

POPULATION PROJECTIONS FOR ALBANIA 2001-2021

Population and Housing Census 2001

This publication was made possible thanks to the financial support of the Swiss Development Cooperation and the Italian Cooperation, as well as to the combined contribution of individuals and their institutions:

Emira Galanxhi, INSTAT, Institute of Statistics of Albania
Ervin Shameti, INSTAT, Institute of Statistics of Albania
Estela Hajdinaj, INSTAT, Institute of Statistics of Albania
Enkelejda Shehi, ISI, Albanian Institute of Social Insurance
Patrick Festy, INED, Institut National d'Etudes Démographiques, Paris

INSTAT thanks Werner Haug of SFSO, the Swiss Federal Statistical Office, Janine Dahinden of SFM, the Swiss Forum for Migration and Population Studies, and Michelle Jouvenal of ISTAT, the Italian National Institute of Statistics, for their constant support. Particular thanks go to Sofia Barletta for the layout.

No part of this publication can be reproduced or transmitted in any form or by any means without the prior written permission of the copyright holder.

The production of the social research publications presents an important moment of the professional life of INSTAT.

The information collected during the Population and Housing Census of 2001, as well as the data of Living Standard Measurement Survey (LSMS) of 2002, were used as the main data sources to analyze phenomena's of the last decade such as emigration and internal movements, labor market situation, the impact these issues had on the lives of women and men in Albania, their living conditions and how the inequalities are distributed in basic sector of the everyday life. Those data were used also in the population projections for the years 2001-2002.

These research publications do represent a special instrument for the policy makers and different disciplinary stakeholders. They can be used to mainstreaming the poverty reduction, to minimize inequalities, to guide the investment funds in services and infrastructure, and to help the local authorities in designing of special strategies in favor of vulnerable groups. These publications will contribute to complete the information on millennium development goals (MDG) in Albania and they will bring new elements for the continuous monitoring of those indicators.

Without the direct collaboration of Albanians and foreigners experts these publications would not be accomplished. The research papers evidence the existence of a network composed by local researchers, from public administrations agencies as well as universities, that do cooperate together in analyzing the social phenomena.

INSTAT take this opportunity to extend its thanks to Swiss Agency for Development and Cooperation and Italian Cooperation, which made all the efforts to support and coordinate the initiative for finalizing these research publications.

Population Projections for Albania

(2001 - 2021)

From 1950 to 1990, the Albanian population experienced decades of rapid population growth, although the pace of this growth has declined in a progressive way. The fertility rate – despite the fall – was much higher than anywhere else in Europe, mortality rate was relatively favorable, in line with a Mediterranean-type pattern, exchanges with the foreign countries through migration were almost null and movements within the country were severely limited. It was (would have been) easy to forecast the future of the population by an extrapolation of ongoing trends at any stage of this smooth process.

The 1990s dramatically modified this picture. Fertility decline accelerated to levels much closer to the European standards, external migration has been massive and has strongly affected the age pyramid whereas internal migration has deeply modified the balance between the country's regions. The economic and political crisis emphasized further the existing trends, which are difficult to disentangle from the impact of one or another. The future – whatever that may be – is now much more uncertain than before.

Besides these difficulties, population projections remain highly reliable due to the inertia that characterises most demographic trends. In 2021, twenty years after the most recent Albanian census, one may estimate that some 70% of the population in the country at that time must have been already present and counted. There would be few uncertainties about this large nucleus of the future population and in particular, we will know for sure the age of these persons since they will all be twenty years older since the time the census was carried out.

This is crucial because age is a basic indicator for the personal needs societies must try to satisfy. Children and adolescents must receive education through schools and teachers; young adults look for a job on the labour market, and then housing when they form couples and eventually families; the elderly need health professionals support and care provided by their kin, the state or private companies, etc. The anticipated number of young children will provide a precious indicator of the emphasis that should be given to school equipments. The forecasts on the number of active persons who reach retirement age will facilitate estimates about the funds needed for the pension system, etc.

Population projections offer a basic tool for social and economic planning. In the following pages, the user will find information on possible trends in the population of Albania till 2021, by sex, age and region. The method we have designed and the assumptions we have chosen are described in the first part, the main results are presented and analysed in the second part, whereas all the figures are published in the third part.

The future population of Albania is not described in a unique forecast that would give the false and comfortable feeling of certainty. A diversity of future trends is proposed, among which three will be given some priority. They reveal nearly inevitable trends of demographic growth and ageing, but their multiplicity reminds the reader that the future is still insecure.

1

Methods and assumptions

1.1 Methods of projection

The number of inhabitants is modified each year by population movements. Persons who die and those who emigrate all contribute to the reduction of the population whereas new-borns and immigrants lead towards its growth.

The number of deaths in a year depends simultaneously on population size and mortality risk. Exposed to similar health conditions, a larger population experiences more deaths than a smaller one. But sanitary conditions also play a part: deaths are more numerous when these conditions are bad rather than good. The very role of demographic analysis is to identify the impact of the two factors through the calculation of mortality risks: the ratio of the number of deaths to the number of inhabitants.

One calculates in the same way also the risk posed by emigration: the ratio of the number of emigrants to the number of inhabitants. By nature, these ratios are “independent from population size”. They can be compared from one country to another; they measure then differences in behaviours regarding emigration or the differences in health conditions.

In the case of births the situation is slightly trickier. What meaning could be given to the ratio of births to the population? Persons who are now living may die or emigrate next year;

Population projections are not a scientific exercise like all others. Our task is not to make a prediction for the future, but to assess the number of the population of Albania if certain assumptions are fulfilled. The methods of calculation are simple and robust. Demographic and socio-economic analyses are fundamental in the identification of the most likely assumptions but there are also some subjective guesses in this choice.

they will not be born next year. Turning around the difficulty, we may assume that women who deliver a child are (approximately) as numerous as the new-borns, then we relate the number of these women to number of all those likely to become pregnant (say women aged 15-50), calculating thus the fertility rates. Fertility rates are higher when women on an average have more children.

Similar difficulties result from immigrants: persons now present will not be newcomers next year. Dividing the number of migrants entering Tirana by the number of people already in the capital does not measure anything comparable to mortality risks or even fertility rates. Apart from this case, demographic analysis has identified the number of deaths and of emigrants out of the population size on one hand, and the rates or risks on the other.

Population projections put things upside down in order to calculate the future number of births,

deaths, and emigrants on the basis of information on the population size on the one hand and a prognosis of the rates or risks, on the other.

The question of migration needs a specific treatment: in Albania in the years to come, we will face the problem of internal migration, i.e. persons leaving one place for another one inside the country. We will make the simplifying assumption that emigrants from any district are immigrants in Durrës or Tirana districts and we will calculate the number of emigrants to get that of immigrants.

Calculations are conducted on an annual basis for the whole country (every five year for the regions), starting from the last census date, where the present population for the whole country is known disaggregated by districts, sex, age and, if needed, by a lot of other characteristics. For convenience's sake, the number of inhabitants has been calculated as of the 1st of January 2001 (by sex, age and district) to be the actual departure point. Afterwards it is moved forward in two steps:

1. The present population of each age (and sex) gets one year older and drops the persons that died and emigrated, according to the mortality and emigration rates ;
2. Newborn boys and girls in the current year are added, except for those who died or emigrated in their first year before the 1st of January 2002. They are calculated on the basis of fertility rates and the number of women in fertile ages on one hand and infant mortality and emigration rates, on the other.

In the districts of Durrës and Tirana, another step is undertaken adding the persons who have migrated from other districts of the country.

This two-step operation (three for Durrës and

Tirana) is repeated until the 1st of January 2021.

Projections have been prepared for the whole country and at the regional level. Districts are too many (36) and their population is too small for projections to be conducted at this level. We have constituted four groups of districts on the basis of their demographic dynamics from 1989 to 2001. We have relied on population growth between the two last censuses, the estimated flows of internal migration (from information on residential changes since the previous census) and indicators of fertility rates (from the ratios of the number of young children to that of mothers in reproductive ages). Neighboring districts have been chosen to delineate Northern, Southern and Central regions; Durrës and Tirana districts have been singled out from the Central region. The composition of the regions can be seen at the Table 1 page 14

In the North, fertility is higher than the average and internal emigration is massive. In the remaining part of the country, fertility is slightly below national average, slightly lower in the South than in the Centre; there is internal migration from the South, emigration to Durrës and Tirana and a balance between those who come and those who leave in the remaining part of the Centre. We have ignored emigration to foreign countries in the regional projections, because most of our knowledge of emigration in the 1990s - thanks to the last census – is probably irrelevant for the present and the future.

1.2 Assumptions on future levels and trends

The crucial point in the projection process is the prognosis on future mortality and emigration risks, as well as fertility rates.

We need to take into account age- and sex-specific mortality and emigration risks in order to obtain the future numbers of deaths and emigrants by age and sex and, and by subtracting from the initial population, the number of inhabitants still present at the end of the year, i.e. neither dead nor emigrated (in the case of regional projections, five-year age group coefficients instead annual ones are sufficient).

Fertility rates are classically calculated for women. Single years of age are not actually needed, since the details of future births by the age of mothers is not necessary, only the total and the gender distinction are the convenient tools.

