyarrhythmias) or other electrical signals. Sensing module **98** may also include a switch module to select which of the available electrodes (or electrode polarity) are used to sense the heart activity, depending upon which electrode combination, or electrode vector, is used in the current sensing configuration. In examples with several electrodes, processor **90** may select the electrodes that function as sense electrodes, i.e., select the sensing configuration, via the switch module within sensing module **98**. Sensing module **98** may include one or more detection channels, each of which may be coupled to a selected electrode configuration for detection of cardiac signals via that electrode configuration. Some detection channels may be configured to detect cardiac events, such as P- or R-waves, and provide indications of the occurrences of such events to processor **90**, e.g., as described in U.S. Pat. No. 5,117,824 to Keimel et al., which issued on Jun. 2, 1992 and is entitled, "APPARATUS FOR MONITORING ELECTRICAL PHYSIOLOGIC SIGNALS," and is incorporated

herein by reference in its entirety. Processor **90** may control the functionality of sensing module **98** by providing signals via a data/address bus.

Processor **90** may include a timing and control module, which may be embodied as hardware, firmware, software, or any combination thereof. The timing and control module may comprise a dedicated hardware circuit, such as an ASIC, separate from other processor **90** components, such as a microprocessor, or a software module executed by a component of processor **90**, which may be a microprocessor or ASIC. The timing and control module may implement programmable counters. If LPD **16** is configured to generate and deliver pacing pulses to heart **12**, such counters may control the basic time intervals associated with DDD, VVI, DVI, VDD, AAI, DDI, DDDR, VVIR, DVIR, VDDR, AAIR, DDIR and other modes of pacing. Example LPDs that may deliver pacing using such modes are described in U.S. patent application Ser. No. 13/665,492 to Bonner et al., entitled, "LEADLESS PACEMAKER SYSTEM," and filed on Oct. 31, 2012, or in U.S. patent application Ser. No. 13/665,601 to Bonner et al., entitled, "LEADLESS PACE-MAKER SYSTEM," and filed on Oct. 31, 2012. U.S. patent application Ser. No. 13/665,492 to Bonner et al. and U.S. patent Ser. No. 13/665,601 to Bonner et al. are both incorporated herein by reference in their entireties.

In addition to detecting and identifying specific types of cardiac rhythms (types of cardiac events), sensing module **98** may also sample the detected intrinsic signals to generate an electrogram or other time-based indication of cardiac events. Processor **90** may also be able to coordinate the delivery of pacing pulses from different LPDs implanted in different chambers of heart **12**, such as an LPD implanted in the other ventricle. For example, processor **90** may identify delivered pulses from other LPDs via sensing module **98** and updating pulse timing. In other examples, LPDs may communicate with each other via telemetry module **94** and/or instructions over a carrier wave (such as a stimulation waveform).

Memory **92** may be configured to store a variety of operational parameters, therapy parameters, sensed and detected data, and any other information related to the therapy and treatment of patient **14**. In the example of FIG. **5**, memory **92** may store sensed ECGs, detected arrhythmias, communications from SD **30**, and therapy parameters. In other examples, memory **92** may act as a temporary buffer for storing data until it can be uploaded to SD **30**, another implanted device, or programmer **20**.

Activity sensor **100** may be contained within the housing of LPD **16** and include one or more accelerometers or other devices capable of detecting motion and/or position of LPD **16**. For example, activity sensor **100** may include a 3-axis accelerometer that is configured to detect accelerations in any direction in space. Specifically, the 3-axis accelerator may be used to detect LPD **16** motion that may be indicative of cardiac events and/or noise. For example, processor **16** may monitor the accelerations from activity sensor **100** to confirm or detect arrhythmias. Since LPD **16** may move with a chamber wall of heart **12**, the detected changes in acceleration may also be indicative of contractions. Therefore, LPD **16** may be configured to identify heart rates and confirm ventricular dyssynchrony sensed via sensing module **98**.

Telemetry module **94** includes any suitable hardware, firmware, software or any combination thereof for communicating with another device, such as programmer **20** or SD **30** (FIG. **1**). Under the control of processor **90**, telemetry module **94** may receive downlink telemetry from and send uplink telemetry to programmer **20** with the aid of an antenna, which may be internal and/or external. Processor **90** may provide the data to be uplinked to programmer **20** and the control signals for the telemetry circuit within telemetry module **94**, e.g., via an address/data bus. In some examples, telemetry module **94** may provide received data to processor **90** via a multiplexer.

In some examples, LPD **16** may signal programmer **20** to further communicate with and pass the alert through a network such as the Medtronic CareLink® Network developed by Medtronic, Inc., of Minneapolis, Minn., or some other network linking patient **14** to a clinician. LPD **16** may spontaneously transmit information to the network or in response to an interrogation request from a user.

In other examples, processor **90** may be configured to transmit information to another device, such as SD **30** using electrodes **52** and **60**. For example, processor **90** may control signal generator **96** to generate electrical signals representative of commands such as the detection of ventricular dyssynchrony, confirmation that ventricular dyssynchrony has been detected, a request to monitor electrical signals for ventricular dyssynchrony, or even signals to "wake up" an SICD in a sleep mode. In other examples, processor **90** may cause telemetry module **94** to transmit information representative of sensed physiological data such as R-R intervals or any other data that may be used by SD **30** to determine a condition of patient **14** (e.g., whether or not patient **14** is experiencing ventricular dyssynchrony). The communication may be in the form of dedicated communication signals.

Alternatively, processor **90** may communicate with SD **30** by delivering pacing pulses at specific intervals that would be identifiable by SD **30** as non-physiologic and intended to convey information. In other words, these pulses intended for communication with SD **30**. SD **30** may be configured to identify, or distinguish, these pulses from signals indicative of normal or non-normal heart beats, signals indicative of ectopic or non-ectopic heart beats, signals indicative of noise (e.g., skeletal muscle noise), or any other signals indicative of typically physiological or therapeutic electrical signals. The communication pulses may or may not be therapeutic pulses or signals. SD **30** may detect the intervals between these pulses as code for specific messages from LPD **16**. For example, the pacing pulses may be varied and/or repeated in certain patterns detectable by SD **30** and still therapeutic. LPD **16** may also be configured to detect such communication messages via electrodes **52** and **60**. Processor **90** may monitor sensing module **98** for such communications. Alternatively, LPD **16** may include a communication module, similar to communication module **80** of FIG. **4**, to detect any communications received via sensing module **98**. In any example, LPD **16** may be configured for one-way communication to or from another device such as SD **30** or two-way communication with another device such as SD **30** using any type of communication protocol.

Power source **102** may be any type of device that is configured to hold a charge to operate the circuitry of LPD **16**. Power source **102** may be provided as a rechargeable or non-rechargeable battery. In other example, power source **102** may incorporate an energy scavenging system that stores electrical energy from movement of LPD **16** within patient **14**.

There may be numerous variations to the configuration of LPD **16**, as described herein. In one example, LPD **16** includes a housing configured to be implanted within heart **12** of patient **14**, one or more electrodes (e.g., electrodes **52** and **60**) coupled to the housing, fixation mechanism **62** configured to attach the housing to tissue of heart **12**, sensing

module **98** configured to sense an electrical signal from heart **12** of patient **14** via the one or more electrodes, and signal generator **96** configured to deliver therapy to heart **12** of patient **14** via the one or more electrodes. LPD **16** may also include processor **90** configured to receive a communication message from SD **30** requesting LPD **16** deliver CRT to heart **12**, where SD **30** is configured to be implanted exterior to a rib cage of patient **14**. Processor **90** may also be configured to determine, based on the sensed electrical signal, whether to deliver CRT to heart **12**, and, in response to the determination, command signal generator **96** to deliver the CRT therapy. Processor **90** may also be configured to control signal generator **96** to deliver post-shock pacing to patient **14** in response to shock detector **99** detecting an anti-tachyarrhythmia shock.

FIG. **6** is a functional block diagram illustrating an example configuration of external programmer **20** of FIG. **1**. As shown in FIG. **6**, programmer **20** may include a processor **110**, memory **112**, user interface **114**, telemetry module **116**, and power source **118**. Programmer **20** may be a dedicated hardware device with dedicated software for programming of LPD **16** and/or SD **30**. Alternatively, programmer **20** may be an off-the-shelf computing device running an application that enables programmer **20** to program LPD **16** and/or SD **30**.

