(54) **MOLDED PLASTIC TABLE TOP**

(57) A table top sized and configured to nest with an adjacent table to reduce a height of a plurality of stacked tables in a nested configuration, the table top being constructed from molded plastic, the table top comprising:  
an upper portion;  
a lower portion;  
a perimeter;  
a receiving portion at least partially formed in the upper portion and the perimeter of the table top, the receiving portion disposed about the perimeter of the table top, the receiving portion including a sidewall with a height and a lower surface with a width, the receiving portion receiv-

ing an engaging portion of an adjacent table when the tables are disposed in a nested configuration; and a plurality of strengthening members disposed in the lower portion of the table top to support the receiving portion, each strengthening member of the plurality of strengthening members including an inner portion that contacts an inner portion of the receiving portion to provide additional strength and support for the receiving portion; wherein the upper portion, the lower portion, the perimeter, the receiving portion, and the plurality of strengthening members are integrally formed during a molding process as part of a unitary, one-piece construction.

## Description

### Cross-Reference to Related Applications

**[0001]** The present application claims priority to and the benefit of United States provisional patent application serial no. 61/478,786, entitled TABLE, which was filed on April 25, 2011; U.S. provisional patent application serial no. 61/478,879, entitled TABLES AND CHAIRS, which was filed on April 25, 2011; U.S. design patent application serial no. 29/390,471, entitled PORTION OF A TABLE TOP, which was filed on April 25, 2011; U.S. provisional patent application serial no. 61/531,081, entitled TABLE, which was filed on September 5, 2011; and U.S. provisional patent application serial no. 61/543,277, entitled TABLE, which was filed on October 4, 2011; each of which is hereby incorporated by reference in its entirety.

### BACKGROUND

#### Field of the Invention

**[0002]** The present invention generally relates to structures including at least a portion constructed from plastic and, in particular, to furniture, such as tables and chairs, that may include molded plastic components.

#### Description of Related Art

**[0003]** Many different types of tables are well known and used for a variety of different purposes. For example, conventional tables may include legs that are pivotally attached to a table top and the legs may be movable between a use position in which the legs extend outwardly from the table top and a storage position in which the legs are folded against the table top. Conventional tables with relatively large table tops and folding legs are often referred to as "banquet tables" and these tables are frequently used in assembly halls, banquet halls, convention centers, hotels, schools, churches and other locations where large groups of people meet. These types of tables can often be positioned in an assortment of different configurations and used in a variety of settings. When the banquet tables are no longer needed, the table legs can be moved into the storage position and the tables may be more easily moved or stored.

**[0004]** Because most banquet tables have a length between six and ten feet and a width between three and four feet, the required storage area for such tables is quite large even with the legs in the collapsed position. This large storage area may be problematic for businesses or facilities such as hotels, schools and churches because a considerable number of these tables may have to be stored.

**[0005]** Conventional tables often include table tops constructed from materials such as wood, particle board or metal. Table tops constructed from wood, particle

board or metal, however, are often relatively heavy and this may make the table awkward or difficult to move. Table tops constructed from wood or metal are also relatively expensive and these types of table tops must generally be treated or finished before use. For example, table tops constructed from wood must generally be sanded and painted, and metal table tops must be formed into the desired shape and painted. In addition, because these wooden and metal table tops are relatively heavy, the cost of shipping and transportation of the tables may be increased. The weight of the table top may make the tables more difficult to move and store.

**[0006]** In order to decrease the weight of conventional tables, table tops may be constructed from relatively light-weight materials such as plastic. Disadvantageously, table tops constructed from light-weight materials may require large reinforcing members or other structural parts such as braces, brackets, support members and the like to strengthen the table top. While these additional parts may increase the strength of the table top, the added parts may also increase the weight of the table. These additional parts may result in increased manufacturing costs and require additional time to assemble the table. In addition, extra fasteners may be required to assemble and connect these parts to the table, which may require extra time and labor during the manufacturing process. The additional parts and fasteners may further increase the cost of the table and make the table more difficult to manufacture. Moreover, these additional parts and fasteners may have sharp edges that can injure a user's legs or arms.

**[0007]** Conventional tables may include a frame that is connected to the table top. The frame may include a pair of side rails connected to sides of the table top using fasteners. Multiple fasteners may be required to securely connect the frame to the table top and transmit forces applied to the table top to the frame. Undesirably, when a relatively large load or force is applied to some known tables, the frame may bend, deform and/or detach from the table top. In addition, the fasteners used to connect the frame to the table top may detach or separate from the table top. The fasteners may even damage and tear through the table top if the load or force exceeds a certain amount. Further, the frames or fasteners of some known tables may collapse in some circumstances.

**[0008]** The table top of some known tables may undesirably bend or deform if a relatively large load or force is applied to a portion of the table top. For instance, if the load or force is applied to an outer portion of a conventional table top, that portion of the table top may undesirably move or bend. In particular, that portion of the table top may deflect downward when the load or force is applied to the upper surface of the table top.

**[0009]** The large size of conventional banquet tables may require a large amount of storage space for manufacturers, retailers and consumers. The large amount of storage space may be particularly problematic for manufacturers, retailers and consumers that have a need to

store, transport and/or display large numbers of tables.

#### BRIEF SUMMARY

**[0010]** A need therefore exists for a table that eliminates or diminishes the above-described disadvantages and problems.

**[0011]** One aspect is a table that may include a table top and one or more legs sized and configured to support the table top above a surface such as the floor or ground. The table may also include a frame and legs connected to the frame. The legs may be movable relative to the table top between a collapsed or storage position and an extended or use position. In particular, the legs may be pivoted between a collapsed position in which the legs are disposed at least proximate a lower surface of the table top and an extended position in which the legs extend outwardly from the table top. If desired, the legs may at least partially contact or abut the lower surface of the table top when the legs are in the collapsed position. In addition, the lower surface of the table top may include one or more recesses sized and configured to receive at least a portion of the legs when the legs are in the collapsed position. Advantageously, this may decrease the amount of space required to store and/or transport the table.

**[0012]** Another aspect is a table that may be relatively lightweight, which may allow the table to be more easily transported and moved. For example, the table may include a lightweight table top and that may reduce the overall weight of the table. The table may also be constructed from a limited number of parts or components, which may allow the weight of the table to be reduced. Further, a limited number of fasteners may be required to assemble the table, which may also reduce the weight of the table. The limited number of fasteners may also allow the table to be quickly and easily assembled.

**[0013]** Yet another aspect is a table that may include a table top constructed from plastic. For example, the table top may be constructed from molded plastic using blow-molding, injection molding, rotary molding or other suitable molding processes. The molded plastic table top may provide a relatively rigid, high-strength structure capable of withstanding repeated use and wear. The molded plastic table top may also be relatively quickly, easily and efficiently manufactured. In addition, the molded plastic table top may be readily molded into a desired size and shape, such as a utility table, card table, personal table and the like. The molded plastic table top may be relatively lightweight because, for instance, it may include a hollow interior portion formed during the molding process. The molded plastic table top may further include two opposing walls, which may be spaced apart by a generally constant and/or predetermined distance, and that may help increase the strength and rigidity of the table top. Additionally, the molded plastic table top may be generally weather resistant and temperature insensitive. Further, the molded plastic table top may not cor-

rode, rust or otherwise deteriorate over an extended period of time, which may help create a long-lasting table.

**[0014]** Still another aspect is a table top that may be constructed from molded plastic and one or more features may be integrally formed during the molding process as part of a unitary, one-piece construction. For example, the molded plastic table top may include one or more depressions (also referred to as "tack-offs") and the depressions may be designed and positioned to increase the strength of the table top and/or interconnect spaced apart walls of the table top. The depressions may also be sized and configured to create a structure with particular characteristics and qualities, such as a table top with generally uniform strength, rigidity and/or structural integrity. The molded plastic table top may also include other features such as structures that increase the strength, rigidity and/or torsion resistance of at least a portion of the table top.

**[0015]** Still yet another aspect is a table that may include components that can be quickly and easily manufactured. For example, the legs and/or side rails of the frame may be relatively straightforward to manufacture. In addition, the legs and/or side rails of the frame may be quickly and easily attached to the table top, which may reduce manufacturing costs. The table may also be constructed from only a few parts and a limited number of fasteners may be required, which may allow the table to be quickly and easily assembled by the manufacturer, retailer and/or consumer.

**[0016]** Another aspect is a table that may facilitate stacking of a plurality of tables. Advantageously, the stacked tables may be disposed in an aligned configuration. For example, one table may be easily aligned with an adjacent table, which may facilitate shipping, storage and/or display of multiple tables. Significantly, the aligned tables may be disposed vertically, horizontally, or at suitable angles depending, for instance, if the tables are to be shipped, stored, displayed, or the like. If desired, the stacked tables may interlock or have a tendency to stay together. For instance, a friction or interference fit between adjacent stacked tables may tend to maintain the tables in a stacked configuration. If the tables have a penchant to stay together, this may help reduce damage to the tables during shipping, storage and/or display.

**[0017]** Still another aspect is a table that may be nested with an adjacent table to reduce space. Significantly, the nested tables may allow the tables to be stored in a smaller area, which may substantially reduce storage and shipping costs. The nested tables may also allow a greater number of tables to be stored in the same area as conventional tables that do not nest together. In addition, the nested tables may help protect the tables from damage. For example, because an upper portion of a table may be disposed within a lower portion of an adjacent table, that may help prevent the table from being damaged. The nested tables may further have table tops that are the same or substantially the same as conventional tables, which may indicate to consumers that the tables

have similar appearances and characteristics such as strength, structural integrity and the like. The nested tables may also have the same general footprint as a conventional table, but the nested tables may allow significantly more tables to be disposed on a pallet or in a shipping container, and/or allow the same number of tables to be disposed in a significantly smaller space.

**[0018]** Yet another aspect is a table that may be nested with an adjacent table in a stacked configuration. Advantageously, the nested tables may have a significantly reduced height in comparison to conventional tables that do not nest together. For example, known tables may have a table top with a height of about 2.125 inches and thirty (30) of these known tables could be stacked with a height of at least 63.75 inches. An exemplary embodiment of a nested table may have a table top with a thickness of about 2.0 inches, but may overlap with an adjacent table by about 0.25 inches so that the height of the stacked portion of a nested table may only be about 1.75 inches. Thus, the height of thirty nested tables may be reduced to about 52.75 inches because adjacent tables may nest together. In particular, because a portion of a table may be disposed within or overlap with an adjacent table in the nested configuration, that may allow the overall height of the nested tables to be decreased. Therefore, in this exemplary configuration, the height of the table in the nested configuration may only be about 1.75 inches. Consequently, the height per nested table may be between about 0.375 and 0.25 inches less than previously known tables. This may allow more tables to be disposed in a stacked configuration, which may greatly increase the number of tables that can be stacked on a pallet or shelf, or disposed in a shipping container or truck.

**[0019]** Yet another aspect is a table that may be nested together with an adjacent table to reduce the overall height of the stacked tables. For example, a conventional table may have a blow-molded plastic table top with a height of about 2.0 inches and a frame with a height of about 1.625 inches. The height of the frame for this type of conventional table is more than eighty percent (80%) of the height of the table top in order to create a table with the needed strength and rigidity. The frame for this type of conventional table may have a rectangular cross-sectional configuration, which may help create a beam-type structure with two opposing walls that are separated by a generally constant distance. It was known that a decrease in the height of the frame may result in a decrease in strength of the table. It was also known that a decrease in the width of the frame may result in undesirable twisting and/or bending in the table. In contrast to these known tables, the frame may allow the nested tables to have the same general height and appearance as a conventional table, and the same general strength and structural integrity as a conventional table, but allows the tables to be nested together. This may also allow consumers to immediately deduce that the nested tables have the same general strength, rigidity and torsion resistance as a conventional table because the tables may

have generally the same size and footprint. The frame of the nested tables, however, significantly decreases the height of two or more stacked tables. Because the nested tables may have a significant decrease in height in the nested configuration, this may result in considerable space savings that may be very important to the manufacturer during the manufacturing and shipping process; to the retailer when storing or displaying multiple tables; and/or to a consumer purchasing, transporting or storing more than one table.