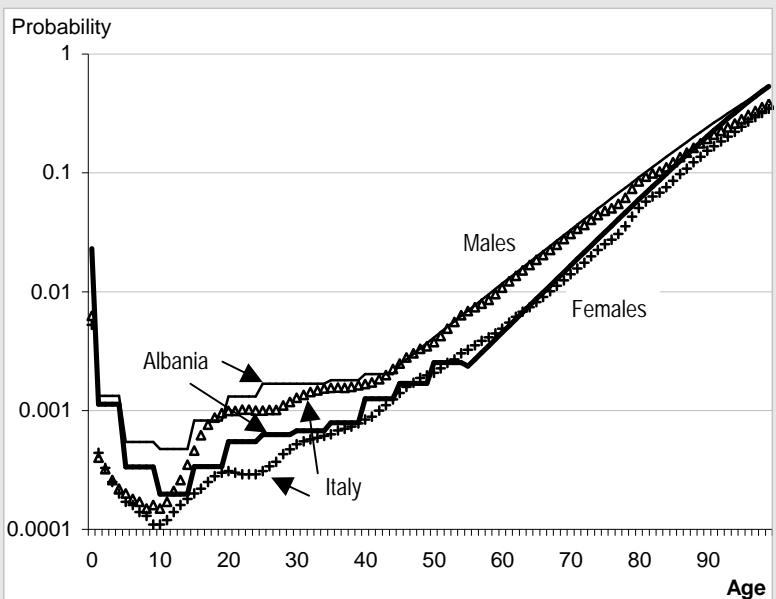

The basis for the prognosis on mortality, emigration and fertility are the recent indicators and, if possible, the trends of the last decades. Extrapolation into the future is guided by knowledge of the past, information from neighbouring countries ... and common sense.

1.2.1 Mortality

Mortality rates in 2000-2001 have been calculated for the whole country by sex and five-year age groups. Life expectancy at birth is 72.1 years (males) and 78.6 years (females).

At any age, the mortality rate is higher for males than females but the incidence of age is similar for both sexes. Mortality declines till the age of 10-14 and it rises continuously afterwards. Most mortality rates below the age of 40 are less than 1 per 1000; by age 80-84, they are 100 times higher, about 1 per 10. For a graphic representation of the rates to be readable, it is

Figure 1. Mortality probability by sex and age, Albania 2000-2001 & Italy 1997

necessary to use a logarithmic scale that magnifies the lower values and minimises the higher ones. On such a graphic, the risks at ages over 45 for men and 55 for women are on a straight line, in agreement with a "universal" observation whereas coefficients grow with age at a constant rate.

This result makes the Albanian data on higher ages more reliable. It is also open to the use of the convenient method of transforming five-year rates into single-year ones through interpolation.

Compared to the mortality rate in Italy (1997), the risks at each age starting from 45 are similar in the two countries. This confirms a result already evidenced by Arjan Gjonça on the mortality tables for previous periods: mortality at higher ages is as favourable in Albania as it is in other Mediterranean countries, despite a large gap in economic development. A major reason could be the type of diet shared by these countries, which seems to favour longevity.

Differences are concentrated in the lower ages, where mortality is higher in Albania than Italy.

Moreover, the validity of the data at younger ages is questionable. A recent survey in Albania points to 23 deaths out of 1000 new-borns before reaching the age of one, twice as high as results gained from the registration of live births. We have introduced the survey data into our calculations instead of the “official” one. We have differentiated infant mortality between boys and girls, in the line with the infant deaths registered in Albania for the years 1997-2001 resulting in the rates of 20 per thousand for girls and 26 for boys.

For younger children, mortality rates are four times higher in Albania than in Italy (infant mortality in Italy is 5 per 1000 new-born girls and 6 per 1000 new-born boys, against an estimate of 20 and 26 per 1000 in Albania). With age increasing, the relative gap between the two countries diminishes and disappears around the age of 45.

For the future, our first assumption (HM: higher mortality) is that mortality risks in Albania, already very favourable, will remain constant till 2021. In the second one (LM: lower mortality), we assume that the present gap with Italy will disappear in two decades from 2001-2005 to 2021-2025, so that by the latter period the Albanian mortality rate will have reached the present Italian level. Two thirds of the gaps are supposed to be filled in the first decade and the remaining third in the second one.

For instance, infant mortality will be halved from 2001-2005 to 2011-2016 (from 23 to 11 p. 1000) and again from 2011-2015 to 2021-2025 (from 11 to 6 p.100). Changes over 45 years are limited since mortality rates in Albania and in Italy are not very different. The future mortality rates (whole country) are found in table 6.

Mortality in the districts has not been documented so far. We have considered that these rates are similar in the four regions, without any harmful consequences for the accuracy of the projections. Mortality tables used in the regional projections are found in table 7; they are

but an abridged version of those used on a national level.

1.2.2 Fertility

Age-specific fertility rates are summarized by their total, which indicates the average number of live born children women would have if they all remained alive in the country till the end of their fertile ages (i.e. from age 15 to 50).

In the most recent period (2001), fertility rate is as low as 2.31 children per woman. The decline has been remarkable since 1960 where levels were as high as 6.85 children per woman. Decrease has maintained a rapid pace in the last decade: from the mid 90s to 2001, fertility rate, though already moderate, has dropped by 12%.

During its transition from high to low levels, fertility rate has diminished at all ages, the steeper the decline, the higher the mothers’age. Fertility rate at ages 40-44 has declined by 95% from 1960 to 2001; at ages 25-29, the drop has “only” been by half. It is a classical pattern during this stage: the largest families, with last children born late, being affected first, before the movement extends to medium- then small-sized families.

The countries that are more advanced on their way towards lower fertility like neighboring Macedonia with 1.89 children per woman in 2001, exhibit prolonged similar trends. Rates at 40-44 years are 50% below those in Albania, while those at 25-29 years are “only” 10% less. The same mechanism is still at work (Figure 2).

If we extend the overview of fertility trends and levels to the whole Europe, we can see more clearly the peculiarities of the Albanian situation. Total fertility rate in 2001 (2.31 births per woman) is the highest on the continent, with only Iceland having an over 2-birth threshold. But Albania is also the country with the most

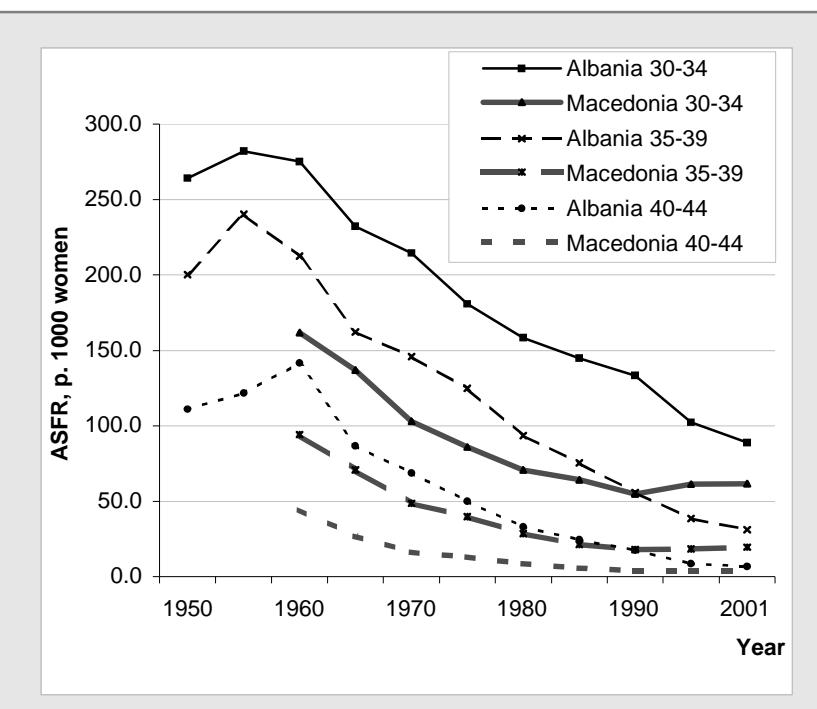

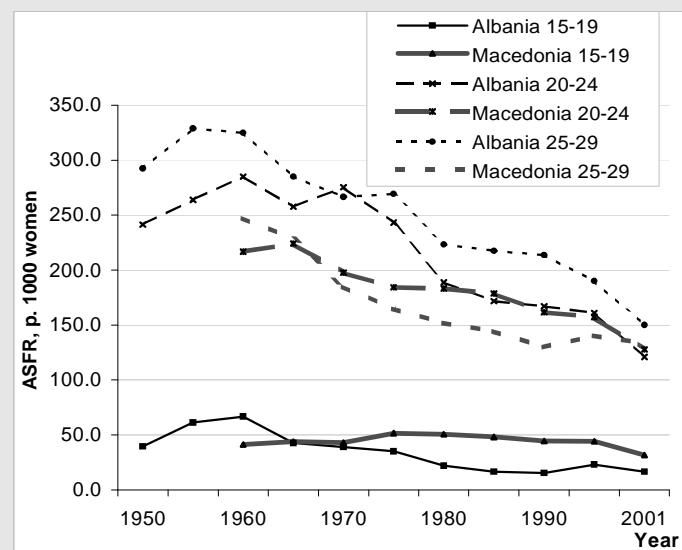

rapid fertility decline in the last decades, together with a few newly independent countries in Caucasus like Azerbaijan. Given the still relatively high fertility rate in the country and the pace of the ongoing decline, there is hardly any doubt that fertility in Albania will go on decreasing in the future decades. The open question is that related to the depth and speed of the decline in the coming years.