A user may use programmer **20** to configure the operational parameters of and retrieve data from LPD **16** and/or SD **30** (FIG. **1**). In one example, programmer **20** may communicate directly to both LPD **16** and SD **30**. In other examples, programmer may communicate to one of LPD **16** or SD **30**, and that device may relay any instructions or information to or from the other device. The clinician may interact with programmer **20** via user interface **114**, which may include display to present graphical user interface to a user, and a keypad or another mechanism for receiving input from a user. In addition, the user may receive an alert or notification from SD **30** indicating that a shock has been delivered, any other therapy has been delivered, or any problems or issues related to the treatment of patient **14**.

Processor **110** can take the form one or more microprocessors, DSPs, ASICs, FPGAs, programmable logic circuitry, or the like, and the functions attributed to processor **110** herein may be embodied as hardware, firmware, software or any combination thereof. Memory **112** may store instructions that cause processor **110** to provide the functionality ascribed to programmer **20** herein, and information used by processor **110** to provide the functionality ascribed to programmer **20** herein. Memory **112** may include any fixed or removable magnetic, optical, or electrical media, such as RAM, ROM, CD-ROM, hard or floppy magnetic disks, EEPROM, or the like. Memory **112** may also include a removable memory portion that may be used to provide memory updates or increases in memory capacities. A removable memory may also allow patient data to be easily transferred to another computing device, or to be removed before programmer **20** is used to program therapy for another patient.

Programmer **20** may communicate wirelessly with LPD **16** and/or SD **30**, such as using RF communication or proximal inductive interaction. This wireless communication is possible through the use of telemetry module **116**, which may be coupled to an internal antenna or an external antenna. An external antenna that is coupled to programmer **20** may correspond to the programming head that may be placed over heart **12** or the location of the intend implant, as described above with reference to FIG. **1**. Telemetry module **116** may be similar to telemetry modules **74** and **94** of respective FIGS. **4** and **5**.

Telemetry module **116** may also be configured to communicate with another computing device via wireless communication techniques, or direct communication through a wired connection. Examples of local wireless communication techniques that may be employed to facilitate communication between programmer **20** and another computing device include RF communication according to the 802.11 or Bluetooth specification sets, infrared communication, e.g., according to the IrDA standard, or other standard or proprietary telemetry protocols. An additional computing device in communication with programmer **20** may be a networked device such as a server capable of processing information retrieved from LPD **16**. In other examples, LPD **16** may not use a shock detector to time the beginning or ending of post-shock pacing. Instead, LPD **16** may determine when to deliver post-shock pacing based on a command from SD **30**. For example, SD **30** may determine that a shock will be delivered and transmit a shock imminent command to LPD **16**. In response to receiving the shock imminent command, LPD **16** may enter a shock state for a predetermined period of time. This predetermined period of time may be stored in memory **92** or sent along with the shock imminent command from SD **30**. The predetermined period of time may have a sufficient duration such that any shock would be delivered prior to the predetermined period expiring. In response to the predetermined period elapsing, LPD **16** may exit the shock state and enter a post-shock pacing state in which LPD **16** delivers post-shock pacing and/or first determines whether post-shock pacing is needed.

FIG. **7** is a flow diagram of an exemplary method **300** in which CRT such as fusion pacing is delivered to cardiac tissue through LPD **16**, in communication with SD **30**, in order to address ventricular dyssynchrony present in a patient. Method **300** begins during or after the SD **30** and LPD **16** are implanted into the patient. If the heart **12** is exhibiting ventricular dyssynchrony during the implant procedure, LPD **16** is activated to immediately deliver fusion pacing. Alternatively, if the heart **12** is not exhibiting ventricular dyssynchrony during the implant procedure, one of the SD **30** and LPD **16** determines whether the heart **12** is exhibiting ventricular dyssynchrony and then delivers CRT (i.e. fusion pacing). While method **300** is described as the SD **30** and LPD **16** in a master-slave communication mode, skilled artisans understand that other communication means described herein can be applied. Additionally, method **300** is not limited to the FIG. **1** embodiment in which LPD **16** is affixed to an inner wall of the left ventricle and is wireless communication with SD **30**. Other configurations can be used such as, for example, the RV can undergo fusion pacing instead of the LV. Additionally, LPD **16** can be placed on an outer wall of the LV and/or RV.

At block **302**, a determination is made as to whether electrical stimuli (e.g. pacing pulses) should be switched to asynchronous pacing of the cardiac tissue. Exemplary cardiac conditions that cause method **300** to switch to asynchronous pacing include an irregular rhythm such as atrial tachycardia (AT), atrial fibrillation (AF), ventricular tachycardia (VT), or ventricular fibrillation (VF). If the condition to switch to asynchronous pacing is met, the YES path continues to block **304**. SD **30** generates a command signal to LPD **16**, which causes LPD **16** to switch to asynchronous pacing. Asynchronous pacing continues until the irregular rhythm is no longer present in the patient. When the suspend condition terminates (NO path from block **302**) the LPD

transitions to block **306** in order to evaluate intrinsic electrical conduction and recalculate parameters applied during synchronous pacing.

If the suspend condition is not met such that the patient has a regular rhythm, the NO path continues from block **302** to block **306**. At block **306**, intrinsic electrical activation of the heart is evaluated using SD **30**. For example, a first electrical signal (also referred to as the baseline rhythm or intrinsic rhythm) is sensed from a heart as a subcutaneous ECG through electrodes **34** associated with the SD **30**. The baseline rhythm is typically determined at implant; however, the baseline can also be updated during a post-implant visit to a physician's office. Data sampled or extracted from the first signal is stored into memory **72** of the SD **30**. Exemplary data from the first electrical signal includes intrinsic electrical activation data (e.g. QRS complex) for the ventricles.

At block **308**, electrical activation time or local electrical activity is determined relative to timing of a fiducial, an indicator of a global cardiac event (e.g. timing of activation of a chamber of the heart, timing of pacing of a chamber of the heart, etc.). For example, the fiducial may be the onset of QRS, the peak of QRS (e.g. minimum values, minimum slopes, maximum slopes), zero crossings, threshold crossings, etc. of a near or far-field electrogram (EGM), onset of application of a pacing electrical stimulus, or the like.

After electrocardiogram (ECG) data has been extracted from the first electrical signal for an intrinsic rhythm during a conduction test beat (or without a conduction test beat), the ECG data is filtered with a low pass filter. For instance, the low pass filter could be implemented as a moving average executed in two loops. The number of samples in the moving average could be adjusted to achieve good attenuation at 50 Hz and 60 Hz line frequencies for the sampling rate set, for example, at 256 Hz. The time derivative of the signal dV/dt can then be calculated. Fiducial points associated with a QRS complex or P-wave can be determined by finding the samples for which the derivative is outside the predetermined boundaries, as described in U.S. Pat. No. 7,941,218 to Sambelashvili, incorporated by reference in its entirety.

The processor **70** of the SD **30** retrieves the data from the first electrical signal (i.e. baseline) from memory **72** and a determination is made by the SD **30** as to the appropriate timing in which electrical stimuli (e.g. pacing pules etc.) are delivered to cardiac tissue at block **310** by the LPD **16**. The timing of the delivery of pacing pulses can be predetermined and stored as a lookup table into the memory **72** of the SD **30** and/or the LPD **16**. The timing could be also programmable by the user of the system. For example, the timing of pacing by the LPD **16** can be optimized by delivering pacing at a pre-specified interval after the end of a P-wave. The pre-specified interval is either a fixed number or calculated by the SD **30** from widths of the P-wave and paced QRS complex. In one or more embodiments, pre-specified interval fixed number ranges from about 0 ms to about 60 ms and can be typically set at about 30 ms. Alternatively, the timing of pacing by LPD **16** can be optimized by delivering pacing at a pre-specified interval relative to the onset of the QRS complex. The pre-specified fixed number can range from 0 to 60 ms and is typically set at 0 ms. In sum, the LPD **16**, in communication with SD **30**, is configured to pace relative to fiducial points with pre-specified intervals (e.g. at the detected onset of QRS, 30 ms after the detected end of the P-wave or another suitable rule for timing of pacing). The SD **30** then wirelessly sends a command signal to the LPD **16** to deliver electrical stimuli (e.g. pacing pulses) to the tissue surrounding LPD **16**.

