libvaxdata: VAX Data Format Conversion Routines

By Lawrence M. Baker

Description

libvaxdata provides a collection of routines for converting numeric data — integer and floating-point — to and from the formats used on a Digital Equipment Corporation[1] (DEC) VAX 32-bit minicomputer (Brunner, 1991). Since the VAX numeric data formats are inherited from those used on a DEC PDP–11 16-bit minicomputer, these routines can be used to convert PDP–11 data as well. VAX numeric data formats are also the default data formats used on DEC Alpha 64-bit minicomputers running OpenVMS (Hewlett-Packard, 2005a, 2005b).

The libvaxdata routines are callable from Fortran or C. They require that the caller use two's-complement format for integer data and IEEE 754 format (ANSI/IEEE, 1985) for floating-point data. They also require that the "natural" size of a C `int` type (integer) is 32 bits. That is the case for most modern 32-bit and 64-bit computer systems. Nevertheless, you may wish to consult the Fortran or C compiler documentation on your system to be sure.

Some Fortran compilers support conversion of VAX numeric data on-the-fly when reading or writing unformatted files, either as a compiler option or a run-time I/O option (Hewlett-Packard, 2002, 2005b). This feature may be easier to use than the libvaxdata routines. Consult the Fortran compiler documentation on your system to determine if this alternative is available to you.

The routines in libvaxdata are:

`from_vax_i2()`	16-bit integer byte swap
`from_vax_i4()`	32-bit integer byte reversal
`from_vax_r4()`	32-bit VAX F_floating to IEEE S_floating
`from_vax_d8()`	64-bit VAX D_floating to IEEE T_floating
`from_vax_g8()`	64-bit VAX G_floating to IEEE T_floating
`from_vax_h16()`	128-bit VAX H_floating to Alpha X_floating
`to_vax_i2()`	16-bit integer byte swap
`to_vax_i4()`	32-bit integer byte reversal
`to_vax_r4()`	32-bit IEEE S_floating to VAX F_floating
`to_vax_d8()`	64-bit IEEE T_floating to VAX D_floating
`to_vax_g8()`	64-bit IEEE T_floating to VAX G_floating
`to_vax_h16()`	128-bit Alpha X_floating to VAX H_floating

[1] Later Compaq Computer Corporation, now Hewlett-Packard Company.

*X*_floating is the nomenclature used on a DEC Alpha for its floating-point formats (Sites and Witek, 1995). S_floating is the IEEE 754 32-bit Single Format. T_floating is the IEEE 754 64-bit Double Format. X_floating is an IEEE 754-conforming 128-bit Double Extended Format.[2]

Usage

All calls take 3 arguments, an input array, an output array, and a conversion count:

C

Declaration
```
#include "convert_vax_data.h"
```

Prototype
```
void name( const void *in_array, void *out_array,
           const int *count );
```

Usage
```
#define ARRAY_LEN n
data_type in_array[ARRAY_LEN], out_array[ARRAY_LEN];
const int count = ARRAY_LEN;
name( in_array, out_array, &count );
```

Fortran

Declaration
```
Subroutine NAME( in_array, out_array, count )
Integer count
data_type in_array(count), out_array(count)
```

Usage
```
Integer ARRAY_LEN
Parameter ( ARRAY_LEN = n )
data_type in_array(ARRAY_LEN), out_array(ARRAY_LEN)
Call NAME( in_array, out_array, ARRAY_LEN )
```

`name` (C) or `NAME` (Fortran) is the name of a libvaxdata routine, `count` contains the number *n* (specified by the caller) of array elements to be converted, and `data_type` is the appropriate type of data for the conversion routine.

The `in_array` and `out_array` parameters may refer to the same array, since conversion is carried out element-by-element from `in_array` to `out_array`. The `in_array` and `out_array` parameters must not otherwise overlap.

[2] The Alpha X_floating format is not necessarily compatible with another system's IEEE 754-conforming 128-bit floating-point format. In particular, it is *not* compatible with the IEEE 754-conforming 128-bit extended floating-point format implemented in software for IBM XL Fortran for AIX (International Business Machines, 2004). It *is* compatible with the IEEE 754-conforming 128-bit extended floating-point format defined for the Hewlett-Packard PA–RISC (Kane, 1995).