The fertility rate decline in Western Europe since the 1960s has been paralleled by major transformations in family formation (later marriages, more divorces, development of informal unions). This complex process has been referred to changes in values (individualization, secularization, increased education), which include changes in the gender roles. In Eastern Europe after the collapse of communism, fertility rate has decreased dramatically, a phenomenon which some researchers explain by similar mechanisms and others by the material difficulties experienced during the transition to market economies.

At the junction of the two movements, Albania and the Balkans are surrounded by some of the countries with the lowest fertility rates like Italy in the West or Bulgaria in the East, with less than 1.3 births per woman.

The uncertainty about future fertility trends is great, considering the still relatively high level of fertility in Albania by European standards, and the forces in the region, which account for very low fertility rates. **In the projections for the whole country, we assume that fertility will go on declining linearly in the next two decades towards averages as high as 1.8 or as low as 1.4 alive born children per woman in 2021.** Rates are supposed to be distributed by mothers' age as in 2001. For convenience, single years of age are used in the national projections. The resulting estimates of fertility rates to be used in the national projections are provided in Table 8 and 9.

Figure 2. Age specific fertility rates

Fertility rates differ according to regions. The last census offered a good basis for an estimate of fertility by district in the five preceding years. The average for the whole country was 2.47 children per woman and the results in the Centre (including Tirana and Durrës) were not much different (2.42). Fertility rate was much higher in the North (3.26) and low the South (2.28) (Table 1). **We assume that national fertility will tend to be 1.8 births per woman and that the relative levels in the three groups will**

Methods and assumptions

Note: The total fertility rate estimate for the country in 1995-2001 has been distributed by district and region proportionally to the child-woman ratios in 2001.

not be altered, with proportional declines throughout the country. The future fertility rates for the regions are found in Table 10.

1.2.3 Migration

In the 1990s, Albania experienced two radically new phenomena: a massive emigration to foreign countries and an intense migration between the districts. Both of them were documented by census data, though only indirectly for the former, which led to the non-enumeration of absent persons. In this case, an estimate must be made of persons that would have been enumerated in Albania if no external migration had occurred (i.e. if the population of the country had only been affected by mortality and fertility), this hypothetical population being compared to the actual one for the purpose of estimating emigration. The estimate is global, covering the whole period of calculation: in Albania, it is the period 1989-2001 between the two censuses.

It is much simpler in the case of internal migration, since persons who have left a district for another can be identified, traced in their new district and numbered. In Albania, two such calculations have been made in the case of those who have moved since the previous census (1989-2001) and those who migrated in the year preceding the census (2000-2001).

External migrants have been estimated to be some 0.6 million in twelve years, i.e. some 50,000 per year, but with important changes from year to year. After a peak in the late 90s, emigration is said to have declined, but little or nothing is known about its present level.

For the purpose of projections, we make two assumptions: in the future, external migration will be null or about 15,000 emigrants per year. For convenience, we reformulate the latter: 0.5 per cent of the population will emigrate each year, i.e. some 15,000 emigrants when the number of inhabitants is about 3 mil-

lion, like in 2001, slightly more or slightly less, depending on future population trends.

For various reasons, it could be considered unrealistic to imagine a zero emigration in future Albania. Nevertheless, we have considered important to fully develop a scenario without emigration, because it is highly relevant for policy makers. If these people wish to prevent Albania being population-drained, they must know how many adults will need a job in the years to come, how many children will need a school, etc. This is precisely what a no migration population projection will reveal.

Sex and age distribution of the future migrants is equally difficult to guess in the absence of recent data on out-flows. We may rely on two pieces of information, partly contradictory. Emigrants during the decade of political, economic and financial turmoil were predominantly young adults, males more than females, together with their young children, if any. The year before the last census (2000-2001), internal migrants were almost equally balanced between males and females and between the various age groups (see just below). On the basis of these two observations, we have made two assumptions concerning the future out-migrations:

- a neutral one, where future emigrants are distributed by sex and age the way the whole population is. In practice the 0.5 per cent assumption concerning the total number of emigrants will also be valid for male and female emigrants of each age. It will be our reference assumption, but an eye will be kept on a second one to appreciate a possible impact of emigration on age structure;

- an age and sex specific assumption, adult emigration being limited to the 20-49 age bracket, with a dominance of the youngest adults over older ones and a dominance of males over females. Emigration of children is supposed to be associated to that of their mothers. In practice the 0.5% assumption concern-

| 0-9 years | 0.70% | 0.70% |
| 10-19 years | 0.30% | 0.30% |
| 20-29 years | 1.50% | 0.90% |
| 30-39 years | 0.75% | 0.45% |
| 40-49 years | 0.40% | 0.25% |
| 50+ years | 0.00% | 0.00% |

ern zone had lost 2.1 % of its inhabitants who had settled elsewhere in Albania. It was three times less in the South (0.7%) and hardly perceptible in the Centre (0.2%, without Tirana and Durrës). On the contrary, the Tirana and Durrës districts had gained more than 16,000 inhabitants. (Tables 3 and 4)

In the twelve years between the two censuses, the total flows were of course more intense, due to the length of the period, but the ranking of the regions was similar: heavy losses in the North, moderate in the South and very limited in the Centre; important gains in Tirana and Durrës. There is much stability in the orientation of the flows.

For the future, we assume that probabilities to leave each of the three regions will remain at their most recent level (2000-2001). Losses in the three regions will result in equal numbers of inhabitants gained in Tirana and Durrës.

The departures from the three regions in 2000-2001 were well balanced between men and women. More surprisingly, probabilities of departure were almost equal at all ages, at least till 60 years; they were only slightly less at older ages. Migration was of a family type, with departures not of individuals, but of larger groups: parents with children and their own parents (Table 5).

Simplicity and reality being in agreement, we assume that probabilities of internal emigration measured in 2000-2001 in each region (2.1% in the North, 0.7 in the South and 0.2% in the Centre) are equally valid for men and women and for each age.

Internal migration only affects the regional balance of the population in Albania; it has no impact on the total population of the country and it is not included in population projections for the whole country. But the reverse is not true for external migration, which affects the total population and which may have a differential impact on the various regions. In the nineties, massive emigration to foreign countries hit the South more than the North.

We have no such information for the current flows that could be extended into the future. **Consequently, projections in the region combine an assumption of internal migration maintained at its 2000-2001 level and no external migration. The assumption of some 15,000 out migrants is not taken into consideration at regional level.**

1.3 Sets of population projections

At national level, there are two mortality rate assumptions (mortality rates remain constant at their 2000-2001 level, or decline slowly towards more favorable figures); they are combined with two fertility assumptions (fertility decreases to 1.8 or 1.4 alive born children per woman) and two external migration assumptions (migrants each year are zero or 0.5% of the population).

It results in eight sets of projections, which combine constant mortality risks (1) or declining ones (2) with:

- a) Relatively low fertility (1.4 children) and no emigration; b) Relatively low fertility and 0.5% emigration; c) Relatively high fertility (1.8 children) and no emigration abroad; d) Relatively high fertility and 0.5% emigration.

At the regional level, the mortality assumption is unique and the same for the different regions (mortality rates are constant at their 2000-2001 level and similar to the ones in the national projection). There is one fertility assumption with national rates declining to 1.8 births per woman, but introducing regional differentiation. There is one migration assumption combining no emigration abroad and internal migration, reproducing the 2000-2001 patterns. It results in a single set of projections

Table 5. Emigration rates per region in 2000-2001, by age in 2001

| Region | Age groups | | | |
|--------|------------|-------------|-------------|-----------|
| | 0-14 years | 15-39 years | 40-59 years | 60+ years |
| North | 2.23% | 2.06% | 2.04% | 1.50% |
| Centre | 0.16% | 0.21% | 0.26% | 0.20% |
| South | 0.75% | 0.74% | 0.75% | 0.57% |

*) Tirana and Durrës districts excluded

National projections provide details by sex and single year of age for each year. In the regional projections, the results are issued every five years and sex and five-years age groups classify the population.

The key issue is the choice of assumptions, based on the analysis of past trends in mortality, fertility and migration rates and their extension into the future. We have summarized here the choices we have made for the national and regional projections. We have avoided the resort to a single hypothesis, which could be interpreted as a certainty about the future. Other assumptions can be envisaged if some users wish so or if new information on mortality, fertility or migration trends identify unexpected paths and require the revisions of the calculations during the period of projection. The flexibility of the engine we have designed makes it

1.4 Conclusion

Population projections are the result of a rather mechanical procedure, which has been briefly described in the first pages of this part and which we have put in an Excel format for an easy semi-automatic manipulation by the people in charge of running the projections.

2

Main results and analysis

2.1 Total population and its growth (2001-2021)

2.1.1 *The Albanian population in 2021*

The projections point to an **increase in the size of the Albanian population in the twenty years to come**, whatever the set of assumptions (Table 12). It will contrast with the recent past where population declined for the first time since World War II.