At block **312**, a determination is made as to whether intrinsic condition of the heart **12** should be re-evaluated. An exemplary re-evaluation condition requires that the heart rhythm is regular and/or a pre-specified time interval has elapsed since the suspend condition ended. The time interval could range from approximately 30 seconds to 24 hours. The time interval could also depend on the daily activity level of the patient, quantified by the activity sensor, so that higher levels of activity correspond to more frequent re-evaluations of intrinsic conduction. For example, periodic conduction tests can be performed to determine whether LPD **16** pacing should be adjusted to maintain AV and VV synchrony. Paced QRS morphology is analyzed by the SD **30** to verify VV synchrony. If the re-evaluation condition is met, then the YES path from block **312** returns to block **306** and the method **300** is continued. For example, when SD **30** re-evaluates the intrinsic conduction, a new baseline signal is recorded and is processed as previously described.

The SD **30** can verify the efficiency and/or efficacy of CRT at block **314**. Efficiency of CRT requires that the post-implant or second electrical signal (i.e. current rhythm) be compared to the first electrical signal (i.e. baseline). The second electrical signal is recorded via electrodes **34** on SD **30** and/or electrode **54** on LPD **16** and then stored into memory **72** of the SD **30**. Data is extracted from the second electrical signal using techniques known in the art. The processor **70** of the SD **30** retrieves the data from the first electrical signal (i.e. baseline) from memory **72** and compares that data to the data extracted from the second electrical signal (i.e. post-implant signal). Exemplary methods for comparing the two signals for the purpose of optimizing the timing of the delivery of pacing pulses can be found, in U.S. Pat. No. 8,145,308 to Sambelashvili et al., entitled METHOD AND APPARATUS FOR DETERMINING A PARAMETER ASSOCIATED WITH DELIVERY OF THERAPY IN A MEDICAL DEVICE, assigned to the assignee of the present disclosure, incorporated by reference in its entirety. Other exemplary methods that can be usefully applied include template matching disclosed in U.S. Pat. Nos. 6,393,316 B1 and 8,521,268, incorporated by reference in its entirety. Another method employs selected data from each signal for comparison purposes as described in US Patent Application No. 20130053906 A1, which is also incorporated by reference in its entirety.

FIG. **8** graphically depicts a comparison that was made between a second electrical signal (i.e. rhythm sensed when ventricular pacing is performed) to a heart's baseline or intrinsic rhythm. In this embodiment, the baseline rhythm (i.e. without ventricular pacing) is associated with ventricular dyssynchrony. As applied to FIG. **8**, the closer the second electrical signal matches the baseline rhythm (i.e. first electrical signal), the more likely the patient is experiencing ventricular dyssynchrony. In contrast, the greater the difference between the first and second electrical signals, the more likely the patient's ventricles are in synchrony. In particular, fusion pacing is deemed to successfully treat ventricular dyssynchrony when the QRS complexes sensed during pacing are sufficiently different from QRS complexes of the intrinsic rhythm. Wavelet analysis was used to perform the QRS complex comparison, as described in U.S. Pat. No. 6,393,316 to Jeffrey Gillberg et al., incorporated by reference. Wavelet analysis can quantify fusion and optimize timing as described in U.S. Pat. No. 8,145,308, incorporated by reference in its entirety. Additionally, AV intervals can be optimized through U.S. Pat. No. 8,214,041 to Van Gelder et al. incorporated by reference in its entirety.

The dashed line is the electrical signal sensed from the ventricle without ventricular pacing (i.e. baseline rhythm) while the solid line is associated an electrical signal sensed from the ventricle during ventricular pacing. The window encompasses an optimal AV delay of 190 ms in which the QRS complexes reveal a 40% QRS match. From FIG. 8, fusion pacing has corrected the ventricular dyssynchrony by setting the AV delay to 190 ms. If the QRS complexes from the baseline rhythm more closely match the QRS complex from ventricular pacing, then fusion pacing is not effective. For instance, effective fusion can be achieved when to the match score between the paced and intrinsic QRS complexes is less than 70%. The target range for the score can be 40-70%, otherwise the resynchronization can be classified as ineffective.

If fusion pacing was ineffective, the NO path from block 314 continues to block 316 in which another pre-specified interval is selected. Another pre-specified interval can be selected from a lookup table, pre-specified by the user, or adjusted by a rule. For instance, the pre-specified interval can be decremented or incremented by 20 ms for a new evaluation of the resynchronization effectiveness. Thereafter, the process flow continues to block 310.

While method 300 is described relative to LPD 16 placed in the left ventricle, skilled artisans appreciate that the present disclosure can be applied to many different embodiments in which SD 30 is used in combination with LPD 16. For example, the LPD can be implanted within a chamber of the heart or substernally/retrosternally, as described in U.S. provisional patent application Ser. No. 61/819,946 filed May 6, 2013 and entitled "IMPLANTABLE MEDICAL DEVICE SYSTEM HAVING IMPLANTABLE CARDIAC DEFIBRILLATOR SYSTEM AND SUBSTERNAL LEADLESS PACING DEVICE", incorporated by reference in its entirety, U.S. provisional patent application Ser. No. 61/820,024 filed May 6, 2013 and entitled "ANCHORING AN IMPLANTABLE MEDICAL DEVICE WITHIN A SUBSTERNAL SPACE, and U.S. provisional patent application Ser. No. 61/820,014 filed May 6, 2013 and entitled "SYSTEMS AND METHODS FOR IMPLANTING A MEDICAL ELECTRICAL LEAD WITHIN A SUBSTERNAL SPACE", all of which are incorporated by reference herein. The SD is configured to deliver shocks to the patient without any leads implanted within the vasculature and/or heart of the patient.

FIGS. 9A-C are conceptual diagrams of a patient 14 implanted with an exemplary implantable cardiac system 400 that includes a substernal/retrosternal LPD 16 in order to deliver CRT (e.g. fusion pacing, biventricular pacing or adaptive CRT (i.e. switching between biventricular pacing and fusion pacing). Implantable cardiac system 400 can implement method 300 as described herein. FIG. 9A is a front view of patient 14 implanted with implantable cardiac system 400. FIG. 9B is a side view patient 14 with implantable cardiac system 400. FIG. 9C is a transverse view of patient 14 with implantable cardiac system 400.

Implantable cardiac system 400 includes an implantable medical device 414 such as an implantable cardiac defibrillator (ICD) or pacemaker connected to a defibrillation lead 416. In the example illustrated in FIGS. 9A-C, IMD 414 is implanted subcutaneously on the left midaxiallary of patient 14. IMD 414 may, however, be implanted at other subcutaneous locations on patient 14 as described herein.

Defibrillation lead 416 includes a proximal end that is connected to IMD 414 and a distal end that includes one or more electrodes. Defibrillation lead 416 extends subcutaneously from IMD 414 toward xiphoid process 20. At a

location near xiphoid process 20 defibrillation lead 16 bends or turns and extends subcutaneously superiorily, substantially parallel to sternum 422. The distal end of defibrillation lead 416 may be positioned near the second or third rib of patient 14. However, the distal end of defibrillation lead 416 may be positioned further superior or inferior depending on the location of IMD 414 and other factors. Although illustrated as being offset laterally from and extending substantially parallel to sternum 422 in the example of FIGS. 9A-C, defibrillation lead 416 may be implanted over sternum 422, offset from sternum 422, but not parallel to sternum 422 (e.g., angled lateral from sternum 422 at either the proximal or distal end).

Defibrillation lead 416 includes a defibrillation electrode 424, which may be an elongated coil electrode, toward the distal end of defibrillation lead 416. Defibrillation lead 416 is placed such that a therapy vector between defibrillation electrode 424 and a housing or can electrode of IMD 414 is substantially across the ventricle of heart 12.

