Convex Optimization — Boyd & Vandenberghe

# 7. Statistical estimation

- maximum likelihood estimation
- optimal detector design
- experiment design

# Parametric distribution estimation

- $\bullet\,$  distribution estimation problem: estimate probability density  $p(y)$  of a random variable from observed values
- parametric distribution estimation: choose from <sup>a</sup> family of densities  $p_x(y)$ , indexed by a parameter  $x$

### maximum likelihood estimation

$$
\mathsf{maximize } \left( \mathsf{over } \; x \right) \; \; \log p_x(y)
$$

- $\bullet\,$   $y$  is observed value
- $\bullet$   $l(x) = \log p_x(y)$  is called log-likelihood function
- $\bullet$  can add constraints  $x\in C$  explicitly, or define  $p_x(y)=0$  for  $x\not\in C$
- $\bullet\,$  a convex optimization problem if  $\log p_x(y)$  is concave in  $x$  for fixed  $y$

## Linear measurements with IID noise

linear measurement model

$$
y_i = a_i^T x + v_i, \quad i = 1, \dots, m
$$

- $\bullet\,\,x\in\textsf{R}^n$  is vector of unknown parameters
- $\bullet \;\, v_i$  is IID measurement noise, with density  $p(z)$
- $\bullet \ \ y_i$  is measurement:  $y \in \mathbf{R}^m$  has density  $p_x(y) = \prod_{i=1}^m p_i$  $\sum\limits_{i=1}^m p(y_i-a_i^T)$  $\frac{T}{i}x\big)$

**maximum likelihood estimate:** any solution  $x$  of

$$
\text{maximize} \quad l(x) = \sum_{i=1}^{m} \log p(y_i - a_i^T x)
$$

 $\left(y\right)$  is observed value)

#### examples

• Gaussian noise  $\mathcal{N}(0, \sigma^2)$ :  $p(z) = (2\pi\sigma^2)^{-1/2}e^{-z^2/(2\sigma^2)}$ ,

$$
l(x) = -\frac{m}{2}\log(2\pi\sigma^2) - \frac{1}{2\sigma^2}\sum_{i=1}^{m}(a_i^T x - y_i)^2
$$

ML estimate is LS solution

• $\bullet$  Laplacian noise:  $p(z) = (1/(2a))e^{-|z|/a}$ ,

$$
l(x) = -m \log(2a) - \frac{1}{a} \sum_{i=1}^{m} |a_i^T x - y_i|
$$

ML estimate is  $\ell_1$ -norm solution

 $\bullet\,$  uniform noise on  $[-a,a]$ :

$$
l(x) = \begin{cases} -m \log(2a) & |a_i^T x - y_i| \le a, \quad i = 1, \dots, m \\ -\infty & \text{otherwise} \end{cases}
$$

ML estimate is any  $x$  with  $|a_i^Tx - y_i| \leq a$ 

# Logistic regression

random variable  $y \in \{0,1\}$  with distribution

$$
p = prob(y = 1) = \frac{exp(a^T u + b)}{1 + exp(a^T u + b)}
$$

- $\bullet$   $a,$   $b$  are parameters;  $u\in\textbf{R}^n$  are (observable) explanatory variables
- $\bullet$  estimation problem: estimate  $a,$   $b$  from  $m$  observations  $(u_i, y_i)$

log-likelihood function (for  $y_1 = \cdots = y_k = 1$ ,  $y_{k+1} = \cdots = y_m = 0$ ):

$$
l(a,b) = \log \left( \prod_{i=1}^{k} \frac{\exp(a^{T} u_i + b)}{1 + \exp(a^{T} u_i + b)} \prod_{i=k+1}^{m} \frac{1}{1 + \exp(a^{T} u_i + b)} \right)
$$
  
= 
$$
\sum_{i=1}^{k} (a^{T} u_i + b) - \sum_{i=1}^{m} \log(1 + \exp(a^{T} u_i + b))
$$

concave in  $a,\,b$ 

Statistical estimation

**example**  $(n = 1, m = 50$  measurements)

 $\bullet\,$  circles show 50 points  $(u_i,y_i)$ 

• solid curve is ML estimate of  $p = \exp(au + b)/(1 + \exp(au + b))$ 

# (Binary) hypothesis testing

## detection (hypothesis testing) problem

given observation of a random variable  $X \in \{1,\ldots,n\}$ , choose between:

- $\bullet$  hypothesis 1:  $X$  was generated by distribution  $p=(p_1,\ldots,p_n)$
- $\bullet$  hypothesis 2:  $X$  was generated by distribution  $q=(q_1,\ldots,q_n)$

#### randomized detector

- $\bullet$  a nonnegative matrix  $T\in{\mathbf R}^2$  $^{\times n}$ , with  $\mathbf{1}^TT=\mathbf{1}^T$
- $\bullet\,$  if we observe  $X=k,$  we choose hypothesis  $1$  with probability  $t_{1k},$ hypothesis 2 with probability  $t_{2k}$
- $\bullet\,$  if all elements of  $T$  are  $0$  or  $1,$  it is called a deterministic detector

detection probability matrix:

$$
D = [Tp \quad Tq \ ] = \left[ \begin{array}{cc} 1 - P_{\text{fp}} & P_{\text{fn}} \\ P_{\text{fp}} & 1 - P_{\text{fn}} \end{array} \right]
$$

- $P_{\text{fp}}$  is probability of selecting hypothesis 2 if  $X$  is generated by distribution <sup>1</sup> (false positive)
- $P_{\text{fn}}$  is probability of selecting hypothesis 1 if  $X$  is generated by distribution 2 (folse negative) distribution <sup>2</sup> (false negative)

## multicriterion formulation of detector design

minimize (w.r.t. 
$$
\mathbf{R}_+^2
$$
)  $(P_{fp}, P_{fn}) = ((Tp)_2, (Tq)_1)$   
subject to  $t_{1k} + t_{2k} = 1, k = 1, ..., n$   
 $t_{ik} \ge 0, i = 1, 2, k = 1, ..., n$ 

variable  $T \in \mathbf{R}^{2 \times n}$ 

scalarization (with weight  $\lambda > 0)$ 

minimize 
$$
(Tp)_2 + \lambda(Tq)_1
$$
  
subject to  $t_{1k} + t_{2k} = 1$ ,  $t_{ik} \ge 0$ ,  $i = 1, 2$ ,  $k = 1, ..., n$ 

an LP with <sup>a</sup> simple analytical solution

$$
(t_{1k}, t_{2k}) = \begin{cases} (1,0) & p_k \ge \lambda q_k \\ (0,1) & p_k < \lambda q_k \end{cases}
$$

- <sup>a</sup> deterministic detector, <sup>g</sup>iven by <sup>a</sup> likelihood ratio test
- if  $p_k = \lambda q_k$  for some k, any value  $0 \le t_{1k} \le 1$ ,  $t_{1k} = 1 t_{2k}$  is optimal  $(i.e.,$  Pareto-optimal detectors include non-deterministic detectors)

#### minimax detector

minimize 
$$
\max\{P_{fp}, P_{fn}\} = \max\{(Tp)_2, (Tq)_1\}
$$
  
subject to  $t_{1k} + t_{2k} = 1$ ,  $t_{ik} \ge 0$ ,  $i = 1, 2$ ,  $k = 1, ..., n$ 

an LP; solution is usually not deterministic

#### example

solutions 1, 2, <sup>3</sup> (and endpoints) are deterministic; <sup>4</sup> is minimax detector

## Experiment design

 $m \$  $m$  linear measurements  $y_i = a_i^T x + w_i, \, i=1,\ldots,m$  of unknown  $x \in \mathbf{R}^n$ 

- $\bullet\,$  measurement errors  $w_i$  are IID  $\mathcal{N}(0,1)$
- ML (least-squares) estimate is

$$
\hat{x} = \left(\sum_{i=1}^{m} a_i a_i^T\right)^{-1} \sum_{i=1}^{m} y_i a_i
$$