After decades of sustained growth, the total number of inhabitants in Albania has been reduced by 113,000 in the period between the last two censuses in 1989 and 2001. The main factor for this inflexion has been heavy external migration, which probably exceeded 600,000 persons, especially after 1995. It is highly likely that several consecutive years in this period registered substantial population decreases. Continuous fertility decline since the 1960s has been a subsidiary factor for a slow down in demographic growth, with rates as low as 2.3 births per woman in 2001, three times less than forty years before.

The eight sets of population projections we have developed till 2021, through a combination of assumptions on future trends in mi-

gration, fertility and mortality, all point to a resumption of population growth. In a twenty year interval, the total number of inhabitants would raise from 3,063,000 to at least 3,221,000 or at most 3,702,000. The total increase would be not less than + 158,000 and not more than + 659,000.

Population growth would be minimal if a major flow of external migration were maintained, if fertility declined to very low levels, and if mortality rate did not increase. In that case, the Albanian population in 2021 would hardly be more than in 1989 and probably even less than in 1995, before the massive departure of emigrants. On the contrary, if external migration stopped, if fertility decline were limited and if mortality experienced better rates, the Albanian population in 2001 would reach its highest historical level, over 3.7 million. Nevertheless, even in this case, population growth in the next two decades would be less than in some periods in the past: for instance, in ten years from 1969 to 1979 and again from 1979 to 1989, the number of inhabitants increased by more than half a million, a total of 1.1 million in twenty years.

2.1.2 The role of emigration, fertility and mortality

There is a large gap between the various sets of projections (Figure 3). Select comparisons two by two reveal the impact of the different factors of population growth: external migration, fertility, and mortality. **External migration has the most decisive incidence, the magnitude of fertility decline comes second, and mortality has but a secondary importance.**

If fertility were to decline slowly and if mortality declined, over the next twenty years, the population in 2021 would be 3,727,000 provided there is no migration, and only 3,371,000 if half per cent of the Albanians left the country every year. The difference ($356,000 = 3,727,000 - 3,371,000$) measures the numerical influence of migration on the future development of the population in the country. Slightly different outcomes are obtained if we make other com-

parisons (e.g. 339,000, if we compare the results of projections without and with migration, when fertility rate declines at a fast pace and mortality gain is null), but the order of magnitude is similar: a 350,000 difference in the number of inhabitants in 2021 is attached to the importance of migration flows in the next two decades.

Provided there is no migration and no changes in the mortality rates, the population in 2021 would be 3,711,000 if fertility declined slowly to 1.8 children per woman a year, but only 3,555,000, if it declined much more rapidly to 1.4 children. The difference (156,000) measures the numerical influence of fertility on the future development of the population in the country. Other comparisons give slightly different results, but the order of magnitude is about 150,000, less than half that attached to external migration.

Figure 3. Albania population projections.
Total population according to various assumptions

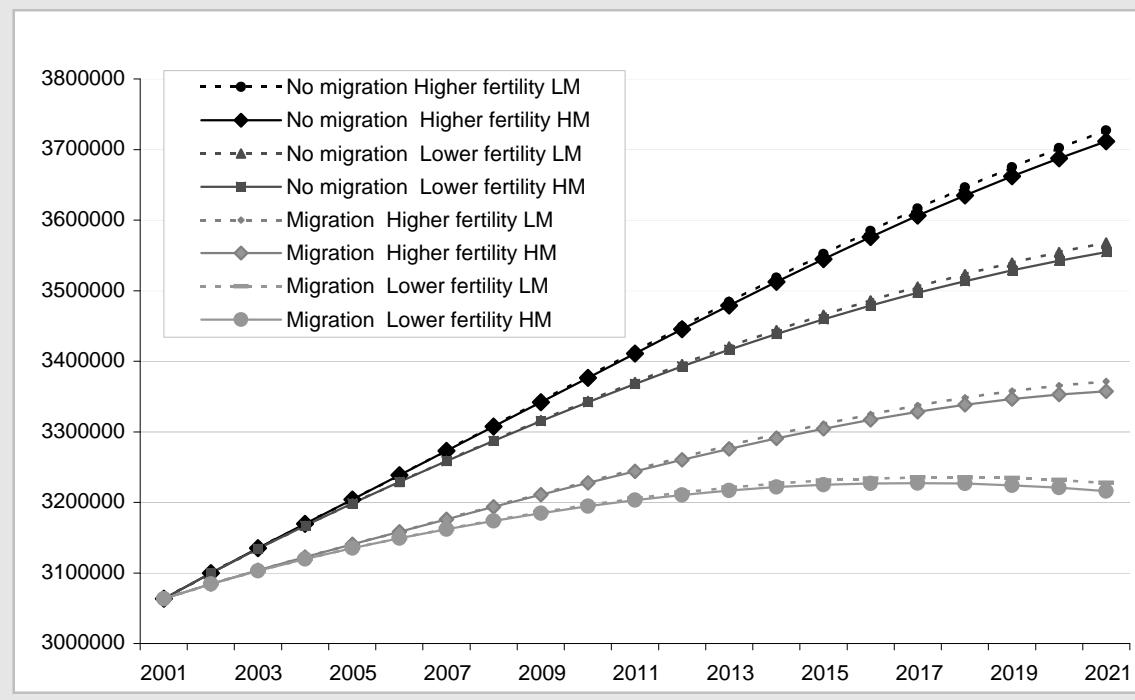

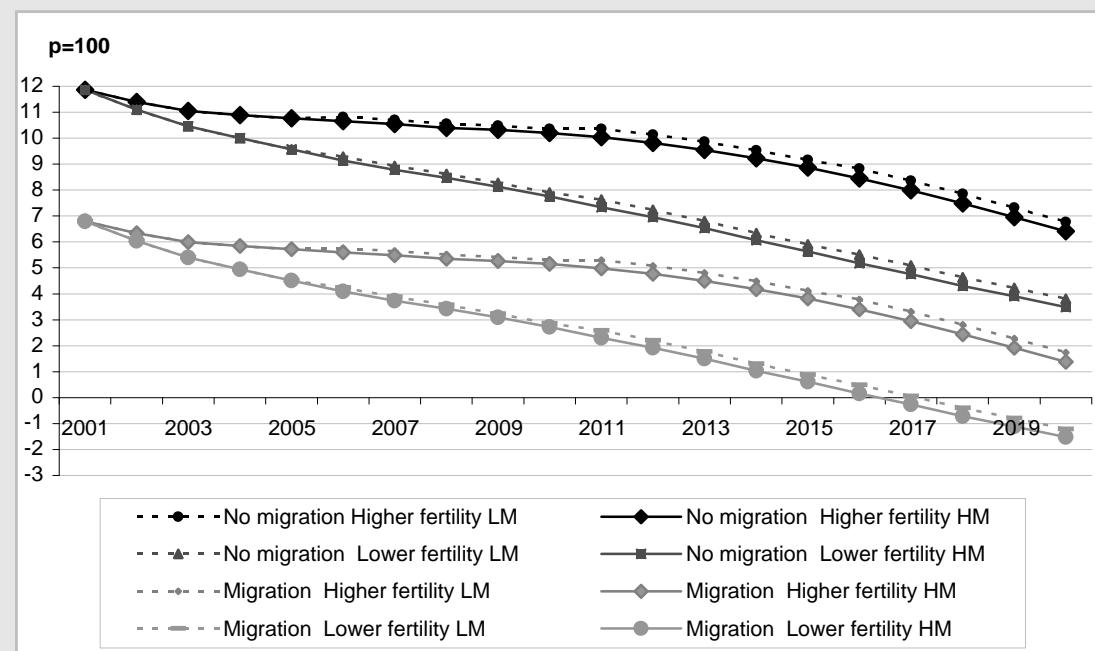

Figure 4. Albania population projections.
Annual growth rates according to various assumptions

Measured in the same way, the incidence of mortality assumptions proves to be minimal. Depending on whether there will be decreases or not in the mortality rates, the number of inhabitants in 2021 will not differ by more than 15,000, namely, ten times less than the influence of fertility assumptions and more than twenty times less than that of migration. We will confirm it with other results, but the practical conclusion is that the sets of population projections can be brought down from eight to four, disregarding the differences between projection with and without changes in the mortality rates in the twenty years to come.

2.1.3 Population growth and its factors

The annual rates of the population growth progressively slowed down from 2.9 per 100 in the 1950s to 2.1 in the eighties, before the drastic collapse at the turn of the millennium.

Future rates will be globally positive again, but at a lesser extent than before. They will decline along with time, reaching very low and even negative levels by the end of the twenty year period, in some sets of assumptions (Figure 4).

With a slowly declining fertility and no migration (whatever the assumptions on mortality), the annual rate of population growth will decrease progressively, while remaining slightly above 1 per 100 in the first decade. It will decline much more rapidly in the second half of the projection period, falling below 0.7 per 100 in 2020. Reference must be made to the age pyramid at the 2001 census to explain this two-phase process: adolescents aged 10 to 15 were relatively numerous compared to younger children and to adults in their twenties and thirties, because both of these groups had been severely affected by emigration, young parents having left the country with their small children in much larger numbers than

older parents with their grown up children. In the initial years of the new millennium, these adolescents will reach fertile ages and their relatively large number will partly compensate for the ongoing slow fertility decline; in later years, newcomers in fertile ages will originate from the more recent cohorts born after 1990, who are much less in numbers, because of low fertility and emigration of small children in the nineties.