**[0020]** A further aspect is a table that may be sized and configured to be nested with at least one other table such that the height of the nested tables is decreased by more than ten percent (10%). For example, the height of a single table may be about 2.0 inches. When the table is nested with another table, the table may only contribute a height of about 1.75 inches to the nested tables because a portion of the tables are nested together. In this embodiment, the nested tables result in a decrease in height of each stacked table by about 0.25 inches. Therefore, the height of a table in the stacked configuration may be about twelve and one-half percent (12.5%) less than in the non-stacked configuration. Advantageously, this may allow tables to be more efficiently stored, transported and displayed because less space may be required. In another example, a standard pallet or shipping configuration may include twenty-one (21) conventional tables, but the tables with the nesting features disclosed herein may allow twenty-seven (27) or twenty-nine (29) tables to be disposed on a standard pallet or in a typical shipping configuration. If twenty-seven tables are disposed on a pallet or in a standard shipping configuration rather than twenty-one tables, then approximately twenty-eight percent (28%) more tables can be stored, transported or displayed. If twenty-nine tables rather than twenty-one tables are disposed on a pallet or in a standard shipping configuration, then a thirty-eight percent (38%) increase in the number of tables may be realized. Advantageously, this may result in significant savings and cost advantages because, for example, considerably more tables may be stored, transported or displayed in the same area; or the same number of tables may be stored, transported or displayed in an area that is at least twenty-five percent (25%) smaller. When large volumes of tables are being transported, such as in a standard or high-capacity shipping container, this may result in sizeable cost savings and advantages.

**[0021]** A still further aspect is a table that may be nested with an adjacent table such that the height of a nested table is decreased by approximately twenty percent (20%). For example, the height of a conventional blow-molded plastic table top is typically 2.0 or more inches. The table top height of a nested table may be about 2.0 inches when it is not nested with another table, but the height of a stacked portion of the table may only be between about 1.5 and 1.75 inches when nested with another table. This may result in a significant reduction in height between twelve and one-half percent (12.5%) and

twenty-five percent (25%) when two or more tables are nested together. In particular, if the nested tables are decreased in height by about twenty percent (20%), then the tables may have a height of about 1.6 inches in the nested configuration. Furthermore, the nested table may have a weight that is less than that of comparable conventional tables. The nested table may therefore contribute less weight when stacked or nested with one or more other tables and this may allow a greater number of nested tables to be stacked without additional weight.

**[0022]** Another further aspect is a table that may include a receiving portion, such as a groove, channel or recessed portion, in an upper portion of the table top sized and configured to receive a portion of an adjacent table to facilitate nesting of the tables. For example, the receiving portion may be disposed about an upper surface and/or outer perimeter of the table top. In greater detail, the receiving portion may have a generally L-shaped configuration with a lower surface generally parallel to the upper surface of the table top and a sidewall generally perpendicular to the upper surface of the table top. A portion of an adjacent table may be disposed in the receiving portion to allow the tables to be nested together. In particular, a portion of the frame, such as a projection or flange, and/or a portion of the table top, such as an edge or corner, may be disposed in the receiving portion. In greater detail, a portion of the side rails of the frame may be disposed in the receiving portion along the sides of an adjacent, stacked table. A lower portion of a lip and/or the corners of the table top may also be disposed in the receiving portion of the adjacent, stacked table.

**[0023]** Yet another further aspect is a table that may include a frame sized and configured to facilitate stacking of the tables. For example, the frame may include an upper portion generally aligned with a lower portion of the table top. The upper portion of the frame may be disposed in a frame receiving portion in the lower portion of the table top and this may help maintain the frame in the desired position. The frame may also include a lower portion sized and configured to contact an upper portion of an adjacent, stacked table. The frame may further include an engaging portion sized and configured to be disposed in the receiving portion of an adjacent, nested table. The engaging portion may include a downwardly extending flange or projection sized and configured to fit within a receiving portion, such as a groove or cutout, of the adjacent, nested table. Advantageously, the frame may directly support at least a portion of the weight and/or forces applied to the tables in the nested configuration, which may help prevent damage to the tables. For example, when the tables are stacked in a horizontal configuration, the frame of one table may contact the adjacent, stacked table in a manner that allows the stacked tables to support a significant amount of weight without damage to the tables. This may allow ten, twenty, thirty or more tables to be disposed in a stacked configuration without damaging any of the tables. In addition, if the engaging portion of the frame is disposed in a receiving

portion of an adjacent table, that may facilitate stacking, storing and/or shipping of the tables because that may help maintain the tables in the stacked configuration and ensure the weight is properly and/or evenly distributed.

5 **[0024]** Still yet another further aspect is a table that may be sized and configured to nest with an adjacent, stacked table in which a weight or load is supported in multiple areas, in different locations and/or by different surfaces. Advantageously, the multiple contact areas may allow stresses and forces to be disposed over a larger area and that may help prevent damage to the tables. For example, the table may include one or more contact areas sized and configured to contact the upper surface of the adjacent table top. In greater detail, the side rails of the frame may include a lower portion, such as a planar contact surface or load bearing surface, disposed generally parallel to an upper surface of the table top. In addition, the side rails of the frame may include an engaging portion, such as a downwardly extending flange or projection, sized and configured to be disposed in a receiving portion of the adjacent, stacked table. A lower portion of the flange may contact a lower surface of the receiving portion, which may be another load bearing surface. Additionally, the table may include other portions, such as corners or lips, sized and configured to be disposed in the receiving portion of the adjacent, stacked table. For instance, the corners and/or lips may include a compression edge that contacts the lower surface of the receiving portion, which may also be load bearing surfaces. When two or more tables are nested together, the multiple contact areas may facilitate stacking of the tables without marring or otherwise damaging the tables.

10 **[0025]** Another aspect is a table that may include a table top with one or more portions formed from compression molded plastic. For example, a portion of the corners and/or lip may be compression molded during a blow-molding process. Advantageously, the compression molded corners and/or lip may help create stronger, more rigid and/or more impact resistant structures, which may increase the durability and usefulness of the table. Significantly, compression molding may allow a portion of the corners and/or lip to be relatively thin because there is little or no gap or space between the walls of the compression molded plastic structure. The compression molded corners and/or lip may also be sized and configured to fit within a receiving portion of an adjacent, stacked table, which may facilitate stacking and nesting of the tables. The compression molded portions may further be sized and configured to contact a portion of the frame. For instance, a compression molded portion may be disposed along at least a portion of the lip and the side rail of the frame may contact or abut the compression molded portion, which may help position and maintain the frame in the desired position.

15 **[0026]** Still another aspect is a table that may include a compression edge. For example, if the table top is constructed from blow-molded plastic, the compression edge may be formed by the outer wall being folded onto

itself such that the compression edge has a thickness approximately equal to twice the outer wall thickness. The compression edge may be disposed about all or a portion of the perimeter of the table top, such as the edges and/or corners. Advantageously, the compression edge may help provide increased strength, stiffness, structural integrity and/or impact resistance. The compression edge may also be sized and configured to be at least partially disposed in the receiving portion of an adjacent, nested table.

**[0027]** Yet another aspect is a table that may include a compression edge with different sizes. For example, the corners of the table top may include a compression edge that has a different size than a compression edge extending along the sides and/or ends of the table top. In particular, the table top may include a downwardly extending lip and the corners may include a compression edge that has a height generally equal to or greater than a majority of the height of the lip. The corners may also include a compression edge with a height generally or at least substantially equal to the height of the lip. The sides of the table top could include a compression edge that is smaller than the compression edge in the corners. For instance, the sides of the table top could include a compression edge with a height that is generally equal to or less than the height of the lip. The height of the compression edge disposed along the sides and/or ends of the table top may also be significantly smaller than the height of the lip. In an exemplary embodiment, the compression edge disposed along the sides of the table top may have a height between about 0.125 inches and about 0.25 inches, and the corners may include a compression edge with a height between about 0.25 inches and about 0.5 inches. The compression edge along the ends of the table top may have a height between about 0.125 inches and about 0.5 inches. Thus, the compression edge in the corners and/or ends of the table top may be two times or more times larger than the compression edge along the sides. The compression edges in the corners may be much larger, if desired, such as three, four, five or more times the height of compression edge along the sides and/or ends.

**[0028]** Still yet another aspect is a table that may include a handle or grip disposed in one or both ends of the table top. The handle may consist of a recess or opening in the downwardly extending lip of a table top and the handle may be integrally formed with the table top as part of a unitary, one-piece construction. Preferably, the handle is sized and configured to facilitate moving and transporting the table. In addition, the handle may assist in separating the tables in a stacked configuration. The table top may further include recesses or openings that may allow a portion of the frame to be disposed along the sides of the table top. For example, the sides of the table top may include openings that allow at least a portion of the frame to be exposed. Therefore, the ends of table may include openings in the lip that form the handles and openings in the sides that allow a portion of the frame

to be exposed. Other portions of the frame may be inset and/or disposed inwardly from an outer perimeter of the table top, which may help protect the frame from damage.

**[0029]** Another aspect is a table that may include a frame with a first portion disposed along one side of the table top and a second portion disposed along a second side of the table top. In particular, the frame may include a first side rail disposed along a first side of the table top and a second side rail disposed along a second side of the table top. The side rails may extend along a length and/or width of the table top and the side rails may help support the table top and/or facilitate connection of the legs to the table top. Each side rail may include a body and the body may be elongated, have one or more engagement surfaces, and may be constructed from relatively strong materials such as metal. In greater detail, the body of the side rails may be disposed at least proximate a downwardly extending lip of the table top and the body of the side rails may be disposed generally vertically relative to the table top. The side rails may also include an upper portion and a lower portion. For example, the upper portion of the side rail may include a flange that extends inwardly at angle, such as a right angle, to the body. The upper portion of the side rail may also include a second flange, such as an inner flange, that extends downwardly. This inner flange may be disposed at least proximate an end of the upper portion of the side rail and it may be disposed generally parallel to the body of the side rail. The lower portion of the side rail may include a flange that extends outwardly towards an outer portion of the table top. The lower portion may also include a downwardly extending portion, such as a flange or projection, which may be disposed perpendicular to the lower portion of the side rail. If desired, the downwardly extending portion may have twice or double the thickness in comparison to other portions of the frame. In particular, the downwardly extending portion may be folded or bent back upon itself and include an upwardly extending portion sized and configured to contact a portion of the table top, such as a lower surface of the downwardly extending lip.

**[0030]** Yet another aspect is a table that may include a table top with one or more receiving portions sized and configured to receive a portion of the frame. For instance, the table top may include a frame receiving portion sized and configured to receive an upper portion of the side rail of the frame. In addition, the table top may include a sidewall sized and configured to contact the body of the side rail and a lip sized and configured to contact the lower portion of the side rail. If desired, an inner wall of the lip may form at least a portion of the sidewall and a lower portion of the lip may contact the lower portion of the frame. Advantageously, the table top may be sized and configured to help position and/or maintain the side rail in a desired position. Additionally, the table top may be sized and configured to help prevent the side rail from bending, twisting or otherwise moving, which may help create a stronger and sturdier table.