Defibrillation lead 416 may also include sensing and/or pacing electrodes 428 and 430 located toward the distal end of defibrillation lead 416. In the example illustrated in FIGS. 9A-C, sensing electrode 428 and 430 are separated from one another by defibrillation electrode 424. IMD 414 may sense electrical activity of heart 26 via a combination of sensing vectors that include combinations of electrodes 428 and 430 and the housing or can electrode of IMD 414. For example, IMD 414 may obtain electrical signals sensed using a sensing vector between electrodes 428 and 430, obtain electrical signals sensed using a sensing vector between electrode 428 and the conductive housing or can electrode of IMD 414, obtain electrical signals sensed using a sensing vector between electrode 430 and the conductive housing or can electrode of IMD 414, or a combination thereof. In some instances, IMD 414 may even sense cardiac electrical signals using a sensing vector that includes defibrillation electrode 424.

ICD 414 may analyze the sensed electrical signals from one or more of the sensing vectors of defibrillation lead 416 to detect ventricular dyssynchrony and/or other cardiac conditions (e.g. tachycardia, fibrillation). In response to detecting the ventricular dyssynchrony, IMD 414 may communicate with LPD 16 to initiate fusion pacing or biventricular pacing in an attempt to terminate the ventricular dyssynchrony. The means of communication between LPD 16 and IMD 414 is the same or similar as that which is described herein.

LPD 16 is implanted substernally/retrosternally and communicatively coupled to IMD device 414. LPD 16 and IMD device 414 may, for example, both include a communication module via which the devices exchange wireless communications. LPD 16 and IMD device 414 may, for example, be coupled via inductive coupling, RF coupling, tissue conductance communication, or other wireless communication mechanism.

As indicated above, LPD 16 is implanted substernally/retrosternally, e.g., in the substernal/retrosternal space underneath the sternum but not within the pericardial space or the pleural space. In one example, LPD 16 may be placed in the mediastinum 436 and, more particularly, in the anterior mediastinum. The anterior mediastinum is bounded laterally by pleurae 440, posteriorly by pericardium 438, and anteriorly by sternum 22. LPD 16 may be implanted within the mediastinum such that the one or more electrodes of LPD 16 are located over a cardiac silhouette of the ventricle as observed via fluoroscopy. In the example illustrated in FIGS. 9A-C, LPD 16 is located substantially centered under

sternum **422**. In other instances, however, LPD **16** may be implanted such that it is offset laterally from the center of sternum.

Although described herein as being implanted in the substernal/retrosternal space, the mediastinum, or the anterior mediastinum, LPD **16** may be implanted in other extra-pericardial locations. In this disclosure, the term "extra-pericardial locations" refers to locations in the region around, but not in contact with, the outer heart surface. The region defined as the extra-pericardial includes the gap, tissue, bone, or other anatomical features around the perimeter of, and adjacent to, but not in contact with the pericardium. These may include the superior mediastinum, middle mediastinum, posterior mediastinum, in the sub-xiphoid or inferior xiphoid area, near the apex of the heart, or other location not in intimate contact with the heart and not subcutaneous.

LPD **16** is configured to include a housing **31**, electrodes **432** and **434** coupled to the housing or formed by the housing, and a fixation mechanism (e.g., tines **35** of FIG. **3**) to attach LPD **16** at a desired substernal/retrosternal location. LPD **16** may have other fixation mechanisms besides tines **35**.

LPD **16** may sense electrical activity of heart **12** via electrodes **432** and **434** and provide pacing pulses to heart **12** via electrodes **432** and **434**. The pacing pulses provided to heart **12** may be responsive to sensed electrical signals of the heart sensed either via electrodes **432** and **434** of LPD **16** or sensed via one or more electrode combinations of defibrillation lead **16**. LPD **16** may generate and deliver pacing pulses with any of a number of amplitudes and pulse widths to capture heart **12**.

LPD **16** may also analyze the sensed electrical signals from one or more of the sensing vectors of LPD **16** and/or from the IMD to detect ventricular dyssnchrony. LPD **16** may not deliver CRT therapy (e.g. fusion pacing or biventricular pacing) until LPD **16** receives a communication from IMD **414** indicating detection of ventricular dyssnchrony by IMD **414**.

The configuration described above in FIGS. **9A-9C** is directed to providing ventricular pacing via LPD **16**. However, other LPDs **16** may be positioned further superior or inferior. In some instances, more than one LPD **16** may be utilized for dual chamber pacing, e.g., with one LPD **16** providing atrial pacing and the other LPD **16** providing ventricle pacing. Alternatively, LPD **16** may be positioned over the ventricle and include a small tether extending up to the atrium with an electrode on the tether. LPD **16** could sense and/or pace via the electrode on the tether. As another alternative, LPD **16** could be elongated to serve this purpose under the sternum, so that there is one or more electrodes on the housing that senses/paces one of the heart chambers and one or more electrodes on the housing that senses/paces ventricle. In yet further embodiments, LPD **16** may be used in combination with a pacing lead implanted substernally to provide dual chamber pacing.

ICD **414** may include a housing that forms a hermetic seal that protects components of IMD **414**. The housing of IMD **414** may be formed of a conductive material, such as titanium. IMD **414** may also include a connector assembly (also referred to as a connector block or header) that includes electrical feedthroughs through which electrical connections are made between conductors within the lead **416** and electronic components included within the housing. As will be described in further detail herein, housing may house one or more processors, memories, transmitters, receivers, sensors, sensing circuitry, therapy circuitry and other appropri-

ate components. The housing **434** is configured to be implanted in a patient, such as patient **414**.

Lead **416** includes a lead body that includes electrodes **424**, **428** and **430** located near the distal lead end or elsewhere along the length of the lead body. The lead bodies of lead **416** also contain one or more elongated electrical conductors (not illustrated) that extend through the lead body from the connector assembly of IMD **414** provided at a proximal lead end to one or more electrodes of lead **416**. The lead bodies of lead **416** may be formed from a non-conductive material, including silicone, polyurethane, fluoropolymers, mixtures thereof, and other appropriate materials, and shaped to form one or more lumens within which the one or more conductors extend. However, the techniques are not limited to such constructions.

The one or more elongated electrical conductors contained within the lead bodies of lead **16** may engage with respective ones of electrodes **424**, **428**, and **430**. In one example, each of electrodes **424**, **428**, and **430** is electrically coupled to a respective conductor within its associated lead body. The respective conductors may electrically couple to circuitry, such as a therapy module or a sensing module, of IMD **414** via connections in connector assembly, including associated feedthroughs. The electrical conductors transmit therapy from a therapy module within IMD **414** to one or more of electrodes **424**, **428**, and **430** and transmit sensed electrical signals from one or more of electrodes **424**, **428**, and **430** to the sensing module within IMD **414**.

The examples illustrated in FIGS. **9A-C** are exemplary in nature and should not be considered limiting of the techniques described in this disclosure. In other examples, IMD **414** and defibrillation lead **416** may be implanted at other locations. For example, IMD **414** may be implanted in a subcutaneous pocket in the right chest. In this example, defibrillation lead **416** may be extend subcutaneously from the device toward the manubrium of the sternum and bend or turn and extend subcutaneously inferiorily from the manubrium of the sternum, substantially parallel with the sternum.

In the example illustrated in FIG. **9**, system **400** includes an IMD system that provides, but the techniques may be applicable to other cardiac systems, including cardiac resynchronization therapy defibrillator (CRT-D) systems, cardioverter systems, or combinations thereof.

Skilled artisans appreciate that the substernal/retrosternal IMD system **400** can be configured to deliver biventricular pacing to synchronize the ventricles with each other. Biventricular pacing consists of pacing the right ventricle (RV) with a RV electrode and a left ventricle (LV) with a LV electrode. Electrodes **428** and **430** can be configured to deliver pacing pulse to the LV. The LV and/or RV is paced by separate electrodes (e.g. a LPD **16** connected through tines to the inner or outer surface of the wall of the RV, an electrode on a medical electrical lead etc.). In one or more embodiments, IMD system **400** can be configured to automatically switch between biventricular pacing and fusion pacing. Typically, the primary goal is to ensure the ventricles are synchronized with each other. Monoventricular pacing or fusion pacing is preferred over biventricular pacing provided the ventricles achieve synchrony. Skilled artisans appreciate that a patient's heart may require adaptive CRT in which biventricular pacing is required during one period of time (e.g. 1 hour, day, week etc.) and at another time, fusion pacing may be all that is necessary to return the ventricles to synchrony. Typically, fusion pacing involves pacing the LV; however, there are conditions in which the RV is solely paced.