When assumptions point to a much more rapid decline in fertility rates and to no migration, compensation by this structural effect is no longer strong enough: annual growth rates will drop continuously, almost linearly from 1.2 per 100 in 2001 to 0.4 in 2020. This last year, the difference between the results of the two sets of assumptions ($0.3\% = 0.7 - 0.4$) measures the impact of fertility levels on annual growth rate, depending on whether fertility by the end of the projections will be 1.8 or 1.4 births per woman.

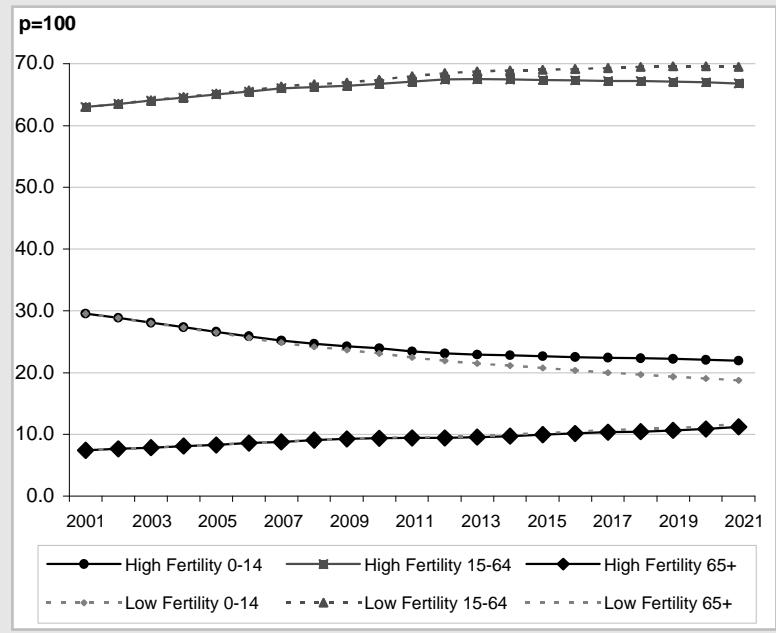

If external migration is supposed to be 0.5 per cent of the total population each year instead of zero, the annual growth rate is reduced at the same rate all along the projection period, without any noticeable change in the shape of the time trend. With a relatively slow fertility decline, population growth will be maintained above 0.5 per cent in the first decade, before declining to 0.2 per cent. By the end of the period, annual population growth would be brought close to zero.

It would be still more spectacular if fertility was to decline more steeply. A continuous and rapid slowing down in population growth rate would result in negative values from 2018 on and a minus 0.1 per cent in 2020. Population in Albania would reach a maximum about 3,230,000 inhabitants (slightly more or slightly less, depending on mortality trends), before starting its decline. It would only be 50,000 more than in 1989 and probably less than in 1995.

2.1.4 Population and its future growth: an overview

In brief, the population of Albania, which was 3.07 million during the last census, will increase by 10% by 2010, if there is no emigration and if fertility declines moderately. It will take one or two years more if fertility decreases more steeply (migration remaining null). The 10% landmark will only be reached by the very end of the twenty-year period of the projection, in case of substantial emigration (and slow fertility decline). It will never be reached if emigration and low fertility combine their effect and both contribute to a limitation of demographic growth: the number of the Albanian population will peak at 5% over the census result.

Figure 5. Albania population projections.
Age structure according to various assumptions

2.2 Population by age

2.2.1 Population in large age groups

Compared to the rest of Europe, the **Albanian population is “young,”** with relatively high proportion of persons below 15 years and low proportions of elderly, aged 65 or more. In the next twenty years, this characteristic will disappear slowly. **The weight of the younger population will decline notably and that of persons in the oldest bracket will increase progressively.**

In 2001, 29.5% of the Albanians were children under the age of 15. In France the same year, the percentage was only 18.8%. These indicators are reversed at the age of 65 or more (Albania: 7.4%; France: 16.1%). This is the result of very different histories in the two populations, essentially in the field of fertility: in 1960, Albanian women still had an average of 7 children, who are now reduced to 2.3; France made its transition to low fertility two centuries earlier and since then has experienced numerous decades of fertility as low as, or

lower than Albania today.

In the next twenty years, the percentage of young children in Albania will substantially decrease to 21.9% if fertility declines moderately and to 18.7% if the movement is accentuated. Note that in the latter case, the level will be similar to that in France. Under both assumptions, the reduction is spectacular: a little less or slightly more than one third. Changes are in the opposite direction at older ages, the proportion of 65+ tending to 11.2 (higher fertility) or 11.7% (lower fertility) in 2021. Note that the results remain a long way from France and differ little according to fertility assumptions.

The Albanian population will continue to age in the next two decades. Compared to European standards, its proportion of children will become as weak as it is already in many countries, but it will keep a relatively low proportion of the elderly. It is a cohort (generations) mechanism: it takes more time for the process of ageing to reach the older ages than to affect the youngest ones. Over a longer term, more ageing is still to be expected, especially

through an increase in the share of the elderly people.

It is no surprise that changes in age structure are the more pronounced the steeper the decline in fertility. On the contrary, no effect is attached to future changes in mortality: gains in survival have been supposed to be spread all over the life span. The situation is slightly different from that in the most advanced Western European countries where progresses are almost exclusively concentrated on older ages; in Albania gains are expected to happen at younger ages (especially infant mortality), the most favourable life tables. Even out-migration is not to have an effect, while it is supposed to affect all ages (neutral assumption) as it has already happened with the recent trends of internal movements of population. It would be slightly different if emigrants proved to be mostly young adults with their young children: ageing would be accentuated with an increase in the proportion aged 65+, which would reach 13.0% in 2021 (low fertility), proportions aged 0-14 and 15-69 being reduced by a few decimal points (see the detailed results in the appendix)..

2.2.2 Age pyramids

The population distribution by sex and age, as illustrated by the age pyramids, gives a more suggestive image of the factors in operation in the next twenty years (see below). By 2021, the children born during the projection period as a result of the fertility assumptions will all be under the age of 20. They form the basis of the pyramids. Persons already present in 2001 in the census data will be above 20; since the census, each and everyone will have aged by twenty years and each group of individuals will have lost some of its members by death or emigration.

The various assumptions concerning mortal-

ity have so tiny an effect that the pyramids do not reflect them. We have limited the representation to a single set of mortality assumptions (HM: higher mortality), when the most recent Albanian life table is supposed to continuously apply in the future, without progressing at any age (Figure 6).