Integer Conversions

VAXes and Intel 80x86 systems (Intel, 2005) store integers in two's-complement format, ordering the bytes in memory from low-order (`l`) to high-order (`h`), called little-endian format:

```
Byte no.            3       2       1       0
                    |       |       |       |
16-bit integer                      hhhhhhhhllllllll
32-bit integer      hhhhhhhhnnnnnnnnmmmmmmmmllllllll
```

Apple Macintosh systems (Apple Computer, 2005) and most Unix systems (*e.g.*, Sun [Sun Microsystems, 2005a], IBM [Silha, 2005], HP) also store integers in two's-complement format, but use the opposite (big-endian) byte ordering:

```
Byte no.            0       1       2       3
                    |       |       |       |
16-bit integer      hhhhhhhhllllllll
32-bit integer      hhhhhhhhnnnnnnnnmmmmmmmmllllllll
```

A VAX-format integer is converted to big-endian format by reversing the byte order. No conversion is required when the caller uses little-endian byte order; the data are copied as-is (unless `in_array` and `out_array` are the same array, in which case the copy is skipped altogether).

Floating-Point Conversions

Intel 80x86 systems (Intel, 2005), Apple Macintosh systems (Apple Computer, 2004), and most Unix systems (Hewlett-Packard, 2002) implement the IEEE 754 floating-point arithmetic standard. VAX and IEEE formats are similar, after the bytes are rearranged. (VAX floating-point formats inherit the PDP–11 memory layout based on 16-bit words in little-endian byte order.)

The high-order bit is a sign bit (`s`), followed by a biased exponent (`e`), and a (usually) hidden-bit normalized mantissa (`m`). They differ in the number used to bias the exponent, the location of the implicit binary point for the mantissa, and the representation of exceptional numbers (*e.g.*, ±infinity).

VAX floating-point formats: $(-1)^s \times 2^{(e-bias)} \times 0.1m$

```
Bit no.             31      23      15      7       0
                    |       |       |       |       |
F_floating          mmmmmmm_m1_mmmmmmmseeeeeeeemm_m0_m   bias=128

D_floating          mmmmmmm_m1_mmmmmmmseeeeeeeemm_m0_m   bias=128
                    mmmmmmm_m3_mmmmmmmmmmmmmm_m2_mmmmmmm

G_floating          mmmmmmm_m1_mmmmmmmseeeeeeeeeee_m0_   bias=1024
                    mmmmmmm_m3_mmmmmmmmmmmmmm_m2_mmmmmmm

H_floating          mmmmmmm_m0_mmmmmmmseeeeeeeeeeeeeee   bias=16384
                    mmmmmmm_m2_mmmmmmmmmmmmmm_m1_mmmmmmm
```

```
mmmmmmm_m4_mmmmmmmmmmmmmm_m3_mmmmmmm
mmmmmmm_m6_mmmmmmmmmmmmmm_m5_mmmmmmm
```

IEEE floating-point formats: $(-1)^s \times 2^{(e-bias)} \times 1.m$ (normalized)
$(-1)^s \times 2^{(1-bias)} \times 0.m$ (subnormal)

```
Bit no.         31      23      15      7       0
                |       |       |       |       |
S_floating      seeeeeeeemm_m0_mmmmmmmmm_m1_mmmmmm     bias=127

T_floating      seeeeeeeeeee_m0_mmmmmmmm_m1_mmmmmm     bias=1023
                mmmmmmm_m2_mmmmmmmmmmmmmmm_m3_mmmmmm

X_floating      seeeeeeeeeeeeeeemmmmmmmm_m0_mmmmmm     bias=16383
                mmmmmmm_m1_mmmmmmmmmmmmmmm_m2_mmmmmm
                mmmmmmm_m3_mmmmmmmmmmmmmmm_m4_mmmmmm
                mmmmmmm_m5_mmmmmmmmmmmmmmm_m6_mmmmmm
```

VAX format to IEEE format Conversions

After rearranging the bytes, a VAX floating-point number is converted to IEEE floating-point format by subtracting *(1+VAX_bias–IEEE_bias)* from the exponent field to (1) adjust from VAX *0.1m* hidden-bit normalization to IEEE *1.m* hidden-bit normalization and (2) adjust the bias from VAX format to IEEE format. True zero (*s=e=m=0*) and dirty zero (*s=e=0, m≠0*) are special cases, which must be recognized and handled separately. Both VAX zeros are converted to IEEE +zero (*s=e=m=0*).

Numbers whose absolute value is too small to represent in the normalized IEEE format illustrated above are converted to subnormal format (*e=0, m≠0*). Numbers whose absolute value is too small to represent in subnormal format are set to zero (silent underflow).