**[0031]** Still another aspect is a table that may include a frame with one or more generally L-shaped and/or U-shaped sections. For instance, the side rails of the frame may include an upper portion with a generally inverted U-shaped configuration and a lower portion with a generally U-shaped configuration. The upper portion of the frame may be sized and configured to be disposed in a frame receiving portion disposed in a lower or underneath portion of the table top. The lower portion of the frame may be sized and configured to contact an adjacent table in a stacked, nested configuration. In particular, the lower portion of the frame may include a lower surface sized and configured to contact an upper surface of adjacent table in the nested configuration. The lower portion of the frame may further include an engaging portion sized and configured to be disposed in a receiving portion of an adjacent table in the nested configuration.

**[0032]** Still yet another aspect is a table that may include a frame that facilitates nesting and stacking of a plurality of tables. The frame may also help support a downwardly extending lip of the table top. For example, the frame may support an inner surface, lower surface and/or outer portion of the lip. In addition, the frame may provide multiple contact areas, such as a planar engagement surface and an engaging portion or flange, which may allow a load to be distributed over multiple areas when multiple tables are nested together. This may allow more tables to be disposed in a stacked configuration and/or help prevent damage to the tables.

**[0033]** A further aspect is a table that may include a frame with an inwardly disposed portion and an outwardly disposed portion. For example, the frame may include a first portion disposed towards an inner portion of the table top and a second portion disposed towards an outer portion of the table top. The inwardly disposed portion may be at least partially or substantially disposed inwardly from a downwardly extending lip of the table top while the outwardly disposed portion may contact and/or enclose at least a portion of the lip.

**[0034]** Another further aspect is a table that may include a frame and a portion of the frame may be disposed along an edge or perimeter of the table top. For example, the table top may include a lip with an opening and an outer portion of the frame may be disposed in or at least proximate the opening. Advantageously, this may allow a portion of the frame to be exposed and the exposed portion of the frame may indicate to consumers the table is strong, high-strength and durable. The exposed portion of the frame may be generally aligned with and/or spaced inwardly from an outer perimeter of the table top. The exposed portion of the frame may also be generally aligned with a lower portion of the table top, such as a lower surface of the corners, lip and/or ends. In greater detail, an opening may be disposed in the lip along the sides of the table top and the exposed portion of the frame may be disposed in and/or generally aligned with the openings. The lower portion of the frame may be aligned with a lowermost portion of the table top or it could extend

outwardly more than other portions of the table top. Thus, in this configuration, the lower portion of the frame may form the lowermost portion of the table top. The exposed frame may also create a table with improved aesthetics and/or style. For instance, the exposed frame may provide a color contrast with the table top. That is, the table top may be one or more colors and the frame may have one or more different colors to create a table with a stylized appearance or an aesthetically pleasing design.

**[0035]** Yet another further aspect is a table that may include a table top with openings to allow a portion of a frame to be exposed and/or disposed proximate a perimeter of the table top. For example, the table top may include one or more openings that allow at least a portion of the frame to be exposed and disposed at least proximate the perimeter of the table top. These openings may extend along at least a majority of the length of the table top. The table top may also include one or more openings for a handle in the ends of the table top. The openings along the sides of the table top are preferably much larger than the openings in the ends of the table top, by a factor such as five, ten, twenty or more times the length of the opening for the handle.

**[0036]** A still further aspect is a table that may include a frame that contacts, engages and/or supports a lip and/or outer perimeter of the table top. Advantageously, if the frame is disposed along the outer edges of the table top, then the frame may provide increased support for the edges or extremities of the table top. In addition, if a portion of the frame is disposed below or proximate the lip, then the frame may help prevent the table top from being damaged. For example, the frame may absorb impacts or forces that otherwise may damage the table top.

**[0037]** Still yet another further aspect is a table that may include a frame with an engaging portion, such as a protrusion or flange, which facilitates nesting and stacking of the tables. The protrusion may be generally aligned with and/or disposed proximate a lower portion of the lip, such as a compression edge. Because the protrusion and compression edge may have double wall thicknesses, this may help prevent the table from being damaged. In greater detail, the protrusion may be formed by bending or folding the frame back upon itself so that it includes two adjacent, parallel walls and a rounded end. The compression edge may include an inner wall and an outer wall that are adjacent, parallel and preferably in contact. If desired, the protrusion and compression edge may include lower surfaces that are generally aligned and disposed in the same plane. Advantageously, the double wall thicknesses of the frame and lip may help prevent that table top from being damaged. Additionally, the double wall thicknesses may promote stacking and nesting of the tables because, for example, it may allow a strong, thin, resilient and/or damage resistant portion of a table to be disposed in a receiving portion of an adjacent table.

**[0038]** Another aspect is a frame for a table that may be less likely to undesirably bend or deform. For example, the frame may have a configuration that resists twisting

or rotating when a load or force is applied to the frame. In addition, the frame may provide more balanced loading on the table when a load or force is applied. For instance, the frame could include multiple bends or angles, such as a plurality of right or 90° angles. Advantageously, the multiple right angles may help increase the strength of the frame, resist twisting or rotating when a load or force is applied to the frame, and/or provide more balanced loading. The frame could also include one or more portions that are bent back or folded with a 180° angle such that portions of the frame have twice the thickness. This may also help increase the strength of the frame, resist twisting or rotating when a load or force is applied to the frame, and/or provide more balanced loading.

**[0039]** Yet another aspect is a table that may include a frame that is at least partially disposed in one or more receiving portions in the table top. The table top may also include one or more receiving portions that are sized and configured to receive other components of the table such as cross members, cross bars and the like. For example, the table top may include receiving portions that are sized and configured to receive an upper portion of a support structure. The table top may also include receiving portions that are sized and configured to receive a portion of the legs when the legs are in the collapsed position. In addition, the frame may include one or more openings that are sized and configured to facilitate attachment of the legs to the table. For instance, the frame may include openings that are sized and configured to receive the ends of a cross member and/or upper portion of a support structure. Depending upon the shape and arrangement of the frame, the openings in the frame may be circular or non-circular configuration. By extending the ends of the cross tube through openings in the frame, the legs may be securely connected to the table top.

**[0040]** Still another aspect is a table that may include a frame and leg assemblies that are constructed from relatively strong and durable materials such as metal, steel and the like. It will be appreciated, however, the frame and leg assemblies may be constructed from other materials with suitable properties and characteristics. In addition, the table, frame, leg assemblies and the like may have a variety of other suitable shapes, sizes, configurations and arrangements depending, for example, upon the intended use of the table.

**[0041]** Another aspect is a table that may include a table top with a plurality of depressions. The plurality of depressions may be closely spaced and may cover at least a majority, substantially all, virtually all or all of a lower surface of the table top. The plurality of depressions may be disposed in a generally uniform pattern in which the depressions have generally the same size, shape configuration, orientation and arrangement. In addition, at least a majority of the depressions in the plurality of depressions may be spaced apart from one or more adjacent depressions by a generally consistent or uniform distance. Advantageously, the depressions may help create a table top with increased strength, rigidity and/or

structural integrity. In addition, if the depressions in the plurality of depressions are generally uniformly spaced and disposed in a generally uniform pattern, that may help create a table top with generally uniform characteristics.

**[0042]** Yet another aspect is a table top that may include strengthening members, such as depressions, ribs, channels and the like, disposed proximate and/or adjacent structural support members or features of the table. For example, the table top may include a plurality of strengthening members disposed proximate and/or adjacent the frame. In greater detail, the table top may include one or more frame receiving portions that are sized and configured to receive the side rails of the frame and the frame receiving portions may include a plurality of strengthening members. When the frame is connected to the table top, the frame may cover all or a portion of the strengthening members in the frame receiving portion. The strengthening members in the frame receiving portions may be disposed in different arrangements and/or configurations, which may be used to create areas of increased strength and/or different characteristics. For instance, the strengthening members may be disposed in first and second configurations. In particular, the first configuration of strengthening members may be generally aligned in a first direction, such as along the length of the table top, while the second configuration of strengthening members may be generally aligned in a second direction, such as along a width of the table top. The first configuration of strengthening members may provide greater strength in one direction or location and the second configuration of strengthening members may provide greater strength in a second direction or location. Because the strengthening members can provide additional strength in different directions and/or locations, that may allow relatively strong, sturdy, stiff and/or rigid structures to be constructed.

**[0043]** Still another aspect is a table top that may include strengthening members with different configurations and/or disposed in different locations to prevent or minimize potential points of weakness, stress concentrations and the like. For example, the strengthening members may be sized and configured to support areas of the table top disposed outside of the frame. The strengthening members may also be sized and configured to help prevent the table top from bending, collapsing or deflecting when a load or force is applied to the table top. Further, the strengthening members may be sized and configured to help prevent the table top from twisting or rotating relative to the frame. Advantageously, because the strengthening members may help support portions of the table top disposed above the frame and/or the edges; a strong, sturdy and well-supported table may be created. This may further facilitate stacking and nesting of the tables because, for example, the lower tables in the stack of tables may be unlikely to be damaged by the weight of the stacked tables.

**[0044]** Still yet another aspect is a table top that may

include one or more strengthening members disposed between and/or connecting a frame receiving portion and an outer portion of the table top such as a lip. In particular, one or more strengthening members may connect the frame receiving portion and a portion of the lip, such as an inner wall or sidewall of the lip. In greater detail, one or more strengthening members may be at least partially disposed in the upper surface and/or sidewalls of the frame receiving portion and in at least a portion of a sidewall of the lip. Because the strengthening members may connect the frame receiving portion and the lip, the strengthening members may increase the strength and/or structural integrity of the frame receiving portion and/or the lip. Additionally, because the frame may cover at least a portion of the frame receiving portion and the sidewall of the lip, these strengthening members may be generally hidden from view.

**[0045]** A further aspect is a table top that may include a plurality of strengthening members that are generally aligned with one another. For instance, the strengthening members may include a body that is generally aligned with an axis and each strengthening member of the plurality of strengthening members may be generally aligned along the same axis or parallel axes. Advantageously, because the strengthening members generally aligned with an axis may have increased strength, structural integrity and/or other characteristics in a particular direction, such as along the axis, aligning the strengthening members along the same axis or parallel axes may help create a table top with generally uniform properties and characteristics. The table top may further include another plurality of strengthening members that are generally aligned along a different axis. For example, the strengthening members disposed along the different axis may provide increased strength, structural integrity and/or other characteristics along this axis. Therefore, the strengthening members disposed along different axes may be used to create portions of the table top with different characteristics. This may allow, for example, some of the strengthening members in the frame receiving portion to be disposed along a first axis, such as generally aligned with a length of the table top, and other strengthening members to be disposed along a second axis, such as aligned with a width of the table top. If desired, one or more of the strengthening members may be sized and configured to help support the outer edges or sides of the table top. For instance, the strengthening members may help prevent the outer edges of the table top, which may not be directly supported by the frame, from unintentionally bending, twisting or deflecting.

**[0046]** A still further aspect is a table top that may include strengthening members, such as ribs, disposed in an outer edge or lip of the table top. For example, the table top may include a lip or edge and a plurality of strengthening members may be formed in the lip. In particular, the inner surface of the lip, such as a sidewall, may include a plurality of inwardly extending strengthening members. In addition, these strengthening members may be at least

partially disposed in a frame receiving portion. Significantly, the strengthening members may provide increased strength, stiffness, rigidity and/or structural integrity to portions of the table top such as the portion of the table top disposed above the frame and portions of the table top that extend beyond the frame such as the lip. Advantageously, the strengthening members may also help prevent undesired bending, twisting or deflecting of the table top.