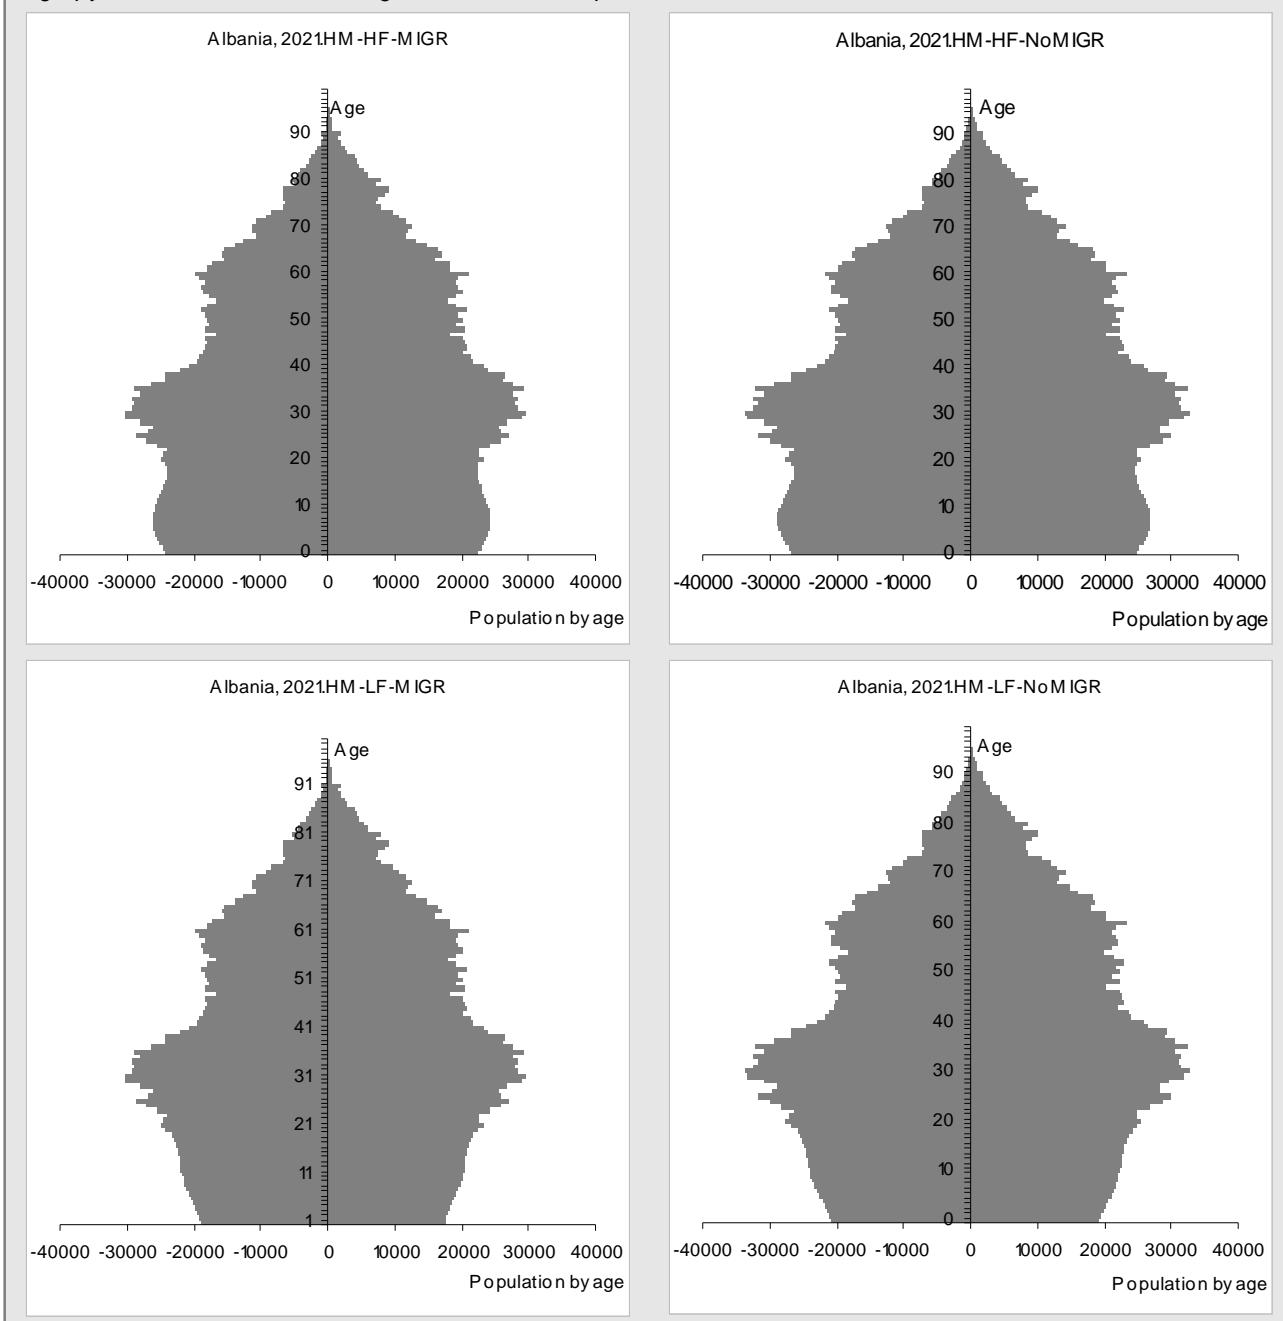

The effect of migration is more easily perceptible despite being limited. The right pyramids reflect projections conducted without migration (NoM); the left ones projections assuming that half a percent of the Albanian population (i.e. some 15,000 persons or more) will leave the country every year (Migr). The difference is not in the shape of the pyramids, but in their **volume**: population at each age is greater in number in the absence of migration, but the excess is proportionate to the numbers.

In case emigration would be differentiated by age and sex, the most visible impact would be the numerical dominance of men over women among young adults (not represented here, but detailed results in the appendix).

Fertility plays a decisive role. Due to its decline, whatever the depth and speed, the number of young children born after 2000 will be smaller than the number of adults born a few years before. When fertility is supposed to decline slowly, the number of these children is little different from age to age; it is slightly more between the age of 5 and 10 and slightly less below 5 and above 10. It is an echo of the relatively high number of persons enumerated in 2001 when they were aged 10 to 15, who will be in age of parenthood in the early 2010s. When fertility is supposed to decline deeply and rapidly, this effect is no longer visible: the number of children declines continuously and the younger are the less numerous. **The basis of the pyramid becomes narrower and narrower.**

Figure 6. Albania population projections.

Age pyramids in 2021 according to various assumptions

In all cases, the shape of the Albanian pyramid will become more and more **uneven**. Compared to older and more recent cohorts, there is a deficit in the number of people born in the seventies, because of the massive flows of emigrants in the second half of the 1990s. They were young adults at the time of the census; they will grow in age all along the projection period. More recent and much larger cohorts born in the eighties and the nineties, little affected by emigration, will replace them

in young adulthood. But the future generations will be deficient in their turn, no longer because of migration but because of low fertility.

These irregularities could create ups and downs in the supply of labor force, in the demand for new housing or in the need for education, which the population projections will help to identify and anticipate.

2.2.3 Age-related specific issues

In 2001, there were 59000 children aged 6 who, due to their age, had just entered the schooling system and who, in the future, will continue to stay in the system through the primary and then the secondary level. Whereas in 2002, there were 62000 of them. The global impact on the system will depend as well on the initial number (59000 and 62000) as on the duration of the curriculum (8 years? 9 years? Or more?). The projections inform us on the former but of course not on the latter. (Figure 7)

The future number of new pupils will first be determined by the number of children aged 5, 4, 3, etc. in 2001, who will progressively enter school in the first years of the projection. In the subsequent period, the numbers will be affected by the fertility assumptions, new pupils reflecting the new births of six years before. Migration plays also a role, the number of children being minimised in case of substantial out-migration, either because the number of births is reduced or because the number of children who are still in the country is diminished.

The number of new pupils will decline till 2005 to 52000 (no migration) or 51000 (migration). It will then slowly rise till the end of the period of projection, only if fertility declines but slowly and if nobody emigrates. Even under these assumptions the numbers will culminate at 56000, well below the 2001-2002 figures. The culminating point will be reduced to 51000 in case of emigration. (Figure 7)

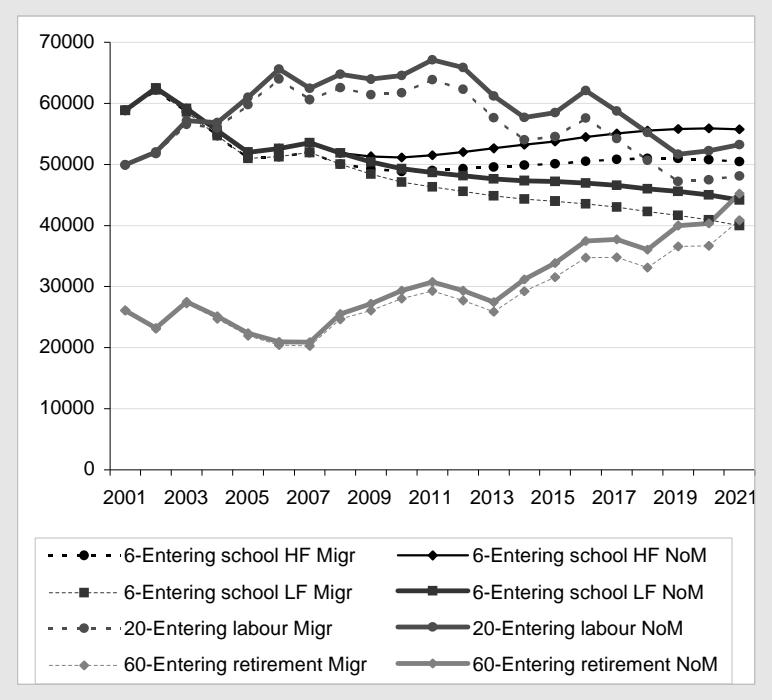

If fertility declines more steeply, the number of new pupils will decline all along the projection period to levels as low as 44,000 (no migration) or even 40,000 (migration). It would be a reduction by at least 30% compared to the initial years of the Millennium.

Age 20 is a less formal barrier for **entry into the labour force**, but the number of persons at that age gives an idea of **the dynamics of the active population**, especially if it is combined with information on those who leave the labour force around the age of retirement.

The persons who will reach 20 years during the period of projection have all been born already. Their numbers are only affected by the assumptions of migration; migration (with a slight accentuation if emigration is concentrated among the young adults, see the appendix); there is almost no impact of differentials on mortality. Year to year fluctuations are in fact an echo of the variations in the number of persons enumerated in 2001 age by age below 20.

The number is 50,000 in 2001. It will raise to 65,000 in the five following years (a 30% increase) and will remain on a plateau during seven years, before a progressive decline that will bring it back to the initial figure by the end of the period of projection (slightly less in case of migration; slightly more in its absence). These ups and downs directly reflect changes in the size of cohorts when we go down along the age scale on the pyramid drawn with the last census data: more persons between 10

Figure 7. Albania population projections.
Population at selected ages, according to various assumptions

and 15, who will enter the labour force in the next 2006-2011 period, than at older and younger ages.

At the other end of the active ages, the number of persons aged 60 gives an idea on the **departure from activity** and the **entry into retirement**. Here again, only the migration assumptions have an impact. The decisive factor is the size of the cohorts aged 40 to 60 in 2001, which will put an end to their activity in the years to come.

They will be some 25,000 each year in the beginning of the period and the figure will gradually increase from year 2008 to the end of the projection period. On this horizon, they will be at least 40,000 (in case of "neutral" migration) or even 45000 (in absence of emigration or if migration is concentrated on young adults).

In the first decade of the projection, entries in active ages each year will exceed exits by at least 30,000. In the second decade, there will be fewer and fewer newcomers together with more and more new retirees. The excess of the former on the latter will decrease rapidly and fall to 8000. The dynamics of the active population will severely slow down. At the same time the group of pensioners, aged 60 or more will receive rapidly growing flows of new entrants, who will increase dramatically the group of the elderly.