Overflow during the conversion is not possible; the largest floating-point number in each VAX format is smaller than the largest floating-point number in the corresponding IEEE floating-point format.

If the mantissa of the VAX floating-point number is too large for the corresponding IEEE floating-point format, bits are simply discarded from the right. Thus, the remaining fractional part is chopped, not rounded to the lowest-order bit. This can only occur when the conversion requires IEEE subnormal format.

A VAX floating-point reserved operand (*s=1, e=0, m=any*) causes a `SIGFPE` exception to be raised. The converted result is set to zero.

IEEE format to VAX format Conversions

Conversely, an IEEE floating-point number is converted to VAX floating-point format by adding *(1+VAX_bias–IEEE_bias)* to the exponent field. +zero (*s=e=m=0*), –zero (*s=1, e=m=0*), ±infinity (*s=any, e=all-1's, m=0*), and *NaN*s (*s=any, e=all-1's, m≠0*) are special cases, which must be recognized and handled separately. Both IEEE zeros are converted to VAX true zero (*s=e=m=0*). Infinities and *NaN*s cause a `SIGFPE` exception to be raised. The result returned has the largest VAX exponent (*e=all-1's*) and zero mantissa (*m=0*) with the same sign as the original.

Numbers whose absolute value is too small to represent in the normalized VAX format illustrated above are set to zero (silent underflow). (VAX floating-point formats do not support subnormal numbers.) Numbers whose absolute value exceeds the largest representable VAX-format number cause a `SIGFPE` exception to be raised (overflow). (VAX floating-point formats do not have reserved bit patterns for infinities or *NaN*s.) The result returned has the largest VAX exponent and mantissa (*e=m=all-1's*) with the same sign as the original.

The bytes are then rearranged to the VAX 16-bit word floating-point fomat.

Examples

The following C function `from_vax_rhdr()` converts the floating-point data header from a data file written on a VAX:

```
/* VAX Data Conversion Routines */

#include "convert_vax_data.h"

#ifndef FORTRAN_LINKAGE
#define FORTRAN_LINKAGE
#endif

/************************************************************ from_vax_rhdr() */

void FORTRAN_LINKAGE from_vax_rhdr( const void *inbuf, void *outbuf ) {

   register const float *in;           /* Microsoft C: up to 2 register vars */
   register float *out;                /* Microsoft C: up to 2 register vars */
   int n;
   float in_null, out_null;

   in  = (const float *) inbuf;
   out = (float *) outbuf;

   in_null = in[1];
   n = 1;
   from_vax_r4( &in_null, &out_null, &n );

   n = 38;                                                /*   1..38   binary */
   from_vax_r4( in, out, &n );
   in += n;
   out += n;

   *out = ( *in == in_null ) ? out_null : *in ;           /*    39     ASCII  */
   in++;
   out++;

   n = 89;                                                /*  40..128  binary */
   from_vax_r4( in, out, &n );

}
```

The equivalent Fortran subroutine `FROM_VAX_RHDR` is:

```
****************************************************************** FROM_VAX_RHDR
*
      Subroutine FROM_VAX_RHDR( inbuf, outbuf )
*
      Real inbuf[128], outbuf[128]
*
      Real in_null, out_null
*
*
      in_null = inbuf[2]
```

```
      Call FROM_VAX_R4( in_null, out_null, 1 )
*                                                                  1..38    binary
      Call FROM_VAX_R4( inbuf[ 1], outbuf[ 1], 38 )
*                                                                   39      ASCII
      If ( inbuf[39] .eq. in_null ) Then
         outbuf[39] = out_null
      Else
         outbuf[39] = inbuf[39]
      End If
*                                                                 40..128   binary
      Call FROM_VAX_R4( inbuf[40], outbuf[40], 89 )
*
      Return
      End
```

Creating the Library

The libvaxdata distribution kit includes make files and batch command files to create a static library of separately compiled modules for both Fortran and C programs. The library is named `libvaxdata.`*`x`*, where *`x`* is the system suffix for object module libraries (*e.g.*, `libvaxdata.a` on Unix).

A test program is created in the same directory with the library. Run it after creating the library to verify the conversions.

To create the library and test program:

1. Download one of the distribution kits from the USGS online web site, http://pubs.usgs.gov/of/2005/1424. Two choices are available:

libvaxdata.tar.gz	Compressed tar format with Unix-style LF line endings
libvaxdata.zip	ZIP format with MS–DOS-style CR-LF line endings

2. Unpack the distribution kit. The most recent versions of Windows, Mac OS X, and Linux have built-in support to unpack the distribution kit directly from the desktop. (*E.g.*, double-click the distribution kit to unpack it or open it, then drag-and-drop the contents from there.) Otherwise, a GUI tool may be available, such as WinZip on Windows, or Stuffit Expander on a Macintosh.