**[0047]** Another further aspect is a table top that may include strengthening members and depressions with different shapes, sizes, arrangements, orientations and/or configurations. For example, the majority or substantially the entire center portion of the table top may include depressions with generally uniform shapes, sizes, arrangements, orientations and configurations. This may help create a table top with generally constant characteristics. The side or edges of the table top, however, may include depressions or strengthening members with different shapes, sizes, arrangements, orientations and/or configurations. For instance, the edges of the table top may include a first group of depressions generally aligned in a first direction and a second group of depressions generally aligned in a second direction. If desired, the first direction may be generally perpendicular, or at an angle such as about 30°, 45° or 60°, to the second direction. Because the depressions or strengthening members may be aligned in different directions, portions of the table top may have different characteristics. The strengthening members proximate the edges of the table top may also have different configurations. For example, a first group of strengthening members may be disposed in the frame receiving portion and a second group of strengthening members may be disposed in at least a portion of the frame receiving portion and the lip. These strengthening members may support the portion of the table top disposed above the frame and/or the portion of the table top extending beyond the frame.

**[0048]** Yet another further aspect is a table top that may include a receiving portion in an upper portion of the table top sized and configured to receive an engagement portion of an adjacent table in a nested configuration. The receiving portion may be supported by strengthening members in the lower portion of the table top. For example, the strengthening members may extend inwardly into the lip along the sides of the table top and/or be disposed in the lower surface of the table top. An inner portion of the strengthening members may contact, engage or abut an inner portion of the receiving portion to provide increased strength, support, rigidity and/or structural integrity for the receiving portion. Advantageously, this may allow multiple tables to be stacked together because the receiving portion can withstand a much greater amount of weight and force from the nested tables.

**[0049]** Still yet another further aspect is a table top that may include a generally uniform pattern of depressions disposed in a plurality of generally aligned rows that extend across a lower surface of the table top. The table

top may also include a plurality of channels in the lower surface that are aligned with the rows of depressions. The lower surface of the table top may further include a recess sized and configured to receive a structural support member such as a cross bar. The channels may be disposed on both sides of the structural support member recess and the ends of the channels may be disposed towards a side or end of the table top. In addition, a plurality of depressions may be disposed in a lower portion of the channels. The channels and depressions may be sized and configured to provide extra strength, rigidity, structural integrity and/or torsion resistance proximate the structural support members and/or the ends of the table top. In greater detail, the channels may be aligned with the rows of depressions and the channels may have different lengths. The width of the channel may be generally equal to the width of the depressions in the lower surface of the table top. The depressions in the channels may have generally the same shape, configuration and arrangement as the pattern of depressions in the lower surface, but with a smaller size. The depressions in the channels may be disposed in generally the same pattern, arrangement and spacing as the depressions in the lower surface, which may provide minimal or no disruption to the support of the upper surface of the table top. This may allow the table top to have generally uniform characteristics such as strength, rigidity, structural integrity and/or torsion resistance.

**[0050]** A further aspect is a table that may include a combination of features, aspects and the like, such as one or more of those discussed above. For example, the table can include a frame with engaging portions that are sized and configured to be disposed in a receiving portion of an adjacent table when the tables are nested together. The table can also include one or more compression edges sized and configured to be disposed in the receiving portion of the adjacent, nested table. Thus, the frame and compression edges may facilitate alignment and nesting of the tables in a stacked configuration. Further, the table may include depressions or strengthening members disposed proximate or adjacent portions of the frame, such as the side rails, and these structures may be sized and configured to increase the strength, rigidity and/or structural integrity of the portion of the table top disposed above and/or proximate the frame, and/or portions of the table top that are not directly supported by the frame. In addition, the table may include depressions and/or strengthening members disposed at an angle relative to the bottom surface of the table top. For instance, the table may include strengthening members in the lip disposed perpendicular to the lower surface of the table top. Additionally, the table may include openings or recesses in the sides that allow a portion of the frame to be exposed and readily visible when the table is being used or stored, and openings in the ends to create handles.

**[0051]** A still further aspect is a table that may be constructed from one or more materials and processes. For example, the table top may be constructed from molded

plastic, such as blow-molded plastic. The frame and legs may be constructed from high-strength materials such as steel. In particular, the frame and/or legs may be constructed from high-strength, low-alloy (HSLA) steel rather than traditional carbon steel. Importantly, HSLA steel may be twenty to thirty percent (20 to 30%) lighter than carbon steel with the same strength. Therefore, a table constructed with HSLA steel may be lightweight and have the same strength as a conventional table constructed with a carbon steel frame because a smaller gage of HSLA steel can be used. For example, sixteen (16) or eighteen (18) gage HSLA steel may be used to construct the table, which is smaller than traditional steel. HSLA steel, however, has not been previously used in this or other related industries because it is much more expensive than traditional steel. That is, HSLA steel is cost prohibitive. The reduction in the amount of steel required to manufacture the table with one or more of the features disclosed herein, however, may be more than sufficient to offset or justify the price of the more expensive HSLA steel. In particular, because the amount of steel required to create the table with the disclosed features may be significantly less than the amount of steel required to create a corresponding traditional table, HSLA steel may no longer be cost prohibitive. Thus, because less steel may be required and/or HSLA steel may be stronger and lighter weight, the table can be manufactured with HSLA steel.

**[0052]** Another further aspect is a table that may include legs with support members that are widely spaced, which may help create a sturdy table that is unlikely to undesirably move or wobble. The table may also include a table top with various shapes, sizes, configurations and arrangements, such as rectangular, square, circular, oblong and the like. In addition, the table top may include one or more openings to allow, for example, a portion of the frame to be exposed and/or to create a handle or grip.

**[0053]** Another aspect is a table top that may be sized and configured to nest with an adjacent table to reduce a height of a plurality of stacked tables in a nested configuration. The table top may be constructed from molded plastic and include an upper surface, a sidewall and a receiving portion at least partially disposed in the upper surface and the sidewall. The receiving portion may be sized and configured to receive an engaging portion of an adjacent table when the tables are disposed in a nested configuration. The table top may also include a lower portion and a plurality of strengthen members may be disposed in the lower portion of the table top that are sized and configured to support the receiving portion. Each strengthening member of the plurality of strengthening members may include an inner portion sized and configured to support an inner portion of the receiving portion. The upper surface, the sidewall, the receiving portion, the lower portion and the plurality of strengthening members may be integrally formed during a molding process as part of a unitary, one-piece construction.

**[0054]** Still another aspect is a table top that may in-

clude an upper surface formed by an outer wall of the molded plastic table top and a lower portion formed by the outer wall of the molded plastic table top. A receiving portion may be formed in the outer wall of the molded plastic table top and a plurality of strengthening members may be formed in the outer wall of the molded plastic table top. The receiving portion may be disposed about a perimeter of the upper surface of the table top. In addition, if the table top is constructed from blow-molded plastic, then the upper surface, the sidewall, the receiving portion, the lower portion and the plurality of strengthening members may be integrally formed as part of the unitary, one-piece construction during a blow-molding process. Additionally, the receiving portion may be disposed between a plane generally aligned with the upper surface of the table top and a plane generally aligned with a lower surface of the table top, and the plurality of strengthening members may be disposed between the plane generally aligned with the upper surface of the table top and the plane generally aligned with the lower surface of the table top. The upper portion of the strengthening members may contact the inner portion of the receiving portion and one or more of the strengthening members may extend inwardly from the lower portion of the table top and contact the receiving portion. One or more of the strengthening members may also extend inwardly into a sidewall of a lip and an inner portion of the one or more strengthening members contact the inner portion of the receiving portion. One or more of the strengthening members may further extend upwardly from the lower portion of the table top and contact the receiving portion. Finally, one or more of the strengthening members may extend inwardly into a sidewall of a lip and an upper portion of the one or more strengthening members may contact the inner surface of the receiving portion, and one or more of the strengthening members may extend upwardly from the lower portion of the table top and contact the receiving portion.

**[0055]** Yet another aspect is a table top that may be sized and configured to nest with an adjacent table to reduce a height of a plurality of stacked tables in a nested configuration, and the table top may be constructed from molded plastic. The table top may include an upper surface, a sidewall, a receiving portion at least partially disposed in the upper surface and the sidewall that is sized and configured to receive an engaging portion of an adjacent table when the tables are disposed in a nested configuration, and a lower portion. A plurality of strengthening members may be disposed in the lower portion of the table top may be sized and configured to support the receiving portion. The upper surface, the sidewall, the receiving portion, the lower portion and the plurality of strengthening members may be integrally formed during a molding process as part of a unitary, one-piece construction. The strengthening members may include a first plurality of strengthening members disposed along a first portion of the table top, each strengthening member of the first plurality of strengthening members may include an inner portion sized and configured to support an inner

portion of the receiving portion. The strengthening members may also include a second plurality of strengthening members disposed along a second portion of the table top, each strengthening member of the second plurality of strengthening members may include an inner portion sized and configured to support the inner portion of the receiving portion.

**[0056]** The first plurality of strengthening members may be disposed along a side of the table top and the second plurality of strengthening members may be disposed in a corner of the table top. In addition, the first plurality of strengthening members may extend inwardly into a sidewall of a lip of the table top and an inner portion of the first plurality of strengthening members may contact the inner portion of the receiving portion. Additionally, the second plurality of strengthening members may extend upwardly from the lower portion of the table top and an inner portion of the second plurality of strengthening members may contact the inner portion of the receiving portion. Further, the first plurality of strengthening members may be disposed generally parallel to the lower portion of the table top and the second plurality of strengthening members may be disposed generally perpendicular to the lower portion of the table top. The first plurality of strengthening members may further comprise a depression disposed between at least a majority of the strengthening members and the inner portion of the receiving portion, and the second plurality of strengthening members further comprise a depression disposed between at least a majority of the strengthening members and the inner portion of the receiving portion.

**[0057]** Still yet another aspect is a table top that may be sized and configured to nest with an adjacent table to reduce a height of a plurality of stacked tables in a nested configuration. The table top may be constructed from molded plastic and include an upper surface, a sidewall and a receiving portion at least partially disposed in the upper surface and the sidewall, the receiving portion may be sized and configured to receive an engaging portion of an adjacent table when the tables are disposed in a nested configuration. The table top may also include a lower portion and a plurality of depressions disposed in the lower portion of the table top may be sized and configured to support the receiving portion, and each depression of the plurality of depressions may include an inner portion sized and configured to support an inner portion of the receiving portion. The upper surface, the sidewall, the receiving portion, the lower portion and the plurality of depressions may be integrally formed during a molding process as part of a unitary, one-piece construction. One or more depressions of the plurality of depressions may be disposed in a lip of the table top and an end of the depressions may contact the inner portion of the receiving portion. In addition, one or more depressions of the plurality of depressions may be disposed in a corner of the table top and an end of the depressions may contact the inner portion of the receiving portion. Further, the plurality of depressions may be disposed along one or

more sides, one or more corners and one or more ends of the table top, and the depressions may be sized and configured to support the receiving portion in the sides, the corners and the ends of the table top.

**[0058]** These and other aspects, features and advantages of the present invention will become more fully apparent from the following brief description of the drawings, the drawings, the detailed description of preferred embodiments and appended claims.