Adaptive LV pacing leverages intrinsic RV conduction by pre-pacing the LV to synchronise with intrinsic RV activation. The timing of the LV pace is automatically adjusted based on the atrial to intrinsic QRS interval measurement (AV interval). One or more embodiments can set the LV pace to occur at about 70% of the intrinsic AV interval, but at least 40 ms prior to the intrinsic QRS.

One or more other embodiments can set the LV pace to occur at about a moderately lengthened QRS. For example, if the QRS width exceeds 120 ms, but does not exceed 160 ms, then LV pacing with fusion is selected. Otherwise, if the QRS width is greater than 160 ms, then BiV pacing is selected. Implementing a moderately lengthened QRS threshold may benefit heart failure patients. Efficacies of LV only pacing or biventricular pacing may be predicted by the moderately lengthened QRS duration. An exemplary moderately lengthened QRS corresponds to QRS width in the range of 130-150 ms. LV pacing for moderately lengthened QRS can achieve superior results compared to echocardiographic optimization. In one or more embodiments, the intrinsic AV conduction is automatically evaluated. In one or more other embodiments, the IMD (e.g. ICD etc.), LPD and/or SD automatically evaluates intrinsic ventricular conduction based upon QRS duration from the far-field EGM or right ventricular sense to left ventricular sense (RVs-LVs) interval from the IMD sensing markers is automatically evaluated by the IMD or SD. U.S. Pat. No. 4,374,382 issued to Markowitz et al. describes IMD sensing markers, which is incorporated by reference in its entirety. Based on the results, fusion pacing (i.e. LV only pacing or RV only pacing) or biventricular pacing. RVs-LVs interval not exceeding 150 ms could correspond to LV only pacing, whereas >150 ms could switch the algorithm to biventricular pacing. In one or more other embodiments, RVs-LVs interval not exceeding 80 ms corresponds to fusion pacing while greater than 80 ms switches to biventricular pacing. Typically, RVs-LVs are shorter than the corresponding QRS width. Therefore, it takes about 40 ms to sense the onset of QRS in the RV and the final portion of the QRS in the LV is also sensed prior to the QRS end.

In one or more other embodiments, the IMD tracks the moderately lengthened QRS over time and then relies on trend data to switch between biventricular pacing and fusion pacing. For example, assume that the moderately lengthened QRS is 120 ms, 125 ms, 130 ms, 135 m, 140 ms, and 145 ms, respectively for 6 consecutive weeks. The increasing trend could trigger the switch to biventricular pacing before the threshold is met for switching to biventricular pacing.

In another embodiment, the SD could send a control signal to the LPD to initiate CRT. The LPD could sense a cardiac signal (i.e. a second electrical signal) from the heart of the patient. Based on the cardiac signal, the LPD could determine whether to deliver CRT to the heart from the LPD. For example, the LPD, based on the second electrical signal, could determine that CRT is not necessary. The LPD could consider whether sensed data meets a pre-specified threshold. For instance if the QRS width does not exceed 120 ms, the LPD may withhold the delivery of CRT therapy (e.g. the LPD could then signal the SD that CRT should not be delivered based upon the cardiac signal. The SD can be configured to perform a more detailed analysis in which at least one or more parameters (such as at least two parameters) are evaluated. The SD could then send another command signal that confirms, denies or overrides the LPD.

In another embodiment, the LPD could sense a cardiac signal that indicates a switch between fusion pacing to biventricular pacing should occur and would signal the SD.

The SD could be configured to send an override signal to the LPD unless certain conditions are met.

In yet another embodiment, the LPD could determine that biventricular pacing is required over fusion pacing in contravention to the SD communication. In one embodiment, the LPD would deliver biventricular pacing. In one or more other embodiments, the LPD could determine that fusion pacing is required over biventricular pacing in contravention to the SD communication. In this scenario, the LPD could deliver fusion pacing.

In another embodiment, the SD transmits a control signal to the LPD to initiate CRT. The LPD senses a cardiac signal (i.e. a second electrical signal) from the heart of the patient. Based on the cardiac signal, the LPD could determine whether to deliver CRT or the type of CRT to deliver to the heart from the LPD. In one or more embodiments, the LPD, based on the second electrical signal, could initially determine that CRT is not necessary. The initial determination by the LPD could use very simplified tests such as a threshold of one or more parameters. In one or more embodiments, the SD could perform a more detailed analysis as to whether CRT should be delivered. Using the sensed data from the LPD and/or SD, the SD could generate another signal to the LPD that either confirms, denies or overrides the LPDs initial determination.

In another embodiment, the LPD could sense a cardiac signal that indicates a switch should occur between fusion pacing to biventricular pacing. Determining whether to switch between fusion pacing and biventricular pacing could be determined based upon one or more parameters (e.g. moderately lengthened QRS, etc.). The LPD could be configured to either automatically switch between fusion pacing and biventricular pacing or to wait until the SD confirms or denies switching between the CRT pacing mode (i.e. fusion pacing and biventricular pacing). The SD could be configured to send a confirmatory signal or a signal denying the LPD switching the pacing mode.

In yet another embodiment, the LPD could determine that biventricular pacing is required over fusion pacing in contravention to the SD communication. In one embodiment, the LPD would deliver biventricular pacing. In one or more other embodiments, the LPD could determine that fusion pacing is required over biventricular pacing in contravention to the SD communication. In this scenario, the LPD could deliver fusion pacing.

In one or more other embodiments, SD is implanted into a patient's heart. For example, the SD could be a conventional ICD or a SD described herein). Electrical signals are then sensed which includes moderately lengthened QRS duration data from the patient's heart. A determination is made as to whether cardiac resynchronization pacing therapy (CRT pacing) is appropriate based upon the moderately lengthened QRS duration in the sensed electrical signals. The CRT pacing pulses are delivered to the heart using electrodes. In one or more embodiments, the SD can switch between fusion pacing and biventricular pacing based upon data (e.g. moderately lengthened QRS, etc.) sensed from the heart.

There are many different embodiments that may be implemented with the methods described herein. One or more LPDs carrying one or more electrodes may be implanted within various chambers of the heart of the patient or otherwise in close proximity of the cardiac muscle. At these locations, an LPD may sense ECG signals with high signal-to-noise ratios to detect arrhythmias. In addition, an LPD may provide cardiac pacing at the location of the implanted LPD. In some examples, one or both of SD and LPD may

share detected signals or physiological information (e.g., R-R intervals, electrogram morphology measurements, and/or electrocardiograms or electrograms) such that the device receiving such information can determine a condition of patient **14** (e.g., determine whether or not patient **14** is experiencing an arrhythmia and or lack of synchrony between ventricles). Communication between an LPD and a SICD is described in U.S. patent application Ser. No. 13/756,085, filed on Jan. 31, 2013, incorporated herein in its entirety.

In some examples, communication between the SICD and an LPD may be used to initiate therapy and/or confirm that therapy should be delivered. The SICD may also transmit a communication message to the LPD instructing the LPD to change one or more parameters that define the CRT therapy. In this one-way communication example the SICD may be configured to transmit communications to the LPD and the LPD may be configured to receive the communication from the SICD. Alternatively, one-way communication may be established such that the LPD may be configured to transmit communications to the SICD (e.g., communication from LPD **16**). In other examples, two-way communication may allow confirmation of a detected of a cardiac condition (e.g. ventricular dyssynchrony, tachyarrhythmia, bradycardia etc.) prior to delivery of any therapy. Communication between the SD and the LPD is described in greater details in U.S. patent application Ser. No. 13/756,085 filed May 26, 2013 and entitled "SYSTEMS AND METHODS FOR LEADLESS PACING AND SHOCK THERAPY", incorporated by reference in its entirety.

The systems and techniques described herein may be generally related to cooperative monitoring of a patient and/or therapy delivery to the patient using multiple implanted devices such as an SD and an LPD. In one example, the SD and LPD may detect the functions of each other and/or communicate to coordinate monitoring and therapy such as CRT. However, the SD and LPD may coordinate other monitoring and therapy features. For example, using the communication techniques described herein, prior to either the SD or LPD delivering therapy, sensed data from both devices may be used to determine if the therapy should be delivered. In some examples, the SD or the LPD may be configured to override the other device in situations in which there is a discrepancy between whether or not physiological condition is occurring. In any case, the SD and LPD may be configured to function together to monitor and/or provide therapy to patient **14**.