   From a Linix command line, type

   ```
   $ tar -xzf libvaxdata.tar.gz
   ```

   On Unix systems without a tar that supports gzip archives, type

   ```
   $ gzcat <libvaxdata.tar.gz | tar -xf -
   ```

   You should see top-level directories named for each supported system type (*e.g.*, `linux`, `macosx`, `win32`, etc.) and one named `src`, containing the C source files.

3. Open a terminal window (Command Prompt on Windows) and navigate to the directory appropriate for your system. For example, Windows users should `cd` to the `libvaxdata\win32` directory.

4. Follow the instructions in the `readme.txt` file there to create the library and test program. The command will be something like:

`> vcmake`	Windows (Visual C++)
`$ @Make`	OpenVMS (CC)
`$ make -f makefile.gcc`	Unix/Linux/Mac OS X (gcc)

5. You can then copy the library to a system-wide directory for everyone to use, such as `/usr/local/lib` on Unix or Linux. Or, you can copy it to your personal library directory, such as `~/lib` on Unix or Linux. See the `readmde.txt` file for the instructions to use the library from your Fortran and C programs.

The following example creates a gcc version of the library on Mac OS X. The `libvaxdata` folder is on the Mac desktop.

```
$ cd ~/Desktop/libvaxdata/macosx
$ make -f makefile.gcc
test -d `uname -p` || mkdir `uname -p`
cd `uname -p` ; make -f ../makefile.macosx \
                             CC="gcc" \
                             CFLAGS="-O3 -ansi" \
                             libvaxdata.a
gcc -O3 -ansi   -c -o from_vax_i2.o ../../src/from_vax_i2.c

 to_vax_i2.o         to_vax_i2_.o        to_vax_i4.o to_vax_i4_.o        to_vax_
r4.o         to_vax_r4_.o to_vax_d8.o         to_vax_d8_.o        to_vax_g8.o to
_vax_g8_.o        to_vax_h16.o        to_vax_h16_.o is_little_endian.o  is_littl
e_endian_.o
cd `uname -p` ; gcc -o test ../../src/test.c -L. -lvaxdata
```

To test the conversions, run the test program in the directory containing the library. For example, after compiling the Mac OS X library above (which created `i386/test`), the following command will test the conversions:

```
$ i386/test
```

The output should look like this:

```
I2
      1
     -1
    256
   -256
  12345
 -12345

I4

                        1
                       -1
                      3.5
                     -3.5
         3.14159265358979
        -3.14159265358979
                    1e+37
                   -1e+37
                    1e-37
                   -1e-37
         1.23456789012345
        -1.23456789012345
```

On an Alpha, the output also includes the H16 conversion:

```
H16
                                       1
                                      -1
                                       2
                                      -2
         3.141592653589793238462643383279
        -3.141592653589793238462643383279
                                   1e+37
                                  -1e+37
                                   1e-37
                                  -1e-37
           1.2345678901234567890123456789
          -1.2345678901234567890123456789
```

The distribution kit includes another useful routine to determine at run-time whether the system uses little-endian byte ordering:

C

Prototype	`int is_little_endian( void );`
Usage	`if ( is_little_endian() ) ...`

Fortran

Declaration	`Integer Function IS_LITTLE_ENDIAN()`
Usage	`If ( IS_LITTLE_ENDIAN() .ne. 0 ) ...`

The prototype is not defined in `convert_vax_data.h`; it must be explicitly declared in a C program.

Compilation Options

The C source code for the libvaxdata routines is in `src/convert_vax_data.c`. The C function prototypes are declared in `src/convert_vax_data.h`.