2.2.4 An overview of the future age composition

Various signs of an **inevitable ageing** will develop in the near future in Albania. The group of young children will be reduced and so will the number of pupils, especially if fertility declines steeply. The elderly will grow in numbers and in proportions, even if their percentage in the total population will remain moderate by European standards. As it is usual at this phase of the process, the number of per-

sons in the large intermediate age group, where most are economically active, will be inflated for a while but that movement will progressively slow down.

Over the longer term, an accentuated ageing is to be anticipated that will affect all the segments of the age pyramid: fewer children, more elderly and an ageing of the active population.

2.3 Population in the regions

2.3.1 Total population and population growth

The regional distribution of the Albanian population will be dramatically modified in the next two decades if the present flows of internal migration are maintained at their present level all over the period. Tirana and Durrës districts will attract almost the entire demographic growth, while population in the rest of the country will stagnate or increase very slightly.

A single population projection has been conducted, which maintains fertility differentials between the regions, as they could be measured at the turn of the century, and flows of internal migration as measured in 2000-2001 (mortality is supposed not to change, fertility declines slowly and external migration is assumed to be null). Nevertheless, a reference calculation has established how population in the regions would tend to be if internal migration was interrupted. The only ambition is to illustrate the importance taken by these movements of persons in the future population changes.

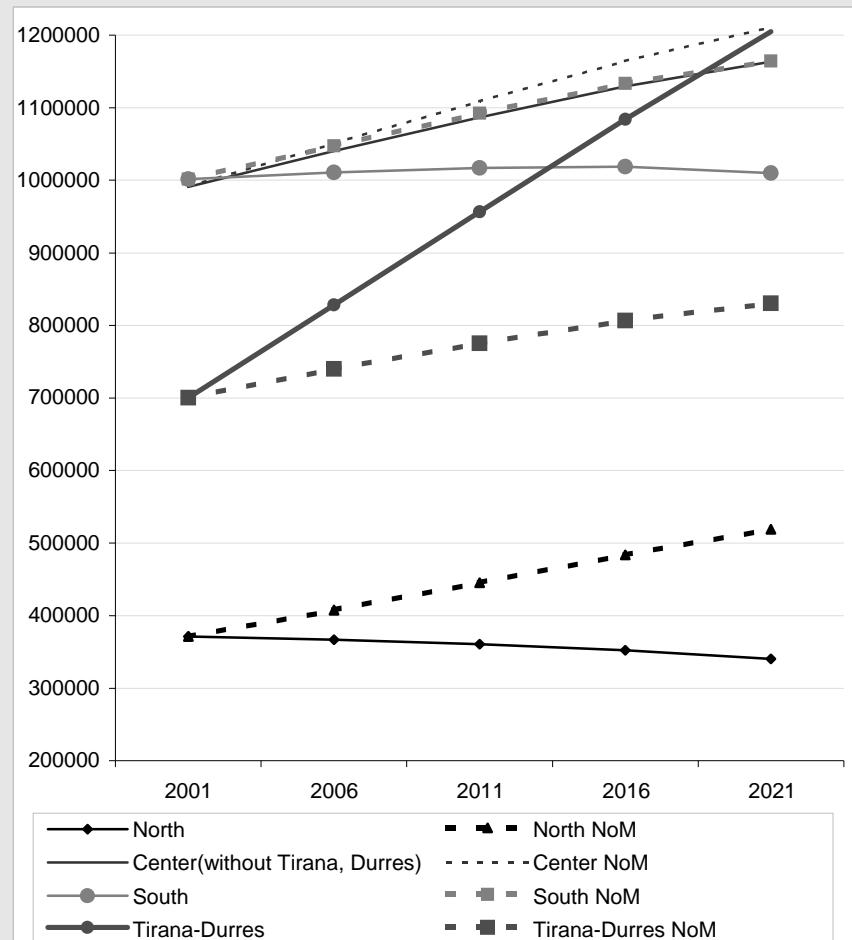

Population in Tirana and Durrës districts would grow from 700,000 to 1,200,000 in twenty years. This 70% increase is to be essentially attributed to the settlement of immigrants origi-

Table 13. Regions of Albania population projections.
Total population every five year and relative distribution in the country

| TOTAL POPULATION (1 st January) | | | | | | | | |
|--|---------|--------|--------------------|--------|---------|--------|---------------|--------|
| Region | North | | Centre (excl. T-D) | | South | | Tirana-Durrës | |
| Years | Numbers | % | Numbers | % | Numbers | % | Numbers | % |
| 2001 | 371396 | 12.10% | 990641 | 32.30% | 1001264 | 32.70% | 700017 | 22.90% |
| 2006 | 366759 | 11.30% | 1040137 | 32.00% | 1010720 | 31.10% | 828120 | 25.50% |
| 2011 | 360546 | 10.50% | 1086544 | 31.80% | 1016994 | 29.70% | 956393 | 28.00% |
| 2016 | 352254 | 9.80% | 1129517 | 31.50% | 1018386 | 28.40% | 1083997 | 30.20% |
| 2021 | 340564 | 9.20% | 1163330 | 31.30% | 1009740 | 27.20% | 1205074 | 32.40% |

Figure 8: Regions of Albania population projections,
Total population according to various migration assumptions

nated from the rest of the country: in the absence of these inflows, population in the two districts would only be 830,000 in 2021. (Figure 8 and Table 13)

Populations in the South and in the Centre (Tirana and Durres excluded) were around 1 million in 2001. In the absence of internal migration, both would grow to 1.2 million slightly less in the South and slightly more in the Centre, due to a somewhat lower fertility in the former region. Anyway, the difference between the two would remain very small because the gap in fertility is very limited too. Internal migration will introduce a more substantial disparity: population growth in the South will be almost entirely non existent with the total number remaining around 1 million, but not in the Centre though, where migration flows are meager and where population would come close to 1.2 million in 2021.

In the North, the natural movement would lead into towards a substantial population increase, due to a still high fertility. In the absence of any migration, the number of inhabitants would increase by 40% from 370,000 to 520,000 in twenty years' time. But it is also the region with the most sizeable emigration compared to the rest of the country. If maintained at its most recent level, this migration will more than counterbalance the effect of high fertility and will result in population decline to 340,000 in 2021.

The percentage of population in Tirana and Durrës districts would notably increase, from less than a quarter to almost a third of the population of the whole country. The relative importance of each of the other three regions would decline: little in the Centre, but substantially in the South and even more so in the North. More than ever, the Albanian population would be concentrated in the central part of the country.

2.3.2 Population by age

Age structure in the regions will show a shift towards ageing that will characterise the whole country. Where fertility is higher (North), population will remain younger; where it is lower (South), ageing will be greater. But migration will not impact on the age structures the way it will do on population growth, creating thus a large gap between Tirana-Durrës and the rest of the country.

Differences in the age composition of the population enumerated in the regions in 2001 essentially reflected differences in past and present fertility levels. With much higher than average fertility, the northern region had a higher proportion of children and a lower proportion of elderly. The South not only had the lowest fertility rates, but also the longest history of low fertility: smaller proportions in population below the age of 15 were combined with relatively high proportions of persons aged 65+. (Figure 9 and Table 14)

Fertility will continue to decline everywhere and so will do the ageing process. However, the indicators for the northern region will remain far from the rest of the country, if no acceleration in fertility decrease brings regional behaviours closer to the national average. After twenty years of further fertility decline, its age pyramid will go on having a rather large basis at very young ages. The shape will be clearly different in the rest of the country, with narrower bases and more uneven pyramids, due to the stronger impact of external migration in the 1990s. The South and Tirana-Durrës will also experience a substantial increase in the proportion of old-aged persons, but the movement will still be moderate under the general assumption of a slow decline in fertility throughout the country.

Internal migration has been supposed to be equally distributed along the ages, in proportion to the population, as it proved to be in the recent past. The hypothesis implies that migration, whatever its intensity, will have no effect over the age structure of the regional popu-

Figure 9. Regions of Albania population projections.
Proportional age pyramids in 2001 and 2021