The techniques described herein may provide for a SD and LPD to operate cooperatively within a patient to monitor the heart for arrhythmias and deliver appropriate therapy to treat any detected arrhythmias. For example, an SD and LPD may detect ventricular dyssynchrony and deliver CRT. Wireless communication between the SD implanted external of the rib cage and one or more LPDs implanted within the heart may provide various ECG or EGM sensing vectors.

The disclosure also contemplates computer-readable storage media comprising instructions to cause a processor to perform any of the functions and techniques described herein. The computer-readable storage media may take the example form of any volatile, non-volatile, magnetic, optical, or electrical media, such as a RAM, ROM, NVRAM, EEPROM, or flash memory. The computer-readable storage media may be referred to as non-transitory. A programmer, such as patient programmer or clinician programmer, or other computing device may also contain a more portable removable memory type to enable easy data transfer or offline data analysis.

In addition, it should be noted that system **400** may not be limited to treatment of a human patient. In alternative examples, system **400** may be implemented in non-human patients, e.g., primates, canines, equines, pigs, and felines. These other animals may undergo clinical or research therapies that may benefit from the subject matter of this disclosure.

The techniques described in this disclosure, including those attributed to SD **30**, LPD **16**, programmer **20**, and various constituent components, may be implemented, at least in part, in hardware, software, firmware or any combination thereof. For example, various aspects of the techniques may be implemented within one or more processors, including one or more microprocessors, DSPs, ASICs, FPGAs, or any other equivalent integrated or discrete logic circuitry, as well as any combinations of such components, embodied in programmers, such as physician or patient programmers, stimulators, remote servers, or other devices. The term "processor" or "processing circuitry" may generally refer to any of the foregoing logic circuitry, alone or in combination with other logic circuitry, or any other equivalent circuitry.

Such hardware, software, firmware may be implemented within the same device or within separate devices to support the various operations and functions described in this disclosure. For example, any of the techniques or processes described herein may be performed within one device or at least partially distributed amongst two or more devices, such as between SD **30**, LPD **16** and/or programmer **20**. In addition, any of the described units, modules or components may be implemented together or separately as discrete but interoperable logic devices. Depiction of different features as modules or units is intended to highlight different functional aspects and does not necessarily imply that such modules or units must be realized by separate hardware or software components. Rather, functionality associated with one or more modules or units may be performed by separate hardware or software components, or integrated within common or separate hardware or software components.

The techniques described in this disclosure may also be embodied or encoded in an article of manufacture including a computer-readable storage medium encoded with instructions. Instructions embedded or encoded in an article of manufacture including a computer-readable storage medium encoded, may cause one or more programmable processors, or other processors, to implement one or more of the techniques described herein, such as when instructions included or encoded in the computer-readable storage medium are executed by the one or more processors. Example computer-readable storage media may include random access memory (RAM), read only memory (ROM), programmable read only memory (PROM), erasable programmable read only memory (EPROM), electronically erasable programmable read only memory (EEPROM), flash memory, a hard disk, a compact disc ROM (CD-ROM), a floppy disk, a cassette, magnetic media, optical media, or any other computer readable storage devices or tangible computer readable media.

In some examples, a computer-readable storage medium comprises non-transitory medium. The term "non-transitory" may indicate that the storage medium is not embodied in a carrier wave or a propagated signal. In certain examples, a non-transitory storage medium may store data that can, over time, change (e.g., in RAM or cache). Various examples have been described for detecting arrhythmias and delivering anti-tachycardia therapy via a subcutaneous implantable cardioverter defibrillator and/or a leadless pac-

ing device. Any combination of the described operations or functions is contemplated. These and other examples are within the scope of the following claims.

What is claimed is:

1. A method of using a subcutaneous device (SD) in a patient and a leadless pacing device (LPD) in the patient's heart, *on the patient's heart, or in a substernal location of the patient*, the method comprising:

sensing *at least one* electrical [signals] *signal* which includes moderately lengthened QRS *duration* data from the patient's heart using the SD, *wherein sensing the at least one electrical signal which includes moderately lengthened QRS duration data from the patient's heart using the SD comprises evaluating an RVs-LVs interval from sensing markers determined by at least one of the LPD or the SD*;

employing the SD to determine whether cardiac resynchronization pacing therapy (CRT pacing) is appropriate based upon the *moderately lengthened* QRS duration *data* in the sensed electrical [signals] *signal*;

employing the SD to determine timing of CRT pacing pulses for delivery to cardiac tissue through the LPD and sending signals indicative thereof to the LPD [responsive to the sent indicative signals];

delivering the CRT pacing pulses to the heart using the LPD *based on the signals sent by the SD indicative of the timing of the CRT pacing pulses*;

thereafter sensing *at least one* subsequent electrical [signals] *signal* from the patient's heart using the SD; and

determining, by the SD based on the subsequent electrical [signals] *signal*, whether the CRT pacing by the LPD provided efficacious resynchronization and whether the delivery and timing of subsequent CRT pacing pulses should be modified.

2. A method of claim of [1] *9*, wherein the moderately lengthened QRS *duration data* corresponds to a QRS width in a range of 120-160 *milliseconds* (ms).

3. A method of claim [1] *9, wherein the at least one electrical signal comprises a far-field electrogram (EGM)*, *the method* further comprising:

evaluating intrinsic ventricular conduction based upon the moderately lengthened QRS duration *data* from [a] *the* far-field [electrogram (] *EGM*[)].

[4. A method of claim 1 further comprising:
evaluating an RVs-LVs interval from sensing markers is automatically evaluated by the LPD or the SD.]

5. A method of claim [4] *1 further comprising switching between fusion pacing and biventricular pacing based on the RVs-LVs interval*, wherein the RVs-LVs interval not exceeding 80 *milliseconds* (ms) corresponds to fusion pacing while *the RVs-LVs interval being* greater than 80 ms [switches] *corresponds* to biventricular pacing.

[6. A method of claim 1 wherein the SD generates a signal to the LPD to switch to another CRT pacing.]

7. A method of claim [6] *1* further comprising switching from the CRT pacing to another CRT pacing.

8. A method of claim 7 wherein the SD generates a signal to the LPD to cause switching from *the* CRT pacing to *the* another CRT pacing.

9. A method of [claim 8] *of using a subcutaneous device (SD) in a patient and a leadless pacing device (LPD) in the patient's heart, on the patient's heart, or in a substernal location of the patient, the method comprising:*

sensing at least one electrical signal which includes moderately lengthened QRS duration data from the patient's heart using the SD;

employing the SD to determine whether cardiac resynchronization pacing therapy (CRT pacing) is appropriate based upon the moderately lengthened QRS duration data in the sensed electrical signal;

employing the SD to determine timing of CRT pacing pulses for delivery to cardiac tissue through the LPD and sending signals indicative thereof to the LPD;

delivering the CRT pacing pulses to the heart using the LPD based on the signals sent by the SD indicative of the timing of the CRT pacing pulses;

thereafter sensing at least one subsequent electrical signal from the patient's heart using the SD;

determining, by the SD based on the subsequent electrical signal, whether the CRT pacing by the LPD provided efficacious resynchronization and whether the delivery and timing of subsequent CRT pacing pulses should be modified; and

switching from the CRT pacing to another CRT pacing,

wherein the SD generates a signal to the LPD to cause the switching from the CRT pacing to the another CRT pacing; and

wherein each of the CRT pacing and the another CRT pacing [being] is a respective one of fusion pacing and biventricular pacing.

10. A method of claim **9** further comprising:

sensing another electrical signal from the [cardiac tissue] *patient's heart* via the LPD, *the another electrical signal* indicating fusion pacing [being] *is* appropriate pacing to deliver to cardiac tissue; and

[generating] *sending* a signal to the SD from the LPD communicating fusion pacing data.

11. A method of claim **10** further comprising:

processing the another electrical signal; and determining by the SD whether the another electrical signal indicates that a switch to [another CRT] *fusion* pacing should occur.

12. A method of claim **7** wherein the SD generates a signal to the LPD *either* confirming *or overriding* switching to *the* another CRT pacing.