To compile all routines into a single object module (assuming `-O` is the C compiler option that requests optimization) from one of the system-specific directories:

```
$ cc -c -O -I../src ../src/convert_vax_data.c
```

To compile a single routine into its own module, define `MAKE_`*`routine_name`*, substituting the upper-case name of the routine for *`routine_name`*, and give the object module a name. This is useful, for example, to insert the routines into a library such that a linker may extract only the routines actually needed by a particular program. For example, to compile only `from_vax_r4()`:

```
$ cc -c -O -o from_vax_r4.o -DMAKE_FROM_VAX_R4 \
     -I../src ../src/convert_vax_data.c
```

Different versions of `convert_vax_data.c` are produced depending on the definitions of the C preprocessor variables `IS_LITTLE_ENDIAN` and `APPEND_UNDERSCORE`:

- If `IS_LITTLE_ENDIAN` is defined as `0` (false), then the conversions are performed for a big-endian system; byte reordering is done for all VAX data types.
- If `IS_LITTLE_ENDIAN` is defined as `1` (true), then byte reordering is done for floating-point formats only; integer formats are identical to their VAX counterparts.
- If `IS_LITTLE_ENDIAN` is not defined, then it is defined as `1` (true) if any of the following macros is defined:

`vax __vax vms __vms __alpha`	DEC VAX C, GNU C on a DEC VAX or a DEC Alpha, or DEC C
`M_I86 _M_IX86 __M_ALPHA`	Microsoft 80x86 C or Microsoft Visual C++ on an Intel 80x86 or a DEC Alpha
`i386 __i386`	Sun C, GNU C, or Intel C on an Intel 80x86
`__x86_64 __x86_64__`	GNU C, Intel C, PathScale C, or Portland Group C on an AMD Opteron or an Intel EM64T

- If `APPEND_UNDERSCORE` is defined, the entry point names are compiled with an underscore appended. This is required so that they can be called from Fortran in cases where the Fortran compiler appends an underscore to externally called routines (*e.g.*, Sun Fortran [Sun Microsystems, 2005b]).

  For example, to create Fortran-callable versions of all the routines in an object module called `fconvert_vax_data.o` on a Sun SPARC system, the compiler command would be:

  ```
  $ cc -c -O -o fconvert_vax_data.o -DIS_LITTLE_ENDIAN=0 \
       -DAPPEND_UNDERSCORE -I../src ../src/convert_vax_data.c
  ```

  because a SPARC is a big-endian system and Sun Fortran appends an underscore to externally called routines.

`convert_vax_data.c` requires an ANSI C compiler. Compilation will fail if a `char` is not 8 bits, a `short` is not 16 bits, or an `int` is not 32 bits.[3]

`convert_vax_data.c` does not use 64-bit arithmetic.[4]

---

[3] On a system whose "natural" size of a C `int` type (integer) is 16 bits, it may be possible to `#define int long` and change the test `UINT_MAX != 4294967295U` to `ULONG_MAX != 4294967295UL` in `convert_vax_data.c`. However, this has not been tested.

[4] It may be possible to compile a version of libvaxdata for SMP parallel execution, since each conversion is independent. However, this has not been tested. To enable conversions in parallel across the outer loop over the conversion `count`, it may be necessary to assert that `in_array` and `out_array` are not aliased (*i.e.*, do not overlap).

Version History

Version 1.0, January 6, 2006

Initial release.

Make files for the following platforms and compilers:

Linux:	GNU gcc, Intel icc, Portland Group pgcc
Mac OS 9:	Apple/Motorola MPW MrC, Metrowerks CodeWarrior mwcc
Mac OS X:	GNU gcc, IBM xlc
OpenVMS:	VAX CC, DEC CC
Solaris:	GNU gcc, Sun cc
Tru64 Unix:	HP cc, GNU gcc
Windows:	Microsoft CL, Metrowerks CodeWarrior MWCC

Version 1.1, February 2, 2010

Bug fixes:

Corrected output byte ordering for d8/g8/h16 conversions on little endian machines.
Corrected exponent positioning in `to_vax_d8()`.
Corrected typo (`VAX_D_EXPONENT_BIAS` should be `VAX_G_EXPONENT_BIAS`) in `to_vax_g8()`.

New features:

Added test program to validate conversions.

Added make files for the following platforms and compilers:

Linux:	PathScale pathcc
Mac OS X:	Intel icc

Removed make files for the following platforms and compilers:

Mac OS 9:	Apple/Motorola MPW MrC, Metrowerks CodeWarrior mwcc
Windows:	Metrowerks CodeWarrior MWCC

Version 1.2, April 15, 2010

Bug fixes:

Corrected f4/g8/h16 conversions to IEEE subnormal form.

Additional Notes

As of the Version 1.1 release, make files for the following platforms and compilers are included in the distribution, but the author no longer has the ability to test them:

Linux:	Intel icc

Solaris: GNU gcc, Sun cc
Tru64 Unix: GNU gcc

Contact the author for assistance in using the library on these or any other platforms or compilers at baker@usgs.gov. And, please, report any bugs.