BRIEF DESCRIPTION OF THE DRAWINGS

**[0059]** The appended drawings contain figures of exemplary embodiments to further illustrate and clarify the above and other aspects, advantages and features of the present invention. It will be appreciated that these drawings depict only exemplary embodiments of the invention and are not intended to limit its scope. Additionally, it will be appreciated that while the drawings may illustrate preferred sizes, scales, relationships and configurations of the invention, the drawings are not intended to limit the scope of the claimed invention. The invention will be described and explained with additional specificity and detail through the use of the accompanying drawings in which:

- Figure 1 is an upper perspective view of an exemplary table;
- Figure 2 is a lower perspective view of the table, illustrating the support structures in an extended or use position;
- Figure 3 is another lower perspective view of the table, illustrating the support structures in a collapsed or storage position;
- Figure 4 is a lower perspective view of a portion of the table, illustrating the table top;
- Figure 5 is an enlarged lower perspective view of a portion of the table top designated by broken lines labeled 5 in Figure 4;
- Figure 6 is an enlarged lower perspective view of a portion of the table top designated by broken lines labeled 6 in Figure 4;
- Figure 7 is an enlarged partial cross-sectional side view along lines 7-7 of a portion of the table top shown in Figure 4;
- Figure 8 is an enlarged partial cross-sectional side view along lines 8-8 of a portion of the table top shown in Figure 3;
- Figure 9 is an enlarged partial cross-sectional side view along lines 9-9 of a portion of the table top shown in Figure 3;
- Figure 10 is an enlarged partial cross-sectional side view along lines 10-10 of a portion of the table top shown in Figure 4;
- Figure 11 is an enlarged partial cross-sectional side view along lines 11-11 of a portion of the table top shown in Figure 3;

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

**[0060]** The present invention is generally directed towards tables. The principles of the present invention, however, are not limited to tables. It will be understood that, in light of the present disclosure, the tables disclosed herein can have a variety of shapes, sizes, configurations and arrangements. In addition, while the tables shown in the accompanying figures are banquet or utility tables, it will be appreciated the tables may have any suitable style or configuration such as round, personal, conference or card tables. Further, the invention disclosed herein may be successfully used in connection with other types of furniture and/or structures.

**[0061]** Additionally, to assist in the description of preferred embodiments of the tables, words such as top, bottom, front, rear, right and left may be used to describe the accompanying figures which may be, but are not necessarily, drawn to scale. It will further be appreciated the tables can be disposed in a variety of desired positions or orientations, and used in numerous locations, environments and arrangements. A detailed description of preferred embodiments the table now follows.

**[0062]** As shown in Figures 1 and 2, an exemplary table 10 may include a table top 12 and the table top may be constructed from molded plastic. The table top 12 may include an upper portion 14, which may be aligned with an upper surface; a lower portion 16, which may be aligned with a lower surface; and a perimeter 18. As shown in the accompanying figures, a sidewall may be disposed about the perimeter 18 of the table top 12. The upper portion 14 may be spaced apart from the lower portion 16 of the table top 12 by a distance, which may be a generally constant distance. The table top 12 may

also include a hollow interior portion disposed between the upper and lower portions 14, 16 of the table top. In addition, the table top 12 may include a lip 20, which may extend downwardly from the lower portion 16 of the table top when the table top is oriented with the upper surface facing up as shown in Figure 1. The table top 12 may further include one or more sides 22, corners 24 and ends 26 depending, for example, upon the shape and configuration of the table 10. The table top 12, including the upper portion 14, the lower portion 16, the hollow interior portion, the lip 20, the sides 22, the corners 24 and/or the ends 26, may be integrally formed as part of unitary, one-piece structure during the molding process. If the table top 12 is constructed from plastic, it may be formed in the desired shape by blow-molding, injection molding, rotary molding, and/or other suitable processes. It will also be appreciated that the table top 12 may be constructed using various materials such as wood, metal and the like.

**[0063]** The table 10 may include a one or more support structures 28, which may be sized and configured to support the table top 12 above a surface such as the floor or ground. The support structures 28 may include one or more legs or supports 30 and the support structures may be movable between an extended or use position and a collapsed or storage position relative to the table top 12. As shown in the accompanying figures, the support structures 28 may include a pair of legs or supports 30 and a connecting member 32 may interconnect the supports.

**[0064]** The table 10 may also include a frame 36 connected to the table top 12. If desired, the support structures 28 may be connected to the frame 36 and the support structures may be movably connected to the frame 36 to allow the legs 30 to move between an outwardly extending or use position and a collapsed or storage position. For example, the support structures 28 may include or be connected to cross members 38, 40 and the legs 30 may be connected to the cross members. The cross members 38, 40 may be connected to the frame 36. In particular, the frame 36 may include elongated members, such as side rails 42, 44, and the cross members 38, 40 may be connected to the side rails. It will be appreciated that the cross members 38, 40 may also be part of the frame 36.

**[0065]** The support structures 28 and/or the legs 30, however, do not have to be connected to the cross members 38, 40 or the frame 36. Instead, the support structures 28 and/or legs 30 may be connected to any suitable portions of the table 10. It will also be appreciated that the table 10 may include any suitable number of support structures 28 and/or legs 30 depending, for example, upon the intended use of the table. In addition, it will be appreciated that the table top 12, the support structures 28 and the legs 30 may have various sizes, shapes, configurations and arrangements depending, for example, upon the intended use of the table 10. It will further be appreciated that the frame 36, the side rails 42, 44 and/or the cross members 38, 40 are not required, and the table

10 may have other components, features, aspects, characteristics and the like, if desired.

**[0066]** The table 10 may include first and second brace assemblies 46, 48, which may be connected to the support structures 28. In particular, the brace assemblies 46, 48 may be connected to the legs 30 and may be sized and configured to allow the legs to move between the use and storage positions. As shown in Figure 2, the brace assemblies 46, 48 may include a first portion 50A connected to the legs 30 and a second portion 50B connected to a cross member 52 and/or the table top 12. The first and second portions 50A, 50B may be interconnected to form the brace assemblies 46, 48.

**[0067]** The table 10 is preferably sized and configured to be stacked with one or more additional tables. In particular, the stacked tables 10 are preferably nested together to reduce the height of the stacked tables, which may allow the tables to be shipped, stored and transported in a smaller area. This may result in significant cost savings to the manufacturer, for example, because less storage space may be required and a substantial reduction in transportation costs may be achieved. An exemplary embodiment of stacked and nested tables is shown in Figures 13 and 14, which are discussed below in more detail. Additional features, aspects and exemplary embodiments of stacked and nested tables are shown in Assignee's U.S. patent application serial no. 13/455,041, entitled TABLES WITH NESTING TABLE TOPS, filed April 24, 2012 (attorney docket no. L1006.10610US01); U.S. patent application serial no. 13/455,055, entitled FRAME FOR A TABLE, filed April 24, 2012 (attorney docket no. L1006.10611US01); and U.S. patent application serial no. 13/455,066, entitled TABLE, filed April 24, 2012 (attorney docket no. L1006.10615US01). Each of these applications and patents is incorporated by reference in its entirety.

**[0068]** The frame 36 may be sized and configured to facilitate nesting of the tables 10. For example, as shown in Figure 2, the side rails 42, 44 of the frame 36 may be disposed along the sides 22 of the table top 12. Advantageously, if the side rails 42, 44 are disposed proximate the sides 22 of the table top 12, then the sides of the table top may be supported by the frame 36, which may help create a strong and sturdy table 10. In addition, the side rails 42, 44 may be sized and configured to help transfer forces towards a center portion of the table and away from the perimeter 18, which also help create a strong and sturdy table 10.

**[0069]** As shown in Figures 1 to 4, the table 10 may include a handle 54 disposed at one or both ends 26 of the table top 12. The handle 54 is preferably sized and configured to facilitate moving and transporting the table 10. In addition, the handle 54 may assist in separating the tables 10 in the nested configuration. The handle 54 may consist of a recess or opening in the lip 20 of the table top 12 and the handle may be integrally formed with the table top as part of a unitary, one-piece construction.

**[0070]** The table 10 may also include openings 56 dis-

posed in the lip 20 along the sides 22 of the table top 12. The openings 56 may be sized and configured to allow a portion of the frame 36, such as an outer surface 58 of the frame, to be visible or exposed along the sides 22 of the table top 12. This may allow, for example, a consumer to readily see the exposed surface 58 of the frame 36. Therefore, the table top 12 may include openings 56 in the sides 22 to allow a portion of the frame 36 to be exposed and openings in the ends 26 to form the handles 54. Thus, the table top 12 may include openings in both the sides 22 and the ends 26, and the openings 56 in the sides may be much larger than the handles 54 by a factor such as five, ten, twenty or more.

**[0071]** As shown in the accompanying figures, the table top 12 may include a plurality of depressions 60. The depressions 60 may be sized, shaped, configured and arranged to provide increased strength, stiffness and/or rigidity to the table top 12. The depressions 60 may also cover the majority, substantially all or the entire lower portion 16 of the table top 12. In addition, the depressions 60 may have a generally uniform shape, size, configuration and arrangement. The depressions 60 may further have an elongated shape that is aligned with an axis and the depressions may be aligned in a series of rows and columns that extend along the length and width of the table top 12. Additionally, the depressions 60 in adjacent rows and columns may be offset, and the distance between adjacent depressions in the rows and columns may be generally the same. For example, the distance between adjacent depressions in each row or column may be generally constant or the same. The distance between adjacent rows and columns may also be generally constant or the same.

**[0072]** The depressions 60 may be used to create a table top 12 with generally uniform characteristics or qualities. For example, if the depressions 60 are consistently spaced, that may allow an upper surface 62 of the table top 12 to be uniformly supported. In addition, if the depressions 60 are separated by a generally constant distance, which may be measured from a center of one depression to a center of an adjacent depression, that may create a table top 12 with more uniform characteristics or qualities. The distance between adjacent depressions 60 may be measured longitudinally, laterally or at an angle depending, for example, upon the arrangement of the depressions.

**[0073]** The depressions 60 may also be disposed in a pattern and the depressions may be generally aligned and/or disposed in predetermined locations within the pattern. The pattern may include, for example, a number of rows 64 and/or columns 66 of depressions 60. The rows 64 could be disposed along a length of the table top 12 and the columns 66 could extend along a width of the table top. The depressions 60 may also be disposed in other suitable forms and patterns, and may have other shapes, sizes, configurations and arrangements, depending, for example, upon the intended use of the table 10.

**[0074]** A plurality of depressions 60 may also be disposed proximate the connection of the frame 36 and table top 12. These depressions 60 proximate the frame 36 may have the same size, shape, configuration and arrangement as the depressions in the pattern. The depressions 60 proximate the frame 36 may also have other sizes, shapes, configurations and/or arrangements as discussed in more detail below. A plurality of depressions 60 may also be disposed between the side rails 42, 44 of the frame 36 and an upper surface 62 of the table top 12. Advantageously, the depressions 60 may help support the portion of the table top 12 disposed above the side rails 42, 44 of the frame 36, which may help prevent the table top from undesirably sagging or otherwise deforming. The depressions 60 may also help prevent portions of the table top 12 disposed above the side rails 42, 44 of the frame 36 from undesirably bending or collapsing if a load or force is applied to that portion of the table top.