[13. A method of claim **12** wherein the CRT pacing being one of fusion pacing and biventricular pacing.]

[14. A method of claim **12** further comprising:
generating an overriding signal from the SD to the LPD.]

[15. A method of claim **14** wherein the SD generates a signal to the LPD confirming switching to another CRT pacing.]

16. A method of claim [1 further comprising] *9, wherein sensing the at least one electrical signal comprises*:

sensing *the at least one* electrical [signals] *signal* from a substernally placed lead extending from the SD.

17. A method comprising:

sensing *at least one* electrical [signals which includes moderately lengthened QRS duration data] *signal* from [the] *a* patient's heart using a subcutaneous device (*SD*);

determining that the at least one electrical signal includes moderately lengthened QRS duration data;

determining [whether] *that a fusion pacing mode of* cardiac resynchronization pacing therapy (CRT pacing) is appropriate based upon the *determination that the at least one electrical signal includes* moderately lengthened QRS duration [in the sensed electrical signals] *data*; and

delivering the [CRT] pacing pulses to the heart *according to the fusion pacing mode* using a leadless pacing device (LPD) *based on a determination that the fusion pacing mode is appropriate*.

18. A method of claim of **17** wherein the moderately lengthened QRS *duration data* corresponds to a QRS width in the range of 120-160 *milliseconds* (ms).

19. A method of claim **17** *wherein the at least one electrical signal comprises a far-field electrogram (EGM),* the method further comprising:

evaluating intrinsic ventricular conduction based upon the moderately lengthened QRS duration *data* from [a] *the* far-field EGM.

20. A method of claim **17** [further comprising] *wherein* determining that the at least one electrical signal which includes moderately lengthened QRS duration data comprises:

evaluating an RVs-LVs interval from sensing markers [is automatically evaluated] *determined* by *at least one of* the LPD or the SD.

21. A method of claim **20** *further comprising switching between the fusion pacing mode and a biventricular pacing mode based on the RVs-LVs interval,* wherein the RVs-LVs interval not exceeding 80 *milliseconds* (ms) corresponds to *the* fusion pacing *mode* while *the RVs-LVs interval being* greater than 80 ms [switches] *corresponds* to *the* biventricular pacing *mode*.

22. A system for cardiac pacing comprising:

a subcutaneous device (SD) *configured for implantation* in a patient;

a leadless pacing device (LPD) *configured for implantation* in the patient's heart, *on the patient's heart, or in a substernal location of the patient*;

sensing means for sensing *at least one* electrical [signals] *signal* which includes moderately lengthened QRS *duration* data from the patient's heart [using the SD], *wherein the sensing means for sensing the at least one electrical signal which includes moderately lengthened QRS duration data from the patient's heart comprises means for evaluating an RVs-LVs interval from sensing markers determined by at least one of the LPD or the SD*;

processing means for [employing the SD to determine] *determining* whether cardiac resynchronization pacing therapy (CRT pacing) is appropriate based upon the *moderately lengthened* QRS duration *data* in the sensed electrical [signals] *signal*;

processing means for [employing the SD to determine] *determining* timing of CRT pacing pulses for delivery to cardiac tissue through the LPD and sending signals indicative thereof to the LPD [responsive to the sent indicative signals];

delivering means for delivering the CRT pacing pulses to the heart using the LPD;

thereafter sensing means for sensing *at least one* subsequent electrical [signals] *signal* from the patient's heart [using the SD]; and

processing means for determining, [by the SD] based on the subsequent electrical [signals] *signal,* whether the CRT pacing by the LPD provided efficacious resynchronization and whether the delivery and timing of subsequent CRT pacing pulses should be modified.

[**23**. A system of claim of **22** wherein the moderately lengthened QRS corresponds to a QRS width in the range of 120-160 ms.]

24. A system of claim **22**, *wherein the at least one electrical signal comprises a far-field electrogram (EGM),* the *system* further comprising:

means for evaluating intrinsic ventricular conduction based upon the moderately lengthened QRS duration *data* from [a] *the* far-field EGM.

[**25**. A system of claim **22** further comprising:

evaluating an RVs-LVs interval from sensing markers is automatically evaluated by the LPD or the SD.]

26. A system of claim [**25**] *22 further comprising means for switching between fusion pacing and biventricular pacing based on the RVs-LVs interval,* wherein the RVs-LVs interval not exceeding 80 *milliseconds* (ms) corresponds to fusion pacing while *the RVs-LVs interval* greater than 80 ms [switches] *corresponds* to biventricular pacing.

27. A method of using a subcutaneous device (SD) in a patient and at least one leadless pacing device (LPD) in the patient's heart, on the patient's heart, or in a substernal location of the patient, the method comprising:

sensing, by at least one of the SD or the at least one LPD, at least one electrical signal from the patient's heart;

determining, by the SD, an intrinsic ventricular activation duration in the at least one sensed electrical signal, wherein determining, by the SD, the intrinsic ventricular activation duration comprises determining, by the SD, an RVs-LVs interval from sensing markers determined by at least one of the LPD or the SD;

comparing, by the SD, the determined intrinsic ventricular activation duration to at least one moderately lengthened ventricular activation duration threshold;

selecting, by the SD, either a first ventricular pacing mode or a second ventricular pacing mode based on the comparison of the determined intrinsic ventricular activation duration to the at least one moderately lengthened ventricular activation duration threshold, wherein at least one of the first ventricular pacing mode or the second ventricular pacing mode comprises a cardiac resynchronization therapy (CRT) pacing mode; and

delivering ventricular pacing to the heart according to the selected one of the first ventricular pacing mode or the second ventricular pacing mode using at least one of the SD or the at least one LPD in response to the selection.

28. A method of claim 33,

wherein sensing, by at least one of the SD or the at least one LPD, the at least one electrical signal from the patient's heart comprises sensing, by the SD, a far-field electrogram (EGM),

wherein determining, by the SD, the intrinsic ventricular activation duration comprises determining, by the SD, an intrinsic QRS duration in the far-field electrogram, and

wherein comparing, by the SD, the determined intrinsic ventricular activation duration to the at least one moderately lengthened ventricular activation duration threshold comprises comparing, by the SD, the determined intrinsic QRS duration to at least one moderately lengthened QRS duration threshold.

29. A method of claim 28, wherein the at least one moderately lengthened QRS duration threshold is 150 milliseconds (ms).

30. A method of claim 28, wherein the at least one moderately lengthened QRS duration threshold is 160 milliseconds (ms).

31. A method of claim 27, wherein the at least one moderately lengthened ventricular activation threshold is 80 milliseconds (ms).

32. A method of using a subcutaneous device (SD) in a patient and at least one leadless pacing device (LPD) in the patient's heart, on the patient's heart, or in a substernal location of the patient, the method comprising:

sensing, by at least one of the SD or the at least one LPD, at least one electrical signal from the patient's heart;

determining, by the SD, an intrinsic ventricular activation duration in the at least one sensed electrical signal;

comparing, by the SD, the determined intrinsic ventricular activation duration to at least one moderately lengthened ventricular activation duration threshold;

selecting, by the SD, either a first ventricular pacing mode or a second ventricular pacing mode based on the comparison of the determined intrinsic ventricular activation duration to the at least one moderately lengthened ventricular activation duration threshold, wherein at least one of the first ventricular pacing mode or the second ventricular pacing mode comprises a cardiac resynchronization therapy (CRT) pacing mode; and

delivering ventricular pacing to the heart according to the selected one of the first ventricular pacing mode or the second ventricular pacing mode using at least one of the SD or the at least one LPD in response to the selection,

wherein the first ventricular pacing mode comprises fusion pacing and the second ventricular pacing mode comprises biventricular pacing, and

wherein selecting, by the SD, either the first ventricular pacing mode or the second ventricular pacing mode comprises selecting, by the SD, fusion pacing based on the intrinsic ventricular activation duration being less than the at least one moderately lengthened ventricular activation duration threshold.