• error  $e = \hat{x} - x$  has zero mean and covariance

$$
E = \mathbf{E} e e^T = \left(\sum_{i=1}^m a_i a_i^T\right)^{-1}
$$

confidence ellipsoids are given by  $\{x \mid (x - \hat{x})^T E^{-1}(x - \hat{x}) \leq \beta\}$ 

**experiment design**: choose  $a_i \in \{v_1, \ldots, v_p\}$  (a set of possible test<br>weeken) to make  $E$  (small) vectors) to make  $E$  'small'  $\,$ 

Statistical estimation

vector optimization formulation

$$
\begin{array}{ll}\text{minimize (w.r.t. } \mathbf{S}_+^n) & E = \left(\sum_{k=1}^p m_k v_k v_k^T\right)^{-1} \\ \text{subject to} & m_k \ge 0, \quad m_1 + \dots + m_p = m \\ & m_k \in \mathbf{Z} \end{array}
$$

- $\bullet\,$  variables are  $m_k$  $_{k}$   $(\#$  vectors  $a_{i}$  equal to  $v_{k})$
- difficult in general, due to integer constraint

#### relaxed experiment design

assume  $m\gg p$ , use  $\lambda_k=m_k/m$  as (continuous) real variable

minimize (w.r.t. 
$$
\mathbf{S}_{+}^{n}
$$
)  $E = (1/m) \left( \sum_{k=1}^{p} \lambda_k v_k v_k^T \right)^{-1}$   
subject to  $\lambda \succeq 0$ ,  $\mathbf{1}^T \lambda = 1$ 

- $\bullet\,$  common scalarizations: minimize  $\log\det E$ ,  $\mathbf{tr}\, E$ ,  $\lambda_{\max}(E)$ ,  $\dots$
- $\bullet\,$  can add other convex constraints,  $\,e.g.$ , bound experiment cost  $\,c^{T}$  $T\lambda \leq B$

## <sup>D</sup>-optimal design

minimize 
$$
\log \det \left( \sum_{k=1}^{p} \lambda_k v_k v_k^T \right)^{-1}
$$
  
subject to  $\lambda \succeq 0$ ,  $\mathbf{1}^T \lambda = 1$ 

interpretation: minimizes volume of confidence ellipsoids

## dual problem

$$
\begin{array}{ll}\text{maximize} & \log \det W + n \log n\\ \text{subject to} & v_k^T W v_k \le 1, \quad k = 1, \dots, p \end{array}
$$

interpretation:  $\{x\mid x^TWx\leq 1\}$  is minimum volume ellipsoid centered at origin, that includes all test vectors  $v_{\bm{k}}$ 

 $\,$  complementary slackness: for  $\lambda,\,W$  primal and dual optimal

$$
\lambda_k(1 - v_k^T W v_k) = 0, \quad k = 1, \dots, p
$$

optimal experiment uses vectors  $v_k$  on boundary of ellipsoid defined by  $W$ 

example  $\left( p=20\right)$ 

design uses two vectors, on boundary of ellipse defined by optimal  $W$ 

### derivation of dual of page 1-13

first reformulate primal problem with new variable  $X\!$  :

minimize 
$$
\log \det X^{-1}
$$
  
subject to  $X = \sum_{k=1}^{p} \lambda_k v_k v_k^T$ ,  $\lambda \ge 0$ ,  $\mathbf{1}^T \lambda = 1$ 

$$
L(X, \lambda, Z, z, \nu) = \log \det X^{-1} + \text{tr}\left(Z\left(X - \sum_{k=1}^p \lambda_k v_k v_k^T\right)\right) - z^T \lambda + \nu (\mathbf{1}^T \lambda - 1)
$$

- minimize over  $X$  by setting gradient to zero:  $-X^{-1}+Z=0$
- minimum over  $\lambda_k$  is  $-\infty$  unless  $-v_k^T Z v_k z_k + \nu = 0$

dual problem

maximize 
$$
n + \log \det Z - \nu
$$
  
subject to  $v_k^T Z v_k \le \nu, \quad k = 1, ..., p$ 

change variable  $W=Z/\nu$ , and optimize over  $\nu$  to get dual of page 1–13