**[0075]** The depressions 60 may also have different characteristics depending, for example, upon the particular configuration of the depressions. For example, the depressions 60 may have an elongated length and a depression may have increased strength along its length. The depression 60 may also have a non-circular configuration with increased strength in one direction in comparison to another direction. Advantageously, if the depressions 60 have different characteristics, then the depressions can be arranged or configured so the structure has certain characteristics. In particular, the depressions 60 may be arranged into a pattern to maximize certain characteristics and/or create a structure with generally uniform characteristics. For instance, the pattern may include generally uniformly spaced depressions 60 that are separated by a generally constant distance and/or disposed in standardized arrangement. A consistent arrangement of the depressions 60 may help create a structure with uniform characteristics. For example, a generally constant pattern of depressions 60 may create a structure with generally uniform strength and structural integrity.

**[0076]** The table 10, the table top 12, the depressions 60 and other components of the table may have a variety of suitable shapes, sizes, configurations and arrangements, such as disclosed in Assignee's U.S. patent no. 7,069,865, entitled HIGH-STRENGTH, LIGHTWEIGHT BLOW-MOLDED PLASTIC STRUCTURES, issued July 4, 2006, which is incorporated by reference in its entirety. In addition, the table 10, the table top 12 and the depressions 60 may have other suitable features and configurations, such as disclosed in Assignee's U.S. patent application serial no. 11/372,515, entitled HIGH-STRENGTH, LIGHTWEIGHT BLOW-MOLDED PLASTIC STRUCTURES, filed March 9, 2006, currently pending, which is incorporated by reference in its entirety.

**[0077]** The table top 12 may also one or more strengthening members 70, which may be disposed proximate the ends 26 of the table top. The strengthening members 70 may also be formed in the lip 20, the sides 22 and/or

the corners 24 of the table top 12. Advantageously, the strengthening members 70 may increase the strength, rigidity, structural integrity and/or impact resistance of the table top 12. Additional exemplary tables, table tops, depressions and strengthening members (along with other features, aspects and components) are disclosed in Assignee's U.S. patent nos. 7,111,563; 7,475,643; 7,814,844 and 8,033,228; which are each incorporated by reference in its entirety. It will be understood the tables disclosed herein may have different shapes, sizes, configurations and arrangements; and may include any suitable number and combination of features, aspects and components; but none of the features, aspects or components may be required.

**[0078]** The table top 12 may include strengthening members, such as the depressions 60 and/or the strengthening members 70, disposed at least proximate stress concentrations. For example, strengthening members may be positioned to help strengthen the upper surface 62 and/or a lower surface 68 of the table top 12, and minimize stress concentrations, such as may occur at the connection of the frame 36 and table top. In particular, strengthening members may be sized and configured to increase the strength, stiffness and/or rigidity of the table top 12 disposed above the 36 frame by minimizing unsupported areas of the table top. Additionally, strengthening members may increase the strength, stiffness and/or rigidity of portions of the table top 12 that extend beyond the frame 36. For instance, strengthening members may be sized and configured to help prevent portions of the table top 12 from undesirably bending or twisting, such as the edges that are disposed about the perimeter 18 of the table top 12.

**[0079]** As discussed above, strengthening members, such the depressions 60 and/or the strengthening members 70, may have a particular size, shape, configuration and/or arrangement to provide increased strength, rigidity and/or structural integrity. Thus, the strengthening members may have a specific size, shape, configuration and arrangement depending, for example, upon factors such as location, intended use, function and the like.

**[0080]** As best seen in Figure 5, the table top may include strengthening members 72 disposed proximate a frame receiving portion 74 sized and configured to receive at least a portion the frame 36. In particular, the frame receiving portion 74 may be sized and configured to receive the side rails 42, 44 of the frame 36. The side rail 42 may contact or abut an upper surface 76 of the frame receiving portion 74. The side rail 42 may also contact or abut an inner sidewall 78 and an outer sidewall 80 of the frame receiving portion 74. The frame receiving portion 74 may be integrally formed in the lower surface 68 of the table top 12 as part of a unitary, one-piece construction.

**[0081]** The strengthening members 72 may be sandwiched or disposed between an upper surface of the side rail 42, 44 and the upper surface 62 of the table top 12. For instance, the strengthening members 72 may include

one end disposed proximate an upper surface of the side rail 42, 44 and an opposing end contacting the upper surface 62 of the table top 12. The strengthening members 72 may further be sized and configured to facilitate air flow during the molding process, which may be particularly helpful if the table top is constructed from blow-molded plastic because the frame receiving portion 74 may extend inwardly from the lower surface 68 of the table top 12 and there may be limited spaced between the upper portion of the frame receiving portion and the upper surface of the table top 12.

**[0082]** As seen in Figures 5 and 7, the strengthening members 72 may be disposed in the upper surface 76 of the frame receiving portion 74. The strengthening members 72 may extend from the upper surface 76 of the frame receiving portion 74 to the upper surface 62 of the table top 12. As shown in the accompanying figures, each of the strengthening members 72 may be a channel or rib that is formed in the upper surface 76 of the frame receiving portion 74 that contacts or abuts the upper surface 62, but the strengthening members may also be grooves, indentations, depressions or the like. The strengthening member 72 may be entirely disposed between or confined within the inner sidewall 78 and the outer sidewall 80 of the frame receiving portion 74. While the strengthening member 72 may have an elongated length as shown in the accompanying figures, the strengthening members may also have other suitable configurations such as round, circular, oval, oblong and the like.

**[0083]** The strengthening members 72 may be sized, shaped, configured and arranged to provide increased strength, stiffness and/or rigidity to the table top 12. The strengthening members 72 may also be used to create a table top 12 with more uniform characteristics or qualities. Advantageously, the strengthening members 72 may help support the portion of the table top 12 disposed above the side rails 42, 44, which may help prevent the table top from undesirably sagging or otherwise deforming. The strengthening members 72 may also help prevent the portion of the table top 12 disposed above the side rails 42, 44 from bending or collapsing if a load or force is applied to that portion of the table top.

**[0084]** As best seen in Figures 5 and 7, the table top 12 may include a first group or plurality of strengthening members 72, which may be substantially or entirely disposed in the upper surface 76 of the frame receiving portion 74. The strengthening members 72 may have an elongated length that is disposed in a first direction, such as generally perpendicular to the length of the table top 12 and located between the inner and outer sidewalls 78, 80 of the frame receiving portion 74. The strengthening members 72 may have a generally constant or consistent spacing, size, shape, configuration and/or arrangement. In addition, the strengthening members 72 may be disposed along an axis and/or in a parallel configuration, and adjacent strengthening members in the frame receiving portion 74 may be separated from one

another by a generally constant distance.

**[0085]** The table top 12 may also include a second group or plurality of strengthening members 82. The second plurality of strengthening members 82 may have generally the same size, shape, configuration and arrangement. The second plurality of strengthening members 82 may also be separated by a generally consistent distance. As shown in the accompanying figures, the first and second pluralities of strengthening members 72, 82 may have different shapes, sizes configurations and/or arrangements. For example, the strengthening members 72, 82 may be disposed at different angles, such as at right angles with respect to one another, or in different directions. For instance, in this embodiment, if the first plurality of strengthening members 72 is generally aligned with the length of the table top 12, then the second plurality of strengthening members 82 may be generally aligned with the width of the table top. If desired, the strengthening members 72, 82 may alternate between a strengthening member from the first plurality of strengthening members and a strengthening member from the second plurality of strengthening members.

**[0086]** As shown in Figures 5 and 7, the strengthening members 72, 82 may have different configurations. For example, the strengthening member 82 may be a rib or channel that extends across the width of the frame receiving portion 74 and may be at least partially disposed in one or more of the sidewalls 78, 80 of the frame receiving portion. If the frame receiving portion 74 is aligned with the lip 20, the strengthening member 82 may also be formed in the lip, such as in an inner sidewall 84 of the lip. The strengthening member 82 may be disposed perpendicular to the lip 20 or an edge of the table top 12, such as the sides 22, and the strengthening members may be disposed in a parallel configuration. The strengthening members 82 may be sized and configured to help prevent bending or twisting of the outer portions of the table top 12 that are not supported by the frame 36.

**[0087]** In greater detail, the strengthening member 82 may be formed in the inner sidewall 78 of the frame receiving portion 74 and the strengthening member may extend along all or only a portion of the inner sidewall. The strengthening member 82 may also spans the entire width of the upper surface 76 of the frame receiving portion 74. Additionally, the strengthening member 82 may be formed in the outer sidewall 80 of the frame receiving portion 74 and/or the sidewall 84 of the lip 20.

**[0088]** As best seen in Figure 5, the strengthening member 82 may have different sizes and configurations. For example, some of the strengthening members 82 may be larger or smaller. Advantageously, because the strengthening members 82 may be disposed in both the frame receiving portion 74 and the lip 20, the strengthening members may help connect the frame receiving portion and the lip. The strengthening members 82 may also provide increased strength, stiffness and/or rigidity to these portions of the table top 12. For instance, the strengthening members 82 may increase the strength,

stiffness and/or rigidity of the portions of the table top 12 that extend or are disposed beyond the frame 36, such as the lip 20. In addition, the strengthening members 82 may be sized and configured to prevent the lip 20 from undesirably bending or twisting.

**[0089]** Therefore, in one exemplary embodiment, a first plurality of depressions or strengthening members 72 and a second plurality of depressions or strengthening members 82 may be disposed between the side rails 42, 44 and the upper portion 14 or upper surface 62 of the table top 12. As shown in Figure 9, the side rails 42, 44 may include an upper portion or surface 86 that contacts the lower surface 68 of the table top 12. In addition, the plurality of strengthening members 72 may be disposed between a first side 88A and a second side 88B of the upper portion or surface 86 of the side rails 42, 44.

**[0090]** As discussed above, the depressions 60, the strengthening members 72 and the strengthening members 82 may provide increased strength, rigidity and/or structural integrity. These structures may also support portions of the table top 12 such as the portions disposed above the side rails 42, 44 of the frame and portions that extend beyond the frame 36. Advantageously, this may allow the table top 12 to have more uniform characteristics.

**[0091]** As shown in Figures 9, 11 and 12, the table top 12 may include a receiving portion 90 that is sized and configured to facilitate nesting of the tables. The receiving portion 90 may be at least partially disposed in the upper portion 14 or upper surface 62 of the table top 12, and may be sized and configured to receive an engaging portion 92 of an adjacent table when the tables are disposed in a nested configuration. The receiving portion 90 is preferably disposed about the perimeter 18 of the table top 12. In particular, the receiving portion 90 is preferably disposed about the entire perimeter 18 of the table top 12 including the sides 22, the corners 24 and the ends 26. Desirably, the receiving portion 90 may be disposed below a plane aligned with the upper surface 62 of the table top 12. The receiving portion 90 may be integrally formed with the table top 12 as part of a unitary, one-piece construction during the molding process, if the table top is constructed from molded plastic. In greater detail, the receiving portion 90 may be disposed at least proximate the intersection of the upper surface 62 and an outer edge of the table top 12. Additionally, the receiving portion 90 may have a generally L-shaped configuration that is open on two sides, which may help facilitate alignment and nesting of the tables 10.

**[0092]** The engaging portion 92 may be a portion of the frame 36, such as a portion of the side rails 42, 44, and/or a portion of the table top 12, such as a portion of the lip 20, the sides 22, the corners 24 and/or the ends 26. If desired, the portions of the lip 20, the sides 22, the corners 24 and/or the ends 26 disposed in the receiving portion 90 may include compression edges. Therefore, the engaging portion 92 disposed in the receiving portion 90 may include a combination of one or more portions of

the frame 36 and/or table top 12. The receiving portion 90 and engaging portion 92 may have various shapes, sizes, configurations and arrangements, such as shown in Assignee's U.S. patent application serial no. 13/455,041, entitled TABLES WITH NESTING TABLE TOPS, filed April 24, 2012 (attorney ref. no. L1006.10610US01); U.S. patent application serial no. 13/455,055, entitled FRAME FOR A TABLE, filed April 24, 2012 (attorney ref. no. L1006.10611US01); and U.S. patent application serial no. 13/455,066, entitled TABLE, filed April 24, 2012 (attorney ref. no. L1006.10615US01). Each of these applications is incorporated by reference in its entirety.