33. A method of using a subcutaneous device (SD) in a patient and at least one leadless pacing device (LPD) in the patient's heart, on the patient's heart, or in a substernal location of the patient, the method comprising:

sensing, by at least one of the SD or the at least one LPD, at least one electrical signal from the patient's heart;

determining, by the SD, an intrinsic ventricular activation duration in the at least one sensed electrical signal;

comparing, by the SD, the determined intrinsic ventricular activation duration to at least one moderately lengthened ventricular activation duration threshold;

selecting, by the SD, either a first ventricular pacing mode or a second ventricular pacing mode based on the comparison of the determined intrinsic ventricular activation duration to the at least one moderately lengthened ventricular activation duration threshold, wherein at least one of the first ventricular pacing mode or the second ventricular pacing mode comprises a cardiac resynchronization therapy (CRT) pacing mode; and

delivering ventricular pacing to the heart according to the selected one of the first ventricular pacing mode or the second ventricular pacing mode using at least one of the SD or the at least one LPD in response to the selection,

wherein the first ventricular pacing mode comprises fusion pacing and the second ventricular pacing mode comprises biventricular pacing, and

wherein selecting, by the SD, either the first ventricular pacing mode or the second ventricular pacing mode comprises selecting, by the SD, biventricular pacing based on the intrinsic ventricular activation duration being greater than the at least one moderately lengthened ventricular activation duration threshold.

34. A system comprising:

a subcutaneous device (SD) configured for implantation in a patient; and

at least one leadless pacing device (LPD) configured for implantation in the patient's heart, on the patient's heart, or in a substernal location of the patient,

wherein at least one of the SD or the at least one LPD is configured to sense at least one electrical signal from the patient's heart,

wherein the SD is configured to:

determine an intrinsic ventricular activation duration in the at least one sensed electrical signal, wherein the SD is configured to determine the intrinsic ventricular activation duration by at least determining an RVs-LVs interval from sensing markers determined by at least one of the LPD or the SD;

compare the determined intrinsic ventricular activation duration to at least one moderately lengthened ventricular activation duration threshold; and

select either a first ventricular pacing mode or a second ventricular pacing mode based on the comparison of the determined intrinsic ventricular activation duration to the at least one moderately lengthened ventricular activation duration threshold, wherein at least one of the first ventricular pacing mode or the second ventricular pacing mode comprises a cardiac resynchronization therapy (CRT) pacing mode, and

wherein at least one of the SD or the at least one LPD is configured to deliver ventricular pacing to the heart according to the selected one of the first ventricular pacing mode or the second ventricular pacing mode in response to the selection.

35. A system of claim 39, wherein the at least one moderately lengthened ventricular activation duration threshold comprises at least one moderately lengthened QRS duration threshold, and the SD is configured to:

sense a far-field electrogram (EGM);

determine an intrinsic QRS duration in the far-field electrogram as the intrinsic ventricular activation duration; and

compare the determined intrinsic QRS duration to the at least one moderately lengthened QRS duration threshold.

36. A system of claim 35, wherein the at least one moderately lengthened QRS duration threshold comprises 150 milliseconds (ms).

37. A system of claim 35, wherein the at least one moderately lengthened QRS duration threshold comprises 160 milliseconds (ms).

38. A system of claim 34, wherein the at least one moderately lengthened ventricular activation threshold comprises 80 milliseconds (ms).

39. A system comprising:

a subcutaneous device (SD) configured for implantation in a patient; and

at least one leadless pacing device (LPD) configured for implantation in the patient's heart, on the patient's heart, or in a substernal location of the patient,

wherein at least one of the SD or the at least one LPD is configured to sense at least one electrical signal from the patient's heart,

wherein the SD is configured to:

determine an intrinsic ventricular activation duration in the at least one sensed electrical signal;

compare the determined intrinsic ventricular activation duration to at least one moderately lengthened ventricular activation duration threshold; and

select either a first ventricular pacing mode or a second ventricular pacing mode based on the comparison of the determined intrinsic ventricular activation duration to the at least one moderately lengthened ventricular activation duration threshold, wherein at least one of the first ventricular pacing mode or the second ventricular pacing mode comprises a cardiac resynchronization therapy (CRT) pacing mode, and

wherein at least one of the SD or the at least one LPD is configured to deliver ventricular pacing to the heart according to the selected one of the first ventricular pacing mode or the second ventricular pacing mode in response to the selection,

wherein the first ventricular pacing mode comprises fusion pacing and the second ventricular pacing mode comprises biventricular pacing, and

wherein the SD is configured to:

select fusion pacing based on the intrinsic ventricular activation duration being less than the at least one moderately lengthened ventricular activation duration threshold; and

select biventricular pacing based on the intrinsic ventricular activation duration being greater than the at least one moderately lengthened ventricular activation duration threshold.

40. A method for delivering cardiac resynchronization therapy (CRT) to a patient using a medical device system comprising one or more implantable medical devices, the medical device system configured to deliver the CRT according to both a biventricular pacing mode and a fusion pacing mode using the one or more implantable medical devices, the method comprising:

sensing, by sensing circuity of the medical device system, at least one electrical signal from a heart of the patient;

determining, by processing circuitry of the medical device system, an intrinsic ventricular activation duration in the sensed electrical signal;

comparing, by the processing circuitry, the determined intrinsic ventricular activation duration to at least one moderately lengthened ventricular activation duration threshold;

selecting, by the processing circuitry, either the biventricular pacing mode or the fusion pacing mode based upon the comparison of the determined intrinsic ventricular activation duration to the at least one moderately lengthened ventricular activation duration threshold; and

delivering the ventricular pacing to the heart according to the selected one of the biventricular pacing mode or the fusion pacing mode using at least one of the one or more implantable medical devices.

41. A method of claim 40, wherein determining the intrinsic ventricular activation duration comprises determining at least one of an intrinsic QRS duration in a far-field electrogram or an RVs-LVs interval.

42. A method of claim 40, wherein selecting either the biventricular pacing mode or the fusion pacing mode comprises selecting the fusion pacing mode based on the intrinsic ventricular activation duration being less than the at least one moderately lengthened ventricular activation duration threshold.

43. A method of claim 40, wherein selecting either the biventricular pacing mode or the fusion pacing mode com-

prises selecting the biventricular pacing mode based on the intrinsic ventricular activation duration being greater than the at least one moderately lengthened ventricular activation duration threshold.

44. A medical device system configured to deliver cardiac resynchronization therapy (CRT) to a patient according to both a biventricular pacing mode and a fusion pacing mode using one or more implantable medical devices, the system comprising:

sensing circuity configured to sense at least one electrical signal from a heart of the patient; and

processing circuitry configured to:

determine an intrinsic ventricular activation duration in the sensed electrical signal;

compare the determined intrinsic ventricular activation duration to at least one moderately lengthened ventricular activation duration threshold;

select either the biventricular pacing mode or the fusion pacing mode based upon the comparison of the determined intrinsic ventricular activation duration to the at least one moderately lengthened ventricular activation duration threshold; and

control delivery of the ventricular pacing to the heart according to the selected one of the biventricular pacing mode or the fusion pacing mode by at least one of the one or more implantable medical devices.

45. A system of claim 44, wherein the processing circuitry is configured to determine the intrinsic ventricular activation duration by at least determining at least one of an intrinsic QRS duration in a far-field electrogram or an RVs-LVs interval.

46. A system of claim 44, wherein the processing circuitry is configured to:

select the fusion pacing mode based on the intrinsic ventricular activation duration being less than the at least one moderately lengthened ventricular activation duration threshold; and

select the biventricular pacing mode based on the intrinsic ventricular activation duration being greater than the at least one moderately lengthened ventricular activation duration threshold.

47. A method of claim 33,

wherein sensing, by at least one of the SD or the at least one LPD, the at least one electrical signal from the patient's heart comprises sensing, by the SD, a far-field electrogram (EGM),

wherein determining, by the SD, the intrinsic ventricular activation duration comprises determining, by the SD, an intrinsic QRS duration in the far-field electrogram, and

wherein comparing, by the SD, the determined intrinsic ventricular activation duration to the at least one moderately lengthened ventricular activation duration threshold comprises comparing, by the SD, the determined intrinsic QRS duration to at least one moderately lengthened QRS duration threshold.

48. A method of claim 47, wherein the at least one moderately lengthened QRS duration threshold is 150 milliseconds (ms).

49. A method of claim 47, wherein the at least one moderately lengthened QRS duration threshold is 160 milliseconds (ms).