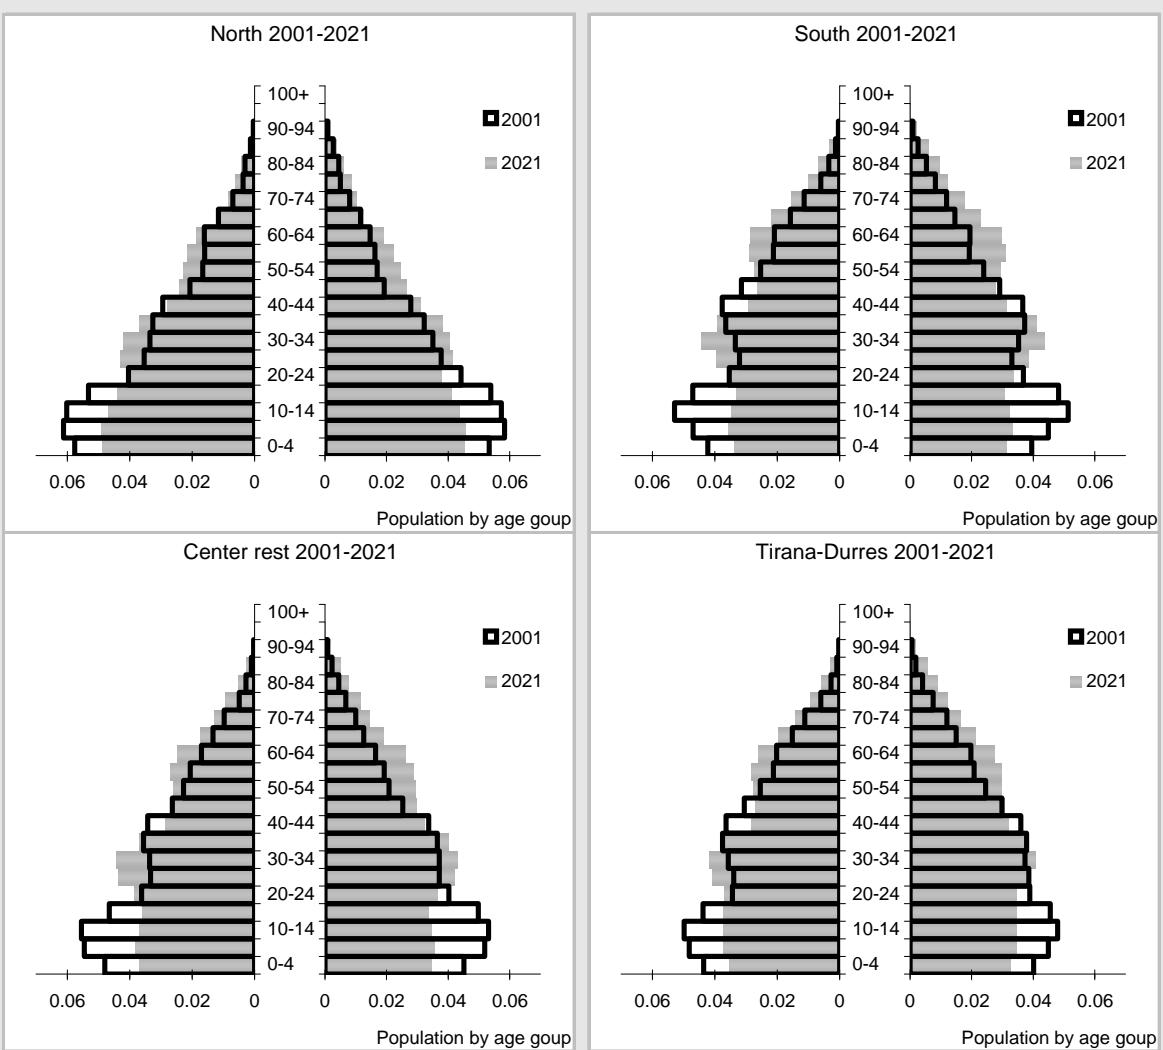

Table 14. Regions of Albania population projections.
Distribution by large age groups

| Region | North | | | Centre (excl. T-D) | | | South | | | Tirana-Durrës | | | |
|--------|-------|--------|--------|--------------------|--------|--------|--------|--------|--------|---------------|--------|--------|--------|
| | Age | 0-14 | 15-64 | 65+ | 0-14 | 15-64 | 65+ | 0-14 | 15-64 | 65+ | 0-14 | 15-64 | 65+ |
| 2001 | | 34.80% | 59.20% | 6.00% | 30.80% | 62.30% | 6.90% | 27.80% | 64.00% | 8.20% | 27.50% | 64.80% | 7.70% |
| 2006 | | 31.90% | 61.30% | 6.80% | 26.80% | 65.20% | 8.00% | 23.70% | 66.60% | 9.70% | 25.00% | 65.90% | 9.10% |
| 2011 | | 29.80% | 63.00% | 7.20% | 23.70% | 67.20% | 9.00% | 21.50% | 68.10% | 10.50% | 23.10% | 66.90% | 10.00% |
| 2016 | | 29.10% | 63.50% | 7.40% | 22.40% | 67.70% | 9.80% | 20.60% | 68.00% | 11.50% | 22.20% | 66.90% | 10.90% |
| 2021 | | 28.00% | 64.40% | 7.60% | 21.70% | 67.50% | 10.80% | 20.10% | 67.00% | 12.90% | 21.20% | 66.80% | 12.00% |

lations. That is why the future age pyramids do not show strong contrasts among regions with a heavy loss of emigrants and the districts that will receive internal migrants. For instance in 2021, the age pyramid in the South will not be very different from that in Tirana-Durrës districts.

Such a similarity, which can be read in the age pyramids as well as in the age distributions in older age groups, is very different from the previous consideration on the trend of the total population in the regions, where the South (and the North) were shown to mark time or even to decline, while Tirana-Durrës will have a dramatic increase in numbers.

2.4 Making one's choice among the sets of projections

In the following pages, the detailed results of the projections are presented with population of the whole country classified by sex and age (single year of age or five-year age groups) for each 1st of January from 2001 to 2021. Eight sets of results are proposed, depending on assumed future trends in mortality, fertility and external migration. Regional population projections are presented every five years by sex and five-year age groups in one set of assumptions.

Any user is free to decide which projection he/she will use. Nevertheless, some guidance may be relevant, on the basis of what we have already read in this huge mass of information ... or in the light of common sense and experience.

2.4.1 National population projections

Mortality risks have been assumed to remain at their 2000-2001 level or to decline at all ages, in order to reach by 2021 the 1997 Italian level. The selection of these assumptions has been guided by the fact that mortality rates in Albania are already very favorable and that it

will not increase much in the future. It has also been shown that Albania belonged to the Mediterranean system, where the diet is a protection against mortality risks, in particular at old ages, even when the degree of economic development is still low.

The results are quite close whether one considers projections with constant mortality or those with slightly reduced rates. The impact on total numbers is very small, while that on age structure is null. The choice between one assumption and the other is inconsequential. In the third part, we publish fully detailed results (i.e. single years of age) only for **constant mortality**. Projections with reduced mortality risks are published based on five-year age groups

Migration is the greatest unknown factor. Most movements are undocumented. They are probably much weaker than at the end of the nineties, but how many people are still now leaving the country and how many are returning home? Do the two flows compensate one another and will they tend to do so in the future? The assumptions we have made are pure guesses for the present and even more for the future (no migration or with 15000 per year). The age distribution of the migrants is an equally unknown factor: they were young adults and small children in the massive flows after 1995 but they are equally spread along the ages in the movements of internal migrants leaving their districts to converge in Tirana-Durrës.

The only solution is probably to keep an eye on the results with and without migration. It is likely that economic development would be the most efficient barrier against important and durable departures of Albanians and that the future will depend on the economic conditions in the country and in the region.

Fertility has declined rapidly in Albania since the 1960s, probably the steepest decrease

ever recorded in Europe. In 2001, women have had an average of 2.3 births, which remains the highest European figure in this period of very low fertility. The lowest low figures, below 1.3 births per woman, are sometimes in countries close to Albania (on the Mediterranean coast, like Italy; in formerly socialist Balkans, like Bulgaria). Part of the decline is explained by modernism, part by difficult economic conditions, in particular, in countries moving towards the market economy.

We have assumed a continuous fertility decline towards moderately low or very low levels (1.8 or 1.4 births per woman). It is open to a vast range of results, with a slower population growth and an accentuated ageing if fertility falls to lower figure. That could be the case if the economic conditions were unfavorable in the next decades: their deterioration could simultaneously be an incentive for young adults not to have children and/or to leave the country. If the economic development was more satisfactory, it is uncertain whether modernization will be a factor for low or very low fertility, but external migration would not accompany the movement. In practice, we propose to consider as equally likely the projections with low fertility and migration, low fertility and no migration, **high fertility and no migration**. For these reasons, we give full details on these three sets of results.

We have developed earlier the arguments why it is important to have a no migration scenario for policy makers who would wish to offer all the Albanians the possibility to remain in their home country.

Due to our uncertainties, not only on the number of emigrants but also on their distribution by age and sex, we publish results on projections with (constant mortality, low fertility and) migration in its two forms: with “neutral” emigration, gender-balanced as well as spread all over ages or with male-dominant emigra-

tion, concentrated on young adult ages and children.

However, the fertility assumptions bring about different results only in the number of children born after 2001, who are below 20 in 2021, below 10 in 2011 or below 5 in 2006. Those who are interested in the population of older ages, when they are concerned only with active population or the retirees, may just compare results in the two sets of projections: with or without emigration.

2.4.2 Regional population projections

There is a unique set of regional projections, applied to four entities associated by the same mortality level, differentiated fertility rates, maintaining constant relative gaps between the regions and internal movements of population converging from the North, the South and the Centre towards Tirana-Durrës districts.

The results point out the major role played by migration in the dynamics of the regions, with a considerable impulse given to Tirana-Durrës and a marked slowing down of demographic growth in the regions, in particular the South and, even further in the North. The assumptions have kept constant the rates of migration measured in 2000-2001, but the fact that internal migration is quite a recent phenomenon in Albania should be taken into consideration. Sustainability of the most recent trends is an open question. Will Tirana-Durrës be able to host constant flows of newcomers during twenty more years? Are the North and South likely to be population-drained for two more decades?

It is probably wise to **limit the use of population projections of the regions in ten rather than twenty years** and to take the results for later years as a mere scenario that would deserve more knowledge on the development of migration in Albania before it can be confirmed or adapted.