**[0093]** As shown in the accompanying figures, the receiving portion 90 is preferably disposed about the perimeter 18 of the table top 12 including the sides 22, the corners 24 and the ends 26. In addition, the receiving portion 90 may be at least partially disposed in the upper surface 62 and edge of the table top 12, and the receiving portion may be disposed below a plane generally aligned with the upper surface of the table top. The receiving portion 90 may be integrally formed with the table top 12 as part of a unitary, one-piece construction during the molding process, if the table top is constructed from molded plastic.

**[0094]** As shown in Figure 14, the receiving portion 90 may have a generally L-shaped configuration that is open on two sides, which may facilitate alignment and nesting of the tables 10. The receiving portion 90 may be a groove or channel with a height and a width. For example, a sidewall 106 of the receiving portion 90 may have a height of between about 0.25 inches and about 0.5 inches, such as about 0.3 inches or 0.4 inches, and a lower surface 106 of the receiving portion 90 may have a width that is greater than the height by a factor such as two, three or more. For example, the width may be approximately two times the height such that, in this exemplary embodiment, if the height is about 0.25 inches, then the width may be about 0.5 inches. The height and the width may also be approximately the same. For instance, if the height is about 0.5 inches, then the width may also be about 0.5 inches. It will be appreciated the width may also be smaller than the height. Thus, for example, if the height is about 0.4 inches, then the width may be about 0.3 inches or less. It will be understood the height and/or the width of the receiving portion 90 may vary depending, for example, upon the intended use of the table 10.

**[0095]** The receiving portion 90 may be supported by strengthening members and/or depressions 94 disposed in the lower portion 16 of the table top 12. For example, as shown in Figure 11, the strengthening members 94 may include an inner portion 96 (such as an upper or inner surface), that contacts, abuts or engages an inner portion 98 (such as an inner surface) of the receiving portion 90. In greater detail, the strengthening members 94 may extend inwardly or horizontally relative to the lower portion 16 of the table top 12. For instance, the strengthening members 94 may be disposed along the

sides 22 and/or ends 26 of the table top 12. In particular, the strengthening members 94 may be disposed in the inner sidewall 84 of the lip 20 and have a generally curved or arc-shaped configuration. An inner surface of the strengthening member 94 may be spaced apart from an outer wall of the lip 20 and the inner portion 96 of the strengthening members may contact the inner portion 98 of the receiving portion 90. For a table 10 that is about six (6) feet in length, thirty-two (32) strengthening members 94 may be disposed along each side 22 of the table top 10. It will be understood additional or fewer strengthening members 94 may be disposed along the sides 22 and/or ends 26 of the table top 12 depending, for example, upon the length or intended use of the table 10.

**[0096]** As shown in Figures 4-7 and 10-11, for example, the strengthening members 94 may be disposed in the sidewall 84 of the lip 20. The strengthening members 94 may also be disposed in the corners 24, such as shown in Figures 2 and 12. Advantageously, the strengthening members 94 may also consist of and/or be referred to as depressions. Further, as discussed below, one or more depressions may be used to connect the receiving portion 90 and strengthening members 94. In will be understood, in light of the present disclosure, the strengthening members 94 may have different shapes, sizes, configurations and arrangements depending, for example, upon the intended use of the table 10.

**[0097]** The strengthening members 94 may also be disposed at other angles and/or connected to the inner portion 98 of the receiving portion 90 in different configuration and arrangements. For example, as shown in Figure 12, the strengthening members 94 may be disposed in the corners 24 of the table top 12. The strengthening members 94 in the corners 24 may extend upwardly from the lower surface 68 of the table top 12. In greater detail, the inner portion 96 of the strengthening member 94 in the corner 24 may contact, abut or engage the inner portion 98 of the receiving portion 90. In particular, the inner portion 96 of the strengthening members 94 may contact the inner portion 98 of the receiving portion 90, such as inner surface of a lower portion 100 and/or an inner surface the sidewall 102. Each corner 24 of the table top 12 may include eight (8) connections between the strengthening members 94 and the receiving portion 90. It will be understood the table 10 may have any appropriate number of connections between the strengthening members 94 and the receiving portion 90, the strengthening members may be disposed in any suitable portions of the table top 12 and the strengthening members may have other sizes, shapes, configurations and arrangements depending, for example, upon the intended use of the table 10.

**[0098]** Advantageously, the strengthening members 94 may provide increased strength, support, rigidity and structural integrity for the receiving portion 90. The strengthening members 94 may also allow the receiving portion 90 to support a considerable amount of weight or force. Significantly, this may allow a number of tables 10

to be disposed in a nested configuration because, for example, the tables disposed in the bottom of the stack may not be damaged by the weight of the tables. For instance, when the tables 10 are nested together as shown in Figures 13 and 14, the engaging portion 92 may contact or abut the lower surface 104 and/or the sidewall 106 of the receiving portion 90 and these may become load bearing surfaces. Because the strengthening members 94 may increase the strength, rigidity and/or structural integrity of the receiving portion 90, this may allow a considerable number of tables 10 to be stacked and nested together without damage to the receiving portion.

**[0099]** One or more depressions may also support the receiving portion 90. For example, one or more depressions may connect the strengthening member 94 and the receiving portion 90. In addition, one or more depressions may be formed in the lip 20 and/or the lower portion 14 of the table top 12, and the depressions may contact, engage or abut the inner portion 98 of the receiving portion 90.

**[0100]** The table 10 may also include other structures that may increase the strength, rigidity and/or structural integrity of the table top 12. For example, the lower surface 68 of the table top 12 may include one or more recesses 110 that are sized and configured to receive a structural support member such as a portion of the support structure 28, the frame 36, the cross member 38, the cross member 40 and/or the cross member 52. For instance, as shown in Figure 16, a first cross member recess 112 may be sized and configured to receive a portion of the cross member 38 and a second cross member recess 114 may be sized and configured to receive a portion of the cross member 40. A third cross member recess 116 may be sized and configured to receive the cross member 52 disposed proximate the center of the table top 12. The lower surface 68 of the table top 12 may also include a first support structure recess 118 and a second support structure recess 120 that are sized and configured to receive the support structures 28 in the collapsed or storage position. The recesses 112, 114, 116, 118 and 120 may facilitate nesting of the tables 10 by allowing an upper portion of an adjacent stacked table to be disposed in a lower portion of the table. The recesses 112, 114, 116, 118 and 120 may also help position the various components in the desired positions.

**[0101]** The lower surface 68 of the table top 12 may also include one or more channels 122, which may be aligned in a parallel configuration. The channels 122 may have a width generally equal to the width of the depressions 60 in the lower surface 68 and the channels are preferably aligned with the depressions. Advantageously, because the channels 122 may be aligned with and have generally the same width as the depressions 60, the channels may not disrupt or interfere with a pattern or arrangement of generally uniformly disposed depressions. The channels 122, however, may have a width that is larger or smaller than the width of the depressions 60, if desired.

**[0102]** As shown in Figures 15-19, a plurality of depressions 124 may be disposed in a lower portion 126 of the channels 122 and the depressions may contact, abut or engage the upper surface 62 of the table top 12.

5 The depressions 124 may have the same general pattern, spacing, size, shape, configuration and arrangement. In addition, the depressions 124 in the lower portion 126 of the channel 122 may be disposed in generally the same pattern as the depressions 60 in the lower surface 68. Significantly, if the depressions 60, 124 are disposed in generally the same pattern, this may create a table top 12 with generally uniform characteristics such as strength, rigidity and structural integrity.

**[0103]** The channels 122 may have a variety of different lengths. For example, some of the channels 122 may have a length that only allows a limited number of depressions 124, such as three (3), to be disposed in the lower portion 126. Other channels 122 may have a longer length that allows a great number of depressions 124 to be disposed in the lower portion 126, such as ten (10) or twelve (12). Further, other channels 122 may extend from one end to the other end of the table top 12. It will be appreciated that the channels 122 may have any suitable length.

20 **[0104]** The channels 122 may be sized, shaped, configured and/or arranged to increase the strength, rigidity, structural integrity and/or torsion resistance of the table top 12. For example, the channels 122 may have opposing walls 128, 130 and the opposing walls may increase the strength, rigidity, structural integrity and/or torsion resistance of the table top 12. The lower portion 126 of the channel may also be spaced proximate the upper surface 62 and that may increase the strength, rigidity, structural integrity and/or torsion resistance of the table top 10.

25 **[0105]** The channels 122 are preferably disposed on both sides of a structural support member such as the cross members 38, 40. In particular, the channels 122 preferably extend through a cross member recess, such as the first and second cross member recesses 112, 114, and past both sides of the cross member recess. In addition, a depression may be disposed at an intersection of one or more of the channels 122 and the recess for the cross member. Additionally, the ends of the channels 122 are preferably disposed proximate a portion of the table top 12 that is not directly supported by the frame 36. For example, the ends of the channels 122 may be disposed proximate the ends 26 of the table top 12, which may extend beyond the ends of the side rails 42, 44 and the cross members 38, 40. In particular, a first end of each channel 122 of the plurality of channels may be disposed proximate a first end of the table top, and the ends of the channels may be generally spaced an equal distance from the first end of the table top. The channels 122 may also have different lengths. Advantageously, the channels 122 and the depressions 124 may increase the strength, stiffness, rigidity and/or structural integrity proximate the structural support members and accompanying recesses, and the ends 26 of the table top 12.

Significantly, this may prevent the ends 26 of the table top 12 from rotating or moving downwardly relative to the cross member 38, 40 and/or ends of the frame 36, which may increase the torsion resistance of the table top 12.

**[0106]** As seen in Figures 18 and 19, the lower surface 68 may be spaced a generally constant distance apart from the upper surface 62 so that the table top 12 has a generally constant height or thickness. The various structures disposed in the lower surface 68 in the table top 12 may have different heights. For example, the cross member recesses 112, 114, 116 may have a height that is slightly less than the thickness of the table top 12. The frame receiving portion 74 may have a height that is smaller than the thickness of the table top 12 and the height of the cross member recess 112. The lower portion 126 of the channel 122 may also have a height that is smaller than the thickness of the table top 12 and the height of the cross member recess 112. As shown in the accompanying figures, the height of the frame receiving portion 74 and the channel 122 may be approximately the same. Thus, the height of the cross member recesses 112, 114, 116 may be between the height of the frame receiving portion 74 and the channel 122. Because the height of the frame receiving portion 74 and the channel 122 may be about the same, and because the frame receiving portion may include the strengthening members 72, 82 and the channel may include the depressions 124, the upper surface 62 of the table top 12 may have generally similar characteristics such as strength, rigidity and structural integrity.

**[0107]** In this exemplary configuration, the upper surface 62 of the table top 12 may be generally uniformly supported, which may allow the table top to have generally consistent characteristics and qualities such as strength, rigidity, structural integrity and smoothness of the upper surface. It will be appreciated that the table 10 and table top 12 may also have other suitable features, aspects, configurations and the like, such as disclosed in Assignee's U.S. patent application serial no. 13/455,073, entitled TABLE WITH MOLDED PLASTIC TABLE TOP, filed April 24, 2012 (attorney docket no. L1006.10612US01); and U.S. patent application serial no. 13/455,081, entitled TABLES TOP, filed April 24, 2012 (attorney docket no. L1006.10614US01). Each of these patents and applications is incorporated by reference in its entirety.

**[0108]** One of ordinary skill in the art may appreciate after reviewing this disclosure that the tables disclosed herein may have a number of different aspects, features, characteristics and configurations. Further, a table may have any suitable number of aspects, features, characteristics and configurations depending, for example, upon the intended use of the table.

**[0109]** Although this invention has been described in terms of certain preferred embodiments, other embodiments apparent to those of ordinary skill in the art are also within the scope of this invention. Accordingly, the scope of the invention is intended to be defined only by

the claims which follow.

## Claims

1. A table top (12) sized and configured to nest with an adjacent table (10) to reduce a height of a plurality of stacked tables (10) in a nested configuration, the table top (12) being constructed from molded plastic, the table top (12) comprising:
  - an upper portion (14);
  - a lower portion (16);
  - a perimeter (18);
  - a receiving portion (90) at least partially formed in the upper portion (14) and the perimeter (18) of the table top (12), the receiving portion (90) disposed about the perimeter (18) of the table top (12), the receiving portion (90) including a sidewall (106) with a height and a lower surface (104) with a width, the receiving portion (90) receiving an engaging portion (92) of an adjacent table (10) when the tables (10) are disposed in a nested configuration; and
  - a plurality of strengthening members (94) disposed in the lower portion (16) of the table top (12) to support the receiving portion (90), each strengthening member (94) of the plurality of strengthening members (94) including an inner portion (96) that contacts an inner portion (98) of the receiving portion (90) to provide additional strength and support for the receiving portion (90);
  - wherein the upper portion (14), the lower portion (16), the perimeter (18), the receiving portion (90), and the plurality of strengthening members (94) are integrally formed during a molding process as part of a unitary, one-piece construction.
2. The table top (12) as in claim 1, wherein the strengthening members (94) extend inwardly or horizontally relative to the lower portion (16) of the table top (12).
3. The table top (12) as in claim 1 or 2, wherein the strengthening members (94) are disposed in the inner sidewall (84) of the lip (20) and have a generally curved or arc-shaped configuration.
4. The table top (12) as in any preceding claim, wherein an inner portion (96) of the strengthening members (94) is spaced apart from an outer wall of a lip (20).
5. The table top (12) as in any preceding claim, wherein the table top is constructed from blow-molded plastic and the upper portion (14), the lower portion (16), the perimeter (18), the receiving portion (90), and the plurality of strengthening members (94) are integrally formed as part of the unitary, one-piece construction.

struction during a blow-molding process.

6. The table top (12) as in any preceding claim, wherein the receiving portion (90) is disposed between a plane generally aligned with the upper portion (14) of the table top (12) and a plane generally aligned with a lower portion (16) of the table top (12); and wherein the plurality of strengthening members (94) are disposed between the plane generally aligned with the upper portion (14) of the table top (12) and the plane generally aligned with the lower portion (16) of the table top (12). 5
7. The table top (12) as in any preceding claim, further comprising an upper portion of the strengthening members (94) that contacts the inner portion (98) of the receiving portion (90). 10
8. The table top (12) as in any preceding claim, wherein one or more of the strengthening members (94) extend inwardly from the lower portion (14) of the table top (12) and contact the receiving portion (90). 15
9. The table top (12) as in any preceding claim, wherein one or more of the strengthening members (94) extend upwardly from the lower portion (14) of the table top (12) and contact the receiving portion (90). 20
10. The table top (12) as in any preceding claim, wherein one or more of the strengthening members (94) extend inwardly into an inner sidewall of a lip and an upper portion of the one or more strengthening members (94) contacts the inner surface of the receiving portion (90); and wherein one or more of the strengthening members (94) extend upwardly from the lower portion (16) of the table top (12) and contact the receiving portion (90). 25
11. A table top (12) as in claim 1 wherein the plurality of strengthening members comprises: 30
- a first plurality of strengthening members disposed along a first portion of the table top (12), each strengthening member (94) of the first plurality of strengthening members including an inner portion sized and configured to support the inner portion (98) of the receiving portion (90); and 35
- a second plurality of strengthening members disposed along a second portion of the table top (12), each strengthening member (94) of the second plurality of strengthening members including an inner portion sized and configured to support the inner portion (98) of the receiving portion (90). 40
12. The table top (12) as in claim 11, wherein the first plurality of strengthening members extend inwardly into an inner sidewall of a lip of the table top; and wherein the inner portion (96) of the first plurality of strengthening members contacts the inner portion (98) of the receiving portion (90). 45
13. The table top (12) as in claim 11 or 12, wherein the second plurality of strengthening members extend upwardly from the lower portion (16) of the table top (12); and wherein an inner portion (96) of the second plurality of strengthening members contacts the inner portion (98) of the receiving portion (90). 50
14. The table top (12) as in any of claims 11 to 13, wherein the first plurality of strengthening members are disposed generally parallel to the lower portion (16) of the table top (12); and wherein the second plurality of strengthening members are disposed generally perpendicular to the lower portion (16) of the table top (12). 55
15. The table top (12) as in any preceding claim, wherein the strengthening members (94) have a generally curved or arc-shaped configuration.
16. A table top sized and configured to nest with an adjacent table to reduce a height of a plurality of stacked tables in a nested configuration, the table top constructed from molded plastic, the table top comprising:
- an upper surface;
- a sidewall;
- a receiving portion at least partially disposed in the upper surface and the sidewall, the receiving portion sized and configured to receive an engaging portion of an adjacent table when the tables are disposed in a nested configuration;
- a lower portion; and
- a plurality of strengthen members disposed in the lower portion of the table top that are sized and configured to support the receiving portion, each strengthening member of the plurality of strengthening members including an inner portion sized and configured to support an inner portion of the receiving portion, the upper surface, the sidewall, the receiving portion, the lower portion and the plurality of strengthening members integrally formed during a molding process as part of a unitary, one-piece construction.
17. The table top as in claim 16, wherein the upper surface is formed by an outer wall of molded plastic table top and the lower portion is formed by the outer wall of the molded plastic table top; wherein the receiving portion is formed in the outer

- wall of the molded plastic table top; and wherein the plurality of strengthening members are formed in the outer wall of the molded plastic table top.
- 18.** The table top as in claim 16 or 17, wherein the receiving portion is disposed about a perimeter of the upper surface of the table top. 5
- 19.** The table top as in any one of claims 16 to 18, wherein the table top is constructed from blow-molded plastic and the upper surface, the sidewall, the receiving portion, the lower portion and the plurality of strengthening members are integrally formed as part of the unitary, one-piece construction during a blow-molding process. 10
- 20.** The table top as in any one of claims 16 to 19, wherein the receiving portion is disposed between a plane generally aligned with the upper surface of the table top and a plane generally aligned with a lower surface of the table top; and 20  
wherein the plurality of strengthening members are disposed between the plane generally aligned with the upper surface of the table top and the plane generally aligned with the lower surface of the table top. 25
- 21.** The table top as in any one of claims 16 to 20, further comprising an upper portion of the strengthening members that contacts the inner portion of the receiving portion. 30
- 22.** The table top as in any one of claims 16 to 21, wherein one or more of the strengthening members extend inwardly from the lower portion of the table top and contact the receiving portion. 35
- 23.** The table top as in any one of claims 16 to 22, wherein one or more of the strengthening members extend inwardly into a sidewall of a lip and an inner portion of the one or more strengthening members contact the inner portion of the receiving portion. 40
- 24.** The table top as in any one of claims 16 to 23, wherein one or more of the strengthening members extend upwardly from the lower portion of the table top and contact the receiving portion. 45
- 25.** The table top as in any one of claims 16 to 24, wherein one or more of the strengthening members extend inwardly into a sidewall of a lip and an upper portion of the one or more strengthening members contacts the inner surface of the receiving portion; and wherein one or more of the strengthening members extend upwardly from the lower portion of the table top and contact the receiving portion. 50
- 26.** A table top sized and configured to nest with an adjacent table to reduce a height of a plurality of stacked tables in a nested configuration, the table top constructed from molded plastic, the table top comprising: 55  
an upper surface;  
a sidewall;  
a receiving portion at least partially disposed in the upper surface and the sidewall, the receiving portion sized and configured to receive an engaging portion of an adjacent table when the tables are disposed in a nested configuration;  
a lower portion;  
a plurality of strengthening members disposed in the lower portion of the table top that are sized and configured to support the receiving portion, the upper surface, the sidewall, the receiving portion, the lower portion and the plurality of strengthening members integrally formed during a molding process as part of a unitary, one-piece construction, the strengthening members comprising:  
a first plurality of strengthening members disposed along a first portion of the table top, each strengthening member of the first plurality of strengthening members including an inner portion sized and configured to support an inner portion of the receiving portion; and  
a second plurality of strengthening members disposed along a second portion of the table top, each strengthening member of the second plurality of strengthening members including an inner portion sized and configured to support the inner portion of the receiving portion.
- 27.** The table top as in claim 26, wherein the first plurality of strengthening members are disposed along a side of the table top and the second plurality of strengthening members are disposed in a corner of the table top.
- 28.** The table top as in claim 26 or 27, wherein the first plurality of strengthening members extend inwardly into a sidewall of a lip of the table top; and wherein an inner portion of the first plurality of strengthening members contacts the inner portion of the receiving portion.
- 29.** The table top as in any one of claims 26 to 28, wherein the second plurality of strengthening members extend upwardly from the lower portion of the table top; and wherein an inner portion of the second plurality of strengthening members contacts the inner portion of the receiving portion.
- 30.** The table top as in any one of claims 26 to 29, where-

in the first plurality of strengthening members are disposed generally parallel to the lower portion of the table top; and  
 wherein the second plurality of strengthening members are disposed generally perpendicular to the lower portion of the table top. 5

wherein the depressions are sized and configured to support the receiving portion in the sides, the corners and the ends of the table top.

**31.** The table top as in any one of claims 26 to 30, wherein the first plurality of strengthening members further comprises a depression disposed between at least a majority of the strengthening members and the inner portion of the receiving portion; and wherein the second plurality of strengthening members further comprises a depression disposed between at least a majority of the strengthening members and the inner portion of the receiving portion. 10 15

**32.** A table top sized and configured to nest with an adjacent table to reduce a height of a plurality of stacked tables in a nested configuration, the table top constructed from molded plastic, the table top comprising: 20

- an upper surface; 25
- a sidewall; 25
- a receiving portion at least partially disposed in the upper surface and the sidewall, the receiving portion sized and configured to receive an engaging portion of an adjacent table when the tables are disposed in a nested configuration; 30
- a lower portion; and a plurality of depressions disposed in the lower portion of the table top that are sized and configured to support the receiving portion, each depression of the plurality of depressions including an inner portion sized and configured to support an inner portion of the receiving portion, the upper surface, the sidewall, the receiving portion, the lower portion and the plurality of depressions integrally formed during a molding process as part of a unitary, one-piece construction. 35 40

**33.** The table top as in claim 32, wherein one or more depressions of the plurality of depressions are disposed in a lip of the table top and an end of the depressions contacts the inner portion of the receiving portion. 45

**34.** The table top as in claim 32 or 33, wherein one or more depressions of the plurality of depressions are disposed in a corner of the table top and an end of the depressions contact the inner portion of the receiving portion. 50

**35.** The table top as in any one of claims 32 to 34, wherein the plurality of depressions are disposed along one or more sides, one or more corners and one or more ends of the table top; and 55
